Table of Contents

Preface and Introduction **1**

Preface: CERME14 – finally in Bozen-Bolzano
. . . *Carl Winsløw* 2

Introduction to the proceedings of the fourteenth Congress of the European Society for Research in Mathematics Education (CERME14)
. . . *Marianna Bosch, Susana Carreira, Giorgio Bolondi, Michael Gaidoschik, and Camilla Spagnolo* 4

Plenary Lectures **9**

Old and new landscapes for mathematics curricula: reflections from an Italian experience
. . . *Ferdinando Arzarello* 10

Climate change and the mathematics curriculum: gestures and entanglements for the future
. . . *Alf Coles and Kjellrun Hiis Hauge* 34

The new role of data in society: Challenges and opportunities for mathematics education in the age of data science and AI
. . . *Rolf Biehler and Michelle H. Wilkerson*. 59

TWG 01: Argumentation and Proof **97**

Introduction to Thematic Working Group 1: Argumentation and Proof
. . . *Andreas Moutsios-Rentzos, Orly Buchbinder, Nadia Azrou, Dimitrios Deslis, Viviane Durand-Guerrier, David A. Reid and Mei Yang* 98

Integrating Fallibilism and Formal Logic: A Peircean Approach to Lakatos' Methodology
. . . *Miglena Asenova* 102

Presumed criteria of validity of proof drive student teachers' actions in conjecturing and proving: a case study
. . . *Paolo Boero* 110

Linguistic analysis of beginning mathematics teachers' discourse about reasoning and proof
. . . *Rebecca Butler and Orly Buchbinder* 118

Examining teachers' motivational views on Lakatos-style investigation: A value-cost-expectancy approach
. . . *Dimitrios Deslis, Andreas J. Stylianides and Mateja Jamnik* 126

A sixth-grade student's first instance of mathematical proof
. . . *Merve Dilberoğlu, Erdinç Çakıroğlu and Çiğdem Haser* 134

A model-theoretic approach for didactics research on proof and proving in mathematics
. . . *Viviane Durand-Guerrier* 142

Justification not Proof as the Scope of Research: The RPA Model of Argumentation
. . . *Christian Fahse and Tim Lutz* 150

A framework for refutations to recipes and algorithms
. . . *Michael Fischer* 158

Investigating the relationship between negating competence and understanding proof by contraposition: A study with Indonesian undergraduate mathematics education students
. . . *Hapipi H and Andreas J. Stylianides* . . . 166
Proving the rule for fraction multiplication: What kind of content knowledge is visible in preservice teachers' arguments?
. . . *Andrea Hofmann and Trond Stølen Gustavsen* . . . 174
Pre-service teachers developing and using mathematical knowledge for teaching proof
. . . *Kasper Højbjerg* . . . 182
Analytic and narrative perspectives on proof and proving in mathematics classrooms - a cultural comparative approach
. . . *Christine Knipping, Fiene Bredow, Takeshi Miyakawa, Hiroki Otani and Yusuke Shinno* . . . 190
Recognising the situation for proving is not obvious
. . . *Zoltán Kovács and Eszter Kónya* . . . 198
A series of mathematical induction activities to promote deritualization processes
. . . *Latifah Mustofa Lestyanto and Kirsten Pfeiffer* . . . 206
Debating the machine: mediations and truth
. . . *Amedeo Matteucci, Francesco Saverio Tortoriello and Ilaria Veronesi* . . . 214
Proof awareness and students' proof evaluations
. . . *Andreas Moutsios-Rentzos and Vassiliki Mantziou* . . . 222
The use of generic examples in students' conjecturing processes
. . . *Julia Niederquell and Leander Kempen* . . . 230
Enhancing Pre-Service Mathematics Teachers' Justification Abilities: Impact of a Brief Intervention on Real Number
. . . *Mehdi Parsinia and Benjamin Rott* . . . 238
Studying the role of synergy between paper folding and a Dynamic Geometry Environment in upper secondary students' conceptualization of conditional statement and proof
. . . *Aliki Iliana Perivolari and Giorgos Psycharis* . . . 246
How do children in primary school prove?
. . . *Melanie Platz* . . . 254
Evaluating arguments: the role of goals and interlocutors
. . . *Marta Saccoletto* . . . 262
Using FullProof to develop geometrical reasoning and proof skills within a practicum course for preservice teachers
. . . *Ruthmae Sears and Orly Buchbinder* . . . 270
Exploring how affect-related constructs predict students' proof construction competence in algebra and geometry
. . . *Gabriel J. Stylianides, Andreas J. Stylianides, Ling Zhang, Dimitrios Deslis and Jisoo Seo* . . . 278
Reasoning and proving opportunities related to Thales' theorem in selected lower secondary textbooks from four different regions
. . . *Kinga Szűcs and Mária Slavíčková* . . . 286
Collaborative problem solving to foster higher-order thinking skills in mathematics: A systematic literature review
. . . *Haydee Ceballos, Theo van den Bogaart, Jeroen Spandaw, Stan van Ginkel and Paul Drijvers* . . . 294
Is it possible to assess the impact of proof assistants on undergraduate students' proofs? Preliminary results
. . . *Clara Sisco and Cécile Ouvrier-Buffet* . . . 296

TWG 02: Arithmetic, Numbers and Operations 298

Introduction to the work of TWG02: Arithmetic, numbers and operations
. . . *Ioannis Papadopoulos, Renata Carvalho, Linda Devi Fitriana, Robert Gunnarsson, Eszter Kónya and Elisabeth Rathgeb-Schnierer* . . . 299
Preservice teachers' decision-making: an empirical study using additive problems
. . . *Mónica Arnal-Palacián and Nuria Begué* . . . 303
Unveiling number sense performance in preservice primary school teachers through hands-on activity
. . . *Linda Devi Fitriana, Zoltán Kovács and Christiyanti Aprinastuti* . . . 311
Students' recognition of characteristics in addition and subtraction problems as prerequisite for flexible mental calculation
. . . *Timo Flückiger and Elisabeth Rathgeb-Schnierer* . . . 319
Teaching two-digit subtraction with a structural approach in the second grade
. . . *Éva Fülöp, Hoda Ashjari, Angelika Kullberg and Marie Fredriksson* . . . 327
Improving primary students' understanding of division
. . . *Michael Gaidoschik, Myriam Burtscher and Heidi Pechlaner* . . . 335
Number sense towards real numbers
. . . *Virginia Garrido Adame, Olimpia Figueras, and Minerva Martínez Ortega* . . . 343
Mastering the basic facts of multiplication and division till the end of grade 3 – selected results of a longitudinal study
. . . *Sandra Gleissberg, Eichler Klaus-Peter, and Seibold Moritz* . . . 351
What is a high-quality solution to an arithmetic task?
. . . *Robert Gunnarsson, and Ioannis Papadopoulos* . . . 359
Primary school student's ability in fractions as operators
. . . *Diana Herreros-Torres, M. Teresa Sanz, Carlos Gómez-Ferragud, Hélia Oliveira, and Renata Carvalho* . 367
Advancing the use of retrieval-based strategies with a new manipulative: The case of Nanuka
. . . *Sarah Hopkins, James Russo, Jane Hubbard, Ann Roche and Janette Bobis* . . . 375
Pupils' understanding of numerical pattern: an analysis of pupils' solutions to similar problems in grades 2 and 3 of primary school
. . . *Darin Jirotkova and Jana Slezáková* . . . 383
Word problems as a possible means of raising awareness of arithmetical structures
. . . *Eszter Kónya* . . . 391
Pupils' Solving strategies of the word problems Fidgets type
. . . *Karolína Mottlová* . . . 399
Problem posing by preservice teachers: The case of open problems
. . . *Ioannis Papadopoulos* . . . 407
Toward a conceptualization of %: Some preliminary advances
. . . *Jerome Proulx* . . . 415
Effects of spoken number words on place value understanding: A comparative study with German and Danish second graders
. . . *Mia Lene Ransiek and Thomas Rottmann* . . . 423
General explanations – conditions and role in the learning process of a child with special difficulties in learning mathematics
. . . *Charlotte Rechtsteiner and Michaela Scheffknecht* . . . 431
Tree graph to improve word problem solving involving rational numbers
. . . *Maria T. Sanz, Carlos Valenzuela García, Sofia Peregrina, Emilia López-iñesta, Francisco Grimaldo and Daniel Garcia-Costa* . . . 439
Pupils with severe difficulties in learning arithmetic: An educational challenge for secondary schools
. . . *Volker Ulm, Annalisa Steinecke and Moritz Zehnder* . . . 447

Assessing students' conceptual place value understanding at the end of primary school
. . . *Gerald Wittmann and Katja Lenz* . . . 455
Exploring the strategies utilized by primary pupils to solve equal group multiplication problems using the 'Stick and Split' app
. . . *Waqas Bin Sarfraz, Dave Hewitt and Ian Jones* . . . 463

TWG 03: Algebraic Thinking **465**

An introduction to TWG3 Algebraic Thinking
. . . *Maria Chimoni, Luis Radford , Jorunn Reinhardtsen and Stefan Korntreff* . . . 466
Understanding mathematical structures: A contribution to the discourse about the nature of algebraic thinking
. . . *Kathrin Akinwunmi* . . . 470
Mathematics teachers' correspondence and covariation approaches to quadratic functions in relation to their covariational reasoning
. . . *Mervenur Belin, Gülseren Karagöz Akar and Işıl İşler Baykal* . . . 478
A 6th grade teacher's and students' togethering in the algebra classroom: A process of overcoming emerging dialectical contradictions
. . . *Martin Carlsen and Jorunn Reinhardtsen* . . . 486
Employing Erroneous Examples in Refutational Text to Address Misconceptions in Equations and Inequalities
. . . *Konstantinos P Christou, Courtney Pollack and Eleni Karagiannidou* . . . 494
From Inductive to Deductive Reasoning: Investigating Grade 6 Students' Algebraic Thinking Abilities
. . . *Pitta-Pantazi Demetra, Maria Chimoni and Christou Constantinos.* . . . 502
The development of a reference epistemological model of upper secondary school algebra in Sweden
. . . *Matilda Hällback and Olov Viirman* . . . 510
Assessing students' emerging awareness of algebraic structures
. . . *Anna Holmlund and Johanna Pejlare* . . . 518
Overcoming the letter-as-object misconception in 4 weeks? An analysis of latent class transitions and contributing teaching practices
. . . *Katrin Klingbeil and Filip Moons* . . . 526
Enhancing students' conceptual understanding of variables with interactive instructional videos in a knowledge organization phase
. . . *Stefan Korntreff and Susanne Prediger* . . . 534
A case study of a seven-year old's reasoning with and understandings of function graphs
. . . *Nathan Liao, Susanne Strachota, Mathías A. Lopez, Bárbara M. Brizuela, Maria Blanton and Angela Gardiner Gardiner* . . . 542
Teachers' conceptualizations of slope in teaching Grade 8 students
. . . *Marios Pittalis and Panagiotis Gridos* . . . 550
Cartesian graphs and co-variational thinking in early algebra
. . . *Luis Radford* . . . 558
Linking a table and a graph of a function: Slovak case
. . . *Daniela Šabaková and Ingrid Semanišinová* . . . 566
Race among the number line: Functional thinking among primary school students
. . . *Stephan Tomaszewski and Marcus Nührenbörger* . . . 574
Constructing varying relationships of quantities and writing equations with fractions: A preliminary analysis of representations produced by Japanese and Turkish teachers
. . . *Zelha Tunç-Pekkan, Keiko Hino, Hisae Kato and Hiraku Ichikawa* . . . 582
Proportional reasoning unleashed: How gifted minds tackle diverse proportional reasoning tasks
. . . *Zeynep Tuncer, Berna İnci and Mine Işıksal Bostan* . . . 590

Experts' structuring processes of equations that can be solved with varying efficiency: An analysis of gaze paths with eye-tracking
. . . *Christof Weber and Georg Bruckmaier* . . . 598
Predictive validity of the algebra concept inventory
. . . *Claire Wladis, Eileen Murray and Geillan Aly* . . . 606
Comparison of structural sense in limit tasks between first and final year engineering students
. . . *Gloria del Carmen Cancec-Murillo, Pablo Flores Martínez and Teresa Rojano Ceballos* . . . 614
Strategies used by students with autism to complete repeating patterns
. . . *Juncal Goñi-Cervera, Irene Polo-Blanco, Maria Chimoni and Demetra Pitta-Pantazi* . . . 616

TWG 04: Geometry Teaching and Learning **618**

Geometry Teaching and Learning at CERME14: TWG4 Synthesis Report
. . . *Alik Palatnik, Lina Brunheira, Taro Fujita, Chrysi Papadaki and Petra Surynková* . . . 619
Applying Duval's Teaching Sequence to 7th-Grade Geometry: A Case Study on the Area of a Disc
. . . *Branka Antunović* . . . 623
Generating 3D virtual models of straight-line helicoids in GeoGebra by animations
. . . *Daniela Bimova, Jiří Břehovský and Petra Pirklova* . . . 631
Designing tasks to connect geometry and art – developing spatial reasoning using tilling
. . . *Lina Brunheira and Cristina Loureiro* . . . 639
Insights into conceptual breaks of individual sine concepts
. . . *Maximilian Büttner and Giada Viola* . . . 647
First graders' conceptions and linguistic descriptions of geometric shapes
. . . *Şahin Danişman and Duygu Arabacı* . . . 655
Encountering improper points through geogebrization
. . . *Agnese Del Zozzo* . . . 663
Theories for the use of both physical and digital tools for developing
. . . *Taro Fujita, Kotaro Komatsu, Satoshi Enomoto and Shogo Obayashi* . . . 671
Fostering Understanding of Inclusion Relationships Through Mathematical Events
. . . *Aehsan Haj-Yahya, Juhaina Shahbari and Huda Shayeb* . . . 679
Subjective theories of teacher trainers as to how to initiate argumentation and proving processes for geometry in lower secondary school classrooms
. . . *Stefan Halverscheid* . . . 687
Fostering students' geometric and spatial reasoning in geometry using duo of digital and tangible artefacts
. . . *Liying Huang and Taro Fujita* . . . 695
Working with student solutions to understand geometry knowledge of preservice teachers
. . . *Daniela Kovalčíková and Ingrid Semanišinová* . . . 703
Geometry to be taught in Taiwanese and Japanese junior high schools
. . . *Takeshi Miyakawa and Yi-Wen Su* . . . 711
Developing geometrical reasoning skills in primary school
. . . *Shogo Obayashi and Taro Fujita* . . . 719
High School Mathematics Teachers' Support for Students' Focus on the Properties of Geometric Solids Using Dynamic Geometry Software
. . . *Samet Okumus and Karen Hollebrands* . . . 727
I see what you're thinking: Embodied collaborative argumentation
. . . *Alik Palatnik, Dor Abrahamson and Catalina Lomos* . . . 735
Analysis and categorization of errors in the geometry of prospective primary teachers
. . . *Petra Pirklova, Jiri Brehovsky and Daniela Bimova* . . . 743

On the mutual relationship of different construction tools and mathematical concepts
. . . *Marc Sauerwein* . . . 751
3D printed manipulatives as an aid in constructing parallel and central projections of solids
. . . *Petra Surynkova* . . . 759
Teaching the concept of minimal definition with the CoD Method
. . . *Leonardo Tortorelli and Francesco Saverio Tortoriello* . . . 767
Dimensions of conceptual knowledge and geometric constructions
. . . *Lukáš Vízek and Libuše Samková* . . . 775
The role of perceptual clues in 3D enumeration tasks
. . . *Edgar Alstad and Maren Berre* . . . 783
Mathematics laboratory on geometric transformations at the museum
. . . *Michela Maschietto and Beatrice Battilani* . . . 785

TWG 05: Probability and Statistics Education **787**
Reimagining Statistics and Probability Education in the Age of Data and AI: An introduction to the work of TWG05
. . . *Aisling Leavy, Daniel Frischemeier, Sibel Kazak, Orlando Rafael González, Luca Lamanna and María Magdalena Gea* . . . 788
Reconsidering Basic Resources for Modern Statistics Teaching and Learning: Opening the Dialogue
. . . *Dionysia Bakogianni and Maria Meletiou-Mavrotheris* . . . 795
How students justify the usability of self-built machine learning models
. . . *Katharina Bata, Angela Schmitz and Andreas Eichler* . . . 803
A classroom experiment: the impact of teaching correlation and regression on students' knowledge of the equation of a line
. . . *Balázs Boller* . . . 811
Risk literacy – a hybrid conceptualization
. . . *Marie-Theres Brehm and Angelika Bikner-Ahsbahs* . . . 819
Can you explain the surprising result? About students' arguments in the context of risk literacy before and after working with a simulation
. . . *Theresa Büchter, Andreas Eichler, Nora Vogel and Karin Binder* . . . 827
How do future teachers interpret a pupil solution to a probabilistic task involving proportionality?
. . . *María Burgos, María del Mar López-Martín and Veronica Albanese* . . . 835
Statistical literacy in middle school students' performance of speech acts when reacting to data-based arguments on social media
. . . *Christian Büscher* . . . 843
Facilitating elementary school students' transitioning from statistical modeling of to statistical modeling for
. . . *Michal Dvir* . . . 851
Novice Students' Engagement with Big Data Modeling
. . . *Ronit Gafny, Michal Dvir and Dani Ben-Zvi* . . . 859
Informal conceptions of appropriate choropleth maps held by in-service Southeast Asian teachers
. . . *Orlando Rafael Gonzalez* . . . 867
Richness of reflective processes on algorithmic decision-making systems by prospective teachers
. . . *Susanne Hilger and Carina Büscher* . . . 875
Middle Grade students' objectification of probability in a computer simulation-based environment
. . . *Kjærand Iversen and Amrit Bahadur Poudel* . . . 883

Exploring the structure of enumerations in combinatorial problem solving: a case study with Italian secondary school students
. . . *Luca Lamanna and Laura Branchetti* . . . 891
Empowering Statistical Learning: The Impact of Growth Mindset on Students' Attitudes towards Statistics
. . . *Aisling Leavy, Esma Emmioglu-Sarikaya, Caterina Primi and Candace Schau* . . . 899
Bringing math into politics: the Decision Theatre Lab and the influence of model knowledge on the interpretation of stochastic simulation results
. . . *Christoph Lieben and Sinah Gürtler* . . . 907
Problem solving and argumentation in probability context: analysis of some examples of necessary object-level narratives
. . . *Francesca Martignone, Daniele De Giorgi and Marta Saccoletto* . . . 915
Type of table and reading levels promoted by Spanish textbooks
. . . *Jocelyn D. Pallauta, María M. Gea, Carmen Batanero and Pedro Arteaga* . . . 923
Teaching data-driven machine learning in mathematics education
. . . *Sarah Schönbrodt and Martin Frank* . . . 931
A local instruction theory to strengthen students' grasp on graphs
. . . *Lonneke Boels* . . . 939
Transferring responsibilities to students in a statistics inquiry through an inter-grade study and research path
. . . *Maria-Josep Freixanet de la Iglesia, Montserrat Alsina Auback, Marianna Bosch Casabò* . . . 941
Gaining insight – developing eye-tracking vignettes for teacher training on misinterpretations of statistical graphs
. . . *Ayline Heursen, Saskia Schreiter, Vuslat Seker, Anita Alexander, Lonneke Boels, Frank Reinhold, Martin Abt, Wim Van Dooren and Markus Vogel* . . . 943
Data science modules for preservice teacher education
. . . *Susanne Podworny, Sibel Kazak and Aisling Leavy* . . . 945
Investigating students' co-construction of statistical argumentation
. . . *Carlotta Vielmo* . . . 947
Case study of a learning environment for collecting and analysing real data in mathematics classrooms with the toolkit senseBox
. . . *Anna-Marietha Vogler and Kirstin Erath* . . . 949

TWG 06: Applications and Modelling **951**
Introducing the CERME14 papers and posters in, and work of, TWG6: Application and Modelling
. . . *Jonas Bergman Ärlebäck, Britta Eyrich Jessen, Gilbert Greefrath, Serife Sevinc, Yana Lacek and Katrin Vorhölter* . . . 952
The wheel of mathematical modelling: Seeking new perspective
. . . *Jonas Bergman Ärlebäck, Serife Sevinc and Lluís Albarracín* . . . 960
Modelling indoors and outdoors: A comparison of the student's interest and competence development in two task settings
. . . *Simon Barlovits, Anton Kunz and Matthias Ludwig* . . . 968
Students' managing of modelling problems with superfluous data
. . . *Caterina Bassi and Rosa Iaderosa* . . . 976
Portfolio as a form of assessment for mathematical modelling with digital tools - Advantages and challenges from students' perspective
. . . *Catharina Beckschulte, Jascha Quarder, Stanislaw Schukajlow and Samuel Blankenstein* . . . 984
Teacher's actions in class discussions after solving a Fermi problem
. . . *Mireia Brunet-Biarnes and Lluís Albarracín* . . . 992

University students learning to model through large amount of data, simulations and ChatGPT
. . . *Louise Meier Carlsen and Britta Eyrich Jessen* . . . 1000
How do teachers manage the phase of horizontal mathematization during the implementation of a modelling task? A case study
. . . *Marina De Simone and Yana Lacek* . . . 1008
Assessment in a two-dimensional curriculum: The case of solid geometry and modelling supported by an "empty" modelling cycle
. . . *Stig Eriksen and Martin Nordskog* . . . 1016
How do pre-service teachers interact with IA to solve modelling problems? Characterising the use of ChatGPT in solving Fermi problems
. . . *César Gallart, Irene Ferrando, Carlos Segura and Lluís Albarracín* . . . 1024
Mathematical knowledge mobilised by a group of prospective mathematics teachers when developing a modeling project
. . . *Jeannette Galleguillos* . . . 1032
Making the Invisible Visible: Exploring the Situation Model
. . . *Isabella Gogesch and Matthias Ludwig* . . . 1040
Financial literacy and mathematical modelling: an analysis of PISA sample tasks
. . . *Gilbert Greefrath and Katharina Kirsten* . . . 1048
One step at a time? – An empirical study on the use of graphical representations for Fermi problems
. . . *Simone Jablonski, Julia Ehemann, Deng-Xin Ken Oehler and Matthias Ludwig* . . . 1056
The role of transpositive analyses when discussing modelling in disruptive times
. . . *Britta Eyrich Jessen* . . . 1064
Secondary students' multifaceted perceptions of the role of data from the perspectives of models, modelling and information
. . . *Takashi Kawakami and Jonas Bergman Ärlebäck* . . . 1072
The role of recursivity and reversibility in mathematical modelling: The bakery mould
. . . *Marcos Marí Bofill, Marianna Bosch Casabò and Berta Barquero Farràs* . . . 1080
Students' use of benchmarks in the process of solving Fermi problems
. . . *Marlena Meyer and Greefrath Gilbert* . . . 1088
Didactic transposition constraints on modelling at upper secondary level: Comparing France and Norway
. . . *Elsa Puchaczewski, Marianna Bosch and Heidi Strømskag* . . . 1096
Modelling in the learning of the definite integral for civil engineering
. . . *Mariela Elizabeth Ramírez Inca and Hugo Rogelio Mejía Velasco* . . . 1104
In-service teachers' scaffolding practices based on diagnosing modelling challenges during instruction
. . . *Liron Schwartz-Aviad and Zehavit Kohen* . . . 1112
Mathematical modelling as part of a general education in mathematics classrooms - challenge for teachers, responsibility for researchers
. . . *Hans-Stefan Siller and Katrin Vorhölter* . . . 1120
The evanescence of mathematical models and modelling in the teaching of combinatorics
. . . *Susana Vásquez Elias, Berta Barquero Farràs and Marianna Bosch Casabò* . . . 1128
Pre-service teachers' judgments of students' solutions to open modeling problems: How important is it to make assumptions?
. . . *Katharina Wiehe, Catharina Beckschulte and Stanislaw Schukajlow ,* . . . 1136
The dishwasher experience: Pre-service teachers' use of extramathematical knowledge while investigating societal topics
. . . *Suela Kacerja, Lisa Steffensen and Trine Foyn* . . . 1144
Bridging mathematics and sustainability: Exploring the role of sustainability in mathematics education
. . . *Carolin Kammrad and Michael Meyer* . . . 1146

TWG 07: Mathematics for Work, Society and Personal Development: Lifelong Learning 1148

An introduction to TWG7: Mathematics for work, society and personal development - lifelong learning
. . . *Pauline Vos, Oda Heidi Bolstad, Javier Díez-Palomar, Michele Giuliano Fiorentino and Peter Frejd* . . 1149

Mathematical literacy – What is missing?
. . . *Oda Heidi Bolstad* 1158

The shaping of mathematics teacher identities in vocational education through a whole organisational approach
. . . *Diane Dalby* 1166

Discussing "Numeracy" beyond the scientific community. How adult learners define numeracy and what challenges arise from that for the coming future
. . . *Javier Díez-Palomar and Kees Hoogland* 1174

Mathematics and vocational disciplines: a co-disciplinary perspective to reduce early leaving school
. . . *Michele Giuliano Fiorentino and Antonella Montone* 1182

Theorizing how citizens and vocational workers interact in co-productivity chains with professional mathematicians
. . . *Peter Frejd and Pauline Vos* 1190

Mathematics workshops in prison: design and practice
. . . *Sofia Galli, Giulia Bernardi, Domenico Brunetto, Helena Dell'Anna and Francesco Nappo* 1198

Teachers' ways of experiencing educationally significant vocational mathematics knowing
. . . *Hanna Knutson* 1206

Not just threats and weaknesses: seeking opportunities for the teaching/learning of mathematics in prison schools
. . . *Federica Mennuni, Andrea Maffia, Luca Decembrotto and Veronica Manzoni* 1214

Subject integrated team teaching vs. textbook learning: A comparative study on students' experiences in vocational mathematics education

Teachers' knowledge and technology: the global model
. . . *Helena Rocha* . . . 2504
Resonance of instrumental functions in geometric constructions: Unpacking teacher and student artifact use
. . . *Zahida Sayadi and Abboud Maha* . . . 2512
Mathematical problem-posing according to defined educational needs utilizing Generative AI as a lever to enhance pre-service mathematics teachers' TPACK
. . . *Ruti Segal and Biton Yaniv* . . . 2520
Teaching computational technology in mathematics education: a comparative analysis of three frameworks
. . . *Andreas Lindenskov Tamborg, Cecilie Carlsen Bach, Camilla Finsterbach Kaup, Raimundo Elicer and Morten Misfeldt* . . . 2528
Investigation of the use of AI as a scaffolding tool during mathematical discussion in geometry problem-solving
. . . *Serdem Yavuz and Ayşe Tekin Dede* . . . 2536
A pre-service mathematics teacher's digital resource design capacity
. . . *Melike Yiğit Koyunkaya and Gülay Bozkurt* . . . 2544
Maths AIde: Can GenAI support mathematics teachers to plan engaging, student centred lessons?
. . . *Eleanor Byrne, Aibhín Bray and Brendan Tangney* . . . 2552
Chatbots performance in problem posing: An exploratory study
. . . *Sara Embid and Josefa Perdomo-Díaz* . . . 2554
Computational literacy in mathematical problem solving
. . . *Jack Jalal Kallo* . . . 2556
Engaging and explorative digital tasks designed by pre-service teachers: A teacher training course design
. . . *Edith Lindenbauer and Eva-Maria Infanger* . . . 2558
Developing lower secondary mathematics teachers' ICT competencies: The case of China
. . . *Bohan Liu, Eirini Geraniou, Cosette Crisan and Jeremy Hodgen* . . . 2560
Group Instrumental Genesis
. . . *Liv Nøhr, Cecilie Carlsen Bach, Andreas Lindenskov Tamborg and Morten Misfeldt* . . . 2562

TWG 16: Learning Mathematics with Technology and Other Resources 2564

Learning mathematics with technology and other resources: A short report from TWG16
. . . *Osama Swidan, Jana Trgalová, Florian Schacht, Eleonora Faggiano, Rogier Bos and Sara Bagossi* . . . 2565
The icosahedron in the room: Revisiting pedagogical dilemmas of individual learning in collaborative activities
. . . *Dor Abrahamson, Catalina Lomos and Alik Palatnik* . . . 2569
Students' use of feedback when working on fractions with a digital learning platform and its effects on mathematical performance
. . . *Larissa Altenburger and Michael Besser* . . . 2577
Supporting cognitive engagement in working with interactive video: Potentials and limitations of video interaction and feedback
. . . *Stephan Bach, Mike Altieri, Stefan Korntreff and Susanne Prediger* . . . 2585
Investigating covariational reasoning: a multimodal analysis including eye-tracking data
. . . *Sara Bagossi, Osama Swidan, Aylin Thomaneck, Yotam Vaknin and Maike Vollstedt* . . . 2593
Identifying design criteria of digital learning environments for geometry learning: A student-centred approach
. . . *Selina Baldinger and Robert Weinhandl* . . . 2601
Programming and mathematics – Experiences using programmable robots in a 6^{th} grade mathematics class
. . . *Ingeborg Lid Berget and Beate Krøvel Humberset* . . . 2609
Investigating the potential of GenAI as a scaffolding tool in Mathematics Education
. . . *Maria Lucia Bernardi, Federica Troilo, Roberto Capone and Eleonora Faggiano* . . . 2617

Examination of eye movements of primary school 4^{th}-grade students during mathematical problem-solving*
. . . *Çağla Bingül and Yeliz Yazgan* . . . 2625
Heuristic trees and their fruits
. . . *Rogier Bos* . . . 2633
Changes in abstraction levels among undergraduate students during game programming using Scratch
. . . *Einav Keisar and Michal Tabach* . . . 2641
Students' mathematical thinking through programming, animation and 3D printing: Early insights in the case of curvature
. . . *Chronis Kynigos and Katia Schiza* . . . 2649
Opportunities for low-achieving students to learn mathematics through design and 3D printing of usable objects
. . . *Laura Levin and Sigal-Hava Rotem* . . . 2657
Promoting Euclidean-Taxicab covariational reasoning to enhance understanding of trigonometric concepts in a digital environment
. . . *Annamaria Miranda and Loredana Saliceto* . . . 2665
Chat GPT as a didactic tool to improve students' abilities in managing different semiotic representations: a first study.
. . . *Giorgia Nieddu, Maria Cristina Carrisi, Maria Polo and Antioco Luigi Zurru* . . . 2673
Students' written and oral verbalizations of a numerical pattern using the tool BookCreator
. . . *Zita Pahlsmeier and Marcus Nührenbörger* . . . 2681
Can you help us? – Task-specific LLM-based support in a digital mathematical escape game
. . . *Lisa Rühl and Daniel Thurm* . . . 2689
Three forms of feedback in digital learning material in mathematics
. . . *Seif Sharif, Samuel Bengmark, Laura Fainsilber, Eva Fülöp, Tommy Gustavsson and Johanna Pejlare* 2697
Enhancing students' techno-mathematical problem-solving skills: Results from a quasi-experimental study with 5th graders
. . . *Ana Claúdia Simões, Hélia Jacinto, Neuza Pedro and Susana Carreira* . . . 2705
Analysis of mixed-types in pre-service teachers' argumentation using a digital tool
. . . *Julia Marie Stechemesser and Florian Schacht* . . . 2713
Learning success while working with (interactive) videos on multiplication derivation strategies
. . . *Juliane Wefers* . . . 2721
Digital Game-Based Learning in Moroccan Mathematics Education: Insights and Challenges
. . . *Tariq Bouzid* . . . 2729
Enhancing mathematics learning through Mixed Reality: The Function Virtuality prototype
. . . *Mosè Colangelo and Andrea Ghersi* . . . 2731
LLMs as a tool for problem solving – A case study on the role of generative AI in the solution of Fermi problems
. . . *Marc Herrmann* . . . 2733
Programming to inscribe geometric entities in circle and in sphere: an embodied approach of textual programming towards assembling a new Conceptual Field
. . . *Charikleia Korompli* . . . 2735
The impact of technology-based collaborative learning on enhancing students' fraction comparison skills
. . . *Nurit Paz-Baruch, Okila Nashif and Iris Schreiber* . . . 2737
Moving forward with AR: Effects of augmented reality on learners' solution behaviour in analytic geometry
. . . *Xenia-Rosemarie Reit and Valerie Wachter* . . . 2739
Students' acceptance of the multimodality of the social robot Pepper as an educational technology for learning mathematics
. . . *Antonio Vitale, Bruno Carbonaro, Gennaro Cordasco, Umberto Dello Iacono and Anna Esposito* . . . 2741

TWG 17: Theoretical Perspectives and Approaches in Mathematics Education 2743
Introduction to thematic working group 17: Centring the function and purpose of theory in mathematics education research
. . . *Heather Lynn Johnson, Felix Lensing, Pedro Nicolás, and Amalie Sødal* . . . 2744
Interdisciplinarity in STEM education: A category-theoretical model the viewpoint of Mathematics
. . . *Miglena Asenova and Roberto Capone* . . . 2752
On the diachronic analysis of a modality of study
. . . *José Ginés Espín Buendía, Josep Gascón Pérez and Pedro Nicolás Zaragoza* . . . 2760
Crisis-driven transformation in tertiary mathematics – A case study connecting TTE and ATD
. . . *Lukas M. Günther, Jana Peters and Reinhard Hochmuth* . . . 2768
Didactic transposition of structuralist praxeologies at the interface between analysis and topology: a case study
. . . *Thomas Hausberger, Reinhard Hochmuth and Erik Hanke* . . . 2776
The professional obligations of mathematics teaching: How measurement and theoretical progress work hand in hand
. . . *Patricio Herbst, Daniel Chazan, Amanda Brown and Karl Kosko* . . . 2784
Using theory as a tool to cultivate and analyse research methods: Theorising positioning to examine task-based interviews
. . . *Heather Lynn Johnson, Evan McClintock and Robert Knurek* . . . 2792
An interactionist perspective on the negotiation of meaning of mathematical representations
. . . *Sebastian Kollhoff and Kerstin Gerlach* . . . 2800
Conceptualising subjective relevance of mathematics education
. . . *David Kollosche and Chiara Nadine Wang* . . . 2808
Pre-service teachers' developing professional identity as mathematics teachers - a theoretical perspective
. . . *Beate Lien, Amalie Sødal, Jorunn Reinhardtsen and Martin Carlsen* . . . 2816
Rationale and methods for an archive and encyclopaedia of "fundamental didactics"
. . . *Nathan Lombard, Marianna Bosch and Claire Margolinas* . . . 2824
Combining a theoretical framework and a statistical measure to assess the reliability of didactic criteria in the analysis of large corpora
. . . *Ismaël Mili, Mickaël Da Ronch and Marie-Line Gardes* . . . 2832
Didactic paradigms to promote creativity in the study of mathematics
. . . *Pedro Nicolás, Ginés Espín and Josep Gascón* . . . 2840
On the concept of epistemic obstacles and its significance to mathematics education (research)
. . . *Kata Sebök and Felix Lensing* . . . 2848
Transposition of research knowledge: From the West to Far East Asia
. . . *Yusuke Shinno and Takeshi Miyakawa* . . . 2856
Mathematical heterotopias: Lessons for the mainstream classroom
. . . *Constantinos Xenofontos* . . . 2864
Reconceptualizing opportunities to learn mathematics through postfoundational theories
. . . *Ayşe Yolcu, İ. Elif Yetkin-Özdemir, Emine Gül Çelebi and Gökçe Ursavaş* . . . 2872
Research mixology: Blending mathematics education & digital sociology for a hybrid approach to experimental design
. . . *Giulia Bini, Sara Gagliani Caputo, Pietro Saccomanno and Diego Ceccobelli* . . . 2880

TWG 18: Mathematics Teacher Education and Professional Development 2882
Subjects and objects of research and theories of learning in the education and professional development of mathematics teachers
. . . *Marita Friesen, Tracy Helliwell, Fanni Biró, Raffaele Casi, Andreas Ebbelind, Janne Fauskanger, Pere Ivars, Libuše Samková and Gil Schwarts* . . . 2883
Teaching fraction multiplication and fraction division to prospective teachers: A design research study
. . . *Theodora Avgeri, Maria Bebeni, Konstantinos Tatsis and Xenia Vamvakoussi* . . . 2891
Preservice teachers' collective proportional reasoning in large-format ratio triangles
. . . *Morten Bjørnebye, Bjarte Rom, Henrik Løvik Njølstad and Jonas Oskarsson* . . . 2899
Tensions emerging when selecting tasks for problem-solving lessons
. . . *Raymond Bjuland, Janne Fauskanger, Reidar Mosvold and Peter Liljedahl* . . . 2907
On making mathematics flourish for students to grasp it: Teachers designing informal mathematics education workshops in museums
. . . *Raffaele Casi and Cristina Sabena* . . . 2915
Investigating how secondary school teachers perceive mathematical concepts in application contexts: The case of ratio and chemistry tasks
. . . *Adam Čech and Libuše Samková* . . . 2923
Pre-service mathematics teachers' conceptualizations and noticing of algebraic thinking
. . . *Makbule Gozde Didis Kabar and Janet Walkoe* . . . 2931
Teaching with technology to foster conceptual understanding: Student level evaluation of a professional development program
. . . *Susanne Digel and Roth Jürgen* . . . 2939
Exploring the notion of individuality in research on mathematics teacher education and professional development
. . . *Andreas Ebbelind and Tracy Helliwell* . . . 2947
Preservice teachers' professional instrumental genesis for integrating programming in the math classroom: the beginning
. . . *Martyna Katarzyna Fojcik, Marie-Frédérick St-Cyr, Chantal Buteau, Eric Muller and Joyce Mgombelo* 2955
Exploring the impact of using silent video task on teacher noticing professional development in mathematics education
. . . *Selen Galiç, Şenol Dost and Zsolt Lavicza* . . . 2963
Development of self-reported technological pedagogical and content knowledge (TPACK) during the preparatory service of prospective mathematics teachers in Germany
. . . *Fabian Grünig and Markus Vogel* . . . 2971
From "anyway using many representations" to targeted practices: A teacher's professional learning in an asynchronous online PD
. . . *Kerstin Hein, Anne Tester, Lena Böing and Susanne Prediger* . . . 2979
Development of the disciplinary identity of the mathematics teacher: A professional development proposal
. . . *Maximiliano Izzi Prato and Francisco Cordero* . . . 2987
Planning considerations stated in intended learning outcomes for primary teacher education in Sweden
. . . *Malin Elisabeth Jones* . . . 2995
Intertwining theory and practice: Design of planning phases in PD training to support effective teacher planning processes
. . . *Katharina Knaudt, Raja Herold-Blasius and Christoph Selter* . . . 3003
Noticing of students' thinking – Is it sufficient for teachers' analysis of interaction in the mathematics classroom? – A vignette-based study
. . . *Sebastian Kuntze, Sigal-Hava Rotem, Yael Nurick, Marita Friesen and Jens Krummenauer* . . . 3011

Discourses of diversity in mathematics teacher education research: An analytical tool for meta-didactic praxeologies
. . . *Natalya Maksym'yak* . . . 3019
Preservice teachers' identity as programmers in mathematics
. . . *Marianne Maugesten, Odd Tore Kaufmann, Khaled Jemai, Toril Eskeland Rangnes and Shipra Sachdeva* . . . 3027
Exploring mathematics teachers' informal use of an online self-learning platform while planning a digital learning environment
. . . *Sophie Mense* . . . 3035
Levels of noticing competence among preservice secondary mathematics teachers in a video analysis of functions
. . . *José Luis Morales-Reyes and Diana Zakaryan* . . . 3043
Supporting pre-service teachers in learning to promote students' proving: the case of general conjectures
. . . *Reidun Persdatter Ødegaard* . . . 3051
Pre-service primary school teachers' curricular noticing: interpreting a sequence of activities about 3D
. . . *Zaira Ortiz-Laso, Antonio Saorín, Melania Bernabeu and Ceneida Fernández* . . . 3059
Using textbook analysis in teachers' professional development
. . . *Marte Krohg Østby* . . . 3067
Inquiry-based learning through problem posing in pre-service teachers' teaching practice: a study of discursive manifestations of contradictions
. . . *Gresa Pozhegu-Ermeni, Svein Arne Sikko and Benedikte Grimeland* . . . 3075
Utilizing a three-phased didactical model in a continuous professional development program for the implementation of inquiry-based mathematics teaching
. . . *Ida Redder Honoré and Louise Laursen Falkenberg* . . . 3083
Fostering the perception of ambiguity and the processing of information in complex diagnostic situations
. . . *Andreas Rieu, Katharina Loibl and Timo Leuders* . . . 3091
Using scriptwriting to examine how pre-service mathematics teachers anticipate and respond to students' productive struggle
. . . *Sigal-Hava Rotem and Adi Eraky* . . . 3099
Shifting from on-site to on-line: How can key design criteria for effective PD be transferred to online, asynchronous programs?
. . . *Gil Schwarts and Marita Eva Friesen* . . . 3107
Values in mathematics education of potential future teachers on entry to a degree in basic education
. . . *Maria de Lurdes Marquês Serrazina, Joana Castro, Elvira Santos, Ana Silvestre, Hélia Jacinto, Cristina Martins, Manuel Vara Pires, Nélia Amado, Rosa Ferreira and Susana Carreira.* . . . 3115
Teaching Simulations as Formative Assessments: Generating Validity Evidence Related to the Test Content
. . . *Meghan Shaughnessy, Timothy Boerst and Rosalie DeFino* . . . 3123
Teacher reflections in lesson study: Transition from external to internal support
. . . *Charlotte Krog Skott* . . . 3131
The impact of pre-service teachers' basic mathematical knowledge on their university mathematics grades: A case study from Norway
. . . *Morten Søyland and Arne Jakobsen* . . . 3139
Teacher professionalisation through the use of a digital diagnostic tool in settings with different forms of additional support
. . . *Anica Stemmer, Katrin Klingbeil and Bärbel Barzel* . . . 3147

Learning to assess and respond to children's mathematical thinking in early arithmetic education: a vignette-based study with pre-service teachers
. . . *Simone Wirth, Marita Friesen, Kathleen Philipp and Christine Streit* . . . 3155
Examining the lesson plan designs and reflections of pre service elementary teachers regarding mathematics teaching
. . . *Bilge Yilmaz Aslan and Mehmet Fatih Ozmantar* . . . 3163
The Reflective Gaze: A Case Study on Eye-Tracking Technology's Role in Shaping Mathematics Teacher's Assessment Identity
. . . *Adi Eraky* . . . 3171
Identifying, monitoring and fostering conceptual understanding of the arithmetic mean
. . . *Laura Geldermann* . . . 3173
Teachers' discussions used to explore students' mathematical writing
. . . *Jonas Jäder* . . . 3175
The interplay between mathematics teachers' professional development and classroom practice: A scoping review
. . . *Therese Karlsson* . . . 3177
Teacher noticing framework to examine multiple teaching skills: Analysis of teaching and lesson planning
. . . *B. Sumeyye Kurutas* . . . 3179
Learning to teach problem-solving using a four-step lesson structure
. . . *Sabine Lit, Marjolein Kool and Paul Drijvers* . . . 3181
Fostering argumentative dialogue in secondary math classrooms: Teacher development trajectories through task-based PD
. . . *Reut Parasha* . . . 3183
Teachers in noticing courses, how are they noticing and what do their educators notice about their discussions?
. . . *Jop Schaap, Theo van den Bogaart and Paul Drijvers* . . . 3185
Contextualisation and complexity in online rehearsal of feedback: Insights from online mathematics teacher education
. . . *Kristofer Sidenvall* . . . 3187
Preservice teachers' awareness of their own developmental trajectories in primary mathematics teacher education
. . . *Michiel Veldhuis, Sonja Stuber and Ronald Keijzer* . . . 3189

