31 **Financial support.** This research did not receive any specific grant from funding agencies in the
32 public, commercial, or not-for-profit sectors.

1 ABSTRACT

2 **Objective.** To investigate predictors of response, remission, low disease activity (LDA), damage
3 and drug discontinuation in patients with systemic lupus erythematosus (SLE) treated with
4 belimumab.

5 **Methods.** We retrospectively analysed data of a multicentre cohort of SLE patients receiving
6 intravenous belimumab. Proportion of patients achieving remission, LDA and SLE Responder
7 Index-4 (SRI-4) were evaluated. SLICC damage index (SDI) was calculated yearly. Predictors of
8 outcomes were investigated by multivariate logistic regression.

9 **Results.** We included 466 active SLE patients from 24 Italian centres: median (range) follow-up
10 18 (1-60) months. SRI-4 was achieved by 49.2%, 61.3%, 69.7%, 69.6% and 66.7% patients at 6,
11 12, 24, 36 and 48 months. Baseline predictors of response at 6 months were SLEDAI-2K \geq 10 (OR
12 3.14, 95%CI 2.033-4.860) and disease duration \leq 2 years (OR 1.94, 95%CI 1.078-3.473); at 12
13 months SLEDAI-2K \geq 10 (OR 3.48, 95%CI 2.004-6.025), SDI=0 (OR 1.74, 95%CI 1.036-2.923);
14 at 24 months SLEDAI-2K \geq 10 (OR 4.25, 95%CI 2.018-8.940), disease duration \leq 2 years (OR
15 3.79, 95%CI 1.039-13.52); at 36 months SLEDAI-2K \geq 10 (OR 14.59, 95%CI 3.54-59.79) and
16 baseline smoking (OR 0.19, 95%CI 0.039-0.69). Patients spending \geq 25% follow-up in remission
17 (42.9%) or \geq 50% in LDA (66.0%) accrued significantly less damage (p=0.046 and p=0.007).
18 Baseline SDI=0 independently predicted LDA \geq 50% and remission \geq 25%; the lower the baseline
19 damage, the higher the probability of remission \geq 25%. Number of previous flares negatively
20 predicted belimumab discontinuation due to inefficacy (p= 0.009)

21 **Conclusions.** The early use of belimumab in patients with active SLE and low baseline damage
22 predicts favourable outcomes in a real-life setting.

27

28

29 **INTRODUCTION**

1 Since its approval for the treatment of systemic lupus erythematosus (SLE) in 2011, belimumab
2 has progressively entered the drug armamentarium in clinical practice, despite some variable
3 indications across countries (1).

4 Since then, a long way elapsed throughout real-life settings showing overall consistent results in
5 terms of efficacy and safety (2-6). Better clinical responses were shown in patients displaying
6 higher disease activity, while a long-standing disease, chronic manifestations and former use of
7 immunosuppressants negatively impacted the response (2-4). Importantly, belimumab was shown
8 to decrease disease activity, glucocorticoid (GC) intake and flare rates, thereby hindering damage
9 progression (2-4).

10 Belimumab has been included in the 2019 updated European League Against Rheumatism
11 (EULAR)-endorsed recommendations on SLE management as an approved biological drug to be
12 used in patients refractory to standard of care (SoC), which means GC and hydroxychloroquine
13 with or without a previously failed immunosuppressant (7).

14 Remission and low disease activity (LDA) have recently emerged as desirable therapeutic targets
15 in SLE, as they are associated with a decreased risk of organ damage and a better prognosis (8-11)
16 especially if achieved early during treatment (12) and should therefore fall among the ultimate
17 goals of any therapeutic strategy.

18 In our former study, we evaluated predictors of response to belimumab in a multicenter cohort of
19 SLE patients (3), which was empowered in the present study becoming the largest European
20 nationwide cohort aimed at investigating belimumab effects on disease activity, damage
21 progression, remission and LDA.

22 **PATIENTS AND METHODS**

23 In Italy, intravenous (IV) belimumab can be prescribed only in reference centres selected by the
24 Health Regional Authorities based on their experience in the management of SLE. BeRLiSS
25 (Belimumab in Real Life Setting Study) is a national multicentre cohort study where physicians
26 working in the Italian reference centres were invited to participate on a free basis and without any
27 financial support.