TWG 19: Mathematics Teaching and Teacher Practice(s) 3191
An introduction to TWG19: Mathematics Teaching and Teacher Practice(s)
. . . *Reidar Mosvold, Helena Grundén, Mark Hoover, Derek Maher, Qëndresa Morina and Nad'a Vondrova* . 3192
Sustainability and Mathematics Education considering the 2030 Agenda: Understandings and Practices of Teacher-Researchers in Portugal
. . . *Andrei Luís Berres Hartmann, Marcus Vinicius Maltempi and António Manuel Dias Domingos* . . . 3200
Mathematics teacher practices to foster reasoning and communication through making connections
. . . *Judit Chico, Genaro De Gamboa, Edelmira Badillo and Miguel Montes* . . . 3208
Identifying the needs of mathematics teachers during the implementation of new mathematics education goals
. . . *Ilze France, Ildze Cakane and Astrida Cirule* . . . 3216
Teacher-student interaction in collaborative problem-solving: In-the-moment perspective on teacher noticing
. . . *Ellen Kristine Solbrekke Hansen and Kristin Krogh Arnesen* . . . 3224
Practices in math discourses in inclusive primary school
. . . *Uta Häsel-Weide and Marcus Nührenbörger* . . . 3232

The Work of Listening to and Hearing Children's Mathematical Competence
. . . *Mark Hoover and Deborah Loewenberg Ball* . . . 3240
Polya's method variant: Developing students' analytical thinking
. . . *Lavinia Suvi Lanting* . . . 3248
How expert mathematics teachers play 'status games'
. . . *Nicholas James McIvor, Jeremy Hodgen, Sai Loo and Rachel Marks* . . . 3256
Implementing the SIMPLE approach: A study on teacher fidelity and perceptions in Kosovo classrooms
. . . *Qendresa Morina and Naďa Vondrová* . . . 3264
Explicating the work of monitoring students' mathematical thinking
. . . *Reidar Mosvold, Janne Fauskanger, Raymond Bjuland and Peter Liljedahl* . . . 3272
Tensions in teachers' attempts to balance mathematical challenge and students' diverse learning needs
. . . *Samaher Ahmed Nama, Despina Potari, Giorgos Psycharis and Chrissavgi Triantafillou* . . . 3280
Selecting and sequencing problems for classroom discussion in a problem-posing task: Insights from prospective elementary teachers
. . . *Mehmet Fatih Öçal, Tuğrul Kar, Merve Özkaya and Ferhat Öztürk* . . . 3288
Mathematics teacher practice in inquiry-based lessons: a case study in a Japanese upper secondary school
. . . *Toshihiko Ogawa and Takeshi Miyakawa* . . . 3296
What do teachers notice when reflecting on vignettes of discussion leading practices? A topic-specific case study
. . . *Monika Post and Dilan Şahin-Gür* . . . 3304
Interactions between talk moves and other teaching moves in classroom discussions in ambitious mathematics teaching
. . . *Kjersti Waege and Reidar Mosvold* . . . 3312
Learning support practices in the fostering of basic arithmetic skills
. . . *Inga Wienhues and Uta Häsel-Weide* . . . 3320
A Preservice Mathematics Teacher's Reflection on In-The-Moment Noticing of Students' Mathematical Thinking
. . . *Ayten Öykü Yaşar, Mine Işıksal Bostan and Erdinç Çakıroğlu* . . . 3328
The implementation of a new curriculum in Greece: The case of learning and teaching statistics
. . . *Georgia Athanasiou, Konstantinos Stouraitis and Despina Potari* . . . 3336
Support shifts in how teachers view their students' capabilities when co-teachers develop ambitious instructional practice
. . . *Anna Bengtsson* . . . 3338
Teaching mathematically gifted students in secondary schools: A systematic literature review
. . . *Peter Kaiser and Moritz Zehnder* . . . 3340
Help-seeking interactions in primary school mathematics classrooms
. . . *Emine Shaka, Natalie Fischer and Elisabeth Rathgeb-Schnierer* . . . 3342

TWG 20: Mathematics Teacher Knowledge, Beliefs and Identity 3344

Introduction to TWG20: Teachers' Knowledge, Beliefs and Identity
. . . *Miguel Montes, Veronika Hubenaková, Federica Ferretti, Thorsten Scheiner, Felix Woltron* . . . 3345
Beliefs of elementary school teachers regarding the inclusion of special education students in mathematics lessons
. . . *Bital Amir and Esther Sharon Levenson* . . . 3353
How teacher education program experiences affect pre-service mathematics teachers' designated teacher identities?
. . . *Okan Arslan* . . . 3361

Teacher knowledge and the incorporation of inclusivity in a primary level generalisation problem
. . . *Ángeles Chico Gómez, Elisabetta Robotti, Nuria Climent Rodríguez and Inmaculada Gómez Hurtado* . 3369
Pre-service teachers' professional development and mathematics large-scale assessment
. . . *Maria Chiara Cibien* 3377
Prospective mathematics teachers' specialised knowledge in response to a task on the density property of rational numbers
. . . *Rosa Delgado Rebolledo and Diana Zakaryan* 3385
Pre-service teachers' knowledge of students' misconceptions and difficulties related to functional thinking: a German and Slovak comparison
. . . *Kerstin Frey, Ute Sproesser, Matej Slabý and Ingrid Semanišinová* 3393
Exploring strategy flexibility and adaptivity in multidigit multiplication: a study with Austrian in-service primary teachers'
. . . *Martina Greiler, Tanja Lobnig and Almut Thomas* 3401
An investigation of TPACK using a 3D Techno-pedagogical integration matrix in the context of mathematics teaching
. . . *Tuğba Hangül Demirci and Hatice Akkoç* 3409
Preservice teachers' self-perceptions about their knowledge for teaching
. . . *Hulya Kilic and Fatma Aslan-Tutak* 3417
The Theory of planned behavior as a tool for linking beliefs and knowledge within the MTSK model
. . . *Monika Krišáková and Veronika Hubeňáková* 3425
Promoting and unpacking pre-service teachers' thinking about students with exceptional difficulties in learning mathematics in the context of a university course
. . . *Philipp Larmann, Leonie Horsch, Samira Reitmann and Matthias Ludwig* 3433
Inconsistencies in the process of posing problems for use in class by pre-service teachers
. . . *Juan Pedro Martín-Díaz, Angeles Chico, Isabel Pascual-Martín and Miguel Montes* 3441
Characteristics of teachers' lesson observations: A comparison of in-service and pre-service teachers' gestures
. . . *Tatsuya Mizoguchi, Yusuke Shinno, Akiko Tomosada and Toru Hayata* 3449
Three-fold meta-didactical conflict. LSA and teacher education
. . . *Serena Monica and Federica Ferretti* 3457
Mathematics teachers' identity in the prison context
. . . *Gabriella Pocalana, Silvia Regola and Agnese Ilaria Telloni* 3465
Towards European measures for upper secondary teacher students' mathematical content knowledge
. . . *Ottavio Giulio Rizzo and Carl Winsløw* 3473
Perceptions of mathematical creativity: The case of one teacher in a special education class
. . . *Maya Ron-Ezra and Esther S. Levenson* 3481
Teachers' beliefs regarding the knowledge they need to teach word problems in middle school
. . . *Iris Schreiber* 3489
Specialized mathematical knowledge in the scope of geometric isometric transformation translation and its impact on teacher's levels of Interpretive Knowledge
. . . *Caroline Silva and Miguel Ribeiro* 3497
Preservice and inservice teachers' understanding of the concept of function: The case of motion problem.
. . . *Matej Slabý and Ingrid Semanišinová* 3505
Impact of an academic intervention on prospective teachers' mathematical world views during their transition to university
. . . *Felix Woltron* 3513
Elementary preservice teachers' knowledge in creating alternative word problems: A guide for mathematics educators
. . . *Fatimah Ahmad* 3521

Teachers' knowledge and beliefs about assessment in mathematics: initial evidence from a national survey of teachers' formative needs
. . . *Giorgio Bolondi, Maria Chiara Cibien, Federica Ferretti, Alessandro Gambini and Francesca Martignone* . . . 3523
Alternatively certified mathematics teachers' perceptions, experiences, and commitment to continue teaching
. . . *Evan Dixon McClintock ,* . . . 3525
Developing prospective kindergarten and primary teachers' specialised knowledge through tasks for teacher education in the scope of operations with natural, integers and rational numbers
. . . *Sandra Menezes, Miguel Ribeiro, Arne Jakobsen and Maria Mellone* . . . 3527

TWG 21: Assessment in Mathematics Education 3529

Introduction to the papers of TWG21: assessment in mathematics education
. . . *Francesca Morselli, Michal Ayalon, Christina Drüke-Noe, Gözde Kaplan-Can, Johanna Rämö* . . . 3530
Graphical tasks with graphical feedback on limits of functions to support abstract reasoning
. . . *Alice Barana, Marina Marchisio Conte, Fabio Roman, Matteo Sacchet, Mirela Vinerean and Yosief Wondmagegne* . . . 3534
Development of screening instruments for mathematics education: Theoretical Framework and item development
. . . *Léon Brings, Michael Kleine, Samuel Coronado Alvarez, Julia Pilet, Sanja Rukavina, Konstantinos Tatsis, Georgios Fesakis, Andreas Moutsios-Rentzos, Miglena Asenova and Doris Dumičić Danilović* . . . 3542
Exploring instrumental orchestration practices for formative assessment through digital technology
. . . *Min Chen, Rogier Bos, Michiel Doorman and Paul Drijvers* . . . 3550
Have you thought about short-cuts? – A recommendation for the design of assessment tasks
. . . *Lukas Donner and Evita Lerchenberger* . . . 3558
How are different competences represented in standard solutions? An empirical study on central exit exams in mathematics in Germany at the end of upper secondary education
. . . *Christina Drüke-Noe and Sebastian Bauer* . . . 3567
Introduction of a practical element in oral examination of mathematics: Teachers learn first
. . . *Frode Olav Haara* . . . 3575
Students' reactions to speech input requests in a digital formative assessment of conceptual understanding
. . . *Corinna Hankeln, Susanne Prediger, Ulf Kroehne and Sonja Hahn* . . . 3583
Preservice teachers' formative assessment strategies they intend to implement in a real classroom
. . . *Gözde Kaplan-Can and Çiğdem Haser* . . . 3591
Written tests through the lens of mathematical competence: how a teacher perceives feedback from test and data collected
. . . *Alice Lemmo, Grazia Cotroni and Laura Polidoro* . . . 3599
Evaluating a multi-indicator assessment scoring approach to support mathematical literacy teaching and learning
. . . *Marta Mikite, Ģirts Burgmanis, Ilze France and Dace Namsone* . . . 3607
The contribution of mathematics didactics to interpreting the results of a standardized national assessment
. . . *Julia Pilet and Brigitte Grugeon-Allys* . . . 3615
Changing the assessment paradigm – What predicts students' choice of assessment method in an undergraduate mathematics course?
. . . *Johanna Rämö, Liisa Myyry, Jokke Häsä and Yan Zi* . . . 3623
Using subscores from the high-stakes assessment to explain first-year performance in Mathematics courses
. . . *Tatiana Sango* . . . 3631

The role of digital tools in enhancing classroom assessment practices
. . . *İpek Saralar-Aras and Sümeyra Tütüncü* . . . 3639
Professional development support helping teachers overcome difficulties of implementing formative assessment
. . . *Catarina Andersson, Torulf Palm and Mikael Winberg* . . . 3647
Effects of the COVID-19 pandemic on mathematics achievement: An investigation in university math precourses
. . . *Andreas Büchter, Frank Osterbrink and Natascha Scheibke* . . . 3649
How can the prison context change teachers' perspective and practices about mathematic assessment?
. . . *Veronica Manzoni, Silvia Regola and Chiara Giberti* . . . 3651

TWG 22: Curricular Resources and Task Design in Mathematics Education 3653
An introduction to TWG22: Curricular resources and task design in mathematics education
. . . *Annalisa Cusi, Patrick Ebers, Dubravka Glasnović Gracin, Shai Olsher and Hendrik Van Steenbrugge* . 3654
Task designs to support connection-oriented mathematical thinking
. . . *Hyman Bass* . . . 3662
Students' perspectives on GPT-4's supported problem solving
. . . *Francesco Contel and Annalisa Cusi* . . . 3670
Noticing of teacher students on an explorative task to exemplify the potential of using technology
. . . *Patrick Ebers* . . . 3678
Synergies and dissonances between designers' and students' perspectives on key features of digital mathematical discussion
. . . *Sara Gagliani Caputo, Laura Branchetti and Annalisa Cusi* . . . 3686
Teacher perspectives on textbooks and their role in Implementing the mathematics laboratory approach in Italy

Preface and Introduction

Preface: CERME14 – finally in Bozen-Bolzano!

Carl Winsløw[1]

[1]University of Copenhagen, Faculty of Science, Copenhagen, Denmark; winslow@ind.ku.dk

The 14th Congresss of the European Society for Research in Mathematics Education (CERME14) marks a genuine return to normality for the congress, in two ways. First, the congresses have been biannual and held in February since CERME2, held 2002 in Prague. Second, we originally planned to have CERME12 in Bolzano in 2021. As we all know, the COVID pandemic disturbed everything from early 2020, resulting in a postponement of CERME12 to 2022, and the decision in December 2021 to have the congress online "from Bolzano" but, indeed, not "in Bolzano". Subsequently, CERME13 was held in Budapest in July 2023, as the first on-site CERME since 2019. Having finally been able to realise CERME14 in February 2025, and in Bolzano, thus marks a restoration of the regular pattern, and of the plan to realise CERME in the capital of the South Tyrol region.

The community of research which is drawn to CERME owes much to the team of Free University of Bozen-Bolzano (UniBz), having organised both CERME12 and CERME14. There was nothing given in the fact that this team, led by Giorgio Bolondi and Camilla Spagnolo, would propose to organise CERME14, after the many challenges and disappointments that had been caused by the pandemic. Indeed, CERME12 became a "real" CERME thanks to them, and despite the impossibility, at the time, to convene on-site. But the dream to have the community come to the beautiful city of Bolzano survived, and was realised as an indisputable success in 2025. The community is rightfully grateful for the heroic efforts of the team over seven years – indeed, the planning for CERME12 had started in 2018 – culminating with the congress that the present proceedings report on. The Local Organising Committee of CERME14 mobilised not only colleagues from Bolzano but also from neighbouring regions of Italy, and was supported by the wonderful administrative staff of UniBz. To all of you dear colleagues, the warmest thoughts and thanks are due, from the entire ERME community.

The organisation of the scientific programme of CERME14 was led by Marianna Bosch (Barcelona) and Susana Careira (Portugal), as well as by the entire International Programme Committee and the leader teams of no less than 29 Thematic Working Group (TWG). The community is equally grateful for your tireless and generous efforts to make the congress a rich and fruitful site of scientific communication, collaboration and cooperation. CERME is not a congress like any other – its success relies on the careful preparation of all participants, whether authors, reviewers, group leaders or committees, to enable the congress to focus on discussion of the contributions rather than mere presentations and decorative questioning. The present proceedings present the outcome of this collective work, not simply the individual contributions which were submitted back in September of 2024. Each TWG represents a specialized subcommunity of ERME, and the interaction of its members makes both the event and its products much more than the sum of what was initially submitted. It is this experience of international scientific community which makes CERME such a productive event and which makes it worthwhile for so many to work for its continued development and success. At CERME14, 848 participants from 50 countries contributed to this work (Table 1).

Table 1: Participants at CERME14 by country

Algeria : 2	Cyprus : 2	Iceland : 2	Mexico : 8	Romania : 1
Australia : 8	Czech Rep.: 15	Ireland : 7	Morocco : 1	Slovakia : 9
Austria : 25	Denmark : 25	Israel : 44	Netherlands: 30	South Africa : 3
Belgium : 3	Estonia : 4	Italy : 94	New Zealand: 1	Spain : 42
Brazil : 7	Faroe Islands : 1	Japan : 7	Nigeria : 1	Sweden : 51
Canada : 10	Finland : 2	Kuwait : 1	Norway : 64	Switzerland: 14
Chile : 5	France : 10	Latvia : 3	Poland : 3	Thailand : 1
China : 3	Germany : 168	Lithuania : 1	Portugal : 18	Turkey : 31
Costa Rica:1	Greece : 20	Luxembourg : 1	Puerto Rico : 1	UK : 39
Croatia : 5	Hungary : 12	Malta : 1	Quatar : 1	US : 40

As the table illustrates, the ERME community is not limited to the geographical region of Europe. The contribution of colleagues from around the world obviously adds to the importance and quality of the CERME concept. Mathematics education research is, indeed, a global endeavour with far-reaching stakes both in terms of the intellectual and societal importance of its subject. Research evidently benefits hugely from considering the variations, difficulties and advances that exist within each national and cultural context. The original purpose of ERME – to share results and ideas across countries in Europe – has clearly caught up with globalization in this sense.

In my preface for the proceedings of CERME13 (Winsløw, 2013), I briefly touched upon the concrete numerical challenges, which the success of CERME poses to organisers. The ERME board has worked closely with both the LOC and the IPC to implement a model which unites inclusivity and fairness in a situation where there is an increasing number of proposals submitted, in fact, more than the capacity of academic venues can currently accommodate. This was already the case for CERME14 and is likely to be so at CERME15 in Bratislava. The solution, to be further developed by the entire ERME community, involves not only a necessary "acceptance rate" (fixed at 75% for CERME14) but also a development of further opportunities for specialized subcommunities to convene to communicate, collaborate and cooperate on research, through still more ERME topic conferences. It also involves an increased effort to support first-time contributors to CERME, a refocused effort to extend financial support to emergent research communities in Europe, and new online events to prepare young researchers for CERME and other activities organised by our society.

Finally, on a personal note, my four years as president of ERME ended with CERME14. I wish to extend my heartfelt thanks to all the board members and other colleagues whose support and kindness have made these years some of the most professionally enriching end enjoyable of my life.

About CERME14

The fourteenth Congress of the European Society for Research in Mathematics Education (CERME14) took place in Bolzano, Italy, from 4 to 8 February 2025. It was hosted by the Free University of Bozen-Bolzano, with the patronage of Associazione Italiana di Ricerca in Didattica della Matematica (AIRDM), of Unione Matematica Italiana (UMI), of Stadtgemeinde Bozen-Comune di Bolzano, of M.C. Escher Foundation, in collaboration with the Tourist Office of the town of Bolzano, and with support of Stiftung Südtiroler Sparkasse (Fondazione Cassa di Risparmio di Bolzano). The congress brought together 924 among researchers, teachers, and PhD students from 53 countries across all continents, who share an interest in advancing the field of mathematics education research through dialogue, collaboration, and exchange.

Marianna Bosch and Susana Carreira were chair and co-chair of the International Programme Committee, which included Giorgio Bolondi, Paul Drijvers, Csaba Csapodi, Alf Coles, Sibel Kazak, Bozena Maj-Tatsis, Janka Medova, Hanna Palmer, Sigal Rotem, Daniel Thurm, Floriane Wozniak (from July 2023). Giorgio Bolondi chaired the Local Organizing Committee, which was co-chaired by Michael Gaidoschik and Camilla Spagnolo.

As in previous editions, the scientific heart of the congress was the work carried out within the Thematic Working Groups (TWGs). CERME14 hosted 29 TWGs, listed in Table 1. TWG7 on *Mathematics for Work, Society and Personal Development: Lifelong Learning*, which was inactive at CERME13, has been reactivated for CERME14. TWG11, previously under the title *Algorithmics*, has re-emerged as an active group on *Teaching and Learning of Discrete and Computational Mathematics*. TWG25 on *Inclusive Mathematics Education – Challenges for Students with Special Needs* was discontinued and replaced by a new TWG25 on *Teaching and Learning of Calculus*. Titles of several TWGs were updated to better reflect evolving research focuses and current terminology. TWG2 changed from *Arithmetic and Number Systems* to *Arithmetic, Numbers and Operations* TWG9 was expanded from *Mathematics and Language* to *Interaction, Communication and Language in Mathematics Education*. Finally, TWG24 was extended from *Representations in Mathematics Teaching and Learning* to *Representations in Mathematics Teaching, Learning and Research*. In total, 159 TWG leaders and co-leaders contributed to shaping the discussions and fostering constructive and critical exchanges. Their efforts, along with those of hundreds of participants who

presented and discussed research papers and posters, lie at the core of CERME's identity: a conference grounded in community, dialogue, and shared commitment to improving mathematics education.

Prior to the congress, the YERME Day offered a dedicated space for early career researchers to present their work, receive feedback, and connect with others. This tradition continues to play a vital role in sustaining and renewing the ERME community, attracting 125 participants.

Table 1: Overview of the TWG leadership teams

Thematic Working Group	Leader	Co-leaders
TWG01: Argumentation and Proof	Andreas Moutsios-Rentzos	Nadia Azrou, Orly Buchbinder, Viviane Durand-Guerrier, David Alexander Reid, Fiene Bredow, Dimitrios Deslis, Mei Yang
TWG02: Arithmetic, Numbers and Operations	Ioannis Papadopoulos	Elisabeth Rathgeb-Schnierer, Renata Carvalho, Robert Gunnarsson, Eszter Kónya, Linda Devi Fitriana
TWG03: Algebraic Thinking	Maria Chimoni	Luis Radford, Jorunn Reinhardtsen, Stefan Korntreff
TWG04: Geometry Teaching and Learning	Alik Palatnik	Lina Brunheira, Taro Fujita, Petra Surynková, Chrissa Papadaki
TWG05: Probability and Statistics Education	Aisling Leavy	Daniel Frischemeier, Orlando Gonzalez, Sibel Kazak, María Magdalena Gea, Luca Lamanna
TWG06: Applications and Modelling	Jonas Bergman Ärlebäck	Britta Eyrich Jessen, Gilbert Greefrath, Katrin Vorhölter, Serife Sevinç, Yana Lacek
TWG07: Mathematics for Work, Society and Personal Development: Lifelong Learning	Pauline Vos	Beth Kelly, Peter Frejd, Michele Giuliano Fiorentino, Javier Díez-Palomar, Oda Heidi Bolstad
TWG08: Affect and the Teaching and Learning of Mathematics	Chiara Andrà	Domenico Brunetto, Robin Göller, Inés María Gómez-Chacón, Hanna Viitala, Janina Krawitz
TWG09: Interaction, Communication and Language in Mathematics Education	Jenni Ingram	Kirstin Erath, Alexander Schüler-Meyer, Máire Ní Ríordáin, Ingólfur Gíslason
TWG10: Diversity and Mathematics Education: Social, Cultural and Political Challenge	Timo Dexel	Laura Black, Juuso Nieminen, Sabrina Bobsin Salazar, Mariam Makramalla, Daniela Steflitsch
TWG11: Teaching and Learning of Discrete and Computational Mathematics	Simon Modeste	Janka Medova, Ulrich Kortenkamp, Sylvia van Borkulo, David Zenkl

TWG12: History in Mathematics Education	Antonio M. Oller-Marcén	Bjørn Smestad, Wendy Goemans, Tanja Hamann, Marianne Thomsen
TWG13: Early Years Mathematics	Andrea Maffia	Camilla Björklund, Dorota Lembrér, Eva Nováková, Chronoula Voutsina, Ergi Acar Bayraktar
TWG14: University Mathematics Education	Irene Biza	Olov Viirman, Ignasi Florensa, Ghislaine Gueudet, Athina Thoma, Mathilde Hitier
TWG15: Teaching Mathematics with Technology and Other Resources	Bärbel Barzel	Ornella Robutti, Eirini Geraniou, Nicola Bretscher, Gülay Bozkurt, Andreas Tamborg
TWG16: Learning Mathematics with Technology and Other Resources	Osama Swidan	Jana Trgalova, Florian Schacht, Eleonora Faggiano, Rogier Bos, Sara Bagossi
TWG17: Theoretical Perspectives and Approaches in Mathematics Education	Heather Johnson	Felix Lensing, Pedro Nicolás, Amalie Sødal
TWG18: Mathematics Teacher Education and Professional Development	Marita Friesen	Raffaele Casi, Andreas Ebbelind, Janne Fauskanger, Tracy Helliwell, Pedro Ivars, Libuše Samková, Gil Schwarts, Fanni Biró
TWG19: Mathematics Teaching and Teacher Practice(s)	Reidar Mosvold	Mark Hoover, Helena Grundén, Nada Vondrova, Qëndresa Morina, Derek Maher
TWG20: Mathematics Teacher Knowledge, Beliefs and Identity	Miguel Montes	Veronika Hubenaková, Federica Ferretti, Thorsten Scheiner, Felix Woltron
TWG21: Assessment in Mathematics Education	Francesca Morselli	Christina Drüke-Noe, Michal Ayalon, Johanna Rämö, Gözde Kaplan Can
TWG22: Curricular Resources and Task Design in Mathematics Education	Annalisa Cusi	Dubravka Glasnović Gracin, Shai Olsher, Hendrik Van Steenbrugge, Patrick Ebers
TWG23: Implementation of Research Findings in Mathematics Education	Linda Marie Ahl	Mario Sánchez Aguilar, Boris Koichu, Oda Helenius, Julie Vangsøe Færch
TWG24: Representations in Mathematics Teaching, Learning and Research	Michal Tabach	Elisa Miragliotta, Anna Baccaglini-Frank, Kate O'Brien
TWG25: Teaching and Learning of Calculus	Laura Branchetti	Anatoli Kouropatov, Vahid Borji, Farzad Radmehr, Jana Peters
TWG26: Mathematics in the Context of STEM Education	Michelle Stephan	Clelia Cascella, M. Sencer Corlu, Nelleke Den Braber
TWG27: The Professional Practices, Preparation and Support of Mathematics Teacher Educators	Ronnie Karsenty	Stefan Zehetmeier, Bettina Rösken-Winter, Hilda Borko, Francisco Javier Rojas, Birte Pöhler-Friedrich

TWG28: Collaborative Settings in Mathematics Teacher Education	Stéphane Clivaz	Pernilla Mårtensson, Aoibhinn Ní Shúilleabháin, Geoff Wake, Paula Gomes
TWG29: Embodied and Material Studies of Mathematical Behaviour	Anna Shvarts	Elizabeth de Freitas, Ricardo Nemirovsky, Nathalie Sinclair, Christina Krause, Giulia Ferrari

Editorial information

These proceedings are available as a complete volume on the ERME website. Each individual contribution is also available through the HAL open archive, where it can be found through keywords, title, or author name. This has been the practice since CERME9, to increase the visibility of the huge work done in CERME conferences.

After the preface by the president of ERME, Carl Winsløw, and this brief introduction by the proceedings' editors, this volume continues with texts of three plenary activities of CERME14. The three plenary sessions address a question that has not yet been tackled directly at CERME. It concerns the evolution of the mathematical curriculum in light of the new society demands, particularly with regard to critical issues such as sustainability and the rapid development of data science. The plenary lecture by Ferdinando Arzarello was entitled "New landscapes for mathematics curricula: reflections from an Italian experience". Drawing on a few recent Italian curricular stories of recent years, the lecture provides an original overview of the challenging issues surrounding the mathematics curriculum that are often overlooked in mathematics education research. It offers productive theoretical frameworks with which to address these issues. The second plenary was a dialogue between Kjellrun Hiis Hauge and Alf Coles titled "Climate change and mathematics education: entanglements, values and hopes". The dialogue explores the entanglements of our living world and how mathematics education could respond to them, building on different intricate "gestures" that can be employed to avoid overlooking them. The contrasts between the English and Norwegian curricula provide insights into possible development paths, highlighting both their urgency and the critical constraints that could hinder the involvement of mathematics in addressing the pressing issues of our world. The third plenary was a dialogue between Michelle Wilkerson and Rolf Biehler titled "The new role of data in society: Exploring challenges and opportunities for mathematics education in the age of data science and AI". The authors provide a comprehensive and helpful overview of research in data science and AI, emphasising the essential role they play in our societies and highlighting the need for curricula to be more closely aligned with them. They also point to critical difficulties associated with the field's inherent interdisciplinarity, while offering concrete and highly stimulating examples based on their own research experiences that open up the prospect of a possible future.

The biggest part of these proceedings consists of the sections corresponding to the TWGs. These sections start with an introduction by the TWG leadership team. According to the team's choice, this is a 4-page introduction presenting the contributions, or an extended 8-page one, which proposes an additional analysis of the current research on the theme of the TWG, and perspectives for the future. Next, the section consists of the paper and poster contributions—in alphabetical order by first author's name.

Acknowledgment

These CERME14 proceedings represents a collaborative effort involving the CERME14 IPC and LOC, the TWG leaders and co-leaders, and the editorial team. We express our sincere gratitude to all those who contributed to the reviewing, editing, and organisational processes that made this publication possible. Particular thanks are due to Domenico Brunetto, Sofia Cavalletti, Chiara Giberti, and Veronica Manzoni for their editorial work. We warmly thank all participants for their contributions, and we hope that these proceedings will continue to nurture the collaborative spirit that defines ERME, inspiring further research and dialogue in mathematics education across Europe and beyond.

Plenary Lectures

Old and new landscapes for mathematics curricula: reflections from an Italian experience

Ferdinando Arzarello

Mathematics Department, University of Torino, Italy

The international research underlines the elusive and multifaceted aspects of what is meant by a mathematics curriculum across countries. Two major driving forces have been identified as significant, even if not always convergent: that of cultural values and that of political movements. Teachers' involvement, ownership and commitment to a curriculum reform must be regarded as a must for its successful implementation: for having a suitable didactic transposition, concrete bottom-up and top-down strategies are needed, developed with a careful theoretical analysis. With new areas and links to other disciplines being introduced in mathematics curriculum reforms, foundational questions about what constitutes mathematics in the school mathematics curriculum are raised, and these are linked to the current changes in professional mathematics and to the rapid increase of technology. The discussion of these issues is mainly developed through examples based on the experiences of the author.

Keywords. Mathematical curriculum, didactic transposition, citizenship education, artificial intelligence.

Looking backward for going forward

The mathematics curriculum: an elusive notion

In his contribution to the *ICMI Study 24* (Ruiz et al., 2022), Mogen Niss recalls the different meanings that the word "curriculum" carries and depicts a (mathematics) curriculum with respect to a given educational setting as a vector with six components, which correspond to its main *facets*: Goals; Content; Materials; Forms of Teaching; Student Activities; Assessment. Moreover, other scholars (e.g. Kulm & Li, 2009) point out that curricula can be analysed at different *levels*: from micro to macro.

At the micro-level, the specific facets of curriculum practices and changes are the focus, e.g. according to the Niss version: these, on their turn, embrace the TIMSS classification (Mullis & Martin, 2017) in *Intended* (mainly Goals and Content), *Implemented* (mainly Materials, Forms of Teaching, Student Activities), and *Attained* (mainly Assessment) curriculum.

At the macro-level, the socio-cultural and historical specificities of curriculum practices and changes are emphasised. For example, the ideas of inquiry, problem solving, and student-centred instruction in the development of China's new standards were built on a strong foundation of learning basic skills, using a centuries-old philosophy of Confucianism to provide support for more modern ideas. In Italy, the same words are used with a very different background, e.g., as we will show in the next section, Italian curricula in the first decades of this century have been inspired to the approach of US New Standards, as well as to the Italian tradition represented for example by the reflections of F. Enriques (Giacardi, 2012) and E. Castelnuovo (Arzarello et al., 2013), hence with an integration of Italian and abroad theoretical frames.

This framework puts forward a structural approach to curriculum analysis with a suitable combination of micro- and macro- features, but without losing their specificity. In fact, it is the same general world globalisation that pushes towards such an integration:

> In recent years the internationalisation and globalisation of the economy, universality of technological development and related needs for new skills and knowledge play the role of strong motivations for curriculum reforms that have brought calls for unified standards for mathematics in school. (Shimizu & Vital, 2023, p. 6)

Specifically, the stress is mainly on promoting at a micro-level specific and more or less sophisticated ways of thinking, like *critical thinking* and *high-order thinking*; *inquiry-based mathematical education*; or *quantitative literacy*.

As discussed by Bosch and O'Meara (2023), such processes can interact productively according to three main macro-level aspects:

- *Theoretical* (analysis tools to deal with the present rapidly evolving situation).
- *Cultural* (what mathematics to teach and how to do it);
- *Political* (how to reconcile the need for a cultural preparation suitable to live in a globalised world, with the links to be kept with personal and cultural reality?).

This double classification (in macro-/micro- levels and micro-facets) illustrates the main problems with curricula: the risk of a *double gap*. On the one side, there are difficulties for an actual merging between the macro- and the micro- levels; on the other side, it may also be difficult to produce an effective and productive interaction among its various micro-facets (e.g., those described by M. Niss). The main problem poses the necessity of an effective theoretical analysis of the double gap to elaborate suitable actions in order to overcome it at the concrete level of curricula implementation.

The Anthropological Theory of the Didactic by Y. Chevallard (2019) can help in solving this problem through the *didactic transposition* construct. It identifies conditions that go beyond the narrow space of the classroom and the subject that has to be studied in it, and deals with:

> the transformations an object or a body of knowledge undergoes from the moment it is produced, put into use, selected, and designed to be taught until it is actually taught in a given educational institution. (Chevallard & Bosch, 2014, p. 170)

In fact, knowledge is not taught directly, but undergoes transformations at different levels of the didactic transposition chain, and different actors participate in this transposition work: producers of knowledge, teachers, curriculum designers, etc. The didactic transposition consists of two basic steps (Figure 1): external didactic transposition carried out outside school, and internal didactic transposition inside the school (Chevallard, 1991; Winsløw, 2011). More specifically, in the external didactic transposition process, the scholarly knowledge that institutions outside school, such as universities or colleges, produce is transposed into knowledge to be taught by the noosphere, in accordance with the social and cultural needs of a society (Bosch & Gascón, 2006; Chevallard, 1991).

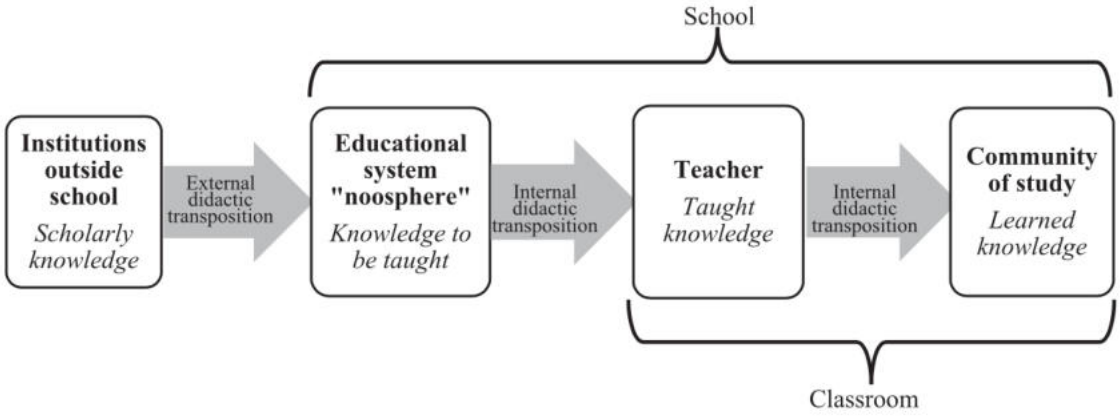

Figure 1. The didactic transposition process
(Akar, N. & Işıksal-Bostan, M., 2021, p. 631; Bosch & Gascón, 2006, p. 56; Winsløw, 2011, p. 121)

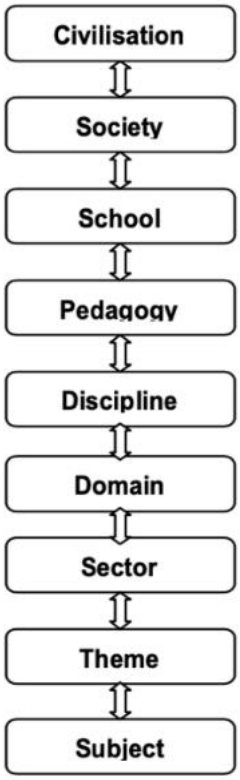

Figure 2. Scale of levels of determinacy
(Bosch & Gascón, 2006, p. 61)

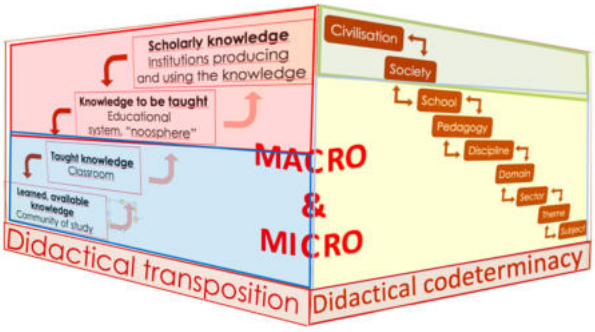

Figure 3. The two scales together

Chevallard introduces also a scale of "levels of codeterminacy" (Figure 2): it suitably frames in a unique process the macro- and micro- levels of a curriculum together with its different facets and can

help researchers to "go beyond the narrow space of the classroom and the subject that has to be studied in it" (Bosch & Gascón, 2006, p. 61).

Figure 3 illustrates the two scales within a double parallel frame: it goes from micro- (white background) to macro- (reddish background) features of the didactic transposition scale, contrasted with the corresponding codeterminacy levels. It must be observed that what we have called the curriculum facets involve more the micro-levels of didactic transposition/codeterminacy, while the macro-levels concern issues that appeared later on the scene of curricula but the variety and speed with which they are appearing in these last years is progressively increasing. For example, they concern globalisation, computational thinking, unified standards, etc., topics that will be discussed in the second part of the paper.

In the next section, I will illustrate how some Italian curricular projects progressively and, so to say "unconsciously", had to concretely face the double gap: their development represents a productive interaction between their micro-facets and a concrete progress from micro- to macro- levels. I will point out how this could happen because of an interesting didactical phenomenon, the meta-didactical transposition.

Mathematics Education: what is already there

I will start my discussion from some important Italian projects and experiences of mathematics teaching, which also deeply influenced national curricula during this first quarter of the century (see Figure 4):

a) *Matematica per il Cittadino* (2000-2005);
b) M@t.abel (2006-2012);
c) *Liceo Matematico* (2015-currently).

I will briefly give some information about the rationale of each project basing mainly on two papers: Arzarello et al. (2021), and Bernardi et al. (2024). I will so be able to elaborate some more general issues that will lead to the reflections of the successive section.

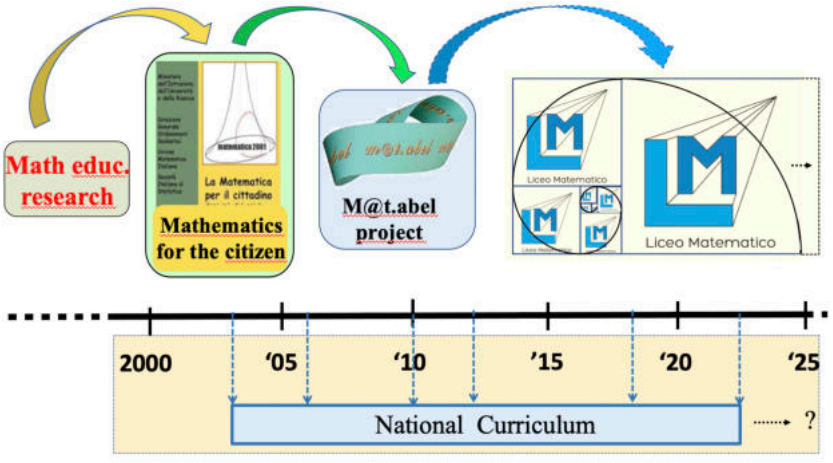

Figure 4: The three main Italian projects for Math teaching in the first quarter of this century

Mathematics for the citizen

At the beginning of the new century, a working group, on behalf of the Italian Ministry of Education, of UMI (Italian Mathematical Union) and SIS (Italian Society for Statistics), was charged to elaborate an updated and compact curriculum of mathematics for primary and secondary schools. It was made of about 30 experts (including myself as chair): they were academics in mathematics and mathematics education, policy makers, and mathematics teachers. All the people involved in the group had a strong expertise in mathematics education, and most of them had been part of research groups promoted since the 1970s by the Italian National Council of Research (CNR) in order to improve the teaching of mathematics in the schools (Arzarello & Bartolini Bussi, 1998). As a result of their work, which lasted four years, the *Matematica per il Cittadino* (MpC: Mathematics for the Citizen) was produced. MpC was inspired by the NCTM Principles and Standards for School Mathematics[1] and by other curricular projects that appeared in those years, by the results of the international mathematics education research and, of course, it took also into consideration the Italian tradition and practices in mathematics teaching. The proposed curriculum was based on the idea of mathematics laboratory, not so much as a place but as a methodology based on activities in which the students can learn by doing, seeing, imitating, communicating with each other, under the guidance of the teacher—that is, "practicing", as in an Italian Renaissance workshop (Arzarello et al., 2003, 2004; Chapman & Robutti, 2008; UMI-CIIM, 2001). The proposed teaching practices fostered a close interaction between novices (students) and expert (teacher), in the frame of cognitive apprenticeship, namely it "stressed the learning-through-guided-experiences based on cognitive and meta-cognitive, rather than on physical, skills and processes" (Collins et al., 1989, p. 455). Another important issue of the project was the particular attention to processes (and not only to contents), such as the use of different communication strategies, conjectures, argumentation and proof, problem-posing and problem-solving, measuring, and modelling. In consonance with the NCTM documents, MpC considered four main areas of mathematics contents (Numbers and Algorithms; Space and Figures; Relations and Functions; Data and Forecasts) and three main transversal areas (Arguing, Conjecturing and Proving; Measuring; Problem Posing and Problem Solving), essentially the same for all the grades of pre-university schools. The curriculum, which distinguished between skills and knowledge, was accompanied by about 150 examples of teaching activities, which illustrated the meaning of the curriculum itself: for each of the areas, the examples made explicit the skills and the knowledge, at which the activity aimed. Each activity was also accompanied by the relative assessment tests. All this huge work was published in three volumes (AAVV, 2001, 2003, 2004), which were sent as books to all the Italian schools, and later made freely available in the web as a PDF publication. The new proposal was spread through the country with many conferences, where its main points were showed to the schools and its content was used in many programs for teachers' professional development; moreover, the Ministry of Education used it to design – in the school reform – the new Mathematics Curriculum (in 2003, 2006, 2010, and 2012, respectively).

[1] https://www.nctm.org/Standards-and-Positions/Principles-and-Standards/

The MpC project can be classified according to the two following indicators: (i) the materials were books, available on the website; (ii) the interactions happened through the traditional format programs for teachers' professional development: meetings promoted by the Ministry of Education and by the schools, where the proposal was illustrated by experts, who had previously shared experiences in mathematical education through the CNR research groups mentioned above.

M@t.abel

Although the new Italian National Curriculum inspired by the MpC project mirrored the influence of this project, school reality was however quite far from being broadly influenced by the new perspectives: innovation was bounded to isolated cases and to primary or middle schools, more than to secondary schools. The believes of teachers about the effective ways they can teach mathematics to "mean achievers" were at the origin of a *didactical gap*, widely studied in the literature (e.g. see Kulm & Li, 2009; Silver, 2009). Hence, in order to fill the gap at the secondary level, the Ministry of Education and the Italian Agency of School (INDIRE) promoted in 2006 a new project, M@t.abel (it is not a web address but an acronym: *Matematica: apprendimenti di base con e-learning* [Basic mathematics with e-learning])[2]. The aim of M@t.abel (M@) was to disseminate the activities and teaching practices of MpC in a mathematics teacher professional development program, carried out over Italy from 2006 until 2012 in blended modality. It involved 6500 teachers, 412 tutors, 56 authors and researchers. The M@ activities were adapted to a double modality—multimodal and static, as downloadable file—presentation in a platform online. PISA tests (2006-2009) certified the success of the project (Stacey & Turner, 2015, pp. 249-260).

A careful analysis of this complex process made ex-post allowed to describe it as a process of *meta-didactic transposition* (MDT: Arzarello et al., 2014; Arzarello et al., 2021; Cusi et al., 2023) between the *praxeologies* of the three subjects involved in it: researchers, tutors, teachers. The word "praxeology" is a neologism introduced by Chevallard made of praxis as the "know how", and logos as the "knowledge", namely the theoretical discourses on praxis (Chevallard, 1999). According to Chevallard, a praxeology is made of the following components: a type of tasks, a technique, that is a way of performing the tasks (*praxis*), and its theoretical justification (*logos*). While Chevallard uses this construct to analyse teachers' didactical praxeologies in their school activity, the MDT adapts it to the analysis of professional development programs for teachers, considering the different praxeologies involved in the M@ program: those of the teachers, because of their basic professional experience in the school, those of the tutors, as experienced teachers, and those of researchers as designers and coachers of the teachers' educational program, because of their competence in mathematics education and in MpC. During the development of the program, the meta-didactical praxeologies of researchers and teachers (different at the beginning) may evolve towards shared praxeologies (Arzarello et al., 2014), through the passage of some of their components from external into being internal (namely used by individuals or by a community). Evolution of the praxeologies does not mean that all the teachers (or researchers) involved in the educational program evolve in the

[2] http://www.scuolavalore.indire.it/superguida/matabel/

same way with the same transformation of components: in fact, different teachers may evolve in different ways, with respect to their histories and experiences.

The M@ program develops in two steps. The first step concerns tutors' training (made by university researchers): the meta-didactical praxeologies of the researchers are shared with those of tutors, giving rise to shared praxeologies. In the second step, the teachers were organized in communities of inquiry (Jaworski & Goodchild, 2006), composed of 15-20 teachers and supervised by tutors. The communities of teachers worked first in some face-to-face meetings with tutors: the tutors presented the activities and the spirit of the project in some meetings, asking the teachers to analyse them from a didactical point of view. Then, the teachers experimented with some chosen activities in their own classrooms and observed their students' processes, writing their notes in a logbook to be uploaded on the platform: in this way, teachers' praxeologies started to change. Finally, the tutor coordinated the group of teachers from remote, through synchronous meetings and asynchronous discussions.

MDT had its strength in the use of a digital *platform* for synchronous and asynchronous activities among teachers. The platform was the environment that gave new techniques to teachers, influencing and supporting them in changing their praxeologies: specifically, if a teacher had worked for many years in a traditional and isolated way, now she was forced to discuss new methodological issues through the platform: this one, together with the brokering function of the tutors, aimed to build a community of teachers with *shared praxeologies*. For instance, the Dynamic Geometry Software productions could be used as concrete boundary objects between the community of tutors and that of teachers. The platform worked as a *communicational-representational infrastructure* (Hegedus & Moreno-Armella, 2009), fostering the use of a shared desktop where the teachers could work together on-line on the same topic or mathematical object. In the MDT model, the platform constitutes an example of an *external component* that becomes an *internal* one over the course of the project.

Through MDT as a process, a complete intertwining of the micro-level facets was realized and important connections between them and the macro-level institutional and cultural components was realized: particularly, the shared platform played a crucial role as a communicational and representational infrastructure in promoting them.

The M@ project ended in 2012 and influenced further the new versions of the official national curriculum until and after that date (Figure 1). However, as it is well known, from that time new characters were already treading the scene of mathematics and of mathematics teaching. In fact, since some decades, mathematics was dramatically changing both for endogenous and exogenous reasons (Borovic et al., 2022; Lolli, 2022). As a long-lasting example of the former, see the Langlands Program (Frenkel, 2013). For the second, one can advocate the development of interconnectivity and the growth of planet-wide crises, for example the effects of COVID-19 on the former and the climate changes on the latter. As a result of such human and social problems, new questions and goals were beginning to emerge. For example:

- What mathematics is necessary to understand interconnectivity?
- What mathematics is needed to understand climate?
- What mathematics is needed to understand biodiversity?
- What mathematics is needed to understand wealth distribution? (Chan et al., 2021, p. 9)

It is not by case that all the three plenary sessions in this conference address the problem of the evolution of the mathematical curriculum given the new society demands, especially concerning critical issues like sustainability and the high development of data science.

Such and similar questions require a concrete content revision of the usual didactical transposition processes. In Italy the experience of the *Liceo Matematico* represents a first partial concrete answer to such queries.

Liceo Matematico

A third initiative that involves Italian mathematics teachers in an ever-growing number consists of the *Liceo Matematico* (LM: Mathematical High School) activities.[3] The general idea of the LM is to give more space to mathematics and science, not to introduce a greater number of notions, but to reflect on foundations and ideas, broaden cultural horizons, deepen, understand better, and in particular underline connections with other disciplines, including humanities. A strongly interdisciplinary approach to the initiative is therefore highlighted. The LM-schools do not require adherence to a rigid scheme of activities but are based on the sharing of some principles that are flexibly declined in the different local realities. The activities always take place in a laboratory manner, in line with the idea of a mathematics laboratory as outlined in the MpC and M@ projects (in fact, some participants and organizers of LM come from those experiences). The design of the activities is featured by a strong collaboration between university researchers and schoolteachers, in both cases not only of mathematics. The collaboration is expressed through the organization of periodic meetings aimed at designing and discussing laboratory paths to be tested and implemented in the classes. The different experiences build a precious common heritage that is shared and compared during an annual National Seminar, where the made experiences, the used teaching methodologies and the addressed disciplinary content are critically discussed.

The training project includes, for the classes involved, an additional hour of mathematics every week. Moreover, for the training of teachers, cycles of meetings with researchers are organized during the school year.

Hence, the main features of LM can be so summarized:

- Collaboration between mathematics education researchers and teachers (MDT frame);
- Additional hours (about 30 per year);
- Mathematics laboratory (from MpC and M@ projects);
- Statistics: currently, more than 25 universities, 150 secondary schools, 400 classes, 7000 students, 300 teachers distributed throughout Italy; but the numbers are increasing.

A recent exploratory study (Bernardi et al., 2024) has investigated whether the LM students learning is on average better than the learning of students at the same schools that do not participate in the project and how the LM project has an effective impact on this learning. It has based its research on the yearly surveys of INVALSI, the Italian National Institute for the Educational Evaluation of

[3] https://www.liceomatematico.it

Instruction and Training[4], which, according to some researches (Gambini et al., 2022), have a good predictive value for students' university careers. The research consists in a longitudinal analysis over time, which compares the performance trend in learning Mathematics and Italian between students who attend the LM and students who do not attend it, within the same schools. Since for many reasons it was not possible the adoption of a probabilistic sampling, a reasoned one was adopted: hence this method prevents the generalization of the results obtained at the level of the entire population but has a value for the examined cohort of students. The research regarded the same cohort of 2588 students from 11 schools in centre-south of Italy and considered their scores in the National INVALSI survey when they attended grade 8 (2017), 10 (2019), and 13 (2022). Of the total of 2588 students, 2232 (86.2%) belong to sections that have not followed the LM, while 356 (13.8%) belong to sections that attended it.

The data from this first exploratory study seem to indicate that participation in the LM project has a positive impact on the level of learning achieved in both Mathematics and Italian, and more markedly for students who obtain low scores in both subjects at the end of the first cycle. Figure 5 gives an idea of the type of results shown by the research. It reports the means of the distributions of scores for Mathematics in the different grades considered, respectively for LM and No-LM students.

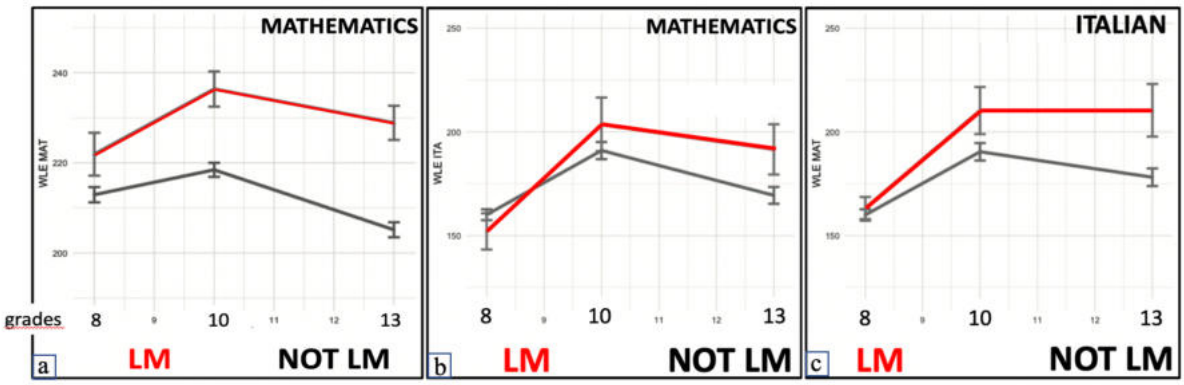

Figure 5. Data from the research on LM students (Bernardi et al., 2024, p. 80, 87)

Figure 5a corresponds to the entire cohort of students, while Figures 5b, and 5c correspond to the subgroup of students who reported at grade 8 (the last year before higher secondary school) a score lower than the first quartile of the distribution in both Mathematics and Italian. In the group under examination, a total of 325 students were identified, of which 44 were participants in the LM and the remaining 281 belonged to non-LM sections. Beyond the limitations due to the relatively small numbers, it is interesting to note from the analysis of the graphs in Figures 5b and 5c that, even for the students apparently most disadvantaged at the start, a significant improvement in the scores of both subjects was found, to which participation in the LM seems to have contributed.

Mathematics Education: what is beginning to be there

In this second part of the paper, I will give some examples and develop some reflections on the changes that are beginning to feature the new landscape of mathematics and of mathematics learning.

Mathematics for world awareness

I will start with an example from the activities of LM, emblematic of these new trends. It is described in a paper written by the teacher (Giovanna Guidone) and four students of the class where the activities were developed in grades 11 and 12 (Di Tuoro et al., in press) in a LM Mathematics and Physics laboratory (the two disciplines are taught by the same teacher), significantly called *Numbers for world awareness.*

The idea of laboratory as a central didactical tool comes from the Italian tradition as illustrated by the work of E. Castelnuovo and further elaborated by the MpC and M@ experiences (see comments in the first section). The contents are outside the usual traditional ones, involve the skills for an aware citizenship through mathematics, and in this sense, they represent a concrete example of the types of new entries within the stream of the didactic transposition at the macro-level, also strongly determining and reshaping the curriculum facets at the micro-level.

Here is a short summary of the activities. In grade 11 the students work to learn how to make 'Fermi estimates' (Nityananda, 2014) with the spirit of a civic education; for example: "how much energy savings would result from reducing shower time from 15 to 5 minutes for ten million of Italians". In grade 12 they face real-life problems like the following: in their town (Fermo, in the Centre of Italy, not far from the sea at about 43° lat. N with a mean temperature of 6°-12° C in December) every year in the main square of the town (34×13 meters) an ice-skating rink is installed for the Christmas holidays for about 50 days: its ice thickness is 7 cm, therefore its mass is 10^5 kg. Consequently, the students face these related questions: "How much energy is needed for maintaining the ice rink? How big is it? What temperature is it at? What is the ambient temperature? How much energy does it absorb? By what mechanism? How long does it take to heat up? What is the average power used? How much energy? From what sources?". To answer these questions the students, with the help of the teacher, rely on an important work of I. Newton about the law of cooling[5] which provides the analytical expression of the temperature *T* as time *t* varies, starting from an initial condition (in grade 12 students learn the concept and basic machinery of derivatives and already know the exponentials from previous years). The proposed model was coherent with the curricular topics, in which they had discussed some models of exponential growth and decay. Making a concrete experiment with different equal containers, each with the same volume of water and the same shape, and measuring with a certain precision the time necessary for getting ice, they could estimate a physical parameter

[5] Newton's law of cooling (also called "of heating") claims that the rate at which the temperature $T(t)$ of a body changes, as time t varies, is proportional to the difference between the temperature $T(a)$ of the environment in which the body is located and the temperature $T(t)$ of the body itself: $T'(t) = k(T_a - T(t)), k > 0$. From this one can get $T(t) = T_a - (T_a - T_i) \cdot e^{-kt}$; knowing the value of the parameter k, it is possible to obtain how long does it take for the heating from an initial temperature T_i to a final temperature T_f.

in the Newton formula[6], so getting a law according to which they could estimate the following quantities (Figure 6):

- the heat quantity necessary to raise the ice rink temperature from -5 °C to -1 °C (~ $2 \cdot 10^8$ J);
- the time τ to pass from -5 °C to -1 °C (~ 1500 s);
- energy necessary to prevent heating (~ 50 000 kWh).

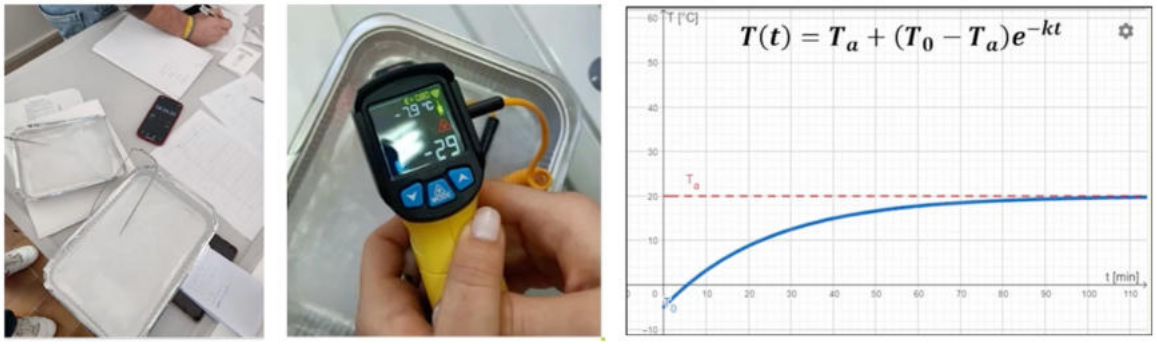

Figure 6. Students' experiment for estimating the parameter *k* in the Newton formula (Di Tuoro et al., in press)

The last estimated quantity poses a typical *citizenship question*: *is it a lot*? *what does it mean?* In order to make the result more intelligible, the students suggested to relate it to the consumption of some activities that are frequently performed in everyday life. The research for such data in the web produced interesting results: for example, 50000 kWh is approximately equivalent to the consumption of an average family's washing machines for 500 years (estimating about 300 washes per year, each of which consumes about 1 kWh); or it is equivalent to the amount of energy used to perform more than two million cell phone recharges; etc. Moreover, through some further calculation and research on the mean temperature in Fermo during winter, they could realize that the rink in their city consumes five times as much as a rink located in a place where temperatures are around 0 °C. Last, but not least, they also estimated that in Italy there is an emission of 0.5 kg of CO_2 per kW of electricity consumption. For the ice rink this is equivalent to 25 000 kg of CO_2: from further research, they found that a hectare of larches absorbs them in one year. This last observation had an interesting "political" result. The class informed the city council about their results and asked to plant 500 larches to offset CO_2 emissions: because of this, the mayor encountered the class and welcomed the request, asking the students to send the technical office some proposals for locations where the trees could be placed. And now we are at this point of the story.

Its value is educationally indisputable: it represents an effective experience of *conscious citizenship* for students. Because of this, it is also relevant from the point of view of the didactic transposition dynamics. In fact, the praxeologies (Chevallard, 1999) that the teacher developed in her class have a double inverse direction. From the one side, they come from the macro levels of nowadays changes in our society and as such have deeply marked the lower microlevels in the two Chevallard's scales (Figures 2 and 3) producing *numbers for world awareness* in students within a *conscious citizenship*

[6] The parameter *k* of Note 1: it was found equal to about $2{,}5 \cdot 10^{-4} s^{-1}$.

frame. From the other side, because of the interaction with the mayor, their research has possibly also reversed the arrow and (hopefully) influenced the higher levels of the scales.

I think that this can suggest an educational productive approach to the educational discourse in schools, where the instances of developing a conscious citizenship are more and more present in curricula. It is precisely these kinds of skills that are needed in schools today, as pointed out by Fadel et al. (2015, p. 41):

> In order to deepen and enhance the learning in these three dimensions—knowledge, skills, and character qualities—there is an important additional fourth dimension needed for a fully comprehensive twenty-first century education: meta-learning (often called learning to learn—the internal processes by which we reflect and adapt our learning). It is not enough to implicitly include this fourth dimension in all the other dimensions—its significance must be highlighted explicitly, so that we are constantly reminded to incorporate meta-learning strategies into the knowledge, skills, and character portions of our learning experiences, learning how to strive to improve no matter what goals we set for ourselves.

In this spirit, I end the section quoting the conclusion of the mentioned paper of Di Tuoro et al. (in press):

> As we mentioned at the beginning, our project was born from the need to make a sensation quantitative, namely the fact that in our latitudes the installation of an ice rink is an ecologically questionable manoeuvre. As we continued with our analyses, the need to share the results obtained made its way into us. In fact, thanks to the sensitivity acquired with our activities on estimates, we increasingly realize that the people around us have behaviours whose global impact they do not understand: it is not a question of bad will, but of misinformation. When the numbers at play are made clear, many can stop to reflect on the fact that changing some behaviours actually costs very little sacrifice, but is a much more responsible way of being in the world. This is the fundamental reason why we thought of writing this work: we would like, through teachers, to be able to spread among our peers an ecological awareness based not on suggestions (in one sense or another), but on reliable and shared scientific models.

Such pieces of activities represent exactly what "begins to be there" in the school and we all hope that they will expand more and more.

It is important that people in mathematics education start (continue) working in this direction, keeping together the two sides of the micro- and macro- levels of the didactic transposition scale. It is an important task for people currently working on curricula: forgetting some of the components in each facet could have negative effects on the school activities, particularly for mathematics.

Moreover, working with such a perspective can also produce aside results of more classical research findings in mathematics education. As an example, the work by Guidone sketched above and other similar activities (e.g. Bagossi, 2024) suggested to the authors an interesting stream of research for what they have called *grounded covariation*. It is a particular aspect of second order covariation (Swidan et al., 2022), which appears in the way Guidone's class has answered the questions about the energy necessary for the ice rink and generally in many other examples where Fermi estimates

are drawn. Grounded covariation is mathematically, physically, and cognitively relevant insofar it allows to unexpectedly grasp the meaning of the relationship between two quantities through a third one within a known environment. The *world awareness* framework allows to achieve this specific mathematical sense of covariation.

However, while from the point of view of the stream represented by the previous discussion, possible didactically and epistemologically clear and feasible paths to follow appear at the horizon of teachers' activities, things seem epistemologically less clear for what regards another issue, that of computational thinking. In this case, it seems that more elaboration is still necessary to have feasible paths through the scales of didactic transposition. This issue will be the focus of the next section.

Changes in mathematics: a new 'New Math'?

Through the LM experience some new faces of mathematics started to enter concrete classroom activities:

- Effective teaching approaches to sustainability;
- From Mathematics Laboratory to citizenship competencies.

Before entering the issue of current transformations in the mathematics thought, a methodological premise is necessary. Changes in mathematics are the rule and not an exception and any temptation to elaborate a fresh comprehensive and normative definition is doomed to precariousness and falsification:

> Falsification in the sense of certain imminent denial and falsification in the sense of a false representation of the present and the past. Such a definition presupposes, in fact, contrary to the repeated teachings of history, that mathematics has reached its true and definitive nature. But whoever proposes it cannot control the elements fermenting in society and which, not yet incorporated into the new synthesis, will inevitably cause cracks. On the other hand, a new proposal can only use the cultural tools available in the present and tested, albeit perhaps in an original way, with the addition of some innovative contribution; these tools, derived from the recent past, however, were developed to serve other problems and other objectives. By bending the tools already possessed to new needs, even unconsciously, the reading of history is distorted into a description either of failures and confusions or of anticipations that were alien to the real concerns of the protagonists. (Lolli, 2022, p. 253, translation by the author)

With this proviso in mind, we can point out that in fact, in the last decades, mathematics has faced some important changes of different types. I will mention two of them: the reduced difference between pure and applied mathematics, and the increasing complexity of the discipline in its new results and the consequent increasing use of automated (ATP) and interactive (ITP) theorem provers in its research activities.

For the first, the increased demand for mathematical application has appeared in two ways: because of multiple "infections" from the science world (social sciences, biology, etc.), or because many aspects of mathematics regarded as "impregnable pure" are now being applied, e.g. algebraic geometry in control theory; graph theory in economics; fibre-bundles in physics; algebraic invariant theory in error-correcting codes.

For the second, it is evident that the research level mathematics is becoming more and more complex, and its proofs are becoming terribly long and difficult so that ATPs and ITPs are used massively by researchers. Today's proof assistants can do more than verification. Their ability to work in interactive mode, allow mathematicians to take the next step and use them to create a new proof from scratch. Well known examples of these are: the four-color theorem (verified in 2005 with the help of the proof assistant Coq); the Kepler conjecture (proved with HOL); the Pythagorean triple problem (proved with Coq and SAT), and many others. This fresh approach is having epistemological and foundational consequences, e.g. the so-called univalent foundations of Vladimir Voevodsky (Grayson, 2018), aiming to explain how mathematics can be encoded in type theory and how this encoding reveals a potentially viable foundation for all of modern mathematics that can serve as an alternative to set theory, via the Curry-Howard isomorphism (Sørensen & Urzyczyn, 2006). Mathematics research, including that relevant to exogenous 21st century challenges (e.g. climate change, the environment, etc.) are likely to be developed from the bottom up in new, proof-assistants-friendly ways. As we will discuss below, these features have also important consequences for mathematics education.

ATPs typically use brute force methods to perform large calculations, while ITPs act as proof assistants that can verify the accuracy of an argument and check existing proofs for errors. However, these two strategies, even when combined (as in the case of newer theorem provers), do not lead to full automated reasoning. Modern proof assistants such as Isabelle/HOL provide increasingly intuitive languages for constructing and representing proofs, but significant scientific progress is still needed to achieve this ambitious goal. Finding a comprehensive solution that integrates both notions of proof can even be understood as a challenge for AI.

The switch to the use of computers as ITPs in production of proofs requires rethinking traditional approaches not only to mathematics (Bayer et al., 2024) but also to mathematics education, which, as hinted above, is struggling through a crisis of its own, socio-economic and political by its nature (Borovic et al., 2022).

For example, Fadel et al. (2015) see the situation of the first decades of this century as "the perfect learning storm", caused by four converging forces: knowledge work, thinking tools, digital lifestyles, and learning research. In fact, today's learners are growing up more and more in a world that is increasingly shaped by digital artifacts (AI technologies included), but many times they have not a social control on them (Benanti, 2022). This trend is making it critical for mathematics education to properly address these new technological realities, going deeply beyond its purely technical features. The same term "computational thinking" is one of the most used (and abused) buzzwords: politicians, ministers, media, educators attribute different meanings to it, some more oriented towards computer science, others more linked to its interdisciplinary value in STEM disciplines. As a consequence, the content of the didactic transposition and determination scales of Figure 5 is going to face a deep change, whose features at macro- and micro- levels are dramatically and rapidly evolving with new productive but previously unsuspected dynamical links between the two. And it is important that mathematics education elaborates suitable epistemological, cognitive, discursive, and instrumental tools to face the new landscape. As pointed out by P. Richard, it is necessary a complete and complex integration of digital artefacts into mathematical activity:

> [It] goes beyond merely facilitating or accelerating tasks; it transforms the nature of mathematical work itself by opening new pathways for problem-solving, exploration, and learning. The human-machine interaction resulting from this integration produces new forms of mathematical activity […] including the dynamic interplay of representations, automated calculations and reasoning, exploratory conjecture, instant feedback, and the cognitive impact of artifact interactions. (Richard, 2024, p. 2214)

This observation points out the complexity of the interactions that this integration entails, provided it must not be reduced to purely technical interventions. For example, it changes the usual "didactical triangle" of Brousseau (knowledge-teacher-students), which, through the instrumentation approach (Artigue, 2002), had been able to integrate the old digital artefacts into its frame. With AI, especially with generative AI, represented e.g. by the interactions with chatbots, things have deeply changed: the interactions happen among four subjects, of which one is not human but has some not so clear resemblance with them. What seems necessary from an educational standpoint is an integration among the different components, considering in particular the specific complexity given by the two forms of AI (symbolic and statistic), which both can be important in fostering and enhancing mathematical explorations and validations but, at the moment, seem limited in performing a full mathematical reasoning.

Some people use terms like "hybridization", "synergy", "technological counterpoint", and the like to indicate the particular new form of integration between human and technology in the new classroom: each underlines a specific feature of the interactions, highlighting this or that particular aspect. Possibly, this variety of expressions indicates that the theoretical elaboration is not yet satisfactory and needs further thoughts and deeper analysis, as it is natural in a situation of fast and radical changes, such as those we are considering. In any case, the literature is beginning to provide concrete examples of integration among the different types of AI for educational purposes (for a survey see Richard, 2024). This "integration problem" is one of the crucial current problems that mathematics education has to face and solve. Together with the issues of "citizenship awareness", introduced above with the ice rink example, they constitute the new stuff upon which new mathematics curricula will be built with fresh and deeply intertwined macro- and micro- facets of the didactic transposition/determinacy scales.

Hoping to give a small contribute to this issue, I will conclude giving an example of an ongoing research I am participating to, and which tries a specific form of the integration hinted above, with some initial consequent theoretical elaboration about the new forms of interactions in the class triggered by some current AI technologies. Of course, one must be aware that since the performance and reliability of LLMs (Large Language Models) are increasing at an astonishing rate, what one writes today may be scaled back or become obsolete tomorrow.

A teaching experiment

Such devices like ChatGPT and chatbots in general have assumed great resonance in the public debate and their use in the classroom can be motivating and productive for the students. A useful methodology may be using them in mathematics teaching/learning as an additional voice that join that of the teacher, and of the students (Conte & Cusi, 2024).

However, ChatGPT, like current generative artificial intelligence systems, is "intelligent" in a different way from human beings: in a sense it is an "alien" voice. Its answers, contrary to those provided by symbolic artificial intelligence, are grounded on a generative AI, hence do not base on a formal theory. For these reasons, as it is well known, even a highly performing system like ChatGPT risks falling and falls into mistakes. These, when detected, can give useful suggestions to those who follow carefully, with intelligence, its ability to produce also fallacious arguments.

It is possible to base on these observations to design a didactical approach to proofs in geometry (Paola, 2025). With a group of Italian researchers and teachers[7] I am now working to a pilot teaching experiment in a class of higher secondary school (10^{th} grade). The didactical scenario involves experimenting with "open problem" activities, in a geometric context in which small groups of students are asked to carry out explorations of geometric configurations. The explorations are made first in paper and pencil environments, then with GeoGebra in such a way as to detect regularities and produce conjectures, validating them with the tools made available by GeoGebra (in particular the `Relation` command[8]), in such a way as to convince themselves of their validity. After this first part of activities, students are asked to interact with ChatGPT trying to detect why the conjectures produced do work or not. ChatGPT, however, may stumble when asked to explain why and sometimes gives answers that are poor or even contradictory; it is the students' task to properly interact with ChatGPT in order to detect, like Sherlock Holmes, when this is the case and why. We have called this an "epistemic challenge" that they have to overcome. After having interacted with ChatGPT, the different groups write in a Padlet the full path they followed for the solutions: its content is then shared in the whole class (Lemmo et al., 2024). In the end, there is a whole class mathematical discussion orchestrated by the teacher (Bartolini Bussi, 1996; Giberti et al., 2025), where their findings are discussed and critically analysed with the teacher.

The aim of our research was to check, through the development of teaching activities like the one above, whether a suitably integration of a geometry software like GeoGebra (which has graphical, numerical, and symbolic features) with ChatGPT (generative AI) can be used to facilitate students' introduction to theoretical knowledge in geometry. The proposal is based on the idea that ChatGPT can and should be used in mathematics teaching and learning as an additional *voice* alongside that of the teacher and the students. It is a particularly significant voice for at least two reasons: first, ChatGPT has gained considerable resonance in public debate, and therefore there is a good chance its use will be motivating for students; second, it is an alien voice. ChatGPT, like current generative AI systems, is intelligent in a profoundly different way than humans. Its answers, unlike those provided by symbolic artificial intelligence, do not refer to a theory: as P. Benanti writes, with

[7] We call ourselves "The skew group" (our logo is a skew quadrilateral). Its members are: F. Arzarello, S. Bagossi, S. Beltramino, P. Cazzaninga, F. Ferretti, C. Giberti, D. Molinari, D. Paola, C. Spagnolo, E. Taranto.

[8] The command previously was purely numerical (e.g. it verified numerically the validity of a property within a certain threshold, the user being warned in a message that the reached conclusion was only numerically valid), now can also activate a symbolic calculation translating the given geometric figure into a collection of polynomial equations and considering, systematically, as a thesis, the algebraic translation of the possible relations one has referred to, between the chosen geometric elements (Kovács et al., 2022, p. 26).

generative artificial intelligence systems "we are witnessing the birth of a new epistemological paradigm, moving from causality to correlation" (Benanti, 2022, p. 82, translation by the author).

Now I will sketch some first provisional results we have found with the first activity of the teaching experiment. Students were asked to investigate the properties of a quadrilateral whose vertices M, N, P, Q are the midpoints of the sides of an arbitrary given quadrilateral ABCD. They were (hopefully) supposed to find and prove that these always form a parallelogram[9]. The justifications (the groups talk about "proof") were always given with the help of GeoGebra (with measurements and with the "Relation" tool, both with numeric and symbolic checks) and only in one case a group proposed a real proof of the theorem in a particular case (when ABCD is a rectangle) using the congruence criteria of triangles. At this point students were asked to engage in a dialogue with ChatGPT to move from their (almost) empirical justifications or "zero-knowledge proofs" (in the case of numerical and symbolic checkings with GeoGebra) to overcome the epistemic challenge, that is, understanding "why" MNPQ is a parallelogram, whatever ABCD is. "Understanding why", in fact, means not only learning how to solve a problem or answer a question, but also understanding—in the deepest sense of knowing—why things are in a certain way, and not only "knowing" that MNPQ "is" indeed a parallelogram and being simply happy with that.

I now move on to some observations relating the first result of our teaching experiment, in particular considering the groups' answers in the Padlet. I limit to refer to some of the main theoretical frameworks that we have chosen for our analysis: (i) the instrumental genesis (Artigue, 2002); (ii) the dialogical perspective of knowledge (Mercer et al., 2020).

(i) According to our a priori analysis, the instrumental genesis would have involved the use of GeoGebra commands, of ChatGPT prompts, and of the communication space provided by Padlet, with recognition of their strengths and limitations. We found that the groups feel comfortable with GeoGebra and Padlet, tools they had already used in the past. The instrumentation process seems less advanced in terms of the ability to modify the prompts so that ChatGPT provides answers more suited to the interlocutor's expectations, although at the end of the activity we observed an increased attention to the posed questions and an attempt to modify and refine them to obtain the desired answers.

(ii) In the a priori analysis, we had conjectured that:

- Dialogue is the tool that fosters the exercise of critical thinking, fostering awareness of the weaknesses and strengths of one's own opinions and those of others. The search for justifications shifts from "knowing how" to "knowing why". This competence seems to have grown up in the long run: the posts in the Padlet contain some significant reflections that show the activation of critical thinking in some cases, although less frequently than the evaluation of elements of correctness. Moreover, we have found observations related to the language used by ChatGPT and considerations on the proposed proofs and on their strengths and weaknesses.

[9] It is the well-known problem of Varignon, whose proof was published in 1731 (Oliver, 2001)

- Today, there is a greater need than in the past for the skills needed to understand a text, verify data and their plausibility, and identify false or incorrect information. Here the results are more than positive: the various groups have understood that ChatGPT's responses cannot be taken as valid, but that they must always be subjected to critical scrutiny and careful verification. This is a very important educational objective from the perspective of citizenship education.

- It is through the dialogical practices implemented in working groups and in whole-class discussions that the primary educational objective should be realized: namely, that students truly understand (after having accepted it in the didactic contract) the role and function of theoretical knowledge as an environment in which the meaning of the different "whys" is clarified and one has to attempt answering them. In short, this is the dialogic practice (in the group, with ChatGPT, with the teacher). This objective seems not to have been completely achieved for the majority of the class. We have not found explicit evidence, except in one group, of this tension towards "understanding why", namely towards the dimension of theoretical knowledge, even if it is present early in at least two groups. However, this tension emerges in the final phase for some students: for reasons of space, I report only a couple of quotes from their posts in the Padlet showing that they are on the way of achieving this delicate goal:

S1: This is why, from the class project, I realized that, first of all, although we want to know the solution to the exercise, we must also ask ourselves how and why the problem was solved that way, in order to understand and use ChatGPT as a learning tool and not just as an exercise solver.
[…] Therefore, the software functions as a coach and not as an exercise solver, to better understand the topic.

S2: It is therefore up to the reader to filter the information obtained to understand whether it is correct or not, in two ways: by pointing again with Chat GPT, asking further questions about it and also explicitly asking if it was sure of what it had just said, or by looking it up in the textbook. It is during this verification step that we learn the most, because if the information provided by Chat GPT is correct, we have gained a useful understanding; otherwise, we are led both to find a correct answer and to understand what was incorrect in that given information.

In these quotes (as in others not reported here), the focus on "correctness" is evident, but a more or less explicit attention also begins to emerge towards the communicative aspects and those related to understanding.

So, in short, the analysis of students' productions and especially of their comments on the Padlet indicate that, even if not for the entire class, they have certainly achieved the goal of understanding the need for a conscious and critical approach to AI tools, whose answers must always be verified. They also understood that it is possible to modify the questions to obtain increasingly satisfactory answers. The focus is always on correctness (epistemic dimension), but some initial tendencies emerge in the final responses, primarily regarding attention to communicative aspects, and, in some cases, also to those related to understanding why, even though it seems that there is no clear commitment to what we have called "the epistemic challenge". On the other side, it is important to consider that the challenge condense a family of objectives of high educational value, which cannot be achieved with an activity alone, however targeted, structured, and well-conducted. The fact that, however, because a tendency toward these objectives appears evident, it seems that this approach to

math learning through AI can be successful, even if with some important refinements to the task, to which our group is now working.

Conclusions

Basing on the Italian experiences in the first decades of this century, the paper illustrates how the innovative aspects of mathematics curricula can become an effective shared heritage in the mathematics teaching community, provided they effectively enter into teachers practices and believes. The concrete course of action through which this process is realized is described by means of the meta-didactical transposition process. In general, from the curricular standpoint, the main analysis tool to properly focus these dynamics is the didactic transposition structure. This theoretical lens also allows to enter into the novelties that currently are modifying mathematics and mathematics teaching and learning in the school, because of cultural, technological and socio-economic reasons.

In the second part, the paper discusses how these big changes are influencing the links between the macro- and micro- facets in the didactic transposition scale and are starting to produce consequent changes in school practices and in their curricula, especially for mathematics.

Within this stream of thought, three issues have been introduced as emblematic examples of these changes and of the necessity of properly and concretely rethinking the mathematics curricular transposition scales:

- the growing use of automated and interactive theorem provers in mathematics research, which in the long run will influence (are already influencing) also mathematics teaching practices;
- the way in which computational thinking can properly enter into school with a critical approach to the new technological instances;
- the contribution of mathematics for developing a form of mathematics for world awareness in students within a wider educative aim of developing a general citizenship awareness.

The changes that these issues bring with them constitute just as many points of attack against the many barriers and constraints at the different levels of the codeterminacy scale and that can hinder possible evolutions of teaching and learning processes: these issues are the main problems that researchers, teachers and policy makers face today to properly address mathematics curricula.

The examples discussed in the paper show how “the spirit of the time” is pushing towards strong changes, of which we are only still partially aware. I think that we are in fact starting to live the wonderful experience that B. Brecht (1963, p. 6) describes for Galileo, when the scholar sensed the big changes of the scientific revolution in everyday phenomena:

> When a young man in Siena, I saw how a couple of builders, after a dispute of five minutes, replaced a thousand-year-old system for moving granite blocks by a new and more practical arrangement of the tackle. Then and there I knew: the old age is past and a new age is here.
>
> (translation by the author)

It is an exciting challenge, in which all of us are called to participate with intelligence and creativity. I think that the motto with which the article starts, *looking backward for going forward*, is more alive than ever and that we, as mathematics education researchers and teachers, must keep it well in mind

to avoid the mistakes made many decades ago with the infatuation for the so-called “new math” in teaching.

Acknowledgments

I wish to thank the many teachers, researchers, and students with whom I have worked in the years and that have made possible the realisation of some of the projects illustrated in the paper. In particular, I express gratitude to Giovanna Guidone and her students of *Liceo Scientifico T. Calzecchi Onesti in Fermo*, who made me aware of their experience about the ice rink. I give also credit to Alessandro Gambini, Claudio Bernardi and their colleagues for sharing with me their researchers about the *Liceo Matematico*. Many thanks also to the referees of the paper for their smart advice and careful revisions. Last but not least, I express gratitude to all the friends of the Skew Group, with whom I am sharing my last research.

Climate change and the mathematics curriculum: gestures and entanglements for the future

Alf Coles[1] and Kjellrun Hiis Hauge[2]

[1]University of Bristol, School of Education, Bristol, UK; alf.coles@bris.ac.uk

[2]Western University of Applied Sciences, Bergen, Norway

Mathematics can be taught as a neutral and value-free enterprise, disentangled from the living world and focusing on non-complex problems with only a single solution. We consider what entanglements mathematics education could respond to, in the context of a world on fire. These include the entanglement of humans and ecosystems, the entanglement of people across the globe and across time, and the entanglement of values, hopes and climate change from a critical, democratic perspective. We discuss how these can be connected to mathematics and mathematics education, and how the entanglements may be overlapping and contradicting. The Norway and the England curriculum are analysed in terms of what values and entanglements they convey, related to climate change, and what kind of citizen is imagined. Finally, we offer examples of projects which point to a curriculum for the future that acknowledges the proposed entanglements, and which can foster hope.

Keywords: *socio-ecological; hope; democracy; values.*

Introduction

In a tragically prescient article, Latour (2004) begins "Wars. So many wars." (p. 225). Latour proposes that, as academics, we have been too slow to adapt the focus of our work and critique to the changing circumstances of the globe, lamenting: "Are we not like those mechanical toys that endlessly make the same gesture when everything else has changed around them?" (Latour, 2004, p. 225). In this article, we want to consider what "gestures" mathematics education has made (we define the term in the next section) and what alternative gestures we could make, in the context of a world on fire (Delpit, 2021), particularly in relation to curriculum. Following this introduction, our writing takes the form of a dialogue—with voices indicated by the major headings. We conclude with a final section in a joint voice. We have chosen a dialogic form of writing, in part because this writing has arisen from a plenary talk which involved the two of us in a dialogue and, in part, because a belief we share is about the importance of dialogue in relation to the content of this writing (Barwell et al., 2022).

A word that will recur in both our sets of writing is that of entanglement, and hence we say briefly what we take this to mean. Entanglement is a concept used in quantum physics (Barad, 2007) which acknowledges the deep and ineradicable interconnection across phenomena often kept apart in more classical thinking (such as culture/nature, mind/body, inner/outer, organism/environment). We use the word in this metaphorical sense. In writing about entanglement, we are asserting something about the common materiality of the binaries just listed (see de Freitas & Sinclair, 2014). We also want to draw on the way the word entanglement, in common language, can point to connection and complication, to joining and to the erecting of barriers.

Mathematics can be taught as a neutral and value-free enterprise, disentangled from the living world and focused on non-complex problems with only a single solution. We do not consider such an approach to be befitting of the world as we now experience it, nor of the needs of students, let alone possible needs of society. We have both been influenced by the insights of critical mathematics education (Skovsmose, 1994) into the way that mathematics formats the world, influencing the very realities it models and predicts. Mathematics has the power to shape worldviews. Skovsmose (1994) called this the *formatting power of mathematics* and, later, the *performative interpretations of mathematics* (Skovsmose, 2020). And, following from the insight about mathematical models and technologies formatting the world, it becomes clear that ethics and values are part of the doing of mathematics and the responsibility of mathematicians.

As well as our focus on curriculum, we consider the particular issues of climate change, climate justice and ask what they might mean for the mathematics curriculum and whether the mathematics curriculum has anything to offer in relation to them. Our broader concern is with the socio-ecological pressures facing the world, of which climate change/climate justice are examples. And, we want to suggest that mathematics has a specific responsibility in relation to climate, such that education about climate cannot just be left to the sciences or other subjects. In particular, mathematics is applied to describe, understand and communicate climate change, its consequences and possible solutions (Barwell, 2013). A range of mathematical representations are used to communicate issues of climate change: numbers, tables, graphs, charts, Sankey diagrams, colour maps of the world, fractions of areas, coloured climate stripes. As citizens, students need to be acquainted with these mathematical representations to understand what is communicated. Mathematics is a tool needed to understand the world. Students need mathematical competence to achieve insights into climate change issues, either from the media, or work with data on the internet or collect data themselves. Climate sceptics and deniers point to "flaws" and limitations of climate models, avoiding communicating uncertainty in presenting their alternative understanding. There is fake news related to climate change and mathematics is needed to discern levels of manipulation.

With these ideas in mind, in the next section, Alf outlines the notion of a gesture and the three gestures for mathematics education, proposed by Coles, Solares-Rojas and le Roux (2024). Kjellrun then responds, adding two further gestures, which she sees as missing, relating to democracy and hope. Kjellrun continues, by looking at the current Norwegian curriculum, in relation to the five gestures we outline. Alf does the same for England and considers similarities and differences across the systems. We then look to the future (with sections in each voice) and consider and exemplify possible gestures. We argue that every mathematics classroom is making a gesture (more or less explicitly) around values—hence the need for reflexivity about the meta-messages of our own practices, and our instantiations of mathematics, and the values of the institutions where we work.

Socio-ecological gestures of mathematics education (Alf)

Influenced by the pioneering work of de Freitas and Sinclair (2014), Coles et al. (2024) propose the term "socio-ecological" to point to the attempt to bring the ecological into our concerns as mathematics educators and to recognise that much (but by no means all) of our research has taken the living world as a stable and benign background to our concerns. Such assumptions, where they exist, are surely no longer tenable; we are perhaps in a situation a little like a scene from a Star Wars film

when the characters land on what they think is an asteroid, only to find they are inside an enormous creature. If we did ever think we were conducting our work on a stable surface, it is now clear that the surface is alive and has begun to move. The three "gestures" proposed, which I will elaborate briefly, are: listening for socio-ecological entanglement; attending to the scales of socio-ecological entanglements; and living entanglement (Coles et al., 2024).