28 **Inclusion criteria**

29 Inclusion criteria were all the following: 1) fulfilment of the 1982 American College of
30 Rheumatology (ACR) revised criteria or SLICC classification criteria for SLE (13,14); 2) active
31 disease defined as clinical (c)SLEDAI>0, refractory to SoC (7); 3) IV belimumab (10 mg/Kg on
32 day 1, 14, 28, and then every 28 days) as add-on therapy; 4) monthly follow-up due to infusion

1 schedule. SoC was defined according to the 2019 EULAR recommendations for the management
2 of SLE (7) as GC and antimalarials (if not absolutely contraindicated), with or without
3 immunosuppressive agents. Patients were considered to have early lupus in case of disease
4 duration at baseline ≤ 2 years. We included SLE patients treated between January the 1st, 2013
5 and March the 31st, 2019. Inclusion and follow-up of patients in this study did not interfere with
6 clinical practice.

7 **Data collection and management**

8 Patients were prospectively followed according to EULAR recommendations (15,16).
9 Anonymized patient data were collected in an *ad hoc* database since belimumab initiation and
10 were regularly updated. Clinical and laboratory variables collected at baseline and every six
11 months included SLEDAI-2K, fatigue (Visual Analogue Scale 0-10), daily prednisone intake,
12 complete blood count, 24-h proteinuria, anti-dsDNA antibodies, C3, C4 and concomitant
13 medications (3). All compiled data were systematically and regularly evaluated. In case of
14 inconsistencies or missing information, centres were required to amend the data. Patients' data not
15 fulfilling inclusion and qualitative control criteria were excluded.

16 The study was approved by the University of Padova Ethics Committee (3806/AO/16) and carried
17 out according to Helsinki Declaration. Informed consent regarding personal data treatment was
18 obtained from patients.

19 **Outcome measures**

20 All centres were requested to provide the SLE responder index (SRI)-4 response (17) for each
21 patient at 6, 12, 24, 36 and 48 months.

22 Organ-specific activity measures included Disease Activity Score (DAS)-28 in patients with
23 musculoskeletal involvement and CLASI (Cutaneous LE Disease Area and Severity Index) (18) in
24 patients with skin involvement (3).

25 Damage was assessed at baseline and annually by Systemic Lupus International Collaborating
26 Clinics (SLICC)-Damage Index (SDI) and disease flares by SELENA-SLEDAI flare index (SFI).

27 All centres were requested to provide flare number up to five years before belimumab initiation,
28 when available.

29 Remission was defined as cSLEDAI=0 and prednisone ≤ 5 mg/day with immunosuppressants
30 and antimalarials at a stable dose according to Zen et al. (19,20), while LDA was defined as

1 cSLEDAI \leq 2 regardless of treatment according to Tselios et al. (21) Moreover, we evaluated the
2 cumulative time spent either in remission or LDA after belimumab initiation: patients were
3 classified in 4 subgroups according to the proportion of follow-up time spent in remission or LDA
4 (0-24%, 25-49%, 50-74% and 75-100%).

5 **Safety and discontinuation**

6 Discontinuation was defined as an interruption of belimumab for more than 6 months. Among
7 reasons for discontinuation, inadequate response was defined by physician judgment according to
8 the presence of flare and/or the persistence of moderate/high disease activity.

9 Adverse events (AE) and severe AE (SAE) (3) were recorded at each clinical evaluation during
10 the follow-up.

11 **Statistical analysis**

12 Data were expressed as mean \pm standard deviation (SD), except for CLASI and anti-dsDNA, which
13 were expressed as median (interquartile range (IQR) 25^o-75^o) due to non-parametric distribution.
14 Continuous data with a parametric distribution were compared with t-test, t-test for paired data and
15 one-way analysis of variance (ANOVA) with Bonferroni's post hoc analysis. CLASI and anti-
16 dsDNA were analysed by the Wilcoxon's rank sum test, Wilcoxon's test for paired data and
17 ANOVA for ranks (Friedman's test). We investigated predictors of SRI-4, remission, LDA,
18 damage and discontinuation for inefficacy (tested variables are reported in **Supplementary Table**
19 **1**). Backward stepwise multiple logistic regression analyses were performed, including variables
20 with a $p < 0.2$ at univariate analysis. SPSS software (version 25.0, Chicago, IL) was used for
21 statistics; statistical significance was considered for $p < 0.05$.

22 **RESULTS**

23 **Baseline patient characteristics**

24 Twenty-four Italian centres joined the BeRLiSS project, enrolling overall 466 SLE patients, with a
25 median follow-up of 18 months, range 1-60. Demographic, clinical and serological features and
26 concomitant treatments are summarized in **Table 1**.

27 Manifestations requiring belimumab as add-on therapy were musculoskeletal in 200 patients
28 (42.9%), mucocutaneous in 110 (23.6%), glomerulonephritis in 56 (12.0%), haematological in 50
29 (10.7%), constitutional in 27 (5.8%), serosal in 23 (4.9%). Renal involvement at the time of
30 belimumab initiation defined patients with proteinuria persistently over 0.5g/day following
31 induction treatment for lupus nephritis or in whom a high prednisone threshold was required to

1 control proteinuria (≥ 7.5 mg/day). Belimumab was never used as induction treatment for lupus
2 glomerulonephritis.

3 Seventy-seven patients (16.5%) had a baseline SLE duration ≤ 2 years. As expected, in comparison
4 with patients with longer disease duration, early patients showed younger age at baseline
5 (38.18 ± 10.78 vs. 41.96 ± 11.2 , $p=0.007$), lower number of previous SLE organ involvement
6 (2.86 ± 1.28 vs. 3.2 ± 1.18 , $p=0.023$), and lower baseline SDI (0.8 ± 1.1 vs. 1.2 ± 1.6 , $p=0.044$). They
7 displayed also lower prevalence of anti-phospholipid antibody syndrome (7.9% vs. 17.2%,
8 $p=0.026$) and higher prevalence of positive anti-Sm antibody (42.1% vs. 23.8%, $p=0.001$). No
9 differences were observed in terms of current organ involvement, SLEDAI-2K and concomitant
10 treatment at baseline.

11 **Activity indices**

12 SLEDAI-2K, fatigue, anti-dsDNA, DAS28, CLASI activity, 24h proteinuria and prednisone daily
13 dosage significantly decreased, while C3 and C4 serum level increased during treatment
14 (**Supplementary Table 2**).

15 Concerning patients with positive anti-dsDNA at baseline, data on anti-dsDNA value were
16 available in 261 patients at 12 months and in 138 at 24 months. Among those, 142/261 (54.4%)
17 became seronegative at 12 months and 46/138 (33.3%) at 24 months.

18 **Response indices**

19 Rates and timing of achievement of therapeutic targets are reported in **Figure 1**.

20 **SRI-4**

21 Once achieved, SRI-4 response was steadily maintained over time in most patients. Notably,
22 60/157 (38.2%) non-responders at 6 months became responders at 12 months, suggesting that 6
23 months could be a too short time to evaluate the response to belimumab. Among non-responders at
24 6 months, 81.8% of early vs. 44.7% of non-early lupus ($p=0.022$) became responders at 24 months.
25 Independent predictors of SRI-4 response are listed in **Table 2**. By multivariate logistic regression
26 analysis, baseline SLEDAI-2K ≥ 10 predicted SRI-4 response at 6, 12, 24 and 36 months ($p < 0.001$
27 for all); SLE duration ≤ 2 years predicted SRI-4 at 6 and 24 months ($p=0.027$ and $p=0.044$,
28 respectively), and SDI=0 at 12 months ($p=0.036$). Musculoskeletal involvement predicted SRI-4 at
29 12 months ($p=0.014$), while skin involvement was a negative predictor of SRI-4 at 6 months
30 ($p=0.001$).

31 Interestingly, smoking emerged as a negative independent predictor of late response ($p=0.014$).

1 **Remission and LDA**

2 Proportions of patients achieving remission and LDA at 6, 12, 24, 36 and 48 months of follow-up
3 are shown in Figure 1. Notably, $\geq 90\%$ of patients achieving LDA at any time point were on
4 prednisone ≤ 7.5 mg/day after 6 months on belimumab.

5 A remarkable proportion of patients spent $\geq 50\%$ follow-up time in LDA (66.1%) or $\geq 25\%$ in
6 remission (44.3%) (Supplementary Figure 1). One third (49/158) of patients who achieved
7 remission $\geq 25\%$ completely stopped GC treatment, achieving remission off-GC.

8 Independent predictors of remission and LDA are listed in **Table 3**.

9 By multivariate logistic regression analysis, baseline SLEDAI-2K < 10 and SDI = 0 predicted
10 remission $\geq 25\%$ ($p = 0.047$ and $p < 0.001$, respectively) and LDA $\geq 50\%$ ($p < 0.001$ and $p = 0.024$,
11 respectively).