The first gesture, listening for entanglement, "focuses on where we place our attention as mathematics educators […] Listening to entanglement will necessarily take our attention away from a sole focus on mathematics and on education and, we believe, can enrich both in the process" (Coles et al., 2024, p. 177). This gesture might be as simple as acknowledging how we are entangled, even if our concerns remain centrally on, say, mathematics learning. In other words, to engage in this gesture might imply becoming conscious that we are bracketing out the "ecological" in order to focus on purely "social" or "socio-political" concerns, in our mathematics education research. This gesture might also involve sitting with, and dwelling in, the potential consequences of recognising that even something as seemingly abstract as learning (say) the calculus in a classroom is a socio-ecological event, an event with ecological (as well as socio-political) implications, an event imbued with values (e.g., precision, coherence, logical reasoning).

The second gesture, scales of entanglement, involves "bringing to awareness from where we are standing, when we attend to aspects of the landscape (both literal and academic), as mathematics educators" (p. 177). This gesture might be expressed through attention to spatial and temporal scales. Spatial gesture(s) imagined here can arise from the disjuncture that is often experienced between the local and global, for example, when the historical accumulation of local actions has had a planetary impact, and yet, as individuals, it seems we are powerless to effect change. How might we work with students while acknowledging such tensions? Alternatively, considering temporal scales implies attention to the past, present and future of any place, context, question, issue. When a school sits on a polluted river, we might consider the oral histories of elders (past), the current levels of pollution (present) and potential routes back to health (future) (Solares et al., 2022). Attention to temporal scales implies the need for activism as a key element of mathematics education. Again, values are implicated in this second gesture, in the move into activism.

The third gesture (or set of gestures), living entanglement, raises ontological and epistemological issues arising from what it means to take seriously the unity of the social and the ecological. If we really believe there is no discontinuity between culture and nature, how does that change how we think about students, and about mathematics and about learning? What does it mean, for example, to acknowledge the materiality of a mathematical concept (de Freitas & Sinclair, 2014), or the culture present in plants? And there is caution needed here. Bullock (2025) warns that too quick a move to extend human concerns to the non-human risks an unquestioned racism by not acknowledging those humans who have never been offered fully human status within colonial, capitalist institutions that span international, national and local scales. Living entanglement implies an ongoing gesture of openness to noticing our own blind spots and a solidarity (Povey & Angier, 2024) with all those (human and non-human) marginalised by historical and present injustices. Yet again, within this gesture, there is a surfacing of values and a need to stand for some values and against other values.

Gestures of mathematics education relating to climate change (Kjellrun)

In this section, I continue to think with the notion of gestures, but now particularly applying them to issues of mathematics education and climate change. In doing this, I have identified two further relevant gestures, democratic entanglement and entanglements of hope—ideas which I see as potentially missing from the three gestures previously outlined.

Starting with democratic entanglement, this gesture acknowledges that mathematics students (and teachers and researchers) may have very different worldviews and thereby very different understandings related to climate change. Because climate change issues are often complex and controversial, there may be disagreement on what the problem is and what should be considered as appropriate solutions, so-called wicked problems (Rittel & Webber, 1973). Whether solutions are considered preferable or not depends on people's values and worldviews.

Much of my work is rooted in post-normal science, which is a philosophy of science that opposes the idea that science and mathematics alone can provide the best answers to complex policy problems, i.e., in cases where knowledge is uncertain, stakes are high and decisions are urgent, such as climate change (Funtowicz & Ravetz, 1994). Because what is considered a good solution also depends on opinions on what is at stake, Funtowicz and Ravetz (1994) argue that quality in science for policy also depends on how values are handled and represented in both how the problem is posed and how it is analysed, including mathematically. A certain choice of simplifying or limiting the scope of a problem through mathematics may benefit one stakeholder over another, which means that knowledge becomes value-laden.

This implies that the process of peer-reviewing expert knowledge is not sufficient for assessing the quality of science for policy. To answer this challenge, Funtowicz and Ravetz (1994) suggest what they call an extended peer-review process, where stakeholders and citizens can contribute by presenting and discussing other forms of knowledge and worldviews, supplying issues on risk and associated risk bearers, and evaluating the relevance of expert knowledge. A range of frameworks have been developed and applied to facilitate extended peer review communities, all of which are participatory and to various degrees deliberative (for an overview, see O'Connor & Douguet, 2024). Similarly with other forms of democratic participation and representation, there are benefits and challenges with extended peer review processes.

There are several connections between post-normal science and mathematics education in relation to climate change. First, both Funtowicz and Ravetz started their careers as mathematicians, and they have given substantial attention to the limitations of mathematics as a tool to cope with complex, wicked or post-normal problems, also on how numerical results could be presented to communicate uncertainty aspects where statistical measures do not represent uncertainty sufficiently (see e.g. Funtowicz & Ravetz, 1990). Second, several scholars within critical mathematics education have pointed to hidden values in mathematical models applied in society (e.g. Ernest, 2018; Skovsmose, 2020). Third, the idea of critical democratic citizenship, proposed by Skovsmose (2023) and others, where the idea is for the students to get acquainted with the benefits and limitations of mathematics in society in order to act on unfairness or what may be harmful in some sense, is quite similar to the idea of extended peer communities (Hauge & Barwell, 2017). Fourth, both post-normal science and

critical mathematics education appreciate the resources laypersons/students bring to the table/class, valuing their views and experiences (Hauge, 2024).

Taken together, the gesture of democratic entanglement can be understood as consisting of two qualities related to democratic citizenship. One is acknowledging the various worldviews of students, teachers and researchers, and nurturing democratic discussions and virtues in mathematics classrooms. The other quality is acknowledging that mathematics is a powerful tool for exploring and understanding climate change, but acknowledging that mathematics can also conceal embedded values in mathematics-based argumentation. This entanglement thus opposes any gesture that mathematics is a value-free enterprise which fosters rational reasoning, as an ideal for democracy and citizenship (for further discussion of citizenship and democracy, see e.g., Chronaki, 2024).

The second further gesture I offer, which again I relate specifically to climate change, is one I label the *entanglement of hopes*. Surveys show that many are worried about climate change. For example, 56% of the survey respondents in Norway answered that they were worried or very worried, and youngsters seem to be more worried than the rest of the population (Gregersen et al., 2023). This is not a trend particular to Norway. Hickman et al. (2021) found that 59% of the 16–25-year-old respondents from ten countries were very or extremely worried, varying from 46% in both Finland and the USA to 84% in the Philippines. Further, youngsters seem not to feel listened to and thereby become disillusioned about adults' ability to solve the climate change crisis (see e.g. Jones & Lucas, 2023). This suggests that they have lost hope of achieving a sustainable future.

How much people worry depends on their beliefs about the causes and consequences of climate change (see e.g. Gregersen et al., 2020). Snyder et al. (2001) operate with three aspects of hope when they discuss the problem of inaction. These are goals, pathways and agency. Relating this to climate change, people have different goals for the future concerning climate change, depending on their beliefs and values. Even in cases where the goal of a sustainable future is the same, people can picture different pathways to reach the goal. For example, techno-optimists will have certain suggestions for how to reach a sustainable future. Concerning agency, research finds correlations between people's environmental engagement and agency (see e.g. Ojala, 2023).

A central question is therefore what gestures mathematics educators can make, which might foster students' hope, when the problems they face are wicked and the future looks grim. A range of concerns need to be balanced, and here follow five suggestions. One is that information about climate change, and why there are reasons to worry, is necessary to awaken a wish to act, but at the same time, it cannot be too overwhelming so that students become apathetic and lose hope. Ojala (2017) uses the term "critical hope" to emphasise the need to both acknowledge the crises and to envision a different future. By introducing complexity to the issues of climate change, more realistic pathways of hope can be developed, enabling students to see the issues from different perspectives to understand others' opinions and suggested solutions. Satterfield (2000) argues that hope is most developed when one has this ability. The complexity requires mathematical competence, including understanding the strengths and limitations of mathematics, when exploring topics through mathematics-based argumentation in reports or in the media, or through applying mathematics themselves. Second, teachers need to be aware that students wish for different futures, so that fostering hope in relation to climate change might collide with other goals which students find more

important. They may not worry about a non-sustainable future. Third, even though students may have the same goal of an environmental-friendly future, they may have different ideas and beliefs on how to reach this goal. Fourth, students may have very different emotions connected to climate change, which requires a particular awareness among educators. A study by Ojala (2021) shows that teachers have different attitudes to climate change emotions in the classroom and have different strategies of dealing with them. While some teachers regarded emotions as irrelevant to teaching about climate change, others regarded all emotions as potentially constructive in mobilising an interest in climate change or willingness to make a change. However, these teachers emphasised that how to cope with emotions is highly situational. Both the first and the fourth point align with the democratic entanglement as they require a deliberative approach in the classroom, combined with critical thinking related to the topic and the applied mathematics. Yet, deliberation and democratic practices can result in opinions or actions that contradict climate change. Fifth, agency is considered key to hope, and studies suggest that people engaging in collective action have more hope (Lorimer et al., 2020).

Hope is an important topic, both for students' well-being and for encouraging environmental-friendly actions. Yet, the significance of values and worldviews must be taken into account in classrooms to strengthen students' values that align with a sustainable future, but also avoid the suppression of the students who do not think that actions need to be taken to reduce climate change.

Summarising the five gestures

We will be using the notions of the five gestures in the remainder of this paper; hence, I summarise them here, giving some examples, before we each use them to consider curricula of the present and the future. The first entanglement is about how we all, teachers and students, are entangled in the issue of climate change, both as being part of nature, e.g. experiencing weather changes, and as members of society, e.g., through politics and regulations. The first gesture is about mathematics education listening for such entanglements.

The second entanglement denotes how we all are being part of nature and connected to other people, both at present and in the future, locally and globally. The second gesture is about becoming aware of the temporal and spatial scales of our entanglement, exploring these relationships (across humans and non-humans) and how actions have consequences at these various scales. We are wary of the dangers in shifting concerns beyond the human, that there are humans who have never been accorded fully human status (Bullock, 2025). Attending to the scales of our entanglement implies a refusal to flatten the experiences of humans and a reckoning with the racism inherent in capitalism.

The third entanglement (and we change the order of presentation from above), the democratic entanglement, is about bringing awareness to how people may disagree on issues of climate change and how mathematics-based argumentation plays an important role in discussions and decision-making. The third gesture is therefore to foster democratic virtues and critical thinking. This implies that students use mathematics as a tool to understand climate change and to provide argumentation, but also explore mathematics-based argumentation in society and what values they are based on.

The fourth entanglement is about the entanglements of emotions related to climate change. Because many worry about the future, a needed gesture in mathematics education is to listen to students and

respond to their emotions regarding climate change. This requires that students have knowledge about climate change (to avoid false hope) and a sense of acting together. An act or actions could be a classroom discussion, where students' voices are heard; a letter to a politician, or an op-ed in a newspaper; or making a practical change, such as reducing the school's CO_2 emissions.

The final entanglement, the living entanglement (put last because it is the most philosophical), is about ontological and epistemological entanglements when taking the other entanglements into account in mathematics teaching and learning. A gesture this entanglement requires is a move from mathematics being a neutral enterprise. It may also include understanding nature as having agency and navigating the complex ecologies binding human and more-than-human life. Another gesture is understanding the relationship between teachers and students as more equal. The complexity of the climate issue makes it impossible for a teacher to be an expert, and the teacher may be unaware of a range of values. This means that students' voices are needed, for their knowledge, perspectives, ideas, experiences, emotions and their values. Students can contribute with something new and something other than the teacher, so that the teacher and students can explore and learn together.

Having set out these gestures and, given our focus on curriculum, in the next section, Kjellrun reflects on the Norwegian curriculum. The aim here is to look at the current curriculum in terms of the gestures (and Alf will also consider the curriculum in England in a similar way) and think about what might be missing, before we both engage in thinking about possible futures.

Climate change in the mathematics curriculum in Norway (Kjellrun)

The Norway Education Act states that "The pupils and apprentices shall learn to think critically and act ethically and with environmental awareness. They shall have joint responsibility and the right to participate." The act thus implies that teaching and learning should include sustainability issues, such as climate change. The mention of environmental awareness suggests that gestures of *listening for socio-ecological entanglement* are relevant, and *democratic entanglement* is supported through highlighting students' critical thinking and participation. It also allows for uniting the social and the ecological, which aligns with our understanding of *living entanglement*.

The statement in the act is further elaborated on under *Respect for nature and environmental awareness,* one of the six core values of the education and training in the Norway curriculum (Ministry of Education and Research, 2017). Statements include "Human beings are part of nature and are responsible for taking good care of it", which can be understood as a gesture that embraces the *socio-ecological entanglement*. The two quotes "The pupils shall develop awareness of how our lifestyles impact nature and the climate, and thus also our societies" and "Children and young people will need to deal with the today's and tomorrow's challenges, and our common future depends on the coming generations and their willingness and ability to protect our world" (Ministry of Education and Research, 2017, p. 9), both relate to *entanglements of scales*, the first regarding geographical scales and the second regarding time.

Another core value in the Norway curriculum is *Democracy and participation* (Ministry of Education and Research, 2017). Two of the associated statements are: "School shall promote democratic values and attitudes that can counteract prejudice and discrimination. Pupils shall learn in school to respect the fact that people are different and learn to solve conflicts peacefully" (p. 9). Climate change can

be argued to be a relevant issue for fostering this core value, as climate change issues are often associated with prejudice and conflicts. The core value emphasises promoting democratic values, which is in line with what we have called *democratic entanglement*, but it can also be associated with *entanglements of emotions*, as learning to solve conflicts peacefully can foster hope. The text explaining the core value also highlights the need to "develop awareness of minority and majority perspectives and ensure that there is room for collaboration, dialogue and disagreement". An aim of this value is to "prepare the pupils for becoming responsible citizens in society" (p. 10). These pieces of text can also be related to climate change, and they align with *democratic entanglement*.

The core values in the Norway curriculum show that teachers are encouraged, and partly obliged, to include activities that align with all the gestures we have proposed in this paper. The curriculum is quite radical. In a blogpost (Hauge, 2022), I reflect on a paradox it represents, as it aims at fostering students to become something different from the societal environment they grow up in. As mathematics educators, we need to start thinking about how to cope with this paradox.

While the core values reflect all five gestures, the mathematics curriculum does not reflect them distinctly. However, there are some statements and elements that are relevant for democratic entanglement and working with climate change. Examples include "Mathematics is an important subject for understanding the patterns and relationships within society and nature through the use of modelling and applications" and "Critical thinking in mathematics includes critical evaluation of reasonings and arguments and can arm the pupils to make their own decisions and take a stand on important questions in their own life and in society" (The Norwegian Directorate for Education and Training, 2019, p. 2). The mathematics curriculum specifically addresses its role regarding the topic of democracy and citizenship. It explains that it includes "giving the pupils the competence to explore and analyse findings from real datasets and data collected from nature, society, working life and everyday life" and "learning how to evaluate the validity of such findings" (p. 4). The aim of such activities is "to formulate one's own arguments and participate in public debate" (p. 4d). A competence aim worth noting is for year 9: "interpret and critically evaluate statistical representations found in media and the local community" (The Norwegian Directorate for Education and Training, 2019, p. 14). The mathematics curriculum thus explicitly includes the gesture of handling *democratic entanglement* through critical thinking on societal issues.

Climate change in the mathematics curriculum in England (Alf)

The current (in 2025) National Curriculum in England was introduced in 2014. The curriculum before then had emphasised skills and competencies. The changes made in 2014 were explicitly about moving towards a view of "knowledge" not skills as being central to education, as reflected in the aims, which are to provide: "pupils with an introduction to the essential knowledge they need to be educated citizens. It introduces pupils to the best that has been thought and said, and helps engender an appreciation of human creativity and achievement." (DfE, 2014).

There was criticism of curriculum documents for their lack of reference to climate change; such criticism was rebuffed by the Department for Education (DfE) during consultation (DfE, 2013). The result is that the first reference to climate change appears in the curriculum for 11-14 year olds, and the only reference is in the statements for Geography and Science, and without any links to wider

social justice issues relating to climate change. The word "climate" appears twice in the Science curriculum for 15-16 year olds (around the "potential" effects of greenhouse gases and "evidence and uncertainties" about human-caused climate change), and three times in the Geography curriculum at the same age. The insufficiency of this situation led to belated recognition of the importance of climate change education after 9 years. In 2023, a government strategy document was published on "Sustainability and climate change" for education (DfE, 2023). The "vision" of this document is that "the United Kingdom is the world-leading education sector in sustainability and climate change by 2030", although no changes were made to the national curriculum. As part of this strategy, a "National Education Nature Park" was launched in October 2023. This initiative is focused on students taking action "to engage with nature in their local areas" (DfE, 2024). One aim is that schools turn some of their grounds to becoming a nature park. A new government in the UK (elected in 2024) is undertaking a wide-ranging curriculum and assessment review—they have promised "evolution" not "revolution" and so it seems unlikely sustainability will feature centrally.

The curriculum in England that was introduced in 2014 represented a backwards step in relation to the extent to which climate change and questions of sustainable development were present across ages and subjects. There is, perhaps, a salutary lesson here that there is no inexorable bending of policy towards a broadly liberal or even scientific consensus.

In terms of the mathematics curriculum, as can be implied from the discussion above, there is no direct mention of climate change or sustainability. Perhaps the closest approach is the mention of "modelling" in the curriculum for 11-14 year olds ("begin to model situations mathematically and express the results using a range of formal mathematical representations") and 15-16 year olds ("model situations mathematically and express the results using a range of formal mathematical representations, reflecting on how their solutions may have been affected by any modelling assumptions") (DfE, 2014/2021 update). There is also limited mention of data literacy and data science, which, along with the study of statistics, could offer scope for considering climate change as a context for learning. There is, therefore, little in the curriculum itself which aligns with any of the gestures we have outlined. Of course, mathematics teachers in their practice may well be engaging in gestures such as *listening for entanglement*, or *democratic entanglement*, but such gestures would seem to me to be taking place in spite of, not because of, the curriculum.

A report by The Royal Society (2024), in the UK, set out a vision for how the mathematics curriculum might change. A key suggestion of this group is combining mathematics and data education, proposing far more use of technology and a closing of the gap between how mathematics is used outside school and what happens in classrooms. The word "climate" has eight mentions in this report and so, although not central, is certainly within the scope of the new plans. It is not currently known to what extent this report will influence the curriculum review.

Reflections on the curricula (Alf)

In this section, I look across the two curriculum contexts above and draw out possible implications. I consider the vexed issue of how and when teachers can take a political stance. The contrasts between England and Norway's curriculum are stark, with the Norwegian case much more closely aligned to UN initiatives such as Action for Climate Empowerment. The Norwegian curriculum includes several

topics (not present in England) with explicit references to sustainability, climate, and criticality. The contrast can also be observed in the aims of education, which for Norway include mention of environmental awareness, compared to a focus on knowledge in the case of England. Gestures relating to *listening*, *democracy*, and *hope* seem visible in Norway's curriculum, which are barely present in England. Starting from these two examples, I want to consider possible aims of a future (mathematics) curriculum, in relation to the five gestures. One of the few commonalities across England and Norway is that, for both countries, the aims of education are linked to the notion of "citizen". In England, the aim is to create "educated citizens", and in Norway, questions around sustainability are linked to the need for "democratic engagement from citizens". So, in discussing the aims of education, we might first need to consider what concept of citizen is being invoked.

Chronaki (2024) has offered a powerful and original analysis of the concept of the "citizen" through time and how this is relevant to the role of mathematics education. Chronaki (2024) traces a move through ideals of a "competent" citizen (in Antiquity) to an "insurgent" citizen (of Modernity) to a "creative" citizen of current (posthuman) times. In each case, she charts the paradoxes or antimonies associated with each image of citizenship. For example, in ancient Greece, citizens were required to develop ethics and wisdom, to partake in democracy. And this requirement for competency served as a means of exclusion of the marginalised. Chronaki traces a direct link to a mathematics classroom focused on consensus and establishing "norms" (as might be seen to be needed in gestures towards democracy), where the space for disagreement and subject agency is reduced (particularly for certain subjects). A key conclusion (Chronaki, 2024) is that the concept of the citizen is politically inflected and, without careful scrutiny, any call for mathematics education to support citizenship: "converts, easily, into a legal tool that, alongside mathematical biopower […] governs people, imposes enclosures, and justifies injustices" (p. 16). Such "biopower" can be observed in the use of mathematics in algorithms for allocating resources (Skovsmose, 2023).

Instead, Chronaki proposes bringing attention to the paradoxes inherent in the concept of citizenship (paradoxes with relevance to living and democratic entanglement), and aligning with grassroot activity that counters oppressive logics of control. Chronaki's (2024) proposals are ones "requiring active/passive participation in political activity that interrogates the institutional legitimisation of injustice always in alliance with people and their social movements" (p. 16). So, when Norwegian and English curricula call for the development of citizenship, it is important to interrogate what image of citizenship is invoked and what paradoxes or tensions are entailed.

The English curriculum advocates for "educated" citizens, educated with the knowledge of the best of what has been "thought and said". Norway calls for citizens able to partake in democracy. Particularly in the English case, I see connections to Chronaki's notion of the "competent" citizen and, following her argument, it is pertinent to ask who are the subjects deemed not to be educated, or without the "basic tenets" that allow them to partake in democracy. In explicitly aiming for a vision of a competent citizen, there is the potential for a legitimisation of the power to exclude individuals and groups who are deemed not to have reached the necessary level of competence.

Chronaki's (2024) work draws on other scholars (e.g., Gutiérrez, 2013; Valero, 2004) who raise questions of politics in relation to mathematics education. And, in considering questions of climate change, it is impossible to avoid questions of politics, both at the macro level of curriculum and the

micro level of the classroom. For example, we are conscious of research into the role of right-wing think tanks and lobbying groups, which are reported as having an enduring influence on education policy in the USA (Foster & Davis, 2004; McDonald, 2014). And that such influence is spreading (Applebaum, 2023). The 2014 curriculum in England was initiated by a right-wing government, explicitly wanting to re-dress a previous competency-based approach. One element of right-wing education policy tends to be the attempt to make teaching "neutral" or "a-political".

Of course, what it means to advocate for "a-political" teaching is an acceptance of the status quo. And while this could seem desirable in times of peace or stability, in relation to the ever-worsening climate chaos being experienced around the world, I want to suggest that, in contexts where they are expected to be a-political, there are acute pressures placed on teachers. In England, for example, DfE guidance (from 2020) banned the use of teaching materials produced by organisations which advocated an end to capitalism (such groups being considered "extremist"). It therefore becomes a potentially career-threatening decision by a teacher to raise questions such as whether there should be an end to the quest for economic growth. Anecdotally, some secondary schools in England are explicit about steering teachers away from discussion of current political issues, partly, no doubt, through fear of media reaction. Our focus on curriculum in this article means we want to consider other possibilities than what is the standard now. In the next section, I look at some research suggestions about climate change education, and then we both move into reviewing work we have each done and what this might imply for the future, continuing to link to the five gestures.

Considerations in thinking about curriculum innovation (Alf)

In a review of past research, Monroe et al. (2017) identified four themes relevant to effective climate change education: (1) deliberative discussion; (2) interactions with scientists; (3) addressing misconceptions; (4) school and community projects (p. 801). All of these four themes are potentially relevant to the mathematics classroom. In the examples of curriculum innovation that follow, each of these themes is present. In another review of past research, Rousell and Cutter-Mackenzie-Knowles (2020) distinguished approaches to climate change education which are knowledge-based from those which are interdisciplinary, affect-driven and experiential. Their review pointed to the predominance of knowledge-based approaches and called for more of the latter. Again, although they were addressing the broader field of climate change education, it seems such a provocation to think that affect and experiential learning are highly relevant to our concerns in this article.

In thinking through how the curriculum, or the teaching approaches, might need to change, it seems important to recognise that the ethics of action are ambiguous (Boylan, 2016) because we cannot know what the effects of our actions will be, and there is a need to navigate ethical dimensions with conflicting priorities. Barwell et al. (2022) proposed a dialogical ethics as a starting point for navigating this ambiguity—listening to the voice of the Other (whether human or not) and answering. And, in a deliberately circular and mutual formulation, we proposed that it is through being recognised by the Other that we gain our capacity for answering and acknowledging our unique obligations (Barwell et al., 2022). Any gesture of living entanglement implies the need for ongoing reflexive work, to continue engaging in and being mindful of how we are ethically implicated.

Ideas around a dialogical ethics relate to Chronaki's (2024) challenge around the paradoxes of citizenship and Bullock's (2025) concerns around the potential racism that lies uncovered or unnoticed in moves to think beyond the human. One potential avenue for thinking through these challenges is through a questioning of the individualism in our concept of "human". Gestures of listening, scales and living entanglement prompt towards a shift away from thinking about mathematics education as relating to individuated beings. In Coles and Sinclair (2024), we try to think through a notion of mathematical "connections", where there is not the assumption that well-defined individuals come to an encounter. If we imagine an encounter momentarily bringing an individual into being (for the duration of that encounter), how might that change our perspective on learning or curriculum? A shift away from individualism might go with attention to the ecologies of habit in which we are embedded. A moment's reflection on any culturally-typical behaviour we engage in (tea with milk in the UK, black coffee in Italy) will point to how patterned our actions are, through all that has come before us. We live most of our lives in patterns of action we do not even notice (and we could not survive long if we did not do so). It might be said that we enact the patterns of others' actions (Coles, 2017). In other words, we never act as an individual and, furthermore, our actions are part of laying down the patterns of others' actions, with all the responsibility this implies. Such thoughts might lead to exploring what a communal mathematics education and curriculum could look like and what gestures and entanglements might be involved.

A curriculum for an uncertain future (Alf)

In the final two sections (before we conclude in a joint section), we begin looking to the future of the curriculum (first, projects I have been involved with and second, Kjellrun). Having considered the gestures of mathematics education and the gestures visible in current curricula, and some broader considerations around climate change education, what possibilities might there be for the future? I draw on the ideas of gestures and ethics set out above to put forward some proposals, drawing on work in which I am currently engaged.

I was privileged to be invited to do some work for the youth group "Teach the Future" (TTF). Students in England are generally excluded from discussions about their curriculum. TTF is a lobbying organisation, run by school students, that has been successful in gaining the ear of politicians about how the curriculum should change (aiming at *listening for entanglement*). One project they ran was "re-imagining" the National Curriculum. I worked with Sarah-Jane Compton-Williams to look at the Mathematics curriculum in England, for ages 11 to 16 (see, https://www.teachthefuture.uk/tracked-changes-project). This work made me realise just how old the mathematics is, in the current offer. My guess would be that, up to age 11, there is little mathematics taught that would not have been recognizable in England 500 years ago.

Sarah-Jane and I wanted to make space for introducing topics including systems thinking and projective geometry—this latter so that students might have an experience of two systems of thought (Euclidean and projective geometry), which lead to contradictory conclusions (such as lines in the same direction meeting or not meeting at a point), allowing reflection on the role of assumptions. One thing we considered is what might we *not* teach if we want to make room for different kinds of mathematics. And a conclusion we came to, in England, is that there is far too much emphasis on number work. For example, do we really need to teach fraction notation?

In framing our alternative proposal, we drew on Roe et al. (2018)'s work on mathematics for sustainability at the undergraduate level. We proposed moving away from curriculum categories such as "Number" and "Algebra" (as they currently exist in England) and instead proposed the following five categories—each with a guiding question:

Measuring: how big (or small) can things get?

Changing/flowing: how quickly do things change/move?

Mapping: how do things occupy space and time?

Risking: when is a risk worth taking?

Deciding: how do we act ethically?

We imagined work within these areas being guided by those key questions, which could be returned to repeatedly, motivating the study of both contexts and mathematics. In my own research, I am currently trying out this curriculum arrangement and the use of the guiding questions, in outreach work I am doing in a prison, fairly local to where I live (for me, this represents an extension of the *scales of entanglement* in mathematics education to which I usually attend, just in terms of context).

Prison education is one of the most marginalised and under-funded sectors of the education system in England (Coates, 2016). The number of prisoners doing "level 3" qualifications (which allow university entrance) has dropped 90% in the last 10 years (House of Commons Education Committee, 2022). The courses on offer (at level 1 and 2, which would be achieved at age 11 and 16 in school), from what I can see, seem to be experienced (by teachers and prisoners) as little more than "tick box" exercises. My university started an access course for STEM degrees, and I wanted to see if we might be able to run this in prison. After a year or so of chasing around a range of different committees, the answer came back as a "no". There were concerns about how quality assurance might happen and about the status of the prisoners as students. This latter point is interesting in terms of the critique I offered around the "competent" citizen (Chronaki, 2024). Here is a clear example of how it seemed impossible for a university committee to imagine how a marginalised group might be given "full" status, as students, and hence as humans, we might say.

My university has been happy for me to engage in "outreach" work in prison, however, so long as the work is not accredited. I have been trying to "mirror" as far as possible the STEM access course run by my university. As it happens, there are some advantages to not offering the full course, not least that I can offer it for free, rather than costing the prisoners several thousand pounds.

If I reflect on the work in prison, moments that stand out are ones of a prisoner seeming to find joy—and these have all been moments of joy in an element of pure mathematics, in amongst the work in context. A future curriculum is surely likely to question the disciplinary boundaries of the present and be more trans/inter-disciplinary. And there is something that remains significant about disciplinary engagement in mathematics. I interpret the experience of joy (e.g., in one case contemplating how differentiating could be iterated and wondering what would happen for different functions) as a form of *living entanglement*. If part of what we are arguing for is a non-separation of nature and culture, then coming into contact with a mathematical structure (such as differentiation of functions) is as much a socio-ecological experience as, e.g., taking a walk by a river (Coles, 2025).

The final example I want to touch on is work with teachers. At the University of Bristol, for the last 10 years, we have slowly been working on introducing questions of sustainability into our teacher education course (Coles & Helliwell, 2022). As part of one Master's unit, done on the course, prospective teachers have to design a task relating to a "global challenge" (including, but not limited to, climate change), implement the task with a class they are teaching and then reflect. Some of these tasks have been written up in a professional journal (see Brown et al., 2021a, 2021b). We also support teachers to work in collaborative groups, doing action research, for some, with a climate change focus (Coles et al., 2023). In the plenary lecture at CERME, we gave participants time to talk in 3s, partway through, to share their thoughts—with the instruction to engage in active listening, not looking to add your own anecdotes, but supporting the articulation of the person speaking. That experience speaking in groups of three, and supporting each other to articulate ideas, is a small example of a practice we use regularly (established by Laurinda Brown)—in which teachers' learning becomes entwined, in a communal endeavour. I am struck by the importance of listening. So, while in an English context, work on climate change in mathematics lessons in schools has a "one-off" feel, developing skills around listening and dialogue can be developed with any curriculum.

I end this section reflecting further on the presence of the five gestures in the practices above and, also, on the questions and challenges, above, from Chronaki (2024) and Bullock (2025) around the paradoxes of the notion of the citizen, and implications arising from how we frame the human and who is allowed human status. Material and social conditions of life are entangled in prison life (as we point to in *living entanglement*), in the sense that a socially sanctioned decision (to jail someone) leads to their physical detention. The curriculum framing around large questions: "How quickly do things change?"; "How do things occupy space?" does seem to have allowed the study of mathematics to be linked to socio-ecological issues of relevance to learners (*listening for entanglement*). Lessons have included an emphasis on dialogue. Time has unusual qualities in a prison—the repetition of the routines of day—and a sense of wasted time, of time standing still, as prisoners look to their release date. Prisoners have little capacity to make changes to the organisation of their lives. Making sense of mathematics is one (small) area of their lives in which they can, perhaps, engage as equals with one another and with people outside prison—it is the quality of arguments that determines what is acceptable, not social position or status (*entanglement of democracy*). Kjellrun's *entanglement of hope* is also relevant. The men are explicit about engaging in study with a view to their possible futures. It is a different kind of hope, perhaps, to think about climate and other earth systems, but it feels significant, nonetheless.

In relation to the teacher education work I have mentioned, I have collaborated previously on writing where we have argued that our course adopts a "communal" approach to initial teacher education (Coles et al., 2023). Our teacher education curriculum is framed at a "meta-level" around supporting teachers with the skills to learn about teaching (not the details of how they might teach). There is a "relentless consistency" (Brown, 2012, p. 31) to practices of moving from "experiences to issues to actions" (Brown et al., 2021) throughout the course. The course aims to equip teachers with the skills to adapt their practice—ready for the curriculum change to come (which relates to temporal *scales of entanglement*). In focusing teacher education at a meta-level, there is a (democratic) space for teachers to bring their own contexts and histories to university sessions and be supported in acting

effectively in those contexts. The intelligent use of affect is a key to the programme, for instance, in de-brief discussions about lessons, we invite prospective teachers to bring to mind moments which felt comfortable or uncomfortable. Using affect, in reflection, helps to identify the focus for work, often in relation to changing habits and noticing implicit assumptions. Prospective teachers are entangled in each other's journeys of learning to teach through consistent three-way discussions and an emphasis on dialogue and working communally on mathematics.

Perhaps one way to respond to the challenges of Chronaki (2024) and Bullock (2025) is to contemplate what it might mean to move to a position where we no longer demand that anyone needs to prove to us their competence, their rationality, their understanding, their humanity (Wolfe, 2016). Recalling the words of Angier and Povey (2025), who draw on Bridle (2022), instead of asking, "Are you like us?", might we be curious about, "What is it like to be you?", shifting, "from empathy and identity to solidarity, recognizing and valuing other things without having to identify with them as being like us" (Angier & Povey, 2015, p. 105). It is perhaps almost unthinkable how schooling in England might not demand that students prove their competence. Current framings of education (e.g., the curriculum and school inspectorate) emphasise tracking of student progress, with an almost constant assessment of competence. And yet, perhaps looking at practices in the early years (children younger than 5) offers some examples, and inspiration even, where it seems to me quite precisely the case that young children are not required to prove anything about themselves. Inspiration from art education may also be relevant, with a focus on the process, not the product of learning (Hay, 2022).

A curriculum for an uncertain future (Kjellrun)

I now present a project which addresses some of the entanglements and which illustrates some challenges with addressing climate change, or sustainable development in general, in mathematics classrooms. A couple of years ago, four preservice teachers, all Master's students in mathematics education, were asked to plan and conduct a three-week project on sustainable development during their practicum. This task was developed by their practicum teacher and two researchers, Trude Fosse and me. The project was to be carried out in all mathematics, natural science and social science classes, and the practicum teacher gave the preservice teachers a list of relevant curriculum goals in the three school subjects. To make the project relevant for the students, who were 14-15 years old, we asked them to start the project with something close to their everyday life (for more information, see Fosse & Hauge, 2025; Hauge, 2024; Hauge et al., 2024).

Giving the task to develop a project on sustainable development originated from a concern about consumption, emissions, pollutions and the loss of nature. It can thereby be considered a gesture of listening to how we humans, and our mathematical practices, are entangled with nature. So, what gestures did the preservice teachers make?

The preservice teachers chose textiles and clothing as the sustainability topic and developed a range of tasks. They showed documentaries and TV debates on problems related to consumption and working conditions in Cambodia and China; they gave a lesson about UN Sustainable Development Goals, and the students learnt about textiles and pollution. This indicates the gestures of *listening* and of *scales of entanglement* because the focus was on the consequences of consumption, which take place in other parts of the world. Because the three-week project facilitated an awareness of a global

problem which the students, as consumers, could respond to through a change in habits, the preservice teachers made a gesture of *living entanglement*.

The students chose subtopics to work with in groups, and they participated in a debate, a role play on the responsibilities of different actors regarding the bad working conditions in factories. They were to find information on the Internet and back up their statements and argumentation with quantified information. The freedom of choice regarding subtopic and how to get hold of relevant information can be interpreted as gestures of *democratic practices* and *hope*. However, the students did not seem to be given the opportunity to voice their opinions about the issues they were working with, and perhaps only the students who were concerned about sustainable development achieved a sense of purpose with the three-week projects.

Projects on sustainable development, such as this one, are formative and call for change. This is challenging for different reasons, as I will now illustrate. The first task given to the students was to write a reflection note on their own habits and consumption of clothes. Later, the practicum teacher and the four preservice teachers discussed this activity, and one of the preservice teachers, Alex, said,

> Alex: I felt many reflected well on their own habits, and so on, but then I kind of "what is OK to ask?" […] If someone can't afford the clothes they want, it can be hurtful for some. […] It can't be like, "Yes, very good, you donate to the Salvation Army." We're not judging people.

Alex points to two ethical considerations related to the task. First, the students at this school came from families with different incomes. Because clothes are a status and identity marker, clothes could be a hurtful topic for some. Second, the task implicitly conveys a moral stance, indicating that certain consumption patterns and certain handling of clothes are better than others. Bringing attention to this may cause shaming of those who feel their practices are not good enough. This challenge will be present when working with sustainable development with the purpose of changing habits. A consequence is that mathematics educators need to think about how to be prepared for emotions in their classrooms, such as shame, anxiety, anger and hope, and how to prepare preservice teachers for students' emotions. Because how to deal with emotions is situational, there is no prescriptive method that can be applied (Ojala, 2021). Conducting projects that promote awareness and change may demand new kinds of relationships between school, family and enterprises.

Towards the end of the three weeks, the students presented their projects for the class, the preservice teachers graded their work and gave the students feedback. One student group had chosen to work with fast fashion because they were concerned about the negative impacts of this industry. They received a good grade, and part of the feedback from the preservice teachers is the following.

> Drew: […] you have worked well and efficiently throughout the whole process. You cooperated well and made a very nice presentation. […] You appear unbound by scripts, and we can hear and see that you have worked well together and are collaborating. Your academic content is sound, and you are very familiar with the content, are reflective, and have included criteria from all the school subjects in a good way. We sense that you have been very united and agreed on what to do in class and at the presentation. And cooperate well.

Then, one of the other preservice teachers, Billie, continues. She goes more into detail, and in the middle of her feedback, she makes the one and only comment related to the problems the students are raising:

> Billie: [..] And I think it was very nice that you talked about problems with fast fashion […]

This made me realise that we need to think carefully about projects on sustainable development and grading. If concerns about nature, working conditions and opinions are less valued than facts and presentation form when grading tasks, engaged students can lose hope and trust that the school supports them in their engagement. Grading and feedback can thereby be an obstacle to all entanglements and gestures: *listening, scales, democratic engagement, hope* and *living entanglements*. We, mathematics educators, need to resolve this obstacle.

Although all the gestures were present in the textile project, there are ways to make them more apparent. For example, discussing solutions and finding ways to act might both have strengthened hope and the gesture of living entanglements. In addition, discussing what is possible, what is desirable and why change is challenging could emphasise the gesture of democratic entanglements. Valuing students' opinions and practising democratic virtues would be vital, together with addressing structural obstacles to change, moving the essential responsibility from the individual.

The following project illustrates the qualities of gestures of democratic practices. Three researchers, a PhD student and a Master's student, went to a town in Lofoten to arrange a classroom discussion with 13-14-year-olds on whether to open the area to petroleum exploitation (for more information, see Breivega & Rangnes, 2019; Herheim et al., 2022). There has been a public and political debate about whether to open offshore Lofoten areas to the oil industry since the 90ies. So far, it is banned because of the important fishing grounds. The scenery in Lofoten is stunning, so tourism is also very important for the area.

The students first worked in groups to develop argumentation, followed by a plenary discussion. The following excerpt is from the last part of the plenary discussion. Previous to the excerpt, some students have argued that if the area is opened to petroleum exploitation, their hometown will grow so that it will need a shopping mall.

> Melissa: You talked about getting a shopping mall here. It's the same thing as if you would remove the Eiffel Tower in Paris and rather build a shopping mall. Then tourism there would drop at once, and the same can happen here. That if we get big oil installations and a shopping mall, and we only have industry here, then it will drop here, too.

A couple of minutes later, Roy declares,

> Roy: I think, personally, that change is the best for Vestvik right now. We need to take a few chances, because now we have lived on fish and dried fish, and tourism, for many, many years—and we are committed […] to try to become a city […] There will be a shopping mall. When you want to go for a walk, there are still mountains […] We're not going to blast [the mountains] to create a shopping mall.

While Melissa is against petroleum exploitation and argues that a shopping mall will affect the iconic value of the area, Roy favours a cultural change and supports the oil industry. This excerpt illustrates that the students clearly disagreed on what is best for their hometown and have different hopes for the future, but still, they showed respect for each other, as illustrated in the next excerpt.

The next excerpt is from earlier in the plenary discussion. Mary states that she and her group are against oil exploitation based on the following argument,

> Mary: The fish can be scared away, and tourism can decline. And it can affect the fisheries.
>
> Researcher (facilitator): Can you say something about why tourism will decline?

Mary struggles to answer this, but Roy wants to help,

> Roy: I can. Most tourists come to Vestvik because they want to see the scenery and to fish. But, if we assume [oil exploitation], then it will be full of oil platforms out there—and when we search "Vestvik" and see how it looks here, then probably the first thing to appear would be oil platforms. […] And not very many will come to look at the oil platforms. Yes.

Here, Roy helps Mary with providing arguments that support her claim, even though he disagrees and supports the oil industry. The classroom discussion can be understood as a *gesture of democratic practices*. The students were encouraged to give their own opinions and to disagree on a controversial issue related to sustainable development and climate change. The research team made efforts to show that the students' contributions were valued. The students showed each other respect as well and had important dialogical qualities. They practised democratic virtues, such as listening, responding, respecting (which Roy was an example of), exploring and including critical thinking when developing argumentation in line with *democratic entanglement* and *listening to socio-ecological entanglement,* in particular when ecological effects were part of the argumentation. The discussion was also an arena for the students to express their hopes for the future.

The other gestures were perhaps not so prominent, and mathematics was not much present in the discussion. With more time, both could be implemented. For example, the students were quite capable of mapping risks (Breivega et al., 2022), which could be explored later through mathematical tools, which again could draw attention to listening to entanglements as positive and negative impacts of an oil industry would become clearer.

Conclusions and discussion

In this paper, we have argued that mathematics education needs to change in response to the impacts of our "new" climate. Our focus has been on curriculum. We proposed five possible "gestures" for an alternative mathematics education. We do not offer these with any sense of completeness, and we also recognise there are significant overlaps. The five gestures and some prompting questions are offered in Table 1 (the questions are not exhaustive of the gesture but rather, specific examples):

Gesture	**Example prompts**

Listening to entanglements	What do we take as fixed for the purposes of our research? What are the implications of taking the environment as fixed?
Scales of entanglements	How has the past influenced the inequalities and issues we face now? What are the implications of our actions for other places on the earth? For other species?
Democratic entanglements	To what extent is the mathematics education we are involved with fostering democracy and critical thinking in relation to climate?
Entanglements of emotions	Whose voices are heard, and how might hope or courage be fostered, as well as awareness of the scale of challenges?
Living entanglements	What does it mean to act from a position of recognising our lives as emerging out of symbiotic collective relations? How do we conceptualise the "human"?

Table 1: Five gestures

We considered the national curriculum in both Norway and England, which showed up some stark contrasts in terms of aims and the presence of questions of the climate and sustainability. It seems extraordinary to us that, in 2025, it still has to be said (e.g., looking at the English National Curriculum) that there needs to be more attention paid to knowledge of climate change and an engagement in what it might mean to respond. We have attempted to show and argue that mathematics is an important tool for exploring and understanding climate change topics. We also questioned the image of the "citizen" evoked in different National curricula and what that image may occlude, and who may be marginalised.