12 High flare number before belimumab initiation decreased the likelihood of remission $\geq 25\%$
13 ($p = 0.005$), showing a negative trend also for LDA $\geq 50\%$ ($p = 0.086$).

14 Except for baseline renal involvement that negatively predicted remission ($p = 0.034$), no other
15 organ involvement influenced the achievement of remission or LDA.

16 We performed a second multivariate analysis to evaluate the effect of different levels of baseline
17 damage on remission. We found that the OR decreased as the amount of damage increased (SDI = 0
18 OR 12.641, 95% CI 3.739-42.557, $p < 0.001$; SDI = 1 OR 5.720, 95% CI 1.662-19.678, $p = 0.006$;
19 SDI = 2 OR 3.976, 95% CI 1.023-15.460, $p = 0.046$; SDI ≥ 3 as reference), meaning that the lower the
20 baseline damage, the higher the probability to achieve remission $\geq 25\%$ of follow-up.

21 **Disease Flares**

22 Among 466 patients, 164 experienced at least one flare (35.2%) after belimumab initiation.
23 Overall 260 flares were observed: 92 (35.4%) musculoskeletal, 84 (32.3%) mucocutaneous, 27
24 (10.4%) haematological, 23 (8.9%) renal, 18 (6.9%) serosal, 9 (3.5%) constitutional and 7 (2.7%)
25 neurological. Seven severe flares were observed in 7 patients: three haematological (haemolytic
26 anaemia, severe lymphopenia and severe neutropenia), two renal (nephrotic flare and nephritic
27 flare with acute kidney injury), one neurological (polyradiculopathy), one inflammatory myopathy
28 and one severe skin vasculitis.

29 We observed a significant decrease in the incidence of flares at 12, 24, 36 and 48 months during
30 belimumab treatment compared to the corresponding period before ($p < 0.001$) (**Figure 2**).

31 **Damage accrual**

1 Data on damage accrual after belimumab initiation were available in 309 patients. Over 7,983
2 person-months of follow-up, we recorded 36 new damage events in 29 patients (9.4%),
3 corresponding to 0.54 events per 10 person-years.

4 At univariate analysis, concomitant antimalarial treatment was associated with lower damage
5 accrual at the end of follow-up ($p=0.037$), while age ($p=0.023$), disease ≥ 10 years ($p=0.013$),
6 baseline SDI >0 ($p=0.002$) were associated with higher risk of damage accrual.

7 Notably, patients with baseline SDI=0 showed no significant damage increase at 1, 2 and 3 years
8 after belimumab initiation (mean SDI 0.02 ± 0.14 , $p=0.083$; 0.05 ± 0.28 , $p=0.182$ and 0.10 ± 0.38 ,
9 $p=0.103$). Patients who experienced remission $\geq 25\%$ or LDA $\geq 50\%$ follow-up had lower rates of
10 damage accrual than those who did not (6.3% vs. 12.8% of patients, $p=0.046$, and 6.7% vs. 17.0%,
11 $p=0.007$, respectively).

12 Accordingly, in the multivariate model achievement of at least 50% LDA during follow-up
13 resulted protective against damage (OR 0.442, 95%CI 0.199-0.983, $p=0.045$) while increased
14 baseline SDI confirmed as independent predictor of further damage accrual (OR 3.22, 95%CI
15 1.25-8.33, $p=0.016$). No other variables were found significant in the multivariate model.

16 **Safety and drug discontinuation**

17 Among 10,104 IV belimumab infusions, no deaths or severe infusion reactions were observed.
18 Among 866 AE in 271 patients, 67.2% were infectious, 19.7% non-infectious, 12.1%
19 hypersensitivity reactions and 0.9% infusion reactions (**Supplementary Table 3**). Patients on
20 mycophenolate mofetil showed higher rate and number of infective AE compared with patients on
21 other immunosuppressants (54.1% vs. 42.6%, $p=0.016$ and 1.58 ± 2.41 vs. 1.11 ± 1.89 , $p=0.026$). A
22 higher rate of non-infective AE was observed in patients affected with other concomitant
23 rheumatic diseases ($p=0.046$) or with hypertension ($p=0.040$).

24 Drug discontinuation was observed in 165 patients after a median follow-up of 12 months (range
25 1-54) (**Figure 3**) due to AE (35.2%), inadequate response (34.5%), lost to follow-up (18.8%),
26 pregnancy (6.7%), remission (4.8%). Inadequate response was observed in 57 patients and was
27 due to renal activity in 19 patients, musculoskeletal in 14, cutaneous in 13, haematological in 4,
28 serosal in 3, neurological in 2 and constitutional in 2.

29 When SRI-4 at 6 months was used to distinguish primary inefficacy (no response at 6 months)
30 from secondary inefficacy (response at 6 months and subsequent worsening), 24/57 (42.1%)
31 patients classified as inadequate responders discontinued due to secondary inefficacy.
32 Interestingly, patients with rhupus ($n=12$), defined as a rheumatoid-like, erosive arthritis in

1 patients with serum positive anti-citrullinated peptides antibodies and/or rheumatoid factor (22)
2 showed a higher discontinuation rate due to inefficacy vs. other patients with musculoskeletal
3 involvement (36.3% vs. 11.1%, $p=0.030$), because of failure in achieving articular remission
4 (DAS28 <2.6) at 6, 12 and 18 months ($p<0.01$).

5 At multivariate analysis, a higher flare rate before belimumab initiation negatively predicted
6 discontinuation due to inefficacy (OR 0.138, 95% CI 0.31-0.606, $p=0.009$).

7 **DISCUSSION**

8 In this study we evaluated belimumab effectiveness, safety and rate of achievement of novel
9 therapeutic targets, i.e. remission and LDA in the largest European nationwide cohort of SLE
10 patients prospectively followed in a real-life setting. Notably, we showed a considerable
11 attainment of remission and LDA as well as a consistent proportion of follow-up time spent in
12 either status, which was shown to protect against damage accrual (11,12,19,20,23). Moreover, an
13 overall stable rate of SRI-4 response was observed.

14 Patients with higher disease activity (SLEDAI-2K ≥ 10) at baseline were more likely to achieve
15 SRI-4 response at different timepoints, but were less likely to achieve a cumulative remission $\geq 25\%$
16 or LDA $\geq 50\%$ of follow-up. This may be explained considering that an initial drop of 4 SLEDAI-
17 2K points may be more promptly achieved in patients with higher baseline disease activity,
18 thereby leading to a faster SRI-4 achievement, while requiring a longer time for a high cSLEDAI
19 to flatten to ≤ 2 or to zero i.e. to reach LDA or remission. Additionally, a higher baseline disease
20 activity could trigger a slower tapering of GC, thereby also impacting on achievement of
21 remission/LDA definitions, which include a GC threshold.

22 Importantly, the use of belimumab in patients with early SLE provided a higher chance of
23 response compared to patients who had a longer disease duration at baseline. The difference
24 between response rates was statistically significant at 6 and 24 months, while temporarily losing
25 statistical power at 12 months, despite maintaining a clinical relevance (69.9% vs. 59.9% response
26 in early vs. non early patients). This suggests that early patients treated with belimumab respond
27 earlier and continue to respond better in the long run, while patients with a long-standing disease
28 at baseline either respond later (around 1 year, when the SRI-4 difference between the groups is
29 not significant) or, in case of non-response at one year, they are significantly less likely to respond
30 in the long term.

1 Interestingly, the greatest achievement of remission, LDA and SRI-4 rates was seen within the
2 first 12 months of treatment (**Figure 1**), which may be considered as a more convenient window to
3 evaluate response to belimumab in respect to 6 months.

4 Absence of baseline damage positively predicted SRI-4 response at 12 months and achievement of
5 remission/LDA, in keeping with recent observations (24,25). Moreover, we showed that the lower
6 the damage at baseline, the higher the probability to achieve remission. In fact, while absence of
7 damage was the strongest predictor of remission, the chance of achieving remission decreased as
8 SDI increased, suggesting that patients should be optimally treated before damage is established,
9 yet not precluding belimumab administration in patients who already bear some damage, as
10 suggested by previous observations on pooled RCT data (26).

11 Not only absence of baseline damage supports the achievement of remission/LDA, but those
12 statuses are themselves protective against damage, as patients spending $\geq 50\%$ of follow-up in
13 LDA or $\geq 25\%$ in remission did not accrue damage throughout the follow-up in our cohort as well
14 as in a large study at the Hopkins Lupus Cohort (23). Moreover, damage accrual under belimumab
15 treatment did not significantly increase in patients with a baseline SDI=0 at 12, 24 and 36 months.
16 This is a relevant finding, as damage was shown to accumulate early (<1 year) and progressively
17 during disease course even among patients without preexisting damage (12,27), further supporting
18 the need of treatment in the early disease stage.