In the section just above, we considered some projects involving curriculum innovation, which we have both been involved in, and what these might suggest about possibilities for the future of the mathematics curriculum and any gestures it may embody. Our perspective is that every mathematics classroom is making a gesture (more or less explicitly) around values—hence there is a need for reflexivity about the meta-messages of our own practices, and our instantiations of mathematics, as well as the values of the broader institutions within which we work. So, whether our specific proposals make sense, or seem relevant in your context, our broader point (which itself is a gesture of *living entanglement*) is a provocation to consider what values are being promoted through our work (e.g., are they values of democracy? do they support awareness and listening for what is ignored? is it possible to consider a current time and place in relation to other times and places?). We have tried to argue that mathematics education is not exempt from taking responsibility to engage in issues relating to climate change and climate justice.

Reflecting on our writing about curriculum projects, there are several points of learning relevant to thinking about the future. One commonality is the way current assessment structures get in the way of interdisciplinary projects and the capacity to allow space for students' ideas to be aired and taken seriously. Alf called for students not to need to prove their competence, their humanity, and Kjellrun reflected on the obstacles of grading, in relation to projects displaying the gestures we have outlined. If a schooling system without assessment seems unthinkable—can we stretch our imaginations?

A second issue arising is the complexity of bringing socio-ecological issues into the classroom. Teachers may need to engage in gestures that have not typically been required in mathematics classrooms in Norway and England. New gestures might need new ways of working, for example: skills of handling opposing and strongly held views; consideration and sensitivity to students' different backgrounds and experiences; skills of noticing and managing students' emotions; skills of allowing for the expression and discussion of controversial ideas in an environment that still feels safe for participants; skills of navigating ambiguity; addressing politics explicitly. One framing of what may be required is a move towards a communal mathematics education. And we do not underestimate the skills of teaching required and the implications for professional development and initial teacher education. This does not mean that teachers need to be experts in everything, but rather that there might need to be the development of a sense of exploring issues together with students. And while this might imply the need for teachers to take risks, there is also a sense that there may be much to be gained from a schooling focused on co-exploration of genuine issues in the world.

To pull out, from the writing, some further suggestions for the future, we want to propose (a) mathematics has a vital role in climate change education (beyond the sciences), (b) there is an urgent need for reconsidering not just how mathematics is taught, but also what mathematics is taught. In relation to (a), we noted right at the start the significance of the recognition that mathematics is not a neutral subject and developing an awareness of the ambiguity and ethics of the uses of mathematics is surely a key element of a curriculum for the future, to say nothing of the mathematical skills required in making sense of and communicating about climate issues. In relation to (b), several proposals can be interpreted through what we have offered, including: inter-disciplinary projects arising from local issues; the importance of dialogue; re-framing of the subject in terms of processes relating to sustainability; reducing an obsession (as we see it in current curriculum documents) with number work; introducing a study of systems (e.g., to develop an awareness of runaway effects, local stabilities, catastrophic change, etc.), including the climate.

We want to end by thanking the organisers of CERME14 for allowing us space to bring to the conference issues relating to climate, justice, sustainability and the future of mathematics education, particularly as these are currently relatively marginal pursuits, looking at mathematics education research in Europe as a whole. We hope that CERME continues to be a space for developing a research agenda around how the living world matters for mathematics education and how mathematics education matters for the living world. We hope others might take up, challenge, refine or rework some of the gestures outlined, and we hope we can continue to engage in conversation and collaboration around such issues at future CERME conferences.

Acknowledgments

We would like to acknowledge the following people (recognising the incompleteness of this list), whose influence on each of our thinking is both profound and impossible to fully elaborate in the text above. For Kjellrun these are: Richard Barwell, Lisa Steffensen, Marit Johnsen-Høines, Inger Elin Lilland, Suela Kacerja, Kjersti Breivega, Marianne Presthus Heggen, Yasmine Abtahi, Trude Fosse and Thea Gregersen. For Alf, these are: Tracy Helliwell, Nathalie Sinclair, Kate le Roux, Armando Solares, Richard Barwell, Mark Boylan, Sigal Rotem, David Wagner and Mariam Makramalla. And we both want to acknowledge the inspiration we gain from the many teachers we have the privilege to work alongside.

The new role of data in society: Challenges and opportunities for mathematics education in the age of data science and AI

Rolf Biehler[1] and Michelle H. Wilkerson[2]

[1]Paderborn University, Germany; biehler@math.upb.de

[2]University of California, Berkeley, USA; mwilkers@berkeley.edu

Data Science and Artificial Intelligence (AI) are reshaping society, entangling (Coles & Hiis Hauge, 2025) mathematics with people, values, and the wider world. This transformation brings new challenges and opportunities for mathematics education, while also calling for broader curricular shifts that connect with other school subjects. In this talk, we examine key skills and literacies students need to navigate a data-driven world and imagine their role in shaping it—critical data literacy, statistical, media, computational, and AI literacy. We discuss how these literacies should evolve within mathematics education and emphasize the importance of interdisciplinary collaboration across data science, the natural and social sciences, and computer science. Classroom examples from our own projects illustrate how these ideas can be brought into practice.

Keywords: Data science education, Data literacies, AI literacy.

1. Introduction

The topic of data has always fallen between the cracks—especially between mathematics and computer science:

> Computer scientists, by nature, don't respect data. They have traditionally been taught that the algorithm was the thing, and that data was just meat to be passed through a sausage grinder.
>
> So to qualify as an effective data scientist, you must first learn to think like a real scientist. Real scientists strive to understand the natural world, which is a complicated and messy place. By contrast, computer scientists tend to build their own clean and organized virtual worlds and live comfortably within them. Scientists obsess about discovering things, while computer scientists invent rather than discover. (Skiena, 2017, p. 2)

We invite readers to consider whether there might be a similar attitude toward data among mathematics educators—that the term "computer scientists" in the passage above might be replaced with the word "mathematicians". Of course, data are part of statistics education, which is taught in the mathematics classroom, and data play a certain role in mathematical modelling. In computer science education "data and information" is a standard topic. And as the quote highlights, data are also central to inquiry across the natural and social sciences.

However, standard current educational practice is far away from taking the emergent new roles of data in society into account. Classes and curricula are still typically organized according to relatively siloed and static visions of school subjects, limiting the extent to which scientific, social, mathematical, and computational explorations can be meaningfully brought together to enable students to make discoveries with data. At the same time, the confluence of all these disciplines and approaches makes planning developmentally appropriate and tractable activities with data

challenging. Exactly what should students know about data, and when should they learn it? And, how can educators be prepared to teach such a dynamic and interdisciplinary set of practices?

In this paper, we review the current state of the field of data science education and provide some examples from our own research and development work. It is based on a plenary talk we gave at CERME 14 in February 2025, where the slides contain many illustrating examples (https://bit.ly/cerme14). We begin by defining *data science* as an emerging, interdisciplinary field and examining its impacts on society, science, and education. We then present pedagogical examples of data science driven activities, drawn from our own work and others at the interface with the natural, social, and computer sciences. Our goal is to plot a course for considering the impact of data science, and related innovations such as machine learning and generative AI, *across* the curriculum—and the implications of these curricular impacts for mathematics education. We invite our readers to consider, within this context:

- What is important for students to know about data?
- What should students be able to do with data?
- What is (or should be) the role of mathematics education in contributing to the knowledge, skills, and dispositions needed for students to understand life with data?

A first answer, which one could have provided at least 20 years ago is: Students should have experience with analysing "tidy data" (Wickham, 2014) with digital tools from the perspective of statistical investigation (Wild & Pfannkuch, 1999). Tidy data are multivariate data, organized in a table in rows and columns, like a survey where each row is a person and columns record their attributes. Attributes can be numerical or categorical. Digital tools for school use have been available (Biehler et al., 2013), as well as material, data sets, and ideas for classroom use, backed by research (see e.g., Ben-Zvi et al., 2018, and the website of the International Association of Statistics Education iase-web.org). However, implementation in standard curricula is far behind the consented goals among statistics educators in many countries.

The new developments of data in science and society demand an even more substantial place of data in the curriculum, which can build on traditional approaches and integrate new aspects. We see the emerging societal pressure on schools to integrate more data literacy or AI literacy as helpful for curricular reform. The Organization for Economic Co-operation and Development (OECD), for example, recently announced an effort to develop an AI literacy framework that extends across the curriculum, so that "educators will be able to better assess students' understanding of AI, as well as broader issues like privacy concerns and digital citizenship with clear, measurable benchmarks [...] not only for academic success but also for active, well-informed participation in an AI-driven, digitally evolving society" (Schleicher, 2025).

2. Characterizing Data Science and its Evolving Meanings and Roles in Society

What counts as data has changed dramatically and rapidly. Data now includes everything from images, text, videos, and webpages to audio data (speech), sensor data, and records of transactions. We have to think also about posts to social media, location data from GPS or location-based services, and even behavioural or health data collected by wearable devices. The explosion of digital data means that conceptions of data literacy, the ability to access, interpret, critically assess, manage, handle, and ethically use data, has to be updated as well as what we understand as democratic participation in a society being transformed by datafication.

Preparing K-12 students for this data-rich reality means ensuring they understand not just how to calculate with numbers, but how to make sense of, use, and critically evaluate data in its many forms.

This changing nature and increasing availability of data have led to new and significant roles for data, data-based models, and data-related algorithms across various spheres.

Data play a new and expanding role in the sciences. In fields like statistics and mathematical modelling, we now encounter new types of data and require new workflows. For instance, the CRISP-DM workflow model (Shearer, 2000) provides new emphasis on data preparation, communication, and deployment. It differs from the traditional PPDAC cycle (Wild & Pfannkuch, 1999, discussed in more detail in Section 4.1) and mathematical modelling cycles, even if they include data as a separate component (English, 2021). Related to the new role of data, new types of models become relevant: predictive models (the dominant type of model in machine learning), algorithmic and computational models (Breiman, 2001), sometimes with millions of parameters. Computer science has seen the emergence of data-driven Artificial Intelligence (AI) and data-driven digital artifacts. Even in natural, social, and life sciences, datafication and new research methods are transforming how questions are asked and answered. For example, data science techniques are being used to understand complex biological systems.

At the same time, data science is emerging as a new discipline itself. It is an interdisciplinary field that combines statistical methods, computer science, and expertise in a particular subject area to gain insights from data. Hazzan and Mike (2023, pp.19) devote a whole chapter to the origins and different characterizations of data science.

Perhaps most visibly for young people, data has new roles in everyday life, including the lives of students. Students interact constantly with data-driven digital artifacts in their private lives through search engines, streaming services, and social media. Wearables and fitness trackers collect personal data. Digital data are woven into the fabric of our cultural, social, political, and economic worlds. Educational conceptions that focus on these aspects of data can be found under the heading of personal data literacies (Pangrazio & Selwyn, 2019) and building students' data awareness (Höper & Schulte, 2024).

Similarly, data and its visualizations have new roles in the media. We see more data and new visualizations in traditional media, as well as websites with embedded interactive visualizations and dashboards. Data journalism is an emerging field. Understanding data in the media requires a new lens, especially when dealing with spatial data or issues of spatial justice (da Silva et al., 2021; Engledowl & Weiland, 2021; Rubel et al. 2021). Media items use data and visualizations to inform the public, present opinions, justify predictions or recommendations, and validate government policies. Data visualizations are not neutral; they are social texts authored from specific points of view that narrate particular stories (Gal, 2022).

Beyond consumer applications, data-based models, and data-related algorithms have profound new roles in society at large. Algorithmic decision systems, often based on machine learning, are used in healthcare (predictive diagnosis, treatment recommendations), finances, transportation, job applications, educational administration, and predictive policing. Many applications raise ethical questions. Examples include examining racial bias in healthcare AI (Chin et al., 2023), predicting school dropouts (Bowers, 2021), or the controversial use of tools like COMPAS software in the justice system (https://en.wikipedia.org/wiki/COMPAS_(software)).

These new roles of data have led to significant political discourses on the ethical aspects of data and AI use, involving associations, initiatives, and state regulations. New scientific journals are devoted to this topic such *AI and Society* and *Big Data & Society*. Key concerns raised in the 400 pages report of Deutscher Ethikrat (2023) include the danger to individuals through statistical stratification, the protection of privacy and autonomy versus threats from surveillance, and the pervasive issues of bias

and discrimination embedded in data and algorithms. Transparency and traceability are crucial for control and responsibility. Counterbalancing these concerns are efforts focused on AI and Data Science for Social Good (https://www.datascienceforsocialgood.org). Critically evaluating data use also requires examining data quality and the strength of evidence presented, issues that are increasingly discussed in the media.

Given this landscape, preparing students for a data-driven world involves fostering data literacy that includes the ability to critically interpret and evaluate data and its sources. This is reflected in educational conceptions such as *critical data literacy* (Weiland, 2017). Data visualizations, while powerful tools for communication, are embedded within structural and ideological relationships of power and can become sites where meanings are contested. Access to learning about data visualization without a deep interrogation of identity and status, national and commercial interests, and power relations can even be counterproductive, potentially reproducing societal hierarchies in the classroom (Bilstrup et al., 2022; d'Ignazio & Klein, 2020; Hall & Dávila, 2022; Lee et al, 2022; Philip et al., 2016). Students need to understand that data can be used to both uphold and expose systems of oppression (Martínez-Castro et al., 2023). Critically reading data visualizations involves understanding how reality is mathematically formatted, how variables and relationships are framed, and what stories are narrated, recognizing that these are texts created by humans with specific viewpoints. Ignoring the social complexities of data and its representation would defeat the democratic purpose of teaching data literacy.

3. How is the Growing Role of Data in Society Impacting K-12 Policy?

Much has been written about the role of data in educational administration and decision-making (e.g., Mandinach et al., 2015; Schildkamp & Datnow, 2022). While these impacts of data are certainly important, here we are interested in a complementary issue: what must students themselves now learn, given the increasing role of data in science and society?

To address this question, we consider what Chevallard called *didactic transposition* of knowledge (1985). Didactic transposition refers to the process by which scholarly knowledge is transformed to become teachable. The challenge with data science is that the relevant scholarly knowledge is in itself interdisciplinary and unstable, and practitioners have different perspectives regarding its nature and function as a field (Tanweer & Steinhoff, 2024). This makes it difficult to identify a stable body of knowledge to be taught or locate where data science might live within the broader curriculum. Chevallard also notes that didactic transposition can introduce tensions between maintaining the legitimacy of the taught knowledge in the eyes of experts and adapting that knowledge for novices in ways that are accessible and socially relevant. This tension is already playing out as school systems grapple with whether and how to introduce data (see Boaler et al., 2024 for a recent example), and how to prepare students for its significant impacts on society outside of academic disciplines, as described in the prior section.

One approach educators have taken to address these tensions when introducing data science at the K-12 level is through integration with a variety of existing school subjects. A recent position statement authored jointly by a collection of organizations in the United States representing teachers of Mathematics, Statistics, Science, Social Studies, and Computer Science argued that "Data science bridges disciplines and thus should be introduced and taught across the curriculum in K-12 schools [...] All subjects in school should recognize the contribution of data to their discipline and take curricular approaches that integrate data with disciplinary lessons where appropriate" (NCTM et al., 2024, p. 1). Such initiatives require a developmental approach to coordinate data science integration

across the grades and subjects, leading some organizations to call for the development of comprehensive frameworks to inform curriculum and instruction (DS4E, 2025; NASEM, 2023).

Cross-curricular integration can be challenging, however, as it requires coordination across different academic departments and potentially changes to existing curricula. To address these challenges, integrative approaches typically emphasize that data science is fundamentally an *investigative* process that involves formulating a question, collecting or considering data, analysing the data, and interpreting and communicating results (Lee, Mojica, et al., 2022). Such references to this cycle of investigation are increasingly emphasized in new related standards and frameworks (e.g., Bargagliotti, 2020; IDSSP Curriculum Team, 2019). And while they may use different terminology, the core concept of inquiry—pursuing a compelling question or evaluating a claim using data—is shared across many disciplines (Manz & Beckert, 2023; Schanzer et al., 2022; Shreiner, 2018; Wild & Pfannkuch, 1999).

Another approach educators have taken to introducing data science at the K-12 level has been through its connections to citizenship education. This approach positions data as a way to empower students to understand and address real-world issues, potentially leading to pro-civic actions and understandings (Engel & Ridgway, 2022; Louie et al., 2021; Rubel et al., 2016). However, defining *what kind of citizenship* data science education aims to foster is itself a challenge. Various projects and curricula cite goals that vary from empowering individual students as (future) citizens; fostering cultural coherence and understanding across diverse societies; advancing society through supporting social mobility and equal opportunity; and boosting economic growth for students through workforce education. However, different stakeholders may prioritize these goals differently, leading to tensions in curriculum design and implementation. An emphasis on workforce preparation might focus heavily on technical skills for specific industries, while an emphasis on equal opportunity might prioritize critical data literacy for evaluating societal claims and advocating for justice (see Rosenberg & Jones, 2024). Navigating these competing priorities and ensuring that data science education effectively contributes to a balanced set of educational goals is a significant challenge for K-12 systems.

Whether data are introduced to students as a tool of inquiry across domains, or as a tool for civic and social engagement, the societal and ethical dimensions of data and its use have become increasingly important (Baumer et al., 2022; European Commission. Directorate General for Education, Youth, Sport and Culture., 2022; Utts, 2021). As a result, many of the emerging standards and frameworks described above emphasize not only data-related *knowledge and skills* but also related *dispositions* and *ethical considerations* as key learning goals for students. For example, the Dana Center's Data Science Course Framework (2024) describes design principles for courses that will "empower students to live skillfully and productively in our data-driven society" (p.4), which includes activities such as "Provid[ing] authentic experiences that empower students to make a positive difference in their communities through data science projects" (p.7).

4. How Could the Growing Role of Data in Society Impact Education and especially the K-12 Curriculum?

While administrators and policymakers are still working to understand how data might best be integrated into K-12 curriculum and instruction, many teachers, researchers, and curriculum developers have already explored new pedagogies, tools, and dispositions to introduce students to data science. A number of pedagogical frameworks concerned with data have been introduced, though typically with a focus on tertiary and professional education rather than the developmental steps needed to prepare students at primary and secondary levels for these intensive tertiary experiences. Here, we review four such adaptations and innovations related to how students are

introduced to data; what are the tools and technologies they use to analyse them; how they are encouraged to develop critical data literacies regarding how data can be used to understand and advocate for change in the world; and how is it possible to develop students' awareness of how datafication is impacting both personal life and societal structures.

4.1 New Models of the Data and Statistical Workflow

Integrating data science into K-12 education demands a fundamental rethinking of how we teach students to work with real-world quantities. For decades, reform-oriented statistics, science, and mathematics educators have emphasized the importance of moving away from solely demonstrative or obviously predetermined "cookbook" data analysis activities toward more authentic engagement in inquiry (Cobb, 1999; Hancock et al., 1992; Lehrer & and Romberg, 1996). These sorts of inquiry-based engagements with data were traditionally described as a structured cycle in which students pose their own investigative questions, collect their own data, and explore those data using appropriate tools and methods. For example, Wild and Pfannkuch's PPDAC (Problem, Plan, Data, Analysis, Conclusions; Wild & Pfannkuch, 1999) cycle is foundational to reform-oriented statistics education. However, data science, with its emphasis on new forms of data and tools, disrupts several components of the investigation cycle, requiring us to further adapt this foundation.

Perhaps the most significant shift that has been introduced to these traditional descriptions has to do with the nature and origin of the *Data* at the centre of the cycle. K-12 statistics and science lessons oriented toward student inquiry often engage students in designing experiments or conducting fieldwork in their schoolyards or neighbourhoods to collect their own small first-hand datasets. Data science, however, frequently involves working with large, complex datasets that already exist – data that are publicly "open" (Zapata-Cardona, 2025), "repurposed" (Wilkerson & Laina, 2018), and so "messy" (Rosenberg et al., 2020) that students may find themselves "awash" (Erickson, 2025).

Consider an example drawn from McDonald's *Handbook of Biological Statistics* (McDonald, 2014, pp. 204–205). Students are invited to address the question "Does species diversity decrease as you move away from the equator?" using the Audubon Society's Christmas Bird Count, a yearly participatory citizen science activity that reports the total count of species spotted in different locations around the United States. The activity presents a small subset of species counts from approximately 15 locations, along with those locations' names and latitudes. The reader is expected to run a linear regression with latitude as the independent variable and species count as the dependent variable, which yields an equation in which the species count declines slightly as latitude increases, and the result does not reach statistical significance. Inviting the student to engage in common-sense reasoning, McDonald writes, "Even if it were significant, I don't know what you'd do with the equation; I suppose you could extrapolate and use it to predict that above the 49th parallel, there would be fewer than zero bird species" (p. 205).

This activity engages students with data in meaningful and careful ways. It encourages them to consider the context and implications of mathematical methods and points out their limitations. But from a data science perspective, there is much more that can be done due to the availability and richness of data we have about the world. Consider, for example, that with the information provided (location names and latitudes), it is relatively easy to link these records with additional geographic information: with not only latitude but also longitude, daily weather patterns, elevation, geological features, and more. Merging the available bird species counts with this richer set of available information (Figure 1) reveals that the subset of bird count records selected by the author are drawn from the U. S. mid-Atlantic region, a location and scale for which bird species diversity is less likely to vary by latitude as the question might suggest, but more likely to vary by proximity to the coast.

Location	Latitude	Longitude*	Number of Species
Bombay Hook, DE	39.22	-75.48	128
Cape Henlopen, DE	38.80	-75.10	137
Middletown, DE	39.47	-75.74	108
Milford, DE	38.96	-75.46	118
Rehoboth, DE	38.60	-75.10	135
Seaford-Nanticoke, DE	38.58	-75.62	94
Wilmington, DE	39.73	-75.56	113

Ocean City, MD	38.32	-75.11	152
Salisbury, MD	38.33	-75.63	108
S. Dorchester County, MD	38.37	-76.11	118
Cape Charles, VA	37.20	-76.03	157
Chincoteague, VA	37.97	-75.41	125
Wachapreague, VA	37.67	-75.69	114

* Obtained by finding locations using Google Maps.

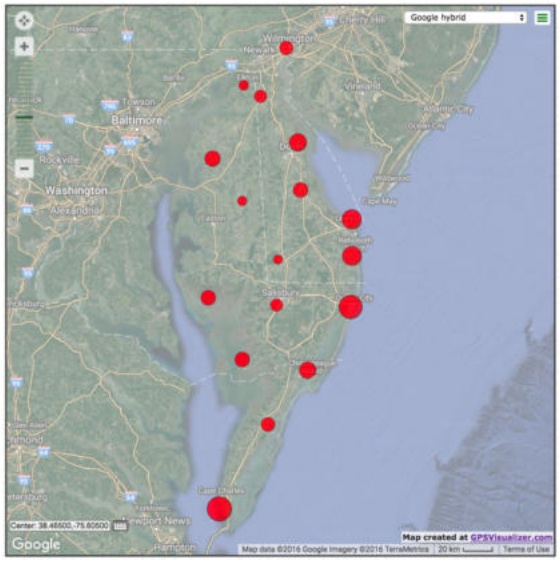

Figure 1. An expanded dataset, constructed by merging locations and latitudes with available longitude information (left) and the resulting map of bird species counts (right)

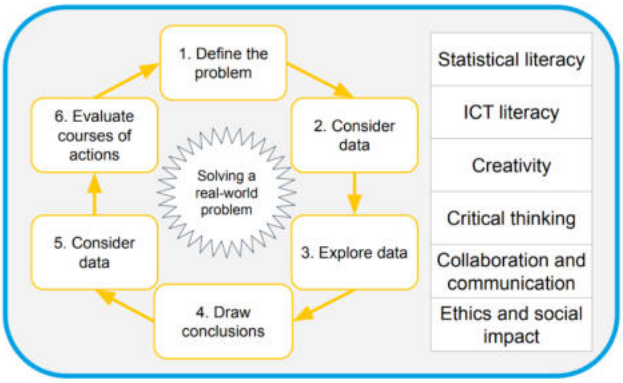
In this way, data that are collected by or provided to students can be merged, supplemented, and otherwise transformed using "found data" in ways that fundamentally change other components of the PPDAC cycle (see, e.g. Biehler & Schulte, 2018). When considering the *Planning* of an investigation, students' attention may shift from a focus on designing data collection protocols toward data preparation and exploration, emphasizing concepts of metadata, and data quality as students consider how datasets acquired from third parties likely include potential anomalies that require attention and further processing. The possibilities and constraints of an expanded, but potentially less reliable, set of data sources can in turn impact the *Problems* that an investigator is willing to take on. Instead of a linear or progressively iterative process where the problem is defined first and then data are collected, students might take a more exploratory approach with a large dataset to identify interesting patterns or generate questions.

The *Analysis* stage that results from an expanded set of available data and data types is also transformed. While traditional statistical tests are still relevant, data science more heavily leverages computational tools for exploration and visualization. As machine learning algorithms and other computational techniques become more common, investigators need to understand which data were used to train a given model and whether such training is appropriate for the new application context. To build on the bird count example, a biostatistician may wonder whether models developed from data in other geographic regions with different characteristics are appropriate to apply in this case.

Finally, the diversity of potential data sources and analysis methods and the complex considerations each brings changes how investigators should *Communicate* the results of their analysis. They should report potential biases in data sources; shifts in paths of inquiry as a result of available or constrained datasets; evaluation of the appropriateness of the algorithms used and their training, and so on. throughout the entire process. This task has become so important that topics such as "data storytelling" have become a focus in disciplines such as the information sciences (Segel & Heer, 2010) and journalism (Matei & Hunter, 2021). Investigators are also increasingly expected to report on the ethical implications of their findings. The goal is not just to analyze data, but to use it responsibly to understand and potentially impact the world. In data science practice, communication

should take into account the principles of reproducible research (Dogucu & and Çetinkaya-Rundel, 2022). How this can be made accessible to secondary students is an open question.

In response to the perturbations to the data and statistical workflow caused by these new data sources and data types, several proposals have emerged to re-envision the data investigation cycle (Figure 2). Kazak and colleages' (2023) Data Analytics Cycle, for example, introduces two separate steps both dedicated to *considering* and then *exploring* data. The explicit inclusion of "considering" data here highlights how the increasing availability and complexity of data requires explicit attention to "getting to know" the data—including reviewing metadata, exploring the history and initial purpose for data collection, evaluating validity, and so on. Lee and colleagues' (2022) Data Investigation Cycle isolates a different dimension, data processing or the preparation, cleaning, re-coding, and otherwise transforming the data in order to permit the desired analyses, as a specific component. Wise's (2020) continuum of "data scientist perspectives" toward data further highlights data generation and storage as concerns in themselves (Figure 2).



Data Analytics Cycle & Competency Areas

Figure 2. New proposals for data-science-ready investigation cycles as described in Kazak et al (2023, top left), Lee et al (2023, top right), and Wise (2020, bottom)

In data practice, especially those that are influenced by computer science, even more different workflow models are used, such as the CRISP-DM cycle (Biehler & Schulte, 2018; Shearer, 2000). One major difference is that an extra stage *deployment* is added, similar to what computer science workflow models already include. Data science does not just end with a conclusion, but a system is constructed (such as a machine learning model) that is implemented in a socio-technical system, where ethical considerations have to be taken into account. Though their emphases are different, all of these proposals highlight how expanding data types and access have shifted definitions of what it means to pursue inquiry with data.

We note that while many of these frameworks are referenced by educators and researchers concerned with K-12 education, most were developed for, and/or heavily informed by, tertiary and professional levels. Even frameworks well known to the K-12 statistics and data science education community such as PPDAC (Wild & Pfannkuch, 1999) and Lee and colleagues' (Lee et al., 2022) more recent data investigations cycle were developed through interviews with professionals and statistics-oriented

students. These shed much needed light on some aspirational *goals* for modern statistics and data science education, but there is still much to be done in order to understand the *developmental processes* that might lead students to these endpoints, and to identify the available pathways through the existing curriculum that might help set the foundations for students' competence and confidence with data.

4.2 New Mathematical and Technological Tools for Working with Data

Access to new tools and technologies is also fundamentally reshaping how we should teach the data and statistical workflow in K-12 education. For decades educators have highlighted the potential for digital tools to transform students' engagement with data and modelling (Ben-Zvi, 2000; Biehler, 1997; Edelson & Gordin, 1998; Hancock et al., 1992; Lehrer & and Romberg, 1996). Topics such as probability and statistics were well situated to benefit from the introduction of computers into schools, because they allowed the easy visualization of large, multivariate datasets and the simulation of probabilistic events that form the foundations of statistical models. Ben-Zvi (2001), building from Pea (1985), argued that computers have redefined statistics as a cultural and disciplinary practice by reorganizing which statistical objects students are able to explore and manipulate, offering them fundamentally new cognitive models and new ways to connect statistical practice to the real world. Some of these same redefinitions are the ones that transformed the professional practice of data analysis and led to the emergence of data science (Biehler, 1993; Cleveland, 2001; Kaplan, 2007).

Since these beginnings, a variety of genres of educational technologies focused on data and statistical processes have become available. Several reviews and classifications of these tools exist, organized by function, interface type, or other such principles (e.g., Ben-Zvi, 2000; Biehler, 2019; Chance et al., 2007; Foley et al., 2024; Israel-Fishelson et al., 2025; A. McNamara, 2019; Pimentel et al., 2022; Pratt et al., 2011; Rubin, 2007), and we refer the reader to those for a comprehensive overview. Here it suffices to note that in general, these reviews include references to tools and technologies for collecting data from the world through automated measurements and recordings; tools for visualizing data through the easy creation of charts and graphs; tools for manipulating and calculating data; mapping tools that associate data with specific geospatial locations; and tools for generating simulated data from user-defined models. More recently, such reviews and frameworks have also expanded to consider how the design of particular tools may facilitate students' transition to professional practice (Foley et al., 2024; A. McNamara, 2019). One family of tools deserves special note here because of their impacts on statistics and data education research and because we both use them extensively in our own work. These include *Fathom* (a powerful GUI-driven educational data analysis and visualization tool; Finzer, 2001), *Tinkerplots* (a version developed for younger students, www.tinkerplots.com), and the *Common Online Data Analysis Platform* (codap.concord.org; Erickson, 2025), a more recent online data analysis tool that builds on the design principles of Fathom and Tinkerplots. It is a cost-free web application in several interface languages. Compared to Fathom and Tinkerplots it can use geographical data and build statistical maps and offers flexible hierarchical data structures. CODAP can be extended by using plug-ins, and we refer to the Arbor plug-in later, when we discuss decision trees. We refer readers to papers by Konold (2007), Biehler et al. (2013), and Finzer and Damelin (2015) for more information about the history of this family of software tools.

Despite this long history, a new focus on "data science education" has led to some new developments in these established tools and technologies that are worth noting here. First, many tools now support or directly integrate more diverse datasets, especially larger, publicly accessible datasets. Tools like CODAP and ESRI's free educational version of ArcGIS Online, a data mapping tool, allow students to easily import a variety of real-world data. New efforts have also made it easier for students to

participate in and access data from citizen science campaigns that are directly relevant to their lives or communities. For example, the Census@School project allows students to contribute to an international dataset recording demographic and behavioral data (Day, 2025), and the WeatherBlur project combined citizen science efforts and environmental probes to allow students to explore weather and wildlife patterns in their local environment (Kermish-Allen et al., 2019). Similarly, some tools, or curricula that are developed to accompany tools, highlight the use of APIs (Application Programming Interfaces) that support students to access dynamic ("live") data from the internet, from sources of data as about topics ranging from weather and sports to music (Fergusson & Wild, 2021; Weintrop & Israel-Fishelson, 2024).

Tools designed for novices are also beginning to highlight new data types and analysis techniques. Some tools and approaches emphasize network data structures and allow students to apply data reasoning to explore traditionally distant domains, such as analyzing relationships described in historical or literary texts (Craig et al., 2021; Legacy et al., 2025). Similarly, curricula and tools have emerged that support students in conducting computational text analysis (Horton et al., 2023) and image analysis. Others allow students to engage with or visualize various predictive modeling and machine learning methods such as decision trees (Biehler & Fleischer, 2021; Erickson & Engel, 2023) and digital classification (Grizioti & Kynigos, 2024). Anna Fergusson (teaching.statistics-is-awesome.org) has developed a suite of tools to help teachers visualize and experiment with simulation-based introductions to a variety of core statistics concepts (Fergusson & Pfannkuch, 2022; Fergusson, 2017).

Finally, as we will review in more detail below, more complex and socially embedded data often demands more interpretive narrative work in order to communicate results clearly and carefully. Many tools for data analysis have started to more explicitly facilitate new ways of communicating the processes and results of a data investigation. Story Builder, a plugin for the CODAP tool, allows students to save "moments" of an analysis cycle and annotate each with photos, rich text, and other explanatory materials (Wilkerson et al., 2021). Similarly, Fleischer and colleagues (Fleischer, Biehler et al., 2022; Fleischer, Hüsing et al., 2022) have begun to explore how students' work with Jupyter Notebooks can be structured to support the construction of "computational essays" that integrate code, outputs (including visualizations), and explanatory text into a coherent narrative. In this approach, half-worked examples and template structures encourage students to write narratives, in the process engaging with issues of data validity and bias, alongside their work through the technical details of an analysis process.

Modern data science practice uses tools with extended libraries that require coding such as R/RStudio or Python. Coding poses obstacles for many, especially younger students. It is an unsolved challenge, how far genuine data analysis practice can be supported at school level without the need of coding, using tools with GUI such as CODAP, and when it is reasonable and possible to move to tools requiring coding and how this transition can be bridged and supported (Fergusson, 2022; McNamara, 2015).

4.3 Critical Data Literacies: New Frameworks for Addressing Socio-scientific and Socio-ecological Problems

In recent years, we can observe two different but related developments, one in statistics and data science education and another in science and mathematical modelling education. In the context of statistics and data science education, we see new emerging frameworks for statistical literacy and data literacy, namely critical data or statistical literacy (Weiland, 2017; Louie, 2022; Martínez-Castro et al., 2023), civic statistical literacy (Ridgway, 2022) or data feminism (d'Igazio & Klein, 2020; Lee et al., 2022). They recognize that data are not neutral but is produced through social processes and

can perpetuate or exacerbate unequal power relations. A further common feature is that the context in which data science should be taught and learned should be actual problems in society and the world, encouraging the development of a critical stance. Similar educational movements include the so-called socio-scientific problem approach in science education (Sadler & Dawson, 2012), socio-ecological problems in mathematics education (Coles, 2023), and the tradition of critical mathematical modeling (Siller et al., 2024; Rosa & Orey, 2015). *Education for sustainable development* and *global citizen education* (which includes, e.g., human rights and democracy education in addition to ecological problems) have also to be mentioned in this context.

In statistics education, an important distinction is between the so-called consumer and producer perspective related to data and statistical products (Gal, 2002). Citizens are much more in the situation of a consumer, when reading newspapers or other documents with data and statistics as compared to doing their own data analysis. Though, from the perspective of education, the experiences and competences gained through conducting one's own analyses may contribute to a critical consumer perspective. The emerging new data literacies are closer to a consumer perspective in the sense that they raise the need to critically reconstruct and deconstruct data uses in science and society instead of inventing completely new ones (Rubel et al., 2021). Advocates of the new literacies sometimes refer to the critical literacy of Freire (2005), who coined the term of *reading and writing the world,* and add "with data" (Weiland, 2022). Writing the world is a metaphor of moving beyond understanding a certain social reality and arguing or working to change it for the better. This of course raises the question of how to deal with political, cultural and social value systems in the classroom.

Data science provides the opportunity to engage students in addressing a range of socio-scientific problems relevant to their lives and communities. This can include exploring environmental issues. Examples include urban planning, participatory mapping, citizen science, and climate investigations (Aridor et al., 2023; Engledowl & Weiland, 2021; Lanouette et al., 2024; Lee et al., 2022; Lim et al., 2023; Louie et al., 2023; Rubel et al., 2021; Wilkerson & Laina, 2018).

For instance, students can analyse some of the "Five Most Important Datasets of Climate Science" (Guimarães et al., 2022), such as CO_2 concentration over the years, using data measured at sites like Mauna Loa, Hawaii (since 1960). For comparison with concentrations before the industrial age, data reconstructed from ice core measurements in places like Vostok, Antarctica (since for over 400.000 years) can be used. The educational challenge is that climate change is not "obvious" from just two data graphs, but evidence relies on theories that explain why measurements taken at two specific places are representative and can be compared at all, and on scientific theories that relate CO_2 concentration to global warming and make plausible that the increase of CO_2 concentration is human-made (Biehler et al., 2025)

Economic issues like the gender pay gap are also fertile ground for critical data investigations. Students can engage in activities exploring the gender pay gap in the U.S., for example, by analysing sample microdata using the new data access tools in CODAP described in Section 4.2 to visualize graphs of wages by sex and educational attainment for a random sample of employed U.S. individuals, using boxplots and dotplots. This allows them to investigate how the gender pay gap varies with the level of education (Louie et al., 2022). On the other hand, the gender pay gap is a complex socio-economic problem, and students will need more background information, for instance what is adjusted and unadjusted pay gap than can be gained through data explorations alone. For instance, the Wikipedia article (https://en.wikipedia.org/wiki/Gender_pay_gap) provides detailed information and several complex graphs that describe historical and geographical variation of the gender pay gap, as well as its variation in different professions, that are usually not taught in statistics

classrooms. This exemplifies the tensions between independent data exploration and critical understanding of argumentative texts of popular science with embedded graphs.

Relegating data to only mathematics and statistics courses may burden such topics, calling for a contribution of the natural and social sciences. Connections between these topics and rich datasets are not hard to find. Many of the topics described above, such as climate and the environment, have a natural home in school science. Data allows students in these courses to also examine deeper intersections between the natural and social, such as through investigations of the disproportionate impacts of climate change on communities of colour and the Global South (Barton et al., in press; Levy & Patz, 2015; Sayavedra et al., under review).

There is a growing literature examining the use and teaching of data within the social sciences (Shreiner, 2018). For example, health issues, prominently highlighted during the COVID-19 pandemic, involve extensive data use and analysis (Calabrese Barton et al., 2021; Engledowl & Weiland, 2021; Rubel et al., 2021). Furthermore, data science is essential for investigating inequalities in society related to race, ethnicity, and migration. Examples include investigating racial bias or uncovering social inequality with data from sources like the U.S. Census (Kahn, 2020; Louie et al., 2022; Rubel et al., 2016).

Different theoretical traditions contribute to shaping the understanding of critical data literacy. In the United States, discussions often center on scrutinizing data for biases and potential misdirection (Engledowl & Weiland, 2021; Kahn et al., 2022), and using data to understand and challenge social oppression and work towards more equitable outcomes (Louie et al., 2022; Rubel et al., 2016). This aligns closely with the principles of teaching mathematics for social justice ("TMSJ"; Gutstein, 2012), which aims to equip students to recognize and counter social injustices using mathematics and data. Key goals include developing social and political consciousness, building agency for social change, and fostering positive identities. This approach views critical data literacy as essential for creating a more just world with data.

The European context, exemplified by initiatives like the ProCivicStat project (Ridgway, 2022), emphasizes Civic Statistics as a means to foster civic engagement through the exploration of evidence. Understanding civic statistics requires comprehending complex social phenomena, often involving dynamic, multivariate data presented through rich texts and novel visualizations. A critical interpretation is essential for informed citizenship in democratic societies, going beyond typical statistics curricula to consider the meaning and implications of data for society and policy. This approach encourages critical thinking and informed decision-making based on evidence. Examples explored in the various chapters include analyzing data related to racial bias in European football, climate change data, or engaging with official statistics and considering their social implications. The project developed a multidimensional framework that shows the multifaceted nature of civic statistics (Figure 3).

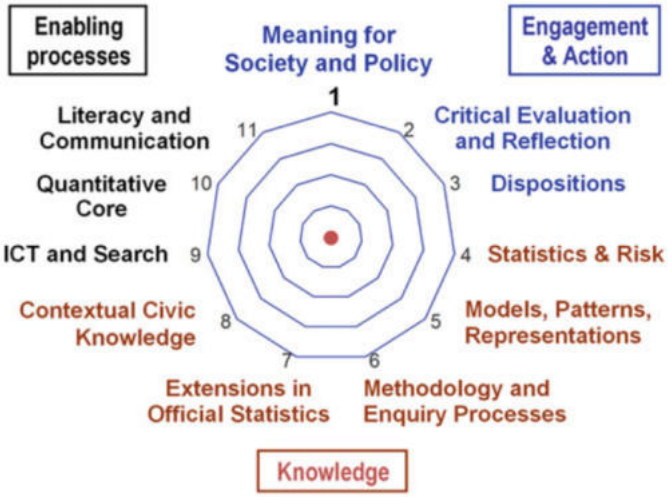

Figure 3. Civic statistical skills, attitudes, knowledge and competences. Graph provided by the authors of Gal et al. (2022).

A particularly rich tradition for understanding critical data literacies emerges from Latin America, heavily influenced by the work of Paulo Freire (2005) and the field of critical mathematics education (Skovsmose, 2014; 2023). This perspective views education as a process of liberation, where individuals develop critical consciousness to understand reality and act to transform it. This involves using statistical investigations to explore societal crises and inequalities, such as repression, conflict, misery, inequity, ecological devastation, and exploitation. The broader field of "critical data studies with Latin America" further elaborates on these ideas, incorporating frameworks of dependence, oppressions, and liberation, viewing datafication as intertwined with existing systems of inequality shaped by class, gender, and race (Campos, 2016; Martínez-Castro et al., 2023; Raffaghelli, 2022; Tygel & Kirsch, 2016; Valente & Grohmann, 2024).

Thus, critical data literacy across these traditions moves beyond technical proficiency to encompass a critical understanding of how data are produced, used, and interpreted within its social, political, and ethical context. It empowers individuals not just to consume data-based arguments critically but to use data actively to understand, challenge, and potentially transform unjust realities. While implementing this approach faces challenges, such as the need for appropriate tools, time, cost, and adequate teacher preparation, the potential benefits for fostering informed and active citizens make it a crucial area for K-12 data science education. However, a central open question is, how to empirically assess the complex goals in knowledge, attitudes, skills and competencies. The available studies do only contribute fragmentary knowledge in specific small-scale studies.

4.4 Presenting the Need for Further Data Literac(ies): From Personal Data Literacy to Datafication Literacy

The datafication of science and society has led to two quite new data-related literacies, which are distinct from what we have discussed so far: *personal data literacies* (Pancrazio & Selwyn, 2019) and *critical datafication literacy* (Sander, 2024a).

Personal data literacies aim at understanding and critically engaging with personal data. This area, sometimes referred to as data awareness, emphasizes that we live in a world where digital devices and platforms are ubiquitous and constantly collect data from us, often without our full awareness. This creates a significant "information asymmetry", where users may not understand where their data

goes, why it is being collected, or how it will be used. The goal of fostering personal data literacies is to help students overcome feelings of powerlessness and develop a sense of self-determination and agency in these interactions.

One framework designed to support this is the *data awareness framework* (Höper & Schulte, 2024; Höper et al., 2024), which provides students with an explanatory model of how data-driven digital artifacts (ddA) work and the role data plays in them. This model helps students become aware of explicit and implicit data collection, the primary and secondary purposes for data processing, and the creation of data models about themselves, often called digital doppelgangers. It also highlights their own role as data sources in these interactions. For instance, one teaching unit designed to build personal data literacy explores location data collected when using a mobile phone, including looking at authentic data like that made available by German politician Malte Spitz. Another unit focuses on recommender systems in streaming services, allowing students to work with a miniaturized engine to see how personalized recommendations are generated based on user data, such as finding "*k* nearest neighbours" to understand how their preferences are used to recommend new films. Learning this explanatory model and applying it to everyday examples seems to encourage students to reflect on these data practices and potentially think about their own behaviour, which is a step toward feeling more empowered rather than resigned (https://www.prodabi.de/en/unterricht/).

Datafication literacy (Sander 2024a; 2024b) broadens the focus from individual data to the larger societal change processes driven by data. In one sentence: The socio-scientific problem addressed by critical datafication theory is the need to critically evaluate the datafication of society and science itself. Critical datafication literacy aims to equip students with the ability to understand and critically reflect on how data are deeply intertwined with social processes and power dynamics An approach that strongly aligns with this is data feminism (d'Ignazio & Klein, 2020), which offers principles such as examining power, challenging power, considering context, and making labour visible, to understand the relationships between data and power. Datafication literacy encourages students to see the labour involved in creating data and to question who benefits and who is marginalized by data practices.

Ultimately, both personal data literacies and datafication literacy are essential for students to navigate our increasingly data-driven world responsibly. Understanding the data collected about oneself (personal data literacies) can serve as a foundational step towards critically reflecting on the broader societal implications of data use (datafication literacy). Issues surrounding the privacy of personal data, for instance, are relevant from both perspectives. However, it's crucial to empower students to look beyond individual actions and understand the need for systemic approaches and collective action to address the challenges posed by datafication. By fostering these literacies, K-12 data science education can move students from passive users to informed and empowered citizens who can critically understand the data that shapes their lives and society and potentially use data to advocate for change.

4.5 AI Literacy from the perspective of mathematics, statistics and computer science education

The data use addressed by these two literacies is also closely connected to data-driven AI systems, particularly those involving machine learning models and algorithms, while also encompassing broader applications of data use that are independent of AI. There has been extensive discussion of AI literacy (e.g. Almatrafi et al., 2024), which analyses these developments in terms of educational requirements.

The emergence of machine learning as a central topic in contemporary AI has led to a paradigm shift in computer science concerning the role of data. Training systems with data instead of classical

programming is the new principle, machines program themselves in a sense, creating algorithms, by being trained with data. This is acknowledged in computer science education, where the new role of data induced a paradigm shift in computer science education itself (Olari & Romeike, 2024; Tedre & Vartiainen, 2023). The topic of what secondary school students should—and are able to—learn about artificial intelligence is primarily explored within the computer science education community. A growing number of publications are addressing this issue, including several comprehensive literature reviews (Almatrafi et al., 2024; Casal-Otero et al., 2023; Chiu & Sanusi, 2024; Olari & Romeike, 2024).

An influential approach are the *five big ideas of artificial intelligence (AI)* of ai4k12.org. They encompass how computers *perceive* the world using sensors, how agents *represent* information and use it for *reasoning* to solve problems, how computers *learn* from data to find patterns (which is machine learning), how intelligent agents interact *naturally* with humans, and the *societal impact* of AI in both positive and negative ways. Data-based machine learning is the closest topic to statistics and mathematics.

Recent literature (Casal-Otero et al., 2023; Long & Magerko, 2020) highlights that AI/ML literacy is not a monolithic concept but spans multiple domains of understanding and engagement. These domains reflect different educational priorities and philosophical orientations toward technology. Three broad categories help to structure current discussions: learning about AI, learning for life with AI, and learning how AI works. The latter entails a conceptual and sometimes technical understanding of how AI systems are developed and deployed. This includes the overall workflow of a machine learning system, from data collection to model deployment, and the role humans play in shaping and overseeing these processes. Within this category, one of the most pressing challenges is addressing what has been termed the multiple opacity problem (Burrell, 2016). Machine learning systems often operate as "black boxes", meaning that the logic behind their outputs is not easily interpretable—even to their creators. This opacity stems from three sources: the complexity of learning algorithms, the abstract nature of the resulting models, and the hidden assumptions embedded in training data.

One approach to dealing with the opacity problem is *black box algorithm auditin*g (Morales-Navarro et al., 2022; 2024). Alternatively, scholars recommend a "white" or "grey" box approach with algorithms where this is possible (Hazzan & Mike, 2023). This means that algorithmic details can be made accessible, at least a simplified version of the professional ones, and reasons for choosing this algorithm. This is very difficult with artificial neural networks, because the required mathematical knowledge about matrices, partial differentiation, and special sigmoid functions are used as activation functions. In contrast, algorithms of methods such as decision trees, k-nearest-neighbours, and linear regression which can be re-interpreted from a machine learning perspective, are mathematically much simpler. We will provide a pedagogical example in section 5.2

4.6 Summary

The frameworks we have reviewed often each come with classroom examples that illustrate the pedagogical approaches and the data science facets that they are designed to support. Although these can be a rich source of guidance for educators, it is clear that not all examples, frameworks, or even data science facets can be taught and learned at K-12 level. Curriculum designers of the various subjects have to select what is suitable and feasible in their educational context. Very recently, the U. S. based *Data Science 4 Everyone* organization, in collaboration with teachers, youth, and experts, have started an initiative to map K-12 data science progressions across the curriculum (DataScienceLearning.org), which is a promising direction though still early in its development.

In the next section, we present pedagogical examples from our own work with colleagues, which of course can illustrate only some of the frameworks and data science facets. These examples serve to illustrate the pedagogical challenges we face already with the relatively small teaching units implemented under very favourable conditions, but also the rich potential such activities hold for conducting truly integrative data investigations even with young students.

5. Pedagogical Examples

To illustrate the many changes and emphasis described above, here we present examples of curriculum focused on data science and data-intensive AI. For each example, we include versions of our curricular approaches that were delivered in excellent conditions, as well as versions that are better adapted to the current constraints of most classrooms and therefore have high potential for immediate scale up. Our goal is to provide some concrete examples of what data science education can look like, and to encourage mathematics educators to consider how such activities might be adopted, supported by, or otherwise intersect with classroom instruction.

5.1 Integrating Data with the Natural and Social Sciences through Data Storytelling in K-12

Teaching data science at the K-12 level presents a significant opportunity to engage students with the world around them. However, moving beyond procedural instruction to foster genuine understanding requires a framework that resonates with how students make sense of complex information. Many approaches have begun to leverage *storytelling* as a potentially powerful, integrative framework for teaching K-12 data science, allowing students to see data analysis not just as a collection of steps or calculations, but as a process of constructing and interpreting meaningful narratives grounded in evidence (e.g., Amato et al., 2022; Finzer & Wilkerson, 2020; Reigh et al., 2022; Sanei et al., 2024; Stornaiuolo, 2020). As we will show, storytelling can make space for students to engage with some of the novel forms of data, workflows, and tools described in Sections 4.1 and 4.2. To the extent that they engage with issues of social and civic relevance, they can also engage students in many of the issues described in Section 4.3, regarding critical data literacies.

In contrast to a traditional statistical report which might review the key features of a dataset, detail the analyses performed, and describe the key results of an analysis and their implications, data storytelling approaches emphasize context and personal expression (Stornaiuolo, 2020), highlighting what might be investigators' motivations for examining a question, providing an accounting of the decisions and processes that underlie the reported analysis (D'Ignazio & Klein, 2020), and invoking aesthetics and emotion to engage the reader and perhaps even persuade them to pursue particular actions as a result of the findings (Reigh et al., 2022). If we consider the producer/consumer distinction introduced above to these ideas about data storytelling, these contextual and social considerations can be written into the stories that students themselves tell as they perform and communicate data analyses, and they can be examined in the stories of others as students work to "read" the stories told in visualizations and statistical reporting in science communication, civic documents, and the media.

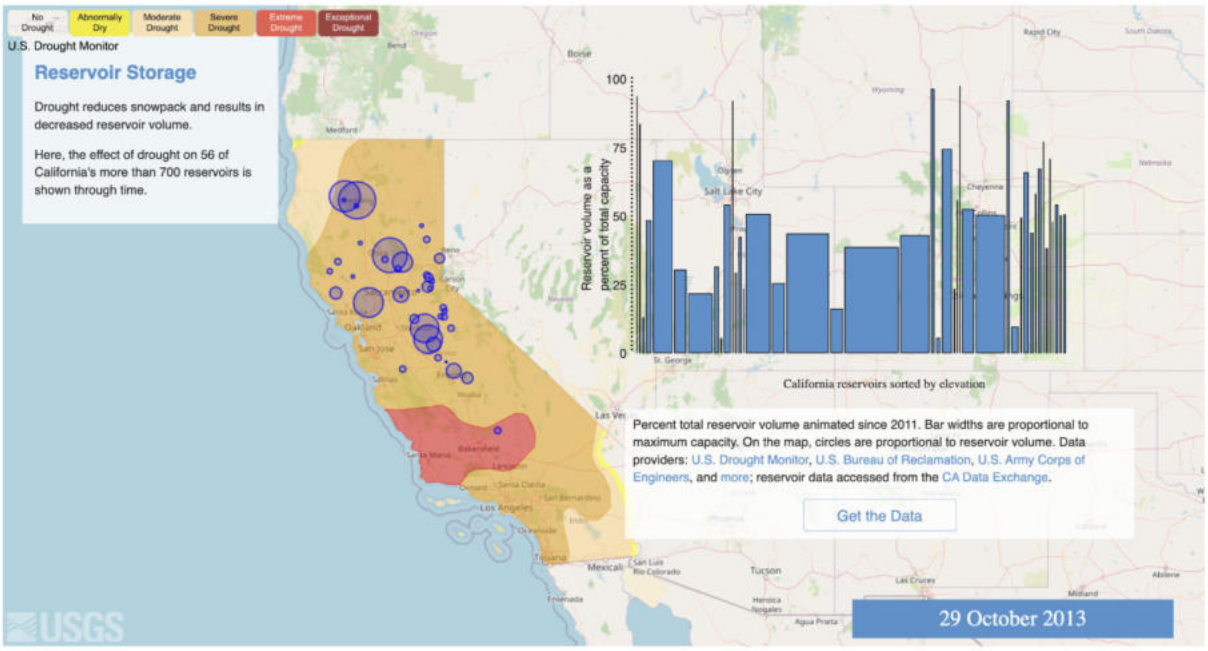
Narrative is often identified as a primary mode of human thought, distinct from but complementary to the logical or paradigmatic thinking often associated with mathematics and science (Bruner, 1991). While logical thinking is associated with decontextualized and verifiable facts, narrative is inherently temporal, contextual, and focused on the meaning and interpretation of events unfolding over time (Healy & Sinclair, 2007; Mor & Noss, 2008). Storytelling provides cognitive and cultural structures to organize thought and motivate coherence in understanding complex situations and multiple perspectives (Bal, 2009; Ochs et al., 1992; Schank & Abelson, 2013). Framing data science through

narrative can bring the analytic and interpretive dimensions of analysis that are so often separated back together (Kemble & Wilkerson, 2024; Pfannkuch et al., 2010).

Example 1: The California Drought. Given the new available tools and technologies described in Section 4.2, students and teachers now have unprecedented access to datasets which often include temporal and geographic features. This creates especially fertile ground for narrative engagement with data. In our work, we have leveraged storytelling approaches to engage science classrooms in week-long investigations of issues at a variety of scales, from personal nutritional decision-making to explorations of regional environmental conditions, to statewide and global climate trends. In these units, a major goal is for students to produce "data stories" that combine data analysis with journalistic research, interviews, personal stories, and expository and persuasive text to highlight issues of personal relevance.

Here, we focus on one investigation we did in collaboration with a 7th grade science teacher, in which students examined water reservoir levels in the U. S. State of California (where this activity was done), from 2011 through 2017. The investigation focused on the question: *What were the main factors that contributed to the California Drought?* We had obtained the dataset and associated visualization that was produced by the U. S. Geological Survey (USGS), and we begin the investigation by exploring a dynamic visualization that was quite complex. It featured a map (Figure 4) that was annotated with circles that changed size to indicate the location and volume of reservoirs and that coloured different regions to indicate regional drought declarations over time. It also featured a bar chart to indicate reservoir volume as a percentage of total capacity. All three of these representations–the reservoir point-locations, regional drought declaration colours, and bar chart–were animated over time. Despite this complexity, the visualization was recommended by the U. S. National Aeronautics and Space Administration (NASA) educational division for use by students as young as 6th grade (students of approximately 11-12 years of age).

There are many patterns, causes, effects, and experiences–some explicit, some implicit, and others only suggested—that a viewer might attribute to the drought as visualized here. When played from beginning to end, it demonstrates dramatic seasonal oscillations in reservoir levels as water is replenished each winter, but also a growing depletion of reserves year-over-year as this replenishment proves insufficient, until the drought finally ends in 2017. Regional patterns demonstrate how the northern regions collect and distribute water to the more populous, and drier, southern cities in the state. Observers with connections to the region may experience emotional reactions as they observe especially dramatic dips in water reserves in 2015, and recall associated public concerns and water use restrictions.



Credit: United States Geological Survey, CC0 1.0 Universal/Public Domain

Figure 4. A dynamic visualization developed by the United States Geological Survey to visualize California drought conditions. As a user scrolls their mouse, the date in the lower right advances and the bar chart and map overlay animate to display changes in reservoir volume across time. We encourage readers to explore the animation at https://bit.ly/cerme14drought or at https://labs.waterdata.usgs.gov/visualizations/ca_drought/index.html.

After exploring this visualization as a class, students were asked to describe what they noticed. We found that students attended to quantitative features inscribed in the visualization, but also to specific locations, time periods, and events represented therein. We also found that many students asked questions about the causes and effects of these patterns and referenced individual water wasting or conserving behaviours, with fewer students also mentioning municipal policies and the impacts of climate change (Barton et al., under review). After they noted these observations, we also provided students with age-appropriate news articles about the drought conditions and impacts. We encouraged students to look across these sources to identify a specific question to investigate related to factors that contributed to the drought, about which they would write a "data story" by combining the provided resources with further data analysis they would conduct throughout the week. Analysing these materials through a storytelling framework encourages students to look for the "plot", and connect resources that might otherwise be treated as isolated.

Based on students' more specific attention and the questions they generated, we then provided the reservoir volume dataset that was used to generate the visualization in CODAP. The dataset included each reservoir's total capacity, location, and the weekly mean volume of water stored for the entire period from Jan 2011 to November 2017. We also made other datasets that addressed students' questions about environmental factors (e.g. monthly precipitation, snowpack, and temperature for each reservoir's nearest weather station) available in CODAP for further investigation. Constructing a data story involves attributing significance and exploring relationships between variables toward a coherent explanation of all factors. As the students engaged with these and other resource materials, competing theories emerged in the class about what is most predictive of drought conditions over time—theories that can be examined, though incompletely, through the lens of data. Students asserted, supported, and analysed one and others' claims using the available datasets, constructing

over time an understanding of the interconnected natural and engineered systems (precipitation, snowpack, water use and distribution via interconnected reservoirs) that impact water access and availability.

This example is one of many from a longer design-based research project exploring students' narrative engagement with data as part of the DataSketch and Writing Data Stories projects (Finzer & Wilkerson, 2020; Kemble & Wilkerson, 2024; Reigh et al., 2022; Roberto et al., 2022; Wilkerson & Laina, 2018). We—Michelle Wilkerson with a team of collaborators including Vasikili Laina, Bill Finzer, Tim Erickson, Hollylynne Lee, Lisette Lopez, Kris Gutiérrez, Emily Reigh, and Cherise McBride—worked in close collaboration with partner grades 7-9 science teachers to identify how curriculum units they already planned to teach could be deepened by asking students to build data stories. Each unit engages students in constructing data stories using a combination of resources including specific publicly available datasets, news stories, scientific argumentation, interviews with family and community members, and personal stories to build connections between data, science, and the social world. It embraces many of the shifts around the pedagogical treatment of data highlighted in Section 4 by leveraging public datasets that incorporate contemporary formats such as GIS and images; interactive artifacts from the media that represent new tools for understanding data in the world; and highlights connections between the data analysed and students' own lives and communities. Additional data storytelling units and associated materials include other dimensions, such as datafication through students' recording and analysis of their own nutritional consumption, can be found at corelab.berkeley.edu and https://bit.ly/wds-units.

Example 2: The DataBytes Discussion Protocol. Weeks-long, open-ended data engagements such as the one described above are not always possible in every classroom. However, there are other ways for students to build deeper interpretive connections to data. One practice that has become increasingly common and can better fit into many existing day-to-day school routines are "data talks", classroom discussions about data visualizations that are intended to build student's everyday competencies as data consumers (Arnold et al., 2022; Boaler et al., 2021; Kahn et al., 2022). Importantly, such discussions are easy to integrate into any school subject, and exploring data visualizations can foreground the relevance of mathematics for understanding topics as varied as global climate, literary sentiment analysis, and consumer opinion.

We developed Data Story Bytes or "DataBytes" to bring a storytelling lens, with attention to the explanatory, social, and contextual features of data analysis and communication, to data talks. DataBytes are a collection of brief structured discussion guides we developed for use with specific visualizations, along with a more general questioning protocol that can help educators lead such discussion about any data visualization (Lee, Wilkerson, et al., 2022; Wilkerson et al., 2025). The DataBytes protocol centres around a four-part questioning framework designed to guide learners through making sense of a data visualization, considering its connections to their own lives and communities, considering the history and context of the data presented, and envisioning how they might use the data and findings in new ways.

To illustrate how the DataBytes protocol works in practice, consider an article from the *New York Times* titled, "Is Sushi 'Healthy'? What About Granola? Where Americans and Nutritionists Disagree" (see https://bit.ly/cerme-nyt; Quealy & Sanger-Katz, 2016). The article features a scatterplot with icons of various food items (e.g. pizza, tofu, coconut oil) positioned to indicate the proportion of "all Americans" (corresponding to the X axis) and the proportion of "nutritionists" (corresponding to the Y axis) that rate each food as "healthy". Already there is interesting mathematical work to be done in the interpretation of this representation, as students are asked to make sense of the position of each food, to reason through the existence and meaning of a dotted line

on the visualization representing $x = y$, and to develop sensibilities around what it means for a food or group of foods to be located "above" or "below" this line.

Moving beyond quantitative interpretation, the discussion guide then prompts students to connect the information and patterns in the data visualization to their own lives and communities. Can they find foods they eat on the graph? Where is their favourite food located, or why might it be missing? Is their own perception of the health of various foods consistent with what is reflected in the visualization? Some might begin to think about how the concept of "healthy" food relates to their own dietary needs, cultural background, or family habits. It is during this phase that we have observed teachers begin to focus more specifically on the scientific context of the data, connecting the quantities indicated in the visualization to the more complex underlying factors and processes they are meant to represent (Wilkerson et al., 2025).

Next, the DataBytes protocol encourages teachers and students to delve deeper into the history and context of the data that are presented within the visualization. This involves considering where the data came from, how it was collected, by whom, and for what purpose (these are called "worry questions" in Gal, 2002)—considerations that might take special precedence as one notices there are particularly salient connections or disconnections between the presentation of data and their relevance to personal or community interests. For example, we find educators and students in this phase begin to question how the specific 52 food items that are featured in the visualization were selected, especially if some of their own favourite foods are missing or appear to be inappropriately assessed. They wonder who was surveyed as part of the "all Americans" or "nutritionists" groups, how those people were contacted, and whether either group may exhibit selection bias that could impact the results.

The final part of the framework asks students to think critically about the data's potential applications, limitations, and future possibilities. This step encourages students to imagine different ways data could be collected or used to answer new questions or represent different perspectives. What would be needed for readers to use the information to make their own dietary decisions? How can the concept of health be indicated more transparently, or represented with more accuracy or precision (for example, through describing macronutritional facts associated with each food, to validate survey participants' responses)? Might the visualization be redesigned to be made more useful or inclusive? In semi-structured clinical interviews with teachers who were considering using the protocol in their own classrooms, we found this step prompted the deepest integration of mathematical considerations with subject matter and social concerns. This is because teachers considered what measurements, calculations, or ways of representing patterns might best reflect the complexities and human impacts of the topic (Wilkerson et al., 2025).

Adopting storytelling as an integrative framework for K-12 data science has helped us to address some of the challenges and necessary adjustments described in Section 4—around the new data types that are now available to explore, the new tools and technologies available, and around social and civic literacies and the impact of data on society. Storytelling is flexible enough to adapt to new representational forms and socially relevant issues. It also can be used across a variety of topic areas and school subjects, allowing for the kind of interdisciplinarity highlighted in the introduction to this chapter. We have found that this approach allows students to engage deeply with data as one part of a bigger story, seeing it as the basis for compelling narratives about the world. Using concrete examples like the California drought, students can explore and model quantitative patterns across time and space while also engaging in the interconnectedness of large, complex systems.

5.2 Integrating Data Science and AI Literacy into Mathematics and Computer Science Education: Decision Trees as an example

We will illustrate the conceptions we characterized in section 4.5. by an example from the ProDaBi project, which is a collaborative project of mathematics and computer science educators, led by Rolf Biehler and Carsten Schulte. Our intention was to integrate mathematical, statistical and computer science aspects into a data science and AI curriculum. We worked with teachers and classrooms in elective courses at secondary level, where no curricular and time constraints limited our experimentation with new ideas and methods, see Biehler et al. (2018) and Heinemann et al. (2018) for the initially different perspectives. One component of the curriculum was machine learning methods. In addition to artificial neural networks, we choose decision trees as relatively transparent machine learning method.

Over the past few years, we—Rolf Biehler, together with Yannik Fleischer and Susanne Podworny—have investigated how decision trees (DT) can be introduced as a machine learning method to students across various grade levels (5/6, 9/10, and 12/13) within the context of the ProDaBi project (Biehler & Fleischer, 2021; Fleischer et al., 2022, 2024; Fleischer & Biehler, 2025; Podworny et al., 2021; 2022; 2025). Classroom materials are available at (https://www.prodabi.de/en/unterricht/), Table 1 provides an overview. The use of DT also illustrates new models of data and workflows with new features (see 4.1). The age verification example we sketch below provides a contribution to critical data literacies (4.3), especially concerning hidden data processing in social media.

Grades and courses	No of lessons	Data	Tools
5/6 (computer science)	10	Nutritional values of food	Data cards (Jupyter Notebook without coding)
9/10 (compulsory elective)	10	Media use	(data cards) CODAP, ProDaBi-JupyterNotebook (without coding)
11-13 (computer science)	16	Media use, data from medicine	Data cards, CODAP, ProDaBi-Jupyter Notebook (without and with coding)
12/13 (elective)	Part of a year-long course	Media use, MNIST data, Parking lot (historical and live data), ..	CODAP, ProDaBi-Jupyter Notebook (without and with coding), coding with Python

Table 1. Decision trees in ProDaBi, different tools and datasets

Exploring decision trees in K-12 education offers a practical way to teach several of the following core concepts, contributing to students'' AI and data literacy. Decision trees are a form of machine learning, directly illustrating how computers can *learn* from data to identify patterns and make predictions. Their transparent, flowchart-like structure makes the hierarchical rule system derived from data relatively easy to grasp, showing students one way knowledge can be *represented* and used for *reasoning* to make classifications or decisions. Furthermore, applying decision tree models to real-world data, such as the media use data of teenagers, clearly demonstrates the *societal impact* of AI, revealing how data collected about individuals can be used to build profiles and influence online experiences through prediction. Discussions around the performance evaluation using metrics like the confusion matrix, and the consequences of different error types (False Positives and False

Negatives) within relatable scenarios (like age verification on platforms), encourage students to think critically about the ethical and societal implications of AI systems that make decisions based on data.

The process of building a decision tree with data cards follows a simplified heuristic of a machine learning algorithm. Students learn to perform a *data split* by selecting a *predictor variable* (like fat content) and a *threshold value* (e.g., more or less than 8 g of fat). The data cards are then divided into two subgroups based on this rule. For each subgroup, the majority label (e.g., most foods in this subgroup are "recommendable") becomes the decision for that branch.

Students evaluate the quality of their decision tree by counting the *number of misclassifications*—the food items that are incorrectly labelled by the rule based on their training data label. To build a multi-level tree, they repeat this process on the subgroups of data that still contain misclassified items, adding more rules based on other predictor variables.

The unplugged approach using data cards offers several benefits. It is a hands-on, active learning experience that helps students deeply understand that a decision tree is a system of rules derived from data. By manually sorting and splitting cards, students can "play the machine", gaining insight into the process before seeing it automated. The relatable context of food makes the topic engaging for young students. Studies on this teaching unit have shown promising results, providing evidence that teaching decision trees as an elementarized data-based model-building process is teachable to middle school students (Fleischer et al., 2024; Fleischer & Biehler, 2025; Podworny et al., 2025)

Decision Trees with CODAP/Arbor in Grades 9-10. After gaining a conceptual understanding through unplugged activities, students can transition to plugged activities using the digital tool CODAP (Common Online Data Analysis Platform, www.codap.concord.com) with the Arbor plugin (see arbor on codap.xyz) for decision trees (Erickson & Engel, 2023). This tool allows students to explore decision trees with larger datasets and witness the automation of the tree-building process. They can also delve into more advanced concepts like evaluating trees with separate test data that was not used for training, understanding overfitting (when a tree performs very well on training data but poorly on test data), and methods like pruning to optimize performance for new data. Combining unplugged and plugged activities provides a balanced approach, where the manual work builds foundational understanding and the digital tools enable exploration of automation and more complex ideas.

The teaching module for grades 9/10 centres around a relevant context for students: analysing data related to teenagers' media use. This is based on the annually conducted representative JIM (Jugend, Information, Medien [Youth, Information, Media]) study in Germany (Rathgeb & Schmid, 2020), which only publishes aggregate data. Our project collected its own microdata with a similar questionnaire, known as JIM-Paderborn (JIM-PB) or YOU-PB, from approximately 1200 teenagers, encompassing 161 questions about their media consumption habits, including digital device ownership, online platform usage (like Instagram, TikTok, YouTube), and gaming. Students are tasked with adopting the role of platform owners using this data to identify users (based on other media use variables) likely to play online games frequently ("frequently" or "rarely") for targeted advertising of a new game. This scenario resonates with students' daily encounters with personalized online experiences.

The Arbor plug-in enables students to build decision trees manually using a visual interface. Students can drag variables from the dataset, which is a reduced version of the full YOU-PB data in this phase for better manageability, into the tree structure. Arbor automatically splits the data based on the variable's values and displays the distribution of the target variable within each resulting branch. Students can assign a predicted label to each branch based on the majority class. A key feature is

Arbor's immediate calculation and display of true positives (TP), true negatives (TN), false positives (FP), and false negatives (FN) for the current tree configuration. This feedback helps students understand the direct outcomes of their chosen rules, seeing how many cases are correctly or incorrectly classified at each step. By adding more variables in layers, students can manually build and refine a multi-level tree, observing the cumulative effect of rules on classification results.

Arbor supports the comparison of different predictor variables' split in terms of misclassifications, so the students can easily improve their trees. After that, they understand the machine learning algorithms, namely how a full automation can happen if a system tests systematically all available predictor variables and continues to add layers as long as further predictor variables are available.

For our educational purposes, specially prepared menu-based Jupyter Notebooks can make powerful ML algorithms accessible to students without requiring extensive programming knowledge by hiding complex code behind interactive widgets. Yannik Fleischer programmed menu-based Jupyter Notebooks with a simplified version of professional algorithms. Using these notebooks, students can apply a decision tree algorithm to larger datasets, including the full YOU-PB data with nearly 1200 cases and 161 variables. This automated process, where a tree is built in seconds, powerfully illustrates the automation central to ML.

We use a second classification topic with these data, namely pursuing a question. To begin, we posed the question: How might TikTok determine a user's real age based on their behaviour on the platform? This was based on a real-world case from a few years ago, when TikTok sought to identify users under 13—who are not permitted on the platform—by making hidden inferences from their usage patterns. Exploring such implicit inferences is an important aspect of citizenship education in the digital age. Following this introduction, we presented a related and solvable proxy problem using the YOU-PB dataset: How can age be predicted based on other variables, such as patterns of media consumption and ownership of digital devices?" (see Figure 5).

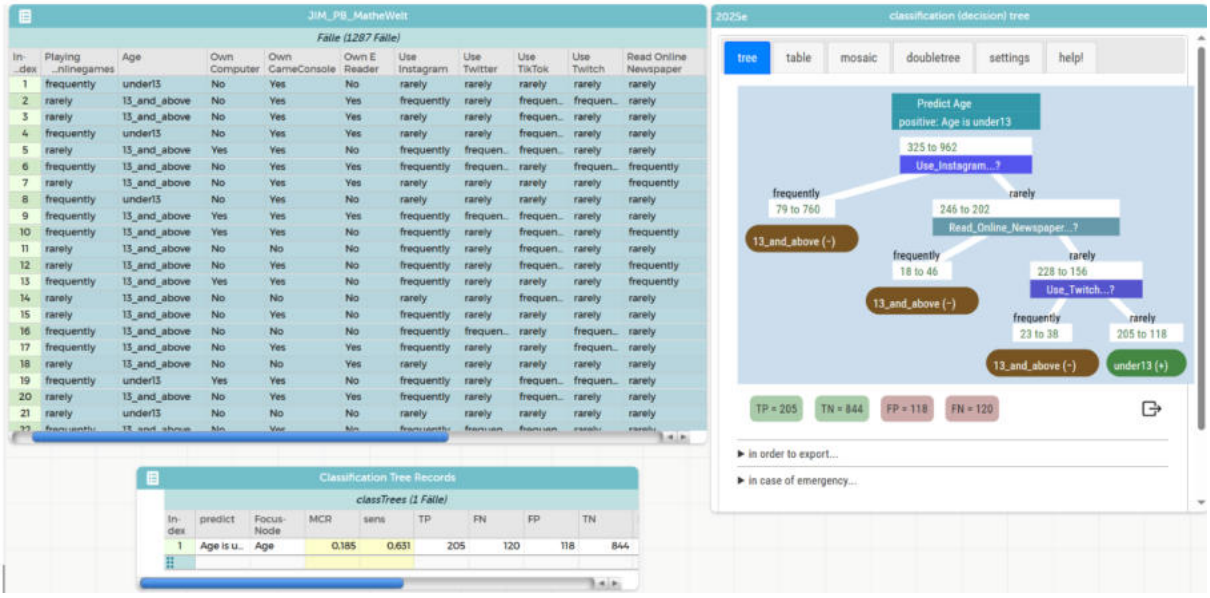


Figure 5. Screenshot from CODAP with plug-in Arbor. The decision tree predicts the variable *age* ("under_13" or "13_and_above") using the variables *Use_Instagram_?*, *Read_Online_Newspaper_?*, *Use_Twich_?* These predictor variables can have the values "rarely" or "frequently". The overall misclassification rate of this tree is 18.5%

The example allowed to discuss the different consequences of two types of misclassifications:

- Predicting that a student is 13 or above 13 years, although younger than 13
- Predicting that a student is younger than 13, although being 13 or above 13 years

The first error is more severe, because the students can use TiKTok although too young. In the second case a ban from the platform is temporary only, because they can present age proofs.

Discussing these nuances is crucial for developing students' critical understanding of how AI systems function and their real-world implications. Plugged tools like Jupyter Notebooks make it straightforward to generate and analyse the confusion matrix and other performance metrics for models built on larger datasets. They also facilitate exploring techniques like pruning, where parts of a potentially overfitted tree are removed to improve its performance on test data. Observing a tree with high training accuracy (e.g., 94.9% in one example) that performs significantly worse on test data (e.g., 75.6%) clearly illustrates overfitting and the value of evaluation and optimization methods.

For students in grades 12 and 13 who are already familiar with Python, the final phase includes hands-on programming: they either develop parts of the algorithm themselves or adapt pre-existing code within Jupyter Notebooks. These notebooks function as worked examples, aligning with the approach outlined by Atkinson et al. (2000). This progression of tools is consistent with the recommendations of Pimentel et al. (2022), commissioned paper for the workshop of the National Academies of Sciences, Engineering, and Medicine (2023), and is supported by research highlighting the educational benefits of using Jupyter Notebooks (Barba et al., 2019) and the instructional value of worked examples (Atkinson et al., 2000).

Further design research is essential to enhance instructional materials, teacher support, and pedagogical strategies. This includes gaining deeper insights into students' prior conceptions, their learning challenges and progress, as well as the specific difficulties teachers face when introducing decision trees in the classroom. While several qualitative studies in experimental classroom settings have already been conducted (Fergusson & Pfannkuch, 2024; Fleischer & Biehler, 2025; Fleischer, Biehler, et al., 2022; Fleischer et al., 2024; Podworny et al., 2025; Zieffler et al., 2021), research aimed at broader implementation and scaling of these teaching approaches remains largely unexplored.

6. Future Challenges: Addressing the multidisciplinary and transdisciplinary nature of data science and AI by staying within and moving beyond discipline-oriented school curricula

At the beginning of this paper, we highlighted Skeina's (2017) assertion that computer scientists "don't respect data" to emphasize the ways in which the domains of mathematics and computer science might be allowing some of the most important features of data—their contextual specificity and social/scientific embeddedness—to slip through the cracks of students' educational experiences. When working with data, Skeina claims, one must "[...] think like a real scientist. Real scientists strive to understand the natural world, which is a complicated and messy place" (p. 2).

It might be no surprise, then, that the examples we present do not actually come from mathematics classrooms, but rather from science and highly contextualized computer science contexts. And even in these cases, we both recognize areas in which our efforts have fallen short. While Michelle has gathered evidence that data storytelling activities engage students deeply in inquiry with data, there is not enough time, space, or preparation in most Science classrooms to address important questions related to validity and uncertainty, such as "how sure are we of this pattern or trend?" More research has begun to focus on the important role of uncertainty in K-12 science instruction (Manz & Suarez,

2018), and this may be one area where deeper data engagements can play a bigger part in the future. And Rolf at times has difficulty convincing collaborators and teachers of the equal importance of situational knowledge and data alongside algorithmic treatment as an important learning goal in Computer Science. Quite a few mathematics teachers are already reluctant to include more data exploration activities in their classroom, given their otherwise full curriculum. Teaching for understanding AI may be assigned to the computer science teacher and ethical, political, and social questions to the social science teacher. However, there is a new trend in mathematics education to explore how generative AI may support teaching and learning processes (Pepin et al., 2025). This may also open the minds for more teaching for understanding the underlying mathematical and statistical principles of AI.

Indeed, effectively integrating data science into the K-12 curriculum presents many challenges. Finzer (2013) calls this the data science education dilemma, lamenting:

> Data science is inherently interdisciplinary, yet it currently has no natural home within the existing, often fragmented landscape of school subjects. Mathematics, while quantitative, often prioritizes abstraction and may be uncomfortable with the rich, messy contexts real data provides. Physical and biological sciences, despite relying heavily on experimental data, are frequently constrained by the need to cover core concepts, pushing data analysis to a secondary, illustrative role. The social sciences, which are increasingly data-driven in practice, have struggled to equip K-12 educators with the quantitative perspective needed for meaningful data use. This lack of a clear disciplinary home means that structured, meaningful opportunities for K-12 students to engage with data analysis are rare, and many teachers may lack the necessary skills and confidence to teach data-driven lessons. (Finzer, 2013, p. 1)

Compounding these practical implementation challenges is the nature of the data science education research field itself, which is also fragmented (Rosenberg & Jones, 2024; Wilkerson, 2025). The field is currently built upon distinct, somewhat isolated clusters of foundational literature that emphasizes data science for undergraduate majors (focused on statistics and computing skills), K-12 education through learning sciences perspectives (focused on data literacy or storytelling), or computational approaches for non-majors (emphasizing specific methods like data mining or simulation). These distinct orientations highlight the need for better communication and collaboration across these scholarly divides.

These orientations are also reflected in the many different definitions and frameworks currently active in the literature, as we briefly reviewed in Section 4.1. We contend that there is nothing problematic in itself about having many different definitions, because these all serve different audiences and purposes. However, these different audiences and purposes should be clearly articulated. The field must stop trying to find a "one size fits all" solution and instead consider what definitions make sense in what contexts, and toward what ends. For example, as described above in Section 4.1, most current frameworks seem most appropriate for the tertiary level and for students who are expected to become specialists in the areas of statistics and data science. And even in our examples, we note that not *all* of the shifts and issues raised in Section 4 are addressed by a single curricular design alone. While they offer examples of what approaching *some* of these new needs and challenges may look like, we are still unsure of *which* challenges are most important to address, and *when*. If we are clearer on these more specific contexts and goals, we can understand how different definitions may build on one another or suggest progressions and paths for students and educators.

Moving forward requires addressing these challenges on multiple fronts (see e.g., Biehler et al., submitted). We need ongoing curriculum development efforts that provide clear progressions of data science concepts and skills, allowing for incremental learning and building upon prior experiences

(see DS4E, 2025 or OECD 2025 for examples). This must be supported by dedicated teacher development and training to build capacity and comfort with data-driven instruction, across subject areas and grade levels (Fergusson & Pfannkuch, 2022; Hudson et al., 2024; NASEM, 2023, Sukol, 2024a; 2024b). Building consensus on standards and core learning goals for K-12 data science is also vital to provide a shared vision and coherence. From a research perspective, fostering deeper engagement and collaboration across existing communities is crucial to build a common literature, shared vision, and convergent understanding of effective pedagogical approaches and learning trajectories.

Ultimately, the goal remains to empower students with the skills and habits of mind necessary to navigate and make sense of the data-rich world. This means incorporating data science thoughtfully across the curriculum, supported by appropriate resources and teacher training. While the field of K-12 data science education research is still coalescing, continued effort to bridge conceptual differences between the disciplines and collaborate on curriculum and pedagogy will be key to realizing the potential of data science education for all students.

Acknowledgement

Both authors contributed equally to this manuscript and share first authorship. The review part of this paper profited from the previous collaboration with the ICME-15 Survey Team 3 "Statistics and data science education as a vehicle for empowering citizens" (Chair Rolf Biehler; Takashi Kawakami, Erna Lampen, Travis Weiland, Lucía Zapata-Cardona, see Biehler et al., submitted).

TWG 01: Argumentation and Proof

Introduction to Thematic Working Group 1: Argumentation and Proof

Andreas Moutsios-Rentzos[1], Orly Buchbinder[2], Nadia Azrou[3], Dimitrios Deslis[4], Viviane Durand-Guerrier[5], David A. Reid[6] and Mei Yang[4]

Introduction

Building upon the rich tradition established in previous CERME conferences, TWG1 has consistently attracted the interest of researchers investigating the multifaceted nature of mathematical argumentation and proof across all educational levels. The group's focus encompasses both theoretical investigations into the nature of mathematical proof and empirical studies of how students and teachers engage with reasoning and argumentation in classroom settings.

At CERME14, TWG1 brought together 32 participants from 15 countries who engaged in in-depth discussions around 26 contributions: 24 papers and 2 posters. The contributions spanned a range of methodologies and educational levels, reflecting the field's diversity, depth, and international scope. The TWG1 sessions featured three whole-group and four split sessions, which fostered critical, collaborative, and respectful engagement among participants while also ensuring the coherence and unity of the TWG1 spirit in the split groups. The main points of interest from each split-group session were reported in a whole-group session for a comprehensive overview of all TWG1 contributions.

In this introductory paper, drawing upon the discussions of our group, the TWG1 papers are organised in four themes: a) Argumentation and Proof in School and Teacher Education, b) Cognitive, Affective, and Metacognitive Dimensions, c) Evaluative Practices, Contextual influences and Epistemological Perspectives, and d) Technological and Collaborative Dimensions.

Argumentation and Proof in School and Teacher Education

A broad range of studies focussed on how argumentation and proof are addressed in both school curricula and teacher education. Szűcs and Slavíčková conducted an international comparison of textbook treatments of Thales' theorem, revealing notable regional variations in reasoning opportunities and prompting discussion about curriculum design. Platz studied how children in primary education engage with proving, while Dilberoğlu, Çakıroğlu, and Haser examined a sixth grader's first proving experience, emphasizing the importance of nurturing proving practices early. At the high-school level, Niederquell and Kempen explored students' use of generic examples for

conjecturing, raising questions about how instructional approaches can help learners move from empirical to formal reasoning.

Teacher preparation and development emerged as a parallel focus. Højbjerg studied pre-service teachers' mathematical knowledge for teaching proof, highlighting the complexity of professional preparation, while Parsinia and Rott investigated how teacher training could enhance justification abilities. Knipping, Bredow, Miyakawa, Otani, and Shinno provided a cross-cultural perspective by comparing proof instruction in Germany and Japan, while Deslis, Stylianides, and Jamnik offer insights into teachers' motivational views on Lakatos-style investigation using a value-cost-expectancy framework. Hofmann and Gustavsen focused on how teachers facilitate understanding of fraction multiplication through proving, while Lestyanto and Pfeiffer explored approaches to teaching mathematical induction. Butler and Buchbinder used linguistic analysis to reveal how beginning teachers conceptualise and communicate about reasoning and proof.

The discussions focused on the importance of coherence across educational levels, the role of institutional supports, and the value of integrating research-based approaches into teacher education. Moreover, the need for more research on how teacher preparation programs can effectively integrate proof instruction across different mathematical domains was stressed. The group identified significant gaps in understanding how teachers transition from personal mathematical knowledge to pedagogical content knowledge for proof instruction. The group also discussed the role of collaborative learning in teacher education and the importance of providing teachers with experiences as mathematical reasoners before expecting them to facilitate student reasoning.

Affective Dimensions

This theme reflected the growing interest in the affective dimensions that shape students' proof-related activity. Stylianides, Stylianides, Zhang, Deslis, and Seo identified affect-related constructs—such as value, self-concept, and self-efficacy—that predict proof competence, prompting conversations on how emotional and motivational factors influence engagement with mathematical proof. Hapipi and Stylianides focused on the cognitive skill of negation and its connection to understanding proof by contraposition. Moutsios-Rentzos and Mantziou introduced the construct of proof awareness, a complex affective and meta-affective lens for gaining deeper understanding about the diverse ways that learners evaluate and reflect on proofs.

The group discussed the bidirectional relationship between cognitive and affective factors in proof learning, noting that emotional responses to mathematical arguments can both facilitate and hinder reasoning processes. Assessment practices can exacerbate proof-related anxiety, underscoring the importance of supportive learning environments, particularly during transitions to formal proof.

Evaluative Practices and Epistemological Perspectives

The evaluation of arguments and proofs and the ways these practices are shaped by broader contexts was the focus of several contributions. Saccoletto studied how students shift their argumentative strategies according to their goals and interlocutors, a topic that prompted wide discussion about the authenticity of proof tasks and communicative expectations. Fahse and Lutz proposed the RPA (rich, pseudo-factual, apodictic) model of argumentation, which distinguishes between justification and

proof; this led to reflection on how these constructs are treated across different educational cultures. Kovács and Kónya explored situational cues that influence whether students recognize a task as proof-related, shedding light on the interplay between task design and learners' framing.

Epistemological and theoretical questions were also prominent. Durand-Guerrier proposed a model-theoretic lens for studying proof didactically, while Boero discussed implicit criteria of proof validity and how they shape conjecturing processes. Matteucci, Tortoriello, and Veronesi examined how students interact with AI systems in argumentative contexts, raising questions about the epistemological status of machine-generated proofs. Fischer provided a Lakatos-inspired framework for generating refutations, while Asenova argued for integrating fallibilism with formal logic in the conceptualization of mathematical proof.

Reflections were raised about what constitutes acceptable mathematical proof and how such judgments are communicated and internalized by learners. Discussions centred on how epistemological assumptions inform instructional decisions and how proof validation practices vary across contexts. The need for educational environments that support multiple modes of reasoning while also cultivating shared norms of rigor and justification was expressed. The group also discussed the importance of making implicit evaluation criteria explicit in both research and teaching contexts.