19 It should be also noted that use of belimumab versus standard of care decreased damage accrual in
20 BLISS studies; herein no control group is available as we are dealing with real-world experience.
21 Interestingly enough, however, mean SDI increase in our cohort was 0.54 per 10-person/year, i.e.
22 about 0.27 per 5-person/year, which is close to the 0.34 retrieved in the BLISS trials and as such it
23 is lower than the mean increase recently reported in the Toronto cohort under sole standard of care
24 (0.78 per 5-person/year) (28). Despite single damage items are not available for comparison before
25 and after belimumab initiation in this cohort, GC-related damage (as defined in (29)) appears to
26 slow down following belimumab initiation (15 out of 36 events overall in our cohort vs. 28 out of
27 33 events under SoC alone (29)), which may be due to the GC-sparing potential of belimumab
28 (**Supplementary Table 2**).

29 Organ manifestations responding better to belimumab include arthritis and skin rashes, especially
30 when acute (3,30); conversely, rhus syndrome was less likely to respond and led to a higher rate
31 of discontinuation due to inefficacy. The refractoriness to belimumab of a rheumatoid-like arthritis
32 compared with a classical lupus arthritis was already shown in a previous paper (4) and may be

1 related to a more aggressive phenotype likely sustained by different mechanisms taking place in
2 the joint, on which the immunomodulation exerted by belimumab is less effective.

3 Overall, DAS-28 and CLASIa significantly improved in our cohort. However, only
4 musculoskeletal involvement emerged as a predictor of SRI-4 response at 12 months, whereas
5 baseline skin involvement hampered a response at 6 months, in line with data from others
6 depicting skin as a predictor of delayed response (31). On the other hand, skin involvement was
7 positively associated with LDA, suggesting that skin manifestations require a longer time to
8 resolve, while paying the price of indexes (CLASIa and SLEDAI-2K) not capturing clinically
9 relevant changes occurring before or instead of a complete resolution.

10 Remarkably, among patients who discontinued due to inadequate response, 42.1% underwent a
11 loss of response, suggesting that more information is needed to better stratify patients at treatment
12 initiation. In this regard, smoke emerged as a negative predictor of long term response in ours as
13 well as in other cohorts (25), as it likely favors loss of efficacy and should be therefore strongly
14 discouraged.

15 We observed a significant decrease of flare rate after belimumab initiation compared to the period
16 before belimumab consistent with RCT findings and observations from real-life cohorts (2-4),
17 suggesting that belimumab may tame a relapsing-remitting disease phenotype, thereby exerting a
18 further protective effect against organ damage. Reasons for flare reduction upon belimumab
19 initiation need to be investigated in detail; so far, it may be argued that a stable control of disease
20 activity together with a tight follow-up connected to belimumab treatment may help to capture
21 even minor signs of disease reactivation.

22 Our study has both strengths and limitations. Among the latter, the main is the lack of a control
23 group, which prevents further inference; however, where possible, published observations on large
24 and known cohorts were taken as comparison. It should be also mentioned that patients not
25 reaching any given timepoint were excluded from the analysis of response at the timepoint where
26 the information was lacking, and this applies either to responders, non-responders and patients
27 who had discontinued due to loss of efficacy before the analyzed timepoint (n=24 throughout the
28 study). This pitfall is in our view connected to the retrospective nature of the study which poses
29 some objective restrictions to the amount of data that can be inferred. As we aimed at being
30 adherent to truly available data, we included in our timepoint analysis of response only patients
31 with complete records and who really reached the given timepoint.

1 The greatest strength is in our view the systematic collection of homogenous measurements
2 among the largest nationwide cohort of non-selected SLE patients in Europe, which could offer
3 insights on the real management of our patients.

4 In summary, our study provided novel evidence of a remarkable achievement of remission or LDA
5 during treatment, which were also likely to persist over time, and confirmed previous results on
6 real-life use of belimumab in terms of decrease in global and organ specific disease activity and
7 prednisone daily dose, flare rate and damage progression. At present, belimumab is frequently
8 used as the last option in SLE treatment. Based on our data, we suggest that an earlier use of
9 belimumab in patients with active SLE may maximize its efficacy, since it improves patient
10 prognosis in terms of better response, achievement of remission/LDA and hindrance of damage
11 accrual.