Technological and Collaborative Dimensions

Digitally enriched learning environments were featured in several contributions. Perivolari and Psycharis examined how dynamic geometry software combined with paper folding supports proof construction, illustrating how physical manipulation can complement digital visualization. Sears and Buchbinder reported on the use of the *FullProof* digital platform to support learners' geometric reasoning through guided interactions. The two posters of TWG1 were focused on this theme, showcasing the growing interest. Ceballos, van den Bogaart, Spandaw, van Ginkel, and Drijvers discussed collaborative problem solving to develop higher-order reasoning, while Sisco and Ouvrier-Buffet presented findings on how students interact with automated theorem provers in proof-writing.

The group engaged in extensive discussions about the transformative potential of artificial intelligence in mathematics education, while emphasizing the importance of teacher agency in selecting and orchestrating technological resources, and designing tasks that leverage technology to deepen conceptual understanding and support proof writing. The participants discussed how technology can enhance collaborative learning experiences, highlighting the need for research on the long-term effects of technology integration on students' mathematical reasoning abilities and the importance of maintaining a balance between technological support and independent reasoning. These works generated lively debate about how to balance automation and human judgement in proof learning, and how to ensure that technological tools support rather than supplant critical mathematical thinking. There was also interest in how collaborative tools and digital environments could promote equitable participation and foster inclusive proof cultures in diverse classrooms.

Discussion and Ways Forward

The TWG1 sessions at CERME14 featured rich discussions that illuminated several cross-cutting concerns and future directions for the field. As reflected in the TWG1 discussions and the four

interconnected themes, three interrelated domains emerged as pivotal for advancing research and practice in argumentation and proof: theory-practice relations, interdisciplinarity and the digital, and socio-cultural perspectives.

The tension and synergy between theoretical development and classroom practice were central in TWG1 discussion: *How can theory remain productively close to the lived realities of students and teachers, while still offering robust conceptual frameworks?* There was a call to develop more holistic constructs that are relevant to the complexity of human argumentation, proof, and proving, which can also meaningfully inform instructional design and curricular decisions. This requires a bidirectional dynamic, not only translating theory into practice, but engaging in a recursive process where classroom observations and empirical work help refine and problematise theoretical assumptions.

The socio-cultural aspects of argumentation and proof were also discussed as an underexplored yet essential dimension, especially when considering that technology accessibility remains a significant equity issue: *How do socio-cultural and institutional contexts shape students' access to and participation in argumentation and proof, and what strategies promote equitable engagement across diverse learner populations?* A way forward involves the greater use of cross-cultural comparative research, longitudinal case studies, and collaborations that include researchers and educators from underrepresented contexts to examine how cultural, linguistic, and institutional factors influence students' opportunities to engage in argumentation and proof.

Interdisciplinarity is a crucial dimension in research about argumentation and proof, which was evident in last CERMEs. At CERME14, interdisciplinarity combined with and digital/multimodal tools emerged as a powerful, yet complex, area of innovation: *In what ways can interdisciplinary integration –drawing from philosophy, linguistics, and computer science– expand our understanding of mathematical argumentation and proof as educational practices?* Argumentation and proof inherently intersect with other domains (e.g., epistemology, logic, linguistics, computer science). These perspectives need to be researched, as AI and technologies such as interactive proof platforms, automated theorem provers, and multimodal environments become increasingly prominent in educational settings. The ways that technological tools affect the nature of argumentation, the epistemic roles of teachers and students, and the balance between automation and human reasoning may be among the areas for future research. The collaboration with other CERME working groups seems to be a fruitful way to gain deeper understanding about these issues. Moreover, to address this sustained and growing interest, the co-leaders of TWG1 initiated the organization of an ERME Topic Conference (ETC) entitled "Argumentation and proof in teaching and learning of mathematics and interactions with other disciplines", which will take place in June 2026 in Milano, Italy.

These areas of interest reflect the central ideas that emerged through our TWG1 deliberations, and should not be interpreted as indicating preferences for particular research directions over others. Mathematical argumentation and proof are investigated through multiple lenses and methodological approaches (including work in other thematic working groups), and TWG1 remains dedicated to celebrating and amplifying this rich diversity of perspectives.

Integrating fallibilism and formal logic: A Peircean approach to Lakatos' methodology

Miglena Asenova

Free University of Bolzano, Faculty of Education, Bozen, Italy; miglena.asenova@unibz.it

Authentic learning of argumentation and proof in mathematics requires active conjecture development rather than passive reproduction of proofs. Lakatos' approach, widely used in mathematics education research, emphasizes this active process. Although Lakatos rejects formal logic as useless for knowledge development, investigating a potential logical framework for his approach could provide insights into its logical foundations and connect fallibilist and classical views on argumentation and proof in mathematics education research. This theoretical paper explores how an epistemic-logical model, mainly based on an intuitionistic version of the Peircean first-order existential graphs, can frame Lakatos' methodology, contributing to theoretical perspectives and offering a new analytic tool for researchers.

Keywords: Lakatos' approach, epistemic-logical model, intuitionistic existential graphs, fallibilism, classical logic.

Rationale

Lakatos' approach in designing and analysing meaningful mathematical activities is widely spread in mathematics education research (e.g. Deslis et al., 2022; Stylianides et al., 2022). Even though, to the best of my knowledge, investigations on the logic that could frame this approach have never been carried out in this research area. Lakatos (1976) calls his approach "the logic of discovery," (p. 3). Still, the term *logic* is intended in that context as rational scientific enterprise inspired by informal logic, i.e. "the logic of proof or of thought-experiment or of construction" (Lakatos, 1976, p. 81), rather than as deductive logic in a formal system (Lakatos, 1976, p. 3). In this sense, trying to frame Lakatos' approach by a logical system might seem nonsense. Nevertheless, discussing this aspect could be useful for at least two reasons in mathematics education research: (1) it could help to shed light on the logical bases of this approach and situate it in the panorama of logical approaches to proof in mathematics education; (2) it could act as a bridge that allows communication between fallibilist approaches to argumentation and proof in mathematics education (e.g. Stylianides et al., 2022) and approaches that suppose mathematical knowledge to be, once established, certain and unrefutable and thus framed by classical logic (e.g. Durand-Guerrier, 2005). This theoretical paper discusses how and to what extent the epistemic-logical model presented in Asenova (2023) and deepened in Asenova (2024), extended here to first-order intuitionistic logic, can frame Lakatos' approach, also keeping the door open for considering mathematical knowledge as certain, according to classical logic. It aims to contribute to the development of theoretical and methodological perspectives. and the design of an analytic tool for research in mathematics education.

Method

Hereafter, some elements of Lakatos' approach are exposed, and the epistemic-logical model (Asenova, 2023, 2024) is presented and extended from propositional to first-order logic. Then the

suitability of the model for framing Lakatos' approach from a logical viewpoint is discussed. Finally, Lakatos' lemma-incorporation method is exemplified, and the conclusions are drawn.

Lakatos' approach and the methods of discovery and verification

Lakatos (1976) challenged the traditional view that mathematical knowledge is timeless, certain, and a priori. He combined Hume's problem of induction with Popper's theory of falsification to highlight the relativity of mathematical knowledge. Lakatos (1976) provided a list of heuristically detected methods used by mathematicians in their mathematical practice for improving a conjecture and its proof through counterexamples. In this process, the type of the discovered counterexample plays a crucial role. A counterexample can be local or global; it is *local* when it affects at least one step of the proof (based on a lemma acting as an argument in the proof); it is *global* when it impacts the main conjecture and thus the conclusion itself. A counterexample can be both local and global or only one of them: if it is only local, the conclusion is not affected and only the 'guilty' argument should be changed; if it is only global, the arguments seem to work but the conclusion does not and one should search for a hidden assumption and incorporate it explicitly as a condition in the conjecture; if the counterexample is both local and global, the problematic proof step affects the conclusion and should thus be incorporated explicitly as a condition.

Lakatos' most famous example (Lakatos, 1976) is the historical refinement of the justification of Euler's formula on the relation between the number of vertices V, edges E, and faces F of a polyhedron: V-F+E=2. Lakatos presents his inquiry in a dialogic form, where a maths class discusses an informal proof of this 'naïve conjecture' provided by the teacher (it is the proof historically provided by Cauchy), introducing counterexamples (e.g. the hollow cube) that force the class to explicitly define the involved concepts and to refine the proof. The proof consists of a thought-experiment that is supposed to: remove a face of the polyhedron; stretch its surface upon a plane; section the surface following certain rules based on triangulation; remove parts of the stretched surface following rules that do not change the initial relation between V, F, and E; show that at the end the relation between V, F and E is V-F+E=2 and thus must have been so at the beginning of the procedure. Below, after introducing the epistemic-logical model, this paradigmatic example is used to exemplify the modeling of one of Lakatos' methods: lemma-incorporation.

The epistemic-logical model with quantifiers

The model, which consists of three elements —Vergnaud's (2009) concepts-in-action and theorems-in-action (Vergnaud, 2009), Duval's value of a verbalised proposition (Duval, 2007), and an adaptation of Oostra's intuitionistic propositional existential graphs (Oostra, 2022), as presented in Asenova (2024) — is extended here to predicate logic to frame the use of (counter)examples.

Concepts-in-action, theorems-in-action and the value of a verbalised proposition

Vergnaud's theory of conceptual fields (2009) aims to establish connections between the operational form of knowledge, linked to actions, and the predicative form of knowledge, linked to symbolic and linguistic expressions. In this context, two main ideas are concepts-in-action and theorems-in-action that are implicit and need to be deduced from a student's actions. Theorems-in-action are expressed as propositional sentences and are either true or false, whereas concepts-in-action are relevant or not

relevant. According to Vergnaud (2009), even if someone believes a false proposition to be true, it still qualifies as a theorem-in-action. What is important is that the individual acts as if the proposition were true. This perspective focuses on the student's knowledge, regardless of how it aligns with normative standards. In Duval's framework of the meaning space of a verbalised proposition (2007), the value-dimension links the proposition to its meaning. Here we focus only on the epistemic value (e.g., obvious, absurd, possible) and the logical value (true or false) because they allow to characterise the kind of reliability that students attribute to their knowledge: the epistemic value aligns with the idea of theorem-in-action, which are based on implicit, proposition-like knowledge, while the logical value corresponds to theorems and is supported by explicit concepts.

The system of intuitionistic existential graphs with quantifiers

Starting from Peirce's diagrammatic logic of existential graphs (EGs), divided into Alpha EGs for propositional logic and Beta EGs for predicate logic, Oostra (2022) formalised a topological system of classical Alpha and Beta EGs and intuitionistic Alpha and Beta EGs. Alpha-intuitionistic EGs (Alpha-IEGs) are composed of some or all the following elements: sheet of assertion (the plane surface), propositional letters (capital letters representing the propositions), two types of closed curves: cuts, that means closed curves that 'cut' the sheet of assertion into two regions: one inside and one outside of the closed curve (Figure 1 a) or scrolls (Figure 1 c, d). Each scroll is composed of a cut with one or more loops folded inside it (e.g., single or double scroll, Figure 1 c, d). According to Peirce, a scroll is: "a curved line without contrary flexure and returning into itself after once crossing itself" (Peirce, CP 4.564). The areas on the sheet of assertion are even or odd, according to the number of curves drawn around them (Figure 1).

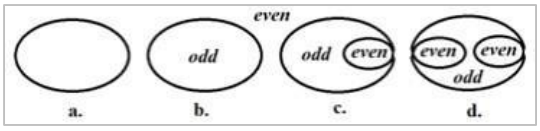

Figure 1: Elements and areas of IEGs: empty cut (a); single and double scrolls (c, d); even and odd areas (b, c, d, and the surface they are drawn upon) (Oostra, 2022, p. 136)

In a scroll, the region limited by the cut and the loops is the outer area of the scroll, and the interior part of the loop is the inner area. The scroll is a purely intuitionistic element as classical EGs work only with cuts; this is the main difference between classical and intuitionistic EGs. The interpretation of the classical and intuitionistic connectives is represented in Figure 2, where '=' stands for equivalence.

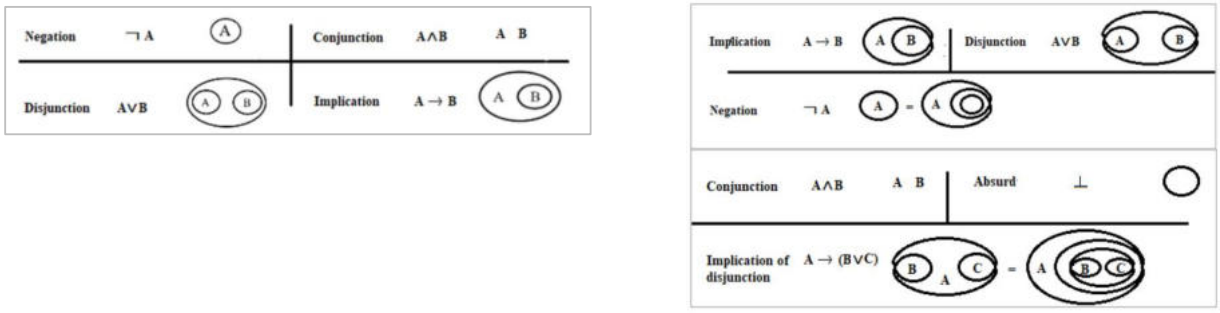

Figure 2: Basic and derived connectives for classical EGs (on the left) and intuitionistic EGs (on the right) (adapted from Oostra (2022, pp. 135–136))

According to Oostra: “we obtain the system of intuitionistic Beta graphs by adding to the Alpha system a line, which stands for a subject, element, or individual, and letters with attached lines, which stand for relatives, or predicates” (Oostra, 2022, p. 147). In this way, the system of Alpha IEGs is extended to the Beta-IEGs.

Graphically, Beta-IEGs differ from Alpha-IEGs by the use of (possibly branched) lines, called lines of identity (Figure 3a), and the use of capital letters with a positive number of (ordered) lines attached, symbolising predicates (Figure 3b); the existential quantifier corresponds to the line of identity, and the universal quantifier to the combination of the line with a scroll (Figure 3c) (Oostra, 2022).

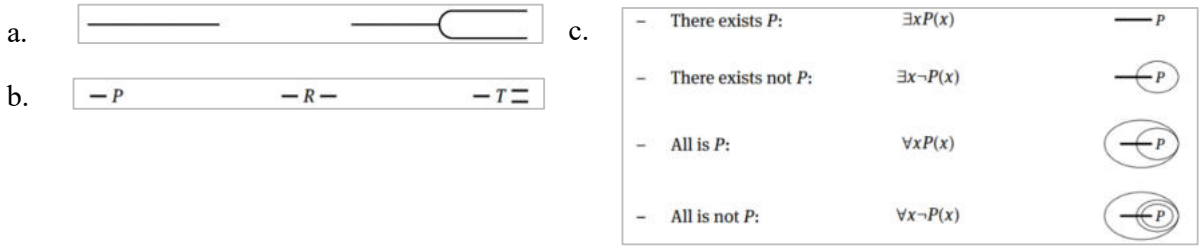

Figure 3: Existential and universal quantifier in Beta-IEGs (adapted from Oostra, 2022 (pp. 147-148))

Summing up, a Beta IEG is a diagram consisting of a finite combination of one or more of the following elements: predicate letters, cuts, scrolls, and lines of identity.

The interpretation of the intuitionistic Beta-IEGs is based on the clauses for Alpha-IEGs, with the addition of the following: drawing an identity line means asserting the existence of an individual; writing a letter with lines attached to it means that the predicate it represents holds for the involved individuals; joining two lines of identity means identifying the individuals they represent.

In Asenova (2024) the Alpha IEGs were introduced with some additional transformation rules compared to Oostra’s (2022) system, without affecting its soundness because these rules can be derived from the others. The additional rules are introduced due to the specific needs in mathematics education research which is interested in linking together aspects related to a logic concerning the epistemic value (here represented by the intuitionistic logic) and aspects related to a logical value concerning certainty (here represented by classical logic), as well as to the need to express an increasing/decreasing epistemic value. Even thought the additional transformation rules are not necessary, they are explicitly formulated as rules to render the system more user-friendly.

The lines of identity do not affect the parity of the areas. Hence, the rules of transformation that hold for Alpha IEGs hold also for Beta-IEGs, with some additions related to the line of identity. In this way, the transformation rules for Beta-IEGs can be conceived as an extension of the transformation rules for Alpha-IEGs and the latter can be conceived as an extension of the transformation rules for classical EGs. Therefore, the system of transformation rules for Beta-IEGS presented below includes the transformation rules (TRs) for classical logic (the part before the first slash in the first five rules), intuitionistic propositional logic (the part between the first end the second slash in the first five rules and rules 6 and 8), and intuitionistic predicate logic (the part after the second slash in rules from 1 to 5 and after the first slash in rules 6 and 8). TR 7 is universal and holds for all kinds of graphs. Below, ‘ITRn’ stands for ‘intuitionistic transformation rule number n.’

ITR1: *Erasure*. In an even area, any graph may be deleted/ any loop within an even area may be erased, together with its contents/ in an even area, any line of identity may be cut. ITR2. *Insertion*. In an odd area, any graph may be added/ if the odd area is limited externally by a cut, a loop containing any graph may be added to the cut/ in an odd area, two lines of identity may be joined. ITR3. *Iteration*. A graph can be repeated in its own area or in any area contained in it that is not part of the graph itself/ any loop may be iterated, together with its contents, on its own cut/ a branch with a loose end may be added to any line and any loose end of a line may be extended inwards through cuts or loops; when there are lines of identity involved in the graph to be iterated, they must correspond exactly to those of the original graph. ITR4. *Deiteration*. Any graph may be deleted if a copy of it persists in the same area or any area around it; a loop, together with its contents, may be erased if another loop with the same contents is present on its cut/ a branch with a loose end may be removed from any line; any loose end of a line may be retracted from the outside (retracted, as a reverse of iterated) through cuts or loops; when there are lines of identity involved in the graph to be deiterated, they must correspond exactly to those of the outside copy of the graph. ITR5. *Scrolling*. A scroll with an empty outer area may be drawn around or removed from any graph on any area/ The application of this rule is not prevented by the presence of lines that cross both the cut and the loop of the scroll with an empty outer area, that is, that pass from outside the scroll to the inside of the loop. ITR6. *Increasing or decreasing loop and increasing or decreasing cut*. In a scroll, the area enclosed by the loop can increase (↑) or decrease (↓) and the area of the cut can increase (↑) or decrease (↓)/ when the initial loop or scroll crosses lines, the increasing or decreasing loop or scroll must keep crossed the same lines. ITR7. *Topological equivalence*. A graph can be transformed into another equivalent by continuously transforming the curves it is composed of. ITR8. *Detachment*. A loop can be detached from the cut/ the detached loop must keep crossed the same lines as before.

The ITRs from 1 to 5 are the original rules formulated by Oostra (2022), while the ITRs 6, 7 and 8 are the rules added for the purposes in mathematics education research. With respect to Asenova (2024), ITR 6 is extended by introducing increasing/ decreasing cuts; this can be justified by ITR7.

Framing Lakatos' approach by the epistemic-logical model with quantifiers

One of the main aspects that makes the model described above useful for framing Lakatos' approach is that it is based on intuitionistic existential graphs which see classical existential graphs as a special case. Indeed, the main difference between intuitionistic and classical EGs is the meaning of the universal quantifier within the corresponding first-order logic.

The graph in Figure 4a represents the intuitionistic universal quantifier referred to the predicate P and its meaning is 'All is P;' in Figure 4b the classical universal quantifier $\forall x P(x)$ is represented; in Figure 4c the negation of 'All is P,' i.e., 'All is not P,' is represented.

Figure 4: Graphs representing the universal intuitionistic quantifier (a), the universal classical quantifier (b), the negation of the universal intuitionistic quantifier (c), and the steps to switch from 'All is not P' to 'There are P' (d)

In intuitionistic logic 'All is not P' does not imply that there are not objects satisfying P, as this is the case in classical logic, where $\forall x \neg P(x)$ implies $\neg \exists x P(x)$ ('$\neg$' represents classical negation and '$\exists$' represents the classical existential quantifier). Indeed, in intuitionistic logic the statement 'There are P' can be derived from the statement 'All is not P' (Figure 4d). This means that the judgment on the domain of a conjecture is formulated 'until proven otherwise.' In this sense, even if at a given moment it seems that a conjecture fails because it is falsified, one could still detect a safety domain where it holds. This aspect is captured by intuitionistic logic and is graphically represented by the existential graphs. Vice versa, in classical logic, the statement '$\exists x P(x)$' cannot be derived from $\forall x \neg P(x)$, as they are contradictory. Summing up, intuitionistic universal quantification keeps open the possibility of increasing or decreasing the domain of a conjecture, as it refers only to the already examined domain of the underlying concept, which could be altered if counterexamples or previously unconsidered examples are discovered.

Furthermore, the model can frame the epistemic value assigned by a subject (obvious, absurd, possible, probable, etc.) to a statement, suspending the judgment on its logical value and expressing his/her increasing or decreasing convincement (ITR6). Nevertheless, the model does not require to agree with the idea that mathematical theorems are never definitely true or false, embracing a fallibilist position on mathematical knowledge. Indeed, it keeps the door open to refutation, as described above, but also allows to shift to certainty. According to the system of IEGs presented in the previous section, switching from the graph represented in Figure 4a to the one in Figure 4b is allowed (ITR8), but not vice versa. This does not contradict Lakatos' position: even if it is generally fallibilist, it does not deny the existence of statements that are undoubtedly true (e.g., *The sum of the angles of a triangle in plane geometry is 180°*), but highlights that they belong to "mature theories," while the fallibilist approach refers to theories that are "under construction" (Lakatos, 1976, p. 42).

Mathematics taught at school (and to a large extent at university) belongs to mature theories (e.g. Euclidean Geometry or Calculus), at least from the expert's point of view. Nevertheless, from the student's point of view, this does not need to be the case: when students formulate a conjecture and try to prove it or try to identify a safety domain for it, they might be more or less convinced that it is right (according to Duval's distinction, they assign an epistemic value to the statement rather than a logical one). If (counter)examples or exceptions arise, they must be considered revising the definition of the involved concepts, the conjecture, or the just provided proof. Usually, the teacher knows the largest domain of the conjecture and the appropriate definition of the involved concept that makes the proof work. Once this domain is achieved, she can support students in shifting from the epistemic to the logical value. Summing up, from a logical point of view, the presented epistemic-logical model reconciles a perspective based on a constructive approach, interested in conjecture formulation and discovery, and based on epistemic aspects, with an approach based on truth-valued logic.

The lemma-incorporation method represents, according to Lakatos, the core of his proof-and-refutation method. It allows for the improvement of the proof itself by incorporating a local counterexample that refutes a proof step, i.e. a lemma. According to the polyhedra example proposed by Lakatos, the result of the lemma-incorporation method is that a polyhedron must be simple and with simple connected faces. This allows for the incorporation of two 'guilty' lemmas that undermine the proof. Lakatos states that this method "virtually *summed up the proof in the lemma-incorporating*

theorem" (Lakatos, 1976, p. 42, emphasis in original). The sequence of Beta-IEGs in Figure 7 shows how the basic idea of lemma-incorporation can be modelled.

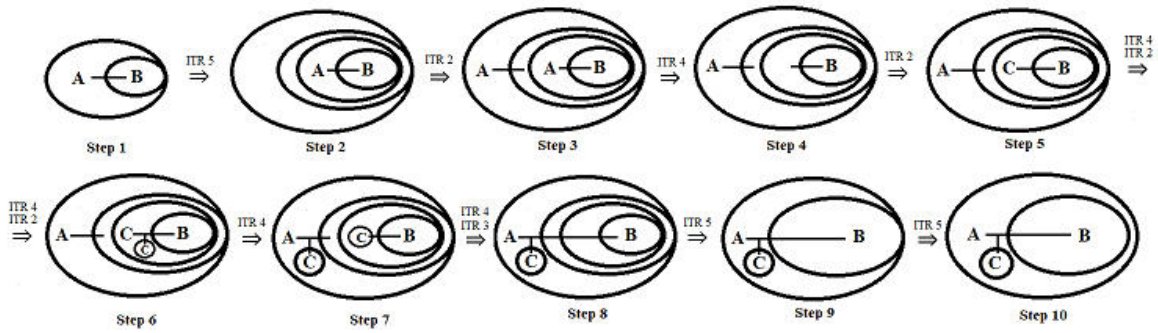

Figure 7: Modelling of the lemma-incorporation method by the epistemic-logical model

In Figure 7, Step 1 represents the statement 'All A are B,' i.e., 'All simple polyhedra are Eulerian.' Steps from 2 to 5 are technical steps needed to introduce a lemma (C) used in the proof. In this way, in step 5, we have the statement 'All A are B because of C', that means 'All simple polyhedra (A) are Eulerian (B) because, in the triangulating process, by drawing a new diagonal edge, one always increases by one the number of edges and faces (C)'. According to Lakatos (1976), this lemma becomes suspicious as it turns out that in the case of the crested cube (a cube with a smaller cube setting on top of it), one needs to increase the edges by two to increase the number of faces by one. Step 6 represents the 'appearance' of the counterexample, i.e., the crested cube, which is a simple polyhedron but for which the lemma does not work. The counterexample is represented by the negation of C: a cut with the propositional letter 'C' inside it. In step 7, the lemma is turned into the condition 'polyhedra for which any face dissected by a diagonal edge falls into two pieces,' equivalent to the 'guilty' lemma. Steps 8 and 9 are technical steps that show how the graphs evolve to the final statement in step 9 ('All simple polyhedra for which any face dissected by a diagonal edge falls into two pieces are Eulerian'), while step 10 represents the possible shift to certainty and classical logic.

The lemma-incorporation method leads to consider the interplay of concepts-in-action (e.g., the concept of simple polyhedron) and theorems-in-action (the incorporated lemma) and their evolution to explicit concepts and theorems. Indeed, step 10 represents the possible shift from a theorem-in-action to a theorem and thus from an epistemic to a logical value, showing how the first two elements of the theoretical framework are used to interpret the third one.

Conclusions

In this paper, the suitability of the presented epistemic-logical model in framing Lakatos' approach to proof and refutations (Lakatos, 1976) was discussed and exemplified. From a theoretical viewpoint, this allows us to situate Lakatos' approach in the panorama of logical perspectives on argumentation and proof in mathematics education, associating it to a constructivist logic that focuses on processes rather than on states of affairs. From a didactic point of view, this analytical tool can be used by the researchers to better frame student's reasoning when it represents aspects difficult to frame with classical logic. Indeed, the technical part of the model allows to symbolically represent the reasoning similarly as this is done by symbolic logic, but the topological form of the representation allows us accounting for continuities and discontinuities in the reasoning process and for growing and

decreasing epistemic values, as it is shown in the examples in Asenova (2023, 2024). Furthermore, it accounts for shifts between an epistemic and a logical value, and thus for shifts from implicit theorems-in-actions to theorems, as shown in the example in figure 7. As the model involves not only a fallibilist but also a truth-value perspective, it helps to bridge communication between fallibilist approaches to argumentation and proof (e.g. Stylianides et al., 2022) and approaches that suppose mathematical knowledge to be, once established, certain and unrefutable (e.g., Durand-Guerrier, 2005). Further research should be done to deepen the model's potential in bridging this gap and in using it for the design of tasks for teacher training courses.

Presumed criteria of validity of proof drive student teachers' actions in conjecturing and proving: a case study

Paolo Boero

Department of Mathematics, Genoa University; paolopriero@gmail.com

The aim of this paper is to show and interpret, in the perspective of Habermas' rationality, how prospective teachers attending a course of mathematics education of the Master Degree curriculum in mathematics behave in a conjecturing and proving activity in elementary theory of numbers. What emerges from the reported study is that (for all students) only algebraic proof guarantees the necessary rigor, and that (for some students) only the exploration of the conjecturing situation by means of algebraic expressions and properties is a productive way of getting conjectures. Moreover, epistemic and strategic pitfalls affect several students' algebraic conjecturing and proving activities. The implications of the results for mathematics teacher education will be discussed.

Keywords: Habermas' construct of rationality, proving and proof, prospective teachers.

Introduction

In the Abstract of their paper (Healy & Hoyles, 2000) the Authors wrote:

> After surveying high-attaining 14- and 15-year-old students about proof in algebra, we found that students simultaneously held 2 different conceptions of proof: those about arguments they considered would receive the best mark and those about arguments they would adopt for themselves. In the former category, algebraic arguments were popular. In the latter, students preferred arguments that they could evaluate and that they found convincing and explanatory, preferences that excluded algebra. (…) The most successful students presented proofs in everyday language, not using algebra (p. 396).

Students' behaviors may depend (among other factors) on teachers' conceptions and experiences about proof and proving, and related teaching choices. Several researchers investigated teachers and prospective teachers' conceptions (see for instance Knuth, 2002, who refers to the USA, and Lesseig, Hine, Na, et al., 2019, who present a comparative study concerning Australia, USA and Korea). A smaller number of studies concern teachers' and prospective teachers' proving. Among them, Dogan and Williams-Pierce (2021) investigate the use of generic examples in teachers' proving.

The aim of this paper is to investigate how prospective mathematics teachers in the first year of their Master Degree studies in mathematics deal with a conjecturing and proving task in elementary theory of numbers. The results of this study shed light on the possible source of school students' behaviors through their assimilation of teachers' ideas and practices developed during the university studies in mathematics, and suggest teacher education choices like, for instance, those presented in Guala & Boero (2017). Results also put into evidence distortions of conjecturing and proving processes, due to the fact that the related epistemic and strategic requirements are not taken in charge by students, thus suggesting more general changes in the mathematics curriculum of prospective teachers.

Theoretical assumptions

Concerning proof, I will refer to the construct of Theorem by Mariotti (2006), which consists of a triple (statement, proof, reference theory), where reference theory provides not only the primitive elements, the axioms, the definition and the theorems that may be used in the proof, but also the criteria of validity of proof. This choice on one side allows to take in charge and compare theorems and proofs of different historical periods and different disciplines, on the other provides the teacher (and the students too!) with the opportunity of considering different kinds of acceptable proofs.

Concerning the proving process, I will refer to the distinction between the process of proving and its product (proof), and to the distinction between two phases of proving: exploration, and construction of the proof (not necessarily in this order, since difficulties in the phase of construction may bring to a new phase of exploration). In the literature we find more detailed segmenting of the proving process, but for the purpose of this study it is sufficient to distinguish between these main phases.

In recent years, the Habermas' construct of rationality (Habermas, 1998) has been used to compare different rationalities in mathematics (Guala & Boero, 2017), to inform the teachers' questioning ("rational questioning", in Zhuang & Conner, 2022), to analyze students' mathematical activities (Urhan & Bülbül, 2023). Indeed, the Habermas' elaboration allows to take in charge both the product of an activity, and the subject's 'rational behavior' during the activity. While the tension towards what should be a rational, ideal behavior may inform actions to promote students' rational behavior (like rational questioning). This variety of uses of the Habermas' construct depends on the nature of its three components in interaction among them: epistemic rationality (justifications for the claims in a given cultural context), teleological rationality (including the identification of the reasons why the chosen strategy resulted or not in the attainment of the goal), communicative rationality (the choice of the means, in a social context, to reach the interlocutor – even the subject, in the inner dialogue). Regarding the subject of this paper, I will make a distinction between the epistemic requirements that should inform the two main phases of proving, in strict connection with the teleological dimension (concerning the strategic choices that result in the evolution of the process towards the aim to be attained). In the exploration phase, a statement resulting from an induction or an abduction or an analogy is acceptable, what counts is its use to build the proof. However during the exploration epistemic and teleological criteria are not irrelevant: algebraic transformations or references to known results must be correct, and the link with the aim to attain (pertinence) must be taken into account.

Method

15 students attended a mathematics education course in the second semester of the first year of the Master Degree studies in Mathematics in an Italian university, after three years and one half of university studies in mathematics; at the beginning of the fourth year they had made the option of a MD curriculum oriented towards the profession of teaching mathematics in secondary schools. This option included about one half of credits of advanced courses of mathematics, and one half of credits for courses that were more or less strictly related to teacher education (mathematics education, history of mathematics, epistemology of mathematics, etc.). The course was based on students' work on problem solving (including proving), with problems that may be currently proposed in the last years of the high school or at the beginning of the university studies, followed by discussions on students'

individual solutions (different strategies, mistakes, obstacles met by students), possibly followed by comparisons with high school and first-year university students' solutions. This activity resulted in theoretical developments (e.g. didactic contract, theories of teaching and learning) and in implications for secondary school teaching of mathematics. The final evaluation of students was based only on their discussion and revision of the personal written productions during the course (solutions of mathematical problems and ideas on the educational problems dealt with during the course). This mode of evaluation encouraged students to write down all their thoughts and essays during problem solving activities (in the perspective of their final revision). The following individual task (to be performed in about 90') was proposed after two weeks of the course. It was aimed at opening a cycle of lessons on proof and proving in school mathematics, according to Guala & Boero (2017).

> Which is the Greatest Common Divisor (GCD) of the products of three consecutive natural numbers? Justify your conjecture in a rigorous way! Then try to generalize your conjecture, and justify such more general statement. Write down your reasonings, even those that you consider useless, according to their order.

Different kinds of proof are possible, according to different epistemic criteria for validity: a purely semantic proof (by considering where multiples of 2 and 3 are in the sequence of natural numbers), a mixed semantic-algebraic proof (by considering the products n(n+1)(n+2) and the necessary presence of one multiple of 3 and at least one multiple of 2 among the factors), and a purely algebraic proof (for instance, the algebraic proof by induction of the divisibility by 6 of the products of three consecutive numbers, based on the lemma that odd and even numbers alternate in the sequence of natural numbers). Students' individual written productions (38 A4-pages from 15 students) and audio-recordings of the subsequent 90' discussion were available. Solutions by 6 students are reported below. They were chosen as representatives of the whole set of solutions.

Analysis of students' productions

Federica starts algebraic exploration: From x(x+1)(x+2) to x^3+3x^2+2x. From (x+n)(x+n+1)(x+n+2) to the division of the resulting polynomial by x^3+3x^2+2x (one page of calculations, ending with "not this way"). Numerical essays follow: 2.3.4, 7.8.9, 10.11.12, 21.22.23, 101.102.103, each of them resulting in careful prime numbers factorization, like for instance 101.102.103=101.2.3.17.103

> It seems that 6 is the GCD because each product of three consecutive numbers contains 2 and 3. Indeed at least one number out of three is even, thus it is divisible by 2, and another will be multiple of 3, because in each triple of consecutive numbers there is 3: n(n+1)(n+2). (n-1)(n-2)(n-3). If n is even, n and n+2 are even, thus divisible by 2. If n is odd, either n+1 even or n-1, n-3 even, thus divisible by 2. If n is multiple of 3, the product is divisible by 3. If n is not multiple of 3, n+1 or n+2 divisible by 3 (indeed I find one multiple of 3 in the product of three consecutive numbers). But this only confirms that 6 is the GCD. I must prove it.

One page of calculations follows, with division of x^3+3x^2+2x by x-6 (repeated twice) and other trials with expressions like those written at the beginning. With the comment "I don't succeed". Federica engages in the use of algebraic transformations to produce the conjecture. Then numerical essays suggest the conjecture. Federica performs well in the following exploration, which in the reality

results in a mixed semantic-algebraic proof construction. In the discussion she will say: “I was not sure of the validity of the proof, only algebra ensures it”. Hence she comes back to the algebraic expressions and their unsuccessful manipulations.

No reflection on chosen unsuccessful strategies emerge from the text (a requirement for teleological rationality). Epistemic criteria privileging algebraic proving prevail on the whole activity (including conjecturing) and inform it in a blind way. Algebraic manipulations are carefully performed, but a clear connection of algebraic expressions with the aims to attain (a conjecture, then a proof) is lacking.

Amelia

> 1.2.3=6 5.6.7=210 I consider the product 1.2.3=6 This is a product of 3 natural numbers, thus the GCD of all the numbers obtained by multiplying three consecutive natural numbers will be one of the numbers 1, 2, 3, 6. I start by an even number: $2m(2m+1)(2m+2)=2[m(2m+1)(2m+2)]$. $(2m+1)(2m+2)(2m+3)= 2[(2m+1)(m+1)(2m+3)$]. Thus 2 is a common divisor of all the products of three consecutive natural numbers. I consider the list of multiples of 3. 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18,19, 20, 21, 22, 23, 24. Given how this table is made up, after 3, I find that after two numbers that are not multiple of 3, I find one number which is multiple of 3. Then I consider the case in which the first number that I choose is the first number after a multiple 3n of 3: $3n+1$ 1°, $3n+2$ 2°, $3n+3$ 3°. Their product will be: $(3n+1)(3n+2)(3n+3)=3(3n+1)(3n+2)(n+1)$. Thus a number that is divisible by 3.

The same reasoning for the second number after a multiple of 3.

> Then my conjecture is that the GCD of all the numbers that are products of three consecutive numbers is 6. In my opinion the only step to be justified in a more rigorous way is the step in which I say that after two consecutive numbers that are not divisible by 3, I find one number multiple of 3. If by absurd 3 would be not a divisor of $n(n+1)(n+2)$ then $n(n+1)(n+3)\neq 3k$ (…) $n^3+3n^2+2n\neq 3k$. If $n=3m$ we get the absurd: $(3m)^3+3n^2+2.3m\neq 3k$. By this way I think to be unable to reach something. I try to exploit the unique factorization of natural numbers.

An algebraic essay with general factorization of n follows.

> It looks useless. I reflect on the construction of the multiples of 3. 3n means 3+3+3…+3 n times. The following multiple of 3 will be 3+3+3…+3 (n times) +3, which means 3+3+3…+3 +3 (n+1 times). Then two numbers, which are not multiples of 3, are between two multiples of 3 by definition of multiplication. The generalization is that the GCD of the products of n consecutive numbers is n!

During the discussion of this proof Amelia says: “It is not a rigorous proof. I was willing to use algebra, but I was not able to do it”. Amelia looks free from the obligation of using algebraic expressions in the conjecturing phase, which in the reality contains a ‘justification’ that looks as a mixed semantic-algebraic proof. In the proving phase she does not rely upon the work done before and tries a proof by absurd. Then she comes back to her previous reasoning, and she moves towards an exploration of what happens on the number line. The reasoning stops and a general conjecture is produced. Then two different unsuccessful trials of proving (by absurd, and by using the unique factorization theorem) follow. Finally, Amelia produces a semantic proof that will not be

acknowledged by her as "rigorous" in the discussion. We may identify in Amelia's work a confusion between the epistemic requirements of conjecturing and those of proving, resulting in a confuse choice of strategies to attain the related aims, without any teleological reflection on them. For her, semantic justifications do not fit epistemic criteria of validity.

Sara gives the definition of GCD of two numbers, then she finds the GCD of 1.2.3=6 and 2.3.4=24, of 2.3.4=24 and 4.5.6=120, of 1.2.3=6 and of 5.6.7=210. For 10.11.12=1332 and 8.9.10=720, she gets the GCD of 1332 and 720 through the Euclid's algorithm and she finds 36 (which in any case is not the GCD of 10.11.12=1220 ≠1332). Then she states that:

> I must find a general rule and to prove it. I observe that all the GCD that I found till now are multiple of 3 and 2. GCD (h,z) is the greatest multiple of 3 that divides h and z. Each natural number h greater than 0 which is the product of 3 consecutive natural numbers contains one multiple of 3, thus h=3k. I re-write GCD (h,z)=GCD (3k, 3f). By definition of GCD, GCD(3k,3f) is a multiple of 3. Now I must prove that g= GCD (h,z) is the greatest multiple of 3 which divides h and z, that is: all the other multiples of 3 are not the GCD. By absurd, let us suppose that g'<g, g'=GCD (h,z) g'=3t g=3k g'<g =>t<k, false because, by definition of GCD, this must be the greatest of the common divisors.

Sara considers a hypothetical GCD suggested by numerical exploration as a multiple of 3 and 2, then she tries to prove that such GCD is the greatest multiple of 3 that divides two products of three consecutive numbers. The first Sara's (logical) mistake derives from the lack of epistemic control of the nature of the conjecture in the transition to proof; it is followed by a second mistake in the management of the proof by absurd.

Giorgio writes that to find the GCD of a(a+1)(a+2) and c(c+1)(c+2) we may represent (according to the theorem of factorization of natural numbers) the two products as products of prime numbers a_1, …a_p and c_1… c_s. "As a generalization, I consider these products: a(a+1)(a+2)… (a+n) and c(c+1)(c+2)….(c+m) where a, n, c, m are natural numbers. These numbers are products of prime numbers, so if I take each number and I write it as product of prime numbers, I can find the GCD".

Giorgio presents what for him is a general method to find the GCD in the case of the products of three consecutive numbers, without realizing that the considered couples of products might not lead to it (epistemic check related to the request of the task is lacking, like in the case of Sara), then he moves to describe a similar method for a more general situation (the GCD of products of any number of consecutive factors). The effort of using the factorization theorem of natural numbers brings Giorgio to a higher level of not well specified generalization. Does the generalization mean that we consider all the products of a whatever number of factors each? Then the GCD would be 2. Giorgio's whole production lacks a clear distinction between the phases of exploration and proof; also the epistemic check of the connection between what could be obtained from the chosen strategy (the GCD of two products of numbers) and what should be obtained (the GCD of all the products of the same number of factors) is lacking in general.

Cecilia starts by considering some examples: 5.6.7, 3.4.5, 6.7.8, 2.3.4 and she finds that all of them are divisible by 6, then she focuses on 1.2.3=6 and she makes the conjecture that a number ≤6

is the GCD of all the products of three consecutive numbers (including 6, which is a divisor of 1.2.3). "The product of three consecutive numbers is even because they may be: even.odd.even=even or odd.even.odd=even", thus Cecilia concludes that " 2≤ MCD ≤6, thus GCD may be 2, 3, 6". Then Cecilia writes the product of any three consecutive numbers in this way: "n≥ 2, (n-1)n(n+1) = n^3-n n^3-n is divisible by 6 ⇔ a natural, positive number k exists, such that n^3-n=6k". Then she draws the Cartesian graph of y=x^3-x ("for x>0 because they are natural numbers") and two parallel lines for k=0 and k=? She finds that (2,8) belongs to the graph of y=x^3-x and she writes that the straight line y=6k meets such graph in the point (2,8) when k=1: "8-2=6k 6=6k=> k=1". Her conclusion is that "n^3-n is always divisible by 6, because k exists, such that n^3-n=6k, which implies that 6 is the GCD".

Cecilia moves from the conjecture "GCD may be 2, 3, 6" (we observe that 3 as GCD contradicts the previous exploration) to a proof related to GCD=6 without any explicit reason for choosing 6. The conjecturing phase looks poor (or poorly reported in her text), even if the justification of the possible value 6 for the GCD shows that attention is paid to the epistemic requirements inherent in the definition of the GCD. The proof results from the solution of an equation, supported by graphic considerations (an algebraic-analytic method). During proof construction, Cecilia loses the contact with the situation modeled by the algebraic expression (a requirement of epistemic type): she looks unaware of the fact that she has justified the validity of the conjecture only in the case n=2.

Anna starts by writing and transforming algebraic expressions (similar to Federica's). After a few essays, she moves to a semantic exploration by using the Euclidean algorithm. She considers 5.6.7 and 18.19.20 and she finds that their GCD is 6 and she writes the conjecture: "The GCD of products of three consecutive numbers is a multiple of 3". Then she tries to prove algebraically that the GCD of n(n+1)(n+2) and (n+8)(n+9)(n+10) is divisible by 3; she transforms both products into polynomials in the x variable, then she concludes "I am not able to go further". Then she generalizes her conjecture to the GCD of the products of n numbers by writing that it should be n, and she tests this conjecture with the products 1.2.3.4 and 9.10.11.12. Then she tries a proof of the conjecture related to the products of 3 numbers by multiplying the polynomials that she had already got before and she finds that some of the coefficients of the product are divisible by 3, while others are not divisible by 3.

Anna's exploration, performed in the case of two products of three consecutive numbers, results in the general conjecture that the GCD is a multiple of 3. This conjecture is immediately considered for an algebraic proof. The failure is followed by a general conjecture (n is the GCD of the products of n numbers) that is weaker than what was conjectured in the case n=3. The conjecturing phase is poor on the teleological side (only one case of two triples of consecutive numbers is considered) and on the epistemic side (multiplication of two polynomials in the x variable). Like in the case of Federica, the initial algebraic exploration is unrelated to the search for the GCD.

Results and conclusion

By considering the students' texts, we may realize that no student considers the possibility of delivering a non-algebraic proof as a valid proof, and even those who produce a semantic or an algebraic-semantic proof (Federica, Cecilia, Amelia) look unsatisfied with it and try to get a purely algebraic proof (by algebraic transformations or by using the unique factorization theorem), or an algebraic-analytic proof, like in the case of Cecilia. For Federica, Giorgio and Anna, conjecturing is

driven by the need of using algebraic expressions and algebraic manipulations, or a theorem. The reason for this behavior was made explicit in the subsequent discussion: 'Only algebra guarantees that the conjecture is a good conjecture" (Federica), "I agree" (Giorgio and Anna). It is like if, in order to be a good conjecture, it must be derived through the same process (algebraic, or relying upon a theorem) that should bring to prove its validity. Even in the case of an exploration of semantic nature, what prevails is not the specific quality of a conjecture (strength in particular), but the immediate search for its validity.

Teleological requirements for conjecturing (to explore the situation in order to get the widest information and to notice regularities, and then to evaluate the outcomes and the adopted ways of exploration) and proving (specially, to evaluate the failures in order to identify possible, alternative strategies) are not taken in charge. What emerges in some cases is that students move from one essay to the other, the only criterium is the use of algebraic language or the unique factorization theorem or the Euclidean algorithm both in the case of conjecturing and in the case of proving.

In general, we may say that epistemic (presumed) reasons for validity of proof drive students' actions in conjecturing (Federica, Giorgio, Anna among the students of this paper, and 9 students out of 15 attending the course) and in proving (5 out of 6 students of this paper, with the only exception of Sara, as well as in the case of 12 students out of 15 attending the course).

The fact that the privileged kind of proof is the algebraic one agrees with Healy and Hoyles' results with younger students (and we may imagine that if no intervention is made on these prospective teachers, they will reproduce a similar situation in the school). Also the fact that only some conjecturing and proving processes that keep a verbal contact with semantic are successful agrees with Healy & Hoyles (2000), with a striking similarity in spite of more than seven intermediate years of studies in mathematics. The only difference concerns the fact that "students preferred arguments that they could evaluate and that they found convincing and explanatory" (Healy & Hoyles, 2000, p. 396), while the prospective teachers of the present study are not satisfied with those arguments.

In some cases (Sara, Giorgio, Cecilia), the contact is lost with the epistemic requirement of mathematical modelling, regarding the necessity of checking the relationship between the model (the algebraic expression) and the modelled situation (in the domain of natural numbers). See Morselli & Boero (2011). And logical mistakes concerning conjecturing and proving emerge: in particular, in Giorgio's work the presumption to be able to derive the GCD of all the products from comparison of factorization of couples of products (performed by using the theorem of factorization of any natural number in an unique product of prime numbers); and the conjecture concerning the GCD of all the products of m and n natural numbers (without realizing that the GCD would be 2). Also Sara tries to derive the conjecture from the Euclidean algorithm applied to couples of products, while Amelia tries to do it to get a valid proof. It is like if the only reference to theorems or theoretically based procedures, learned in the Algebra course, would guarantee the validity of the results.

The number of students in this study is low, but similar behaviors were observed in the same course in previous years on similar tasks. What emerges from the performed analyses suggests that a big gap exists between how students were prepared in the standard mathematics courses at the university, and the needs inherent in their future profession as teachers. Authentic conjecturing looks as a rather

strange activity for the majority of the students considered in this study; proving is dominated by the need of conformity with an algebraic proof. Semantic proofs or mixed algebraic-semantic proofs are excluded from the range of 'rigorous proofs'. However a program of cultural analysis of the content to be taught, like that hypothesized and exemplified in Guala & Boero (2017) and related to Mariotti' construct of theorem (Mariotti, 2006), might be only a partial answer to the needs emerging from the present study. Indeed, the present study puts into evidence more general, problematic aspects of the basic preparation in mathematics (proving in particular) of future mathematics teachers. The resulting needs concern, in particular, genuine conjecturing and proving activities by students at the high school and the university levels, and related reflections on what conjecturing and proving and proof mean. Moreover a careful checking of propositions in proving should be related to the aims of their use, according to a joint consideration of epistemic and teleological requirements of proving and proof.

Linguistic analysis of beginning mathematics teachers' discourse about reasoning and proof

Rebecca Butler[1] and Orly Buchbinder[1]

[1]University of New Hampshire, USA; orly.buchbinder@unh.edu

Humans' use of language and the choice of words they use in their discourse on a particular topic, may reveal their inner conceptions and feelings about this topic. We apply this perspective to analyze three beginning secondary mathematics teachers' language about reasoning and proof (RP) – the topic that poses persistent challenges for students and teachers alike. In this longitudinal study, we examined characteristics of beginning teachers' RP language during their supervised student teaching (internship) and the first year of autonomous teaching. The data collected through observation debriefs and interviews were analyzed using a combination of innovative computational methods (R-software) and grounded theory. The results reveal that, while the three participants had similar mathematical and pedagogical backgrounds in RP, they recontextualized RP differently in their classroom practice, according to their respective contexts and views.

Keywords: Reasoning and proof, Linguistic perspective, Novice secondary mathematics teachers

Introduction

Teacher education programs worldwide aim to prepare future mathematics teachers to enact reasoning and proving (RP) in their classrooms (Conner et al., 2014; Wasserman et al., 2023). As teacher candidates transition from university to school teaching, they face additional challenges, specifically integrating RP into their teaching practices. For example, Stylianides et al. (2013) found that novice elementary teachers with strong mathematical knowledge and productive RP beliefs had to overcome students' pre-existing unproductive classroom norms and habits of mind. Given their limited knowledge of students' conceptions, these beginning teachers struggled to enact proof-related tasks and maintain high cognitive demand. Even more experienced teachers often struggle to enact RP in their classrooms (e.g., Bieda, 2010). These challenges have been attributed to teachers' insufficient mathematical knowledge of proof or unfavorable dispositions toward proof (Ko, 2010). Other researchers point to alternative external factors like rigid school culture and norms, lack of professional support, or institutional constraints (Herbst & Chazan, 2011; Stylianides et al., 2017).

To support teacher preparation specific to RP, Buchbinder and McCrone (2023) developed a special capstone course *Mathematical Reasoning and Proving for Secondary Teachers*. The course supported multiple cohorts of prospective secondary teachers developing mathematical knowledge for teaching proof, productive dispositions toward proof, and practical skills for integrating RP in classrooms. The course participants were followed for four years after graduation into their supervised internship and autonomous teaching practice to examine how their competence for teaching RP evolved.

In this paper, we focus on three beginning teachers from that project, Olive, Nancy, and Diane (pseudonyms) within two periods: a year-long internship and the first year of teaching. We collected rich data about each teacher from multiple sources (lesson plans, sample student work, classroom videos, and interviews). We conducted a linguistic analysis of their discourse by analyzing the words

they used when talking about RP and their mathematics teaching, in general, to reveal how these beginning teachers recontextualize (Ensor, 2001) RP in their teaching as they transition from university to school practice. Our research question was: *How do beginning mathematics teachers talk about RP in their teaching within more general mathematical discourse?*

Theoretical Perspectives

We draw on several theoretical perspectives. First, in considering beginning teachers' transition from university teacher preparation programs to school teaching, we draw on Herbst and Chazan's (2011) theory of practical rationality. This theory conceptualizes teaching as a social practice embedded in the institution of schooling. Teaching decisions are grounded in four professional obligations: to mathematics as a discipline, to students as individuals, to classrooms as collectives, and to schools as educational institutions. Teachers wishing to enact RP in their classrooms cannot act solely upon their beliefs but must consider these obligations (either consciously or unconsciously).

Additionally, we conceptualize teachers' learning-to-teach under Vygotsky's (1978) sociocultural perspective, holding that learning is a fundamentally social process with language as a key mediator of this process. Learning is also situated within social contexts. As teachers transition between contexts: university, internship, and schools, they adjust their practices and recontextualize discourses constructed in one setting into another (Ensor, 2001; Gomez Marchant et al., 2021). Focusing on language, we further conceptualize it within the psychological theory of "words as attention," which holds that the specific words people choose, consciously or unconsciously, in spoken language provide insight into aspects of their psychology by revealing how individuals cast their attention (Boyd & Schwartz, 2021). Dating back to the 1960s, this perspective has an extensive history in psychology, with numerous studies connecting word frequencies to various psycho-social conceptions (e.g., people with higher confidence and social status more frequently used "you" and "we" pronouns than "I" pronouns (Boyd & Schwartz, 2021)). While psychological approaches typically sort frequent words into predefined categories, we use an open approach to categorize frequent RP and non-RP-related words to understand the specific mathematical and pedagogical features of their use by our teachers.

Methods

Three beginning secondary teachers, Olive, Nancy, and Diane, volunteered to participate in the study and remained with it for the entire duration of the project, allowing for continuous and comprehensive data collection. As undergraduates, the participants excelled in both mathematical and pedagogical coursework and exhibited positive dispositions toward proof. Thus, these teachers were well-prepared and eager to integrate RP into their teaching. However, transitioning to classroom teaching brought challenges that resulted in RP-related topics being sparsely represented in their discourse. For this reason, the data from a year-long internship and the first year of autonomous teaching were combined.

The primary data sources were video-recorded interviews conducted about an observed or teacher-described lesson (five during the internship and three during autonomous teaching). All interviews were transcribed and initially coded with Herbst & Chazan's (2011) professional obligations framework. For the current analysis, we exclusively focus on obligation to the discipline of

mathematics and specifically the place of RP discourse within it. To capture and characterize the specifics of these discourses, we used *R*-computational software to analyze the most frequent substantive words in teachers' utterances. First, within general mathematical talk, we identified utterances specific to RP. Next, the *SpacyR* package was used to filter only nouns, verbs, and adjectives and to "tokenize" these words according to their underlying roots (e.g., "understand," "understood," and "understanding" are replaced with their common root "understand"). The *TidyText* package was applied to determine the most frequent words in each teacher's discourse (Silge & Robinson, 2017). A word was judged as "frequent" if it appeared at least three times in a teacher's RP and/or mathematics-specific utterances. For each teacher, the package identified 15 frequent words. These words were categorized using open coding (Corbin & Strauss, 2015) into meaningful categories based on the interview transcripts to capture different aspects of teachers' talk about RP and mathematics. For each frequent word, we examined the surrounding text to understand the meaning in which the word was used and to sort it into appropriate categories.

Results

Figure 1 summarizes the percentage of frequent RP and non-RP mathematical words by the three participants. For each teacher, the data from the internship and autonomous teaching was combined. We use the abbreviation INT for interns and NT for novice teaching periods.

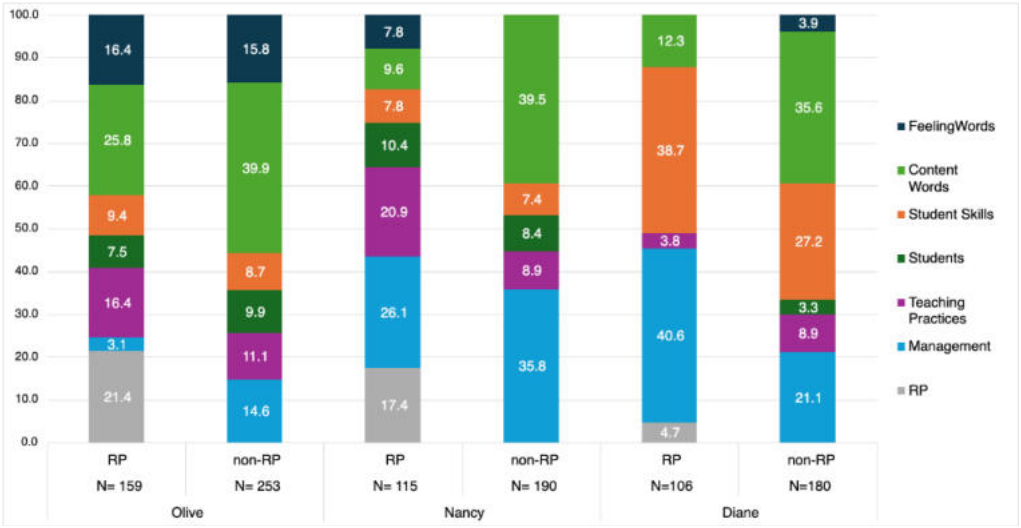

Figure 1: Teachers Frequent Words by Group, in percentages

Reasoning and Proof-Specific Terms

RP-related terms included words such as "proof," "reasoning," "true," "counterexample," and others. The three teachers used RP terms to different degrees. Olive used RP-related terms substantially: 21% of her RP-related talk included words like "proof," "counter," "true," and "reasoning." For example, when describing a lesson where students explored how the sign of inequality changes when inequality is multiplied by a negative number, Olive said: "Obviously, an example doesn't constitute proof, and we all know that. [but] I kind of scratched that idea when I said [the rule] is always true. […] it was

probably more, a more reasoning way of proving". For Olive, RP is a spectrum of justifying mathematical truths, between informal "reasoning" to formal "proof."

Nancy also frequently used RP-related words (17.4%), but her talk was skewed toward "reasoning" as a primary teaching focus in her algebra class (e.g., "We are doing a lot more reasoning than doing proving […] I ask them why and how questions […] It gets them thinking about justifying and explaining."). Diane, who, as an NT, taught a geometry course largely focused on "two-column proofs," talked about how she intended to "weave proofs into every unit." She emphasized proof as a wide-range tool for mathematical justification.

Management

Within mathematics-focused discourse, there were frequent words describing how teachers managed classroom environments to integrate RP. All teachers discussed how they plan, implement, and refine the mathematical content they teach but their discourse varied in the words and frequency of the words used. Olive mostly focused on "time," saying that she "would love to do [more RP activities], which we haven't had the time for." But beyond that, management was Olive's least frequent category in both RP and non-RP-related talk (3.1% and 14.6%, respectively). In Nancy and Diane's discourse, words related to managing the mathematics teaching were both prominent (~20-40%) and diverse (e.g., "activity," "lesson," "class," and "unit" and the "topic" or "stuff" (i.e., content)). Diane's language communicated the effort it took to reconcile her institutional obligation to uphold the school curriculum with integrating RP into her "lessons", "activities", and "units," saying things like: "I forget to sit down for every single lesson and think, oh, how could I make this more exploration-like?" and that she needed to "move forward" or "move on" with the curriculum. Alternatively, Nancy's management talk focused on making her "activities" more 'exploratory" to facilitate RP-oriented "goals" (e.g., "my goal was just for [students] to explore pi", "I'm trying to do more exploratory stuff […] where I'm trying to get them to reason and try to get them to see things on their own"). The teachers talked differently of RP and classroom management: Diane saw it as a planning burden, Nancy as helping students achieve learning outcomes, and Olive as being time-consuming.

In all three teachers' non-RP-related talk, the words related to managing mathematics learning were more prominent. Diane and Olive both took a descriptive stance, talking about the "activities" they implemented. Opposite to Diane, Nancy seemed willing and eager to modify the existing curriculum, talking about how she "changed" "activities" and "lessons" based upon whether they were too "hard" or too "easy" for students and aiming to make them "cool" or "fun" for them.

Teaching Practices

Frequent words in the teaching practice category included "answer," "wrong," "explain," "question," "rule," and others. This category comprised 16.4% of Olive's and 20.9% of Nancy's RP-related talk. For Diane, this category comprised just 3.8% of her RP-related talk and 8.9% of her non-RP-related talk. In her RP-related talk, Diane often used the word "question" to express her efforts to "throw in like little questions, so [students] can form an opinion on something and argue it, whether it's super proof-y or not, but just to hear why they made a choice or why they think something." In her non-RP-related talk, Diane frequently used "rule," expressing her desire to have students understand the

origins and proper application of mathematical rules (e.g., "I would add a row [to the example] that is $x^5 \cdot x^3$, just so that they [students] know that the rule also works with variables").

Nancy discussed how she focused on asking students "why and how questions" to engage students in reasoning. Among Nancy's frequent non-RP terms was the word "talk," capturing how she presented information to students. She positioned "talk[ing]" as "direct" instruction, contrasting it with RP-related teaching practices, which she saw as inferior to RP ways of teaching (e.g., "I'm trying to get them to reason, see things on their own, but sometimes I feel like I'm doing more direct instruction."

Olive frequently used "wrong" and "answer" when talking about her teaching but used them differently in RP vs. non-RP-related talk. In non-RP talk, the word "wrong" signified incorrect student answers or methods. In her RP talk, Olive described wanting students to explore these "wrong" "answers" to foster their justification skills and increase student confidence (e.g., "Can you see why what you're doing doesn't work? It's not that it's wrong; you're just not getting anywhere," "They are all going to start saying, why, why does that happen? And [...] we should give them an answer"). That is, Olive viewed the justification aspect of RP as essential to her teaching.

Students and Student Skills

Students were foregrounded to varying degrees and in different ways in teachers' talk. Both Olive and Nancy used terms like "kids" and "people" in addition to "students." Student-related terms comprised 10.4% of Nancy's RP-related codes and 8.4% of non-RP-related codes, indicating her strong focus on student engagement with RP, whereas "student" did not appear in Diane's RP-related codes and only in 2.4% of non-RP-related codes. However, Diane had the largest percentage of words in the students' skills category: 38.7% of RP-related codes and 27.2% of non-RP-related codes.

The word usage in the student skills category provides further insight into how teachers viewed students' roles in the mathematics discipline. Diane's RP-related activities had students "discover" mathematical "rules," emphasizing that students should "figure out" problems for themselves. But the goal of these discovery activities was to aid students "memoriz[ing]" the "rules." Diane's frequent words include "remember," "memorize," and "stick (in student memory)". Diane explained:

> These kinds of activities jump out, and when there is a hands-on piece to it, they [students] remember it. […] Just so they would have that process so that when they do get stuck on a quiz and they don't remember the rule, they know what they could do to figure it out.

Outside of the RP context, Diane's emphasis on student investigations was less prominent, although she still wanted them to "create" physical models, "measure" quantities, and "figure out" problems. In the non-RP-related talk, these words were paired with more traditional words like "practice" and "talk" in the sense of classroom discussions. Thus, while she still had elements of student-led activity in her non-RP-related talk, this was less focused on discovery than in her RP-related talk.

Olive showed the least word variation in the student skills category, but interestingly, she used the same words with different meanings. For example, in her RP-related talk, Olive used the word "understanding" to convey her goal of students obtaining "conceptual understanding" and "understanding why" mathematical rules work, while in the non-RP context, "understanding" referred to mastering content. Similarly, the word "struggle" in the RP-related context was positioned

as productive for student learning (e.g., "when they really, really understand something is when […] "struggle" alongside other students to arrive at a conclusion"). In her non-RP-related talk, Olive wanted students to explain answers rather than "struggle". Thus, her emphasis on the justification was consistent across her RP and non-RP-related talk.

For Nancy, students' RP skills manifested in students being able to "explain" concepts to one another, justify their answers, and "participate" in the class (e.g., "Reasoning was in this activity where the students were explaining to each other how they were doing things). In another lesson, she reflects that her students were able to "participate openly and just have a discussion... students were recognizing what was happening, seeing, and were able to participate and engage". Nacny's notion of "explaining" is similar to Diane's notion of "discover[y]" and to Olive's "understanding why" since all teachers wanted their students to be able to recognize where mathematical results come from.

Content Words

The teachers also frequently mentioned words related to the mathematical content they were teaching. Mathematical vocabulary was more frequently used in non-RP-related rather than RP-related ones, indicating that our teachers tended to talk about RP more generally, focusing on the affordances and challenges of RP in their classrooms. The variation across teachers and frequent terms highlights the range of content our teachers had to handle in their classrooms. For example, Olive, in her non-RP-related talk, used many verbs (e.g., "move", "flip", "set", "fold"), while Nancy and Diane tend to use a single verb ("stay" and "expand") focusing more on nouns (e.g. "equation", "angle", "line"). Olive's emphasis on mathematical actions in addition to mathematical objects suggests that she emphasized mathematical processes in her teaching, while Nancy and Diane's focus on mathematical objects suggests a greater emphasis on concepts.

Additionally, both Nancy and Diane frequently mentioned mathematical subject areas such as "geometry" and "algebra" but did so exclusively in their RP-related talk, while reflecting on how some content areas more aptly lent themselves to the incorporation of RP. For example, Nancy who taught both algebra and geometry, said: "I feel like I know a lot of more exploratory and application stuff, more critical thinking stuff for geometry. And I'm struggling with algebra, trying to get them to experience things." While these teachers were trained in integrating RP across mathematical contents (Buchbinder & McCrone, 2023), their expertise in this was still developing. As they were adjusting to the responsibilities of independent teaching, they were more apt to integrate RP into geometry than into algebra while still expressing a desire to learn how to integrate RP more widely in their teaching.

Feeling Words

Our teachers also frequently used words to convey a sentiment (e.g., "love," "nice") or hedge their thoughts (e.g., "sense," "guess" (in the meaning of supposing)). Nancy and Olive used the term "feel" to indicate their perceptions and intuitions about classroom events or teaching approaches (e.g., "That's something I feel like I've wanted to do" - Olive, "I just feel like some of the lessons were just over some students' heads" -Nancy).

The teachers varied in their expression of affect and emotion across their RP and non-RP-related talk. Olive had the greatest variation in these types of terms but used them approximately evenly through

her RP and non-RP-related talk (16.4% vs 15.8% respectively), indicating that such words may be intrinsic features of her vernacular. Nancy and Diane have less variation in the types of these words. Nancy expressed feelings more frequently in RP-related talk, while Diane did in non-RP-related talk. This variation is significant as it indicates that teachers express different levels of confidence in RP.

Discussion

The different aspects of RP identified in the teachers' talk highlight how RP can be incorporated into teaching to varied extents and in different ways. While all teachers mention that it is difficult to find time for RP activities, Nancy prioritized these types of tasks, modifying curriculum resources given to her, because of their affordance for supporting students' exploration, while Daine found such activities difficult to incorporate. Additionally, all teachers used RP teaching practices as a way to center student contributions in their classrooms. Diane and Nancy accomplished this by focusing on "questions" and Olive focusing on "answers," but all communicate the importance of RP for student thinking. Our teachers also viewed RP as a means of fostering students' deeper understandings of mathematical content (c.f., Buchbinder & McCrone, 2023; Ko, 2010) but formulated this in distinct ways, with Diane focusing on students' "remembering" and Olive focusing on students "understanding." However, this implementation varied depending on the content to be taught, with several teachers finding RP more suited to geometry courses than algebra.

While the teachers in this study had similar backgrounds in RP during their teacher training, we see that, in their first year of teaching, they emphasized different aspects of RP in their classroom enactment of RP. While individual differences are expected, our findings emphasize the flexibility of ways to integrate RP into teaching. That is, despite their differing individual personalities, teaching philosophies, and institutional contexts (Herbst & Chazan, 2011), each beginning teacher had a strong sense of the role of RP across aspects of their teaching. These teachers varied in the frequency and nature of discussion of the identified categories, but these categories provide a sense of the areas in which beginning teachers and pre-service teachers need support to integrate RP into their teaching.

Our study offers a methodological contribution, showing how computational language tools can be incorporated alongside qualitative approaches to understand the nuances with which participants speak about mathematical topics (Silge & Robinson, 2017). While we have described here how teachers' conceptualizations of RP in the classroom vary, future studies should examine whether and how these differences impact student learning.

Examining teachers' motivational views on Lakatos-style investigation: A value-cost-expectancy approach

Dimitrios Deslis[1], Andreas J. Stylianides[1] and Mateja Jamnik[1]

[1]University of Cambridge, UK; dd544@cantab.ac.uk

Despite the affordances of Lakatos-style investigation (LSI) for mathematics instruction, research has focused on students, and left a gap in understanding teachers' perspectives. To address this gap, we explore primary teachers' views on incorporating LSI in the classroom, focusing on perceived value, cost, and expectancy for themselves and their students. Through a survey with 331 participants, we found a generally positive inclination towards LSI, though perceptions vary by demographic factors. Female teachers perceive higher personal costs but also higher personal value, while older teachers report lower personal costs and reduced expectations of students. Academic background relates to teacher views, with stronger mathematical foundations linked to higher personal expectancy and lower perceived personal costs. These findings underscore that tailoring teacher education to demographic-specific factors may be crucial for promoting teachers' openness to LSI.

Keywords: Proof and proving, Lakatos-style investigation, primary school teachers, teacher views, value-cost-expectancy framework.

Introduction

Mathematical proof has long been a cornerstone of the mathematics discipline, and its significance in school mathematics is increasingly recognised (Stylianides et al., 2022). Despite this recognition, opportunities for students to engage with proof tasks remain limited, and even more limited are authentic proof-related activities that can expose students to the nature and genuine practices of mathematical inquiry, like the interplay between conjecture formulation and proof construction (Stylianides et al., 2022). This dynamic relationship, especially the critical role of example examination, is central to Lakatos' (1976) philosophical-historical account of the growth of mathematical knowledge. A growing body of educational research suggests that elements of Lakatos' account can effectively be incorporated into school mathematics, even at the primary level (Komatsu, 2016; Reid, 2002; Zack, 1997). By engaging with an authentic mathematical activity that has enabled historical advancements, students can develop an understanding of the nature of mathematics and the underlying principles of mathematical investigation, thus helping bridge the gap between academic and school mathematics (Stylianides et al., 2022).

However, research on integrating methods of mathematical investigation akin to those described in Lakatos' account into school mathematics has predominantly focused on students and on the design of classroom instruction, leaving a gap in the field's understanding of teachers' perspectives on such instructional approaches. Teachers' ability to facilitate proof-related activities is closely tied to their own understanding of proof (Deslis et al., 2021, 2023; Lada & Forbregd, 2022). Beyond capability, however, a crucial yet underexplored factor is teachers' willingness and motivation to incorporate Lakatos-style investigation into their classrooms. This paper aims to address this gap by exploring the following research question: *What are primary school teachers' views about the perceived value,*

cost, and expectancy related to Lakatos-style investigation, and how are these views associated with primary school teachers' gender, age, academic and professional backgrounds?

Theoretical Frameworks

Framework LSI: Lakatos-style Investigation

Building on Lakatos (1976) and classroom applications of his approach (e.g., Komatsu, 2016; Reid, 2002; Zack, 1997), we developed Framework *Lakatos-style Investigation* (LSI), which offers an iterative approach to conjecture exploration through systematic exploration (Deslis et al., 2021). This model, structured in four interrelated phases, describes participants' engagement in a dynamic process of conjecture development and refinement. Initially, solvers are presented with a proving task, prompting them to formulate a conjecture (*Phase 1: Formulation*). As they begin to check various cases, they may identify examples that appear to support the conjecture, suggesting its potential truth (*Phase 2: Validation*). However, they might also encounter counterexamples that challenge the conjecture's truth (*Phase 3: Refutation*). Reflecting on the attributes of both the supportive examples and counterexamples, solvers proceed to modify their original conjecture. This modification might involve narrowing the conjecture's scope to exclude the counterexamples or broadening it so that previously identified counterexamples now support the conjecture (*Phase 4: Modification*). The process then repeats, allowing for continuous refinement and deeper investigation of the conjecture. Past findings suggest that this activity is within students' reach; for example, Komatsu (2016) reports that fifth graders effectively used examples to develop a conjecture related to the sums of two-digit integers and reflected on the evidence provided by the counterexamples they discovered to refine it.

Framework VCE: Value-Cost-Expectancy

We developed Framework *VCE* (Value-Cost-Expectancy) by synthesising insights from research in educational psychology (e.g., Eccles & Wigfeld, 2020), education (Dixon et al., 2024) and mathematics education (e.g., Gaspard et al., 2015; Rach & Schukajlow, 2024) to examine the motivational factors that influence teachers' willingness to engage with LSI. The framework identifies three primary view dimensions that shape motivation: Value, Cost, and Expectancy. The *Value* dimension refers to the perceived *Importance*, *Usefulness*, and *Interest* that teachers associate with the activity. The *Cost* dimension involves the perceived cost in *Time*, *Effort*, and *Emotional* cost required to engage in the activity. The *Expectancy* dimension pertains to the anticipated *Ease* of the task, the anticipated *Competence*, and the anticipated *Likelihood of success*.

Crucially, Framework VCE posits that teachers assess these factors not only for themselves but also consider their implications for their students. Thus, each component is analysed through two distinct strands of view components: the *Teacher strand [T]* and the *Student strand [S]*, which span these three dimensions, resulting in six view components: *Value [T], Value [S], Cost [T], Cost [S], Expectancy [T], Expectancy [S]* (see Figure 1). For instance, when evaluating the costs of introducing a new activity into the classroom, teachers may consider how much effort this endeavour would demand both from themselves and their students, and whether the required effort is manageable for both themselves and their students. This dual-dimensional approach allows for a more comprehensive understanding of how motivational factors influence both teaching and learning in the context of LSI.

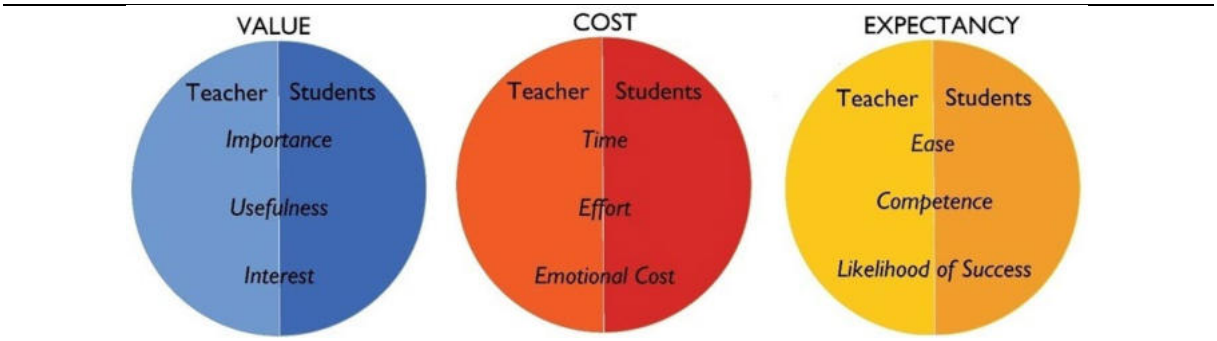

Figure 1: The three interconnected VCE dimensions: Value, Cost, Expectancy, and the six view components: Value [T], Value [S], Cost [T], Cost [S], Expectancy [T], Expectancy [S]

Methods

Data Collection

Data were collected using an online survey, which employed contextualised comic-style vignettes to illustrate classroom situations (see Figure 2). The survey was completed by a sample of 331 participants, comprising 149 in-service primary teachers, teaching at various schools across Greece, and 182 pre-service primary teachers, studying at nine different Greek universities. The vignettes depicted classroom episodes adapted from Zack (1997) and Reid (2002), featuring comic-style teacher and student characters exploring the "Count the Squares" problem (Zack, 1997): "How many squares are there in a four-by-four square grid? Try to design or imagine other similar grids of your choice. How many squares are there in each of them? Can you find a general rule that applies to grids of all sizes?" Specifically, the characters discuss the conjecture: "The number of squares in an n-by-n grid is a multiple of five" while navigating through all four LSI phases. The survey consisted of 16 short episodes, showcasing a diverse range of reasoning strategies, student understandings, and teaching practices related to the LSI phases. These episodes were developed based on insights gained from a prior interview study with ten primary teachers (Deslis et al., 2021) to probe various aspects of the participants' LSI-related mathematical knowledge (see Deslis et al., 2023 for more details).

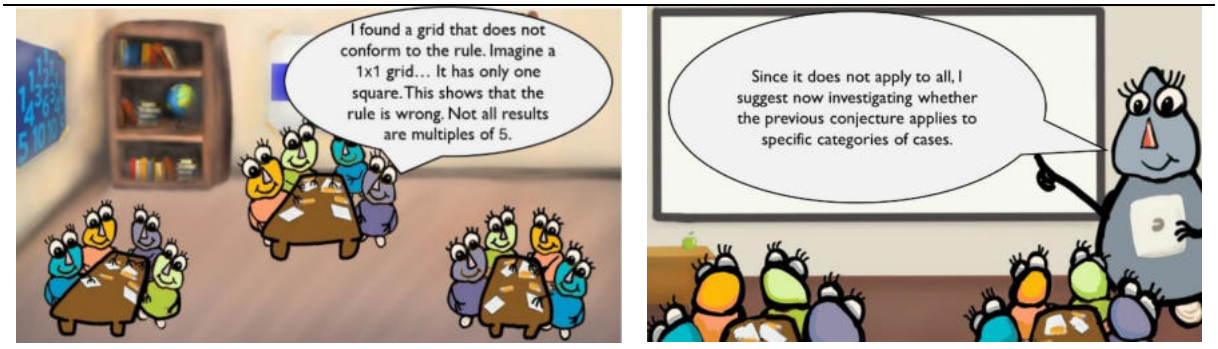

Figure 2: Two sample comic-style episodes pertaining to LSI Phases 3 (Refutation) and 4 (Modification)

Upon engaging with all 16 episodes, which offered participants a good sense of what this activity is and what it entails, they were invited to respond to 18 Likert-type items (ranging from 1: disagree to 5: agree), each corresponding to a sub-component of VCE (see Figure 1). For example, the following

item was used to address the sub-component Interest [S]: "*I think that students would find activities like this interesting*". These responses were transformed into 0–1 scores (0, 0.25, 0.50, 0.75, 1) for each view sub-component. The score for each view component was the average score of its sub-components (see Figure 1); for example, Value [T] = (Importance [T] + Usefulness [T] + Interest [T]) / 3 and Value [S] = (Importance [S] + Usefulness [S] + Interest [S]) / 3.

Data Analysis

Considering participants' VCE scores as the dependent variables and their demographics as the independent variables, we employed various statistical analysis techniques, adapting them to the nature of each independent variable: independent samples t-tests for binary variables, one-way ANOVAs for categorical variables, and linear regression analyses for continuous variables. Adopting an exploratory approach, each view score was tested against all independent variables.

Findings

Figure 3 below presents the mean scores for the six view components for the entire sample, and Table 1 gives an overview of the associations between view scores and demographics.

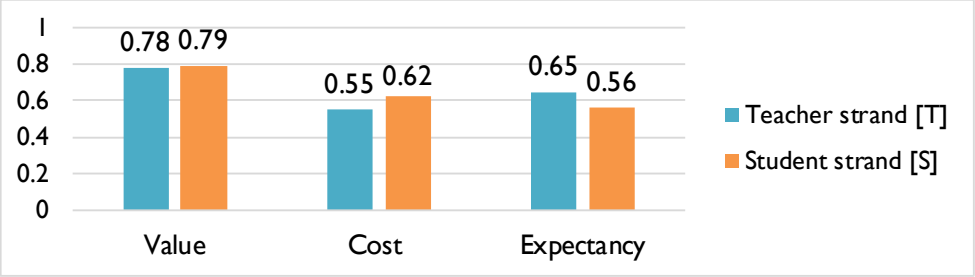

Figure 3: View scores by VCE component

Gender & Age. The t-tests revealed that female participants (n=281) perceived significantly higher costs for both students ($t(329)= 2.005$, $p < .05$) and teachers ($t(329)= 3.339$, $p < .001$), as well as a higher value for teachers ($t(329)= 2.198$, $p < .05$), compared to male participants (n=50). Specifically, the mean scores were higher for females in Cost [S] (M=.63, SD=.20 vs. M=.57, SD=.22), Cost [T] (M=.57, SD=.25 vs. M=.44, SD=.20), and Value [T] (M=.79, SD=.21 vs. M=.72, SD=.26). Gender was not found to be associated with any other view components.

Significant regression equations were identified for both Expectancy [S] and Cost [T] scores as functions of age. For Expectancy [S], the equation ($F(1,329)= 9.01$, $p < .01$, $R^2 = .027$) indicated that the predicted score is .658, decreasing by 0.003 for each additional year of age. Similarly, the regression for Cost [T] ($F(1,329)= 4.00$, $p < .05$, $R^2 = .012$) showed a predicted score of .636, also decreasing by .003 per year. No other view components were significantly associated with age.

Academic Background. The t-tests revealed a significant difference between pre- (n=182) and in-service teachers' (n=149) Expectancy [S] scores; specifically, pre-service teachers had significantly higher expectations of students (M=.61, SD=.17), than in-service teachers (M=.51, SD=.22), $t(329) = 4.685$, $p<.001$. Pre- and in-service teachers did not have any other significant differences.

In the final high school year, students select a direction of studies and take the Panhellenic Examinations, with subjects and university options varying by direction. Schools of Primary Education accept students from any direction, including those without mathematics. The t-tests showed that those who chose a direction including mathematics (n=89) perceived a lower personal cost (Cost [T], M=.48, SD=.23) than those who chose a non-mathematical direction (n=242, M =.58, SD=.24), $t(329) = 3.563$, $p < .001$. They also had higher Expectancy [T] (M=.72, SD =.17 vs. M =.62, SD =.20), $t(329) = -3.856$, $p < .001$. The differences for the other view scores were not significant.

According to t-tests, participants with a master's degree in education (n=136) had significantly lower expectations of students (Expectancy [S]; M=.50, SD=.21) compared to those without (n=195; M=.60, SD=.17), $t(329) = 4.823$, $p<.001$, but no other significant differences. Furthermore, no statistically significant differences were found in relation to PhD studies.

Participants who had taken compulsory mathematics education courses at undergraduate level (n=317) showed significantly higher Value [T] scores (M=.77, SD=.22) than those who had not (n=14; M=.64, SD=.22; $t(329)=-2.434$, $p <.05$), but non-significant differences in the other view components. Additionally, attending or planning to attend optional mathematics education courses (has attended or will attend: n=209 vs. n=122) was significantly associated with lower Cost [T] (M= .53, SD=.25 vs. M=.59, SD=.23) and higher Expectancy [T] scores (M=.67, SD=.21 vs. M=.61, SD=.18), while for the other view components no significant association was found.

Table 1: Overview of the associations between demographics and VCE scores (Note: —, non-significant)

	Value [T]	Cost [T]	Exp [T]	Value [S]	Cost [S]	Exp[S]
Gender (Female/Male)	F>M	F>M	—	—	F>M	—
Age (↑)	—	↓	—	—	—	↓
Pre-/In-service	—	—	—	—	—	Pre>In
Math direction	—	No>Yes	Yes>No	—	—	—
Master's	—	—	—	—	—	No>Yes
PhD	—	—	—	—	—	—
Compulsory math ed	Yes>No	—	—	—	—	—
Optional math ed	—	No>Yes	Yes>No	—	—	—
Teaching experience (↑)	—	—	—	—	—	↓
Upper primary/secondary	—	—	—	—	Yes>No	No>Yes
Public/private	—	—	—	—	—	—
School location	—	—	—	—	—	—

Professional Background. Single linear regression analyses were used to test if teaching experience significantly predicted any of the participants' scores. A significant regression equation was found

($F(1,291)=12.16$, $p<.001$) with an R^2 of .040. Expectancy [S] decreased .005 for each year of teaching experience. No other scores were significantly associated with teaching experience.

To investigate whether the grades participants had taught were associated with any differences, we employed ANOVAs with a categorical variable: 0 "No grade taught" (n=38); 1 "has taught, but neither upper primary, nor secondary grades" (n=104); 2 "has taught upper primary and/or secondary grades" (n=186), indicating significant differences in two components. Those taught in upper primary or secondary school had significantly lower Expectancy [S] (M=.53, SD=.20) than the other two groups (0: M=.62, SD=.14; 1: M=.60, SD=.20) ($F(2, 325) = 4.07$, $p < .05$). Additionally, this group exhibited significantly higher Cost [S] (M=.64, SD=.20) than those who had teaching experience but not in upper primary nor secondary school (M=.58, SD=.21) ($F(2, 325) = 4.03$, $p < .05$).

The results of the independent samples t-tests suggest that whether participants taught at a public or a private school at the time of the study was not associated with any significant differences. Likewise, the examination of various alternative binary or categorical variables related to participants' school location (e.g., large city vs. countryside) did not generate any significant differences.

Discussion

The findings reveal a generally positive inclination among participants towards incorporating LSI into their classrooms, as evidenced by the high perceived value for both teachers and students, the moderate perceived costs, and the cautious optimism reflected in their expectations (Eccles & Wigfield, 2002). The analysis also uncovered several interesting associations between teachers' demographic and professional characteristics and their views on LSI.

Female teachers perceived higher costs for themselves and students and greater personal value compared to males, recognising both the challenges and benefits of such activities. Gender-based differences have also been observed in other studies employing variations of the expectancy-value theory (Eccles & Wigfield, 2002). For example, in Gaspard et al.'s (2015) intervention targeting high school students' perceived task values, female students benefited more. These differences may stem from broader socio-cultural or biological factors, an interesting avenue for future research on LSI.

Age was linked to decreased personal cost, though the lack of association with teaching experience suggests broader professional development influences. Conversely, both age and years of teaching experience were associated with lower expectations of student success in engaging with LSI, reflecting conservative expectations likely shaped by classroom challenges. Shifts in motivation-related views as teacher grow older and gain teaching experience have also been reported in past studies. For instance, Dixon et al. (2024) found that the value and expectancy teachers perceive in pursuing postgraduate degrees evolved throughout their academic journey. Additionally, in this paper pre-service teachers exhibited higher expectations of students than in-service teachers, likely due to exposure to contemporary theories during training (Rach & Schukajlow, 2024), which could contrast with the pragmatic challenges faced by in-service teachers. Additionally, those who had taught upper primary or secondary grades reported lower expectations and higher costs for students, indicating that experience in higher grades might lead to a more cautious or even sceptical view of students' capacity to engage with advanced LSI. Furthermore, those with a master's degree, also had lower expectations of students, indicating that concerns about the practical challenges of implementing innovative

teaching approaches like LSI in the classroom are shaped by both classroom experience and teachers' postgraduate education (Dixon et al., 2024). Qualitative studies can illuminate why and how teachers' motivational views change with teaching and academic experience.

Academic background is also connected with teachers' views, particularly in terms of their perceived personal value, cost, and expectancy. Those who had attended compulsory mathematics education courses perceived greater value in LSI, likely due to their exposure to contemporary developments in mathematics education, which may foster a deeper appreciation for innovative teaching methods (Rach & Schukajlow, 2024). Additionally, teachers who pursued a mathematical direction in high school or took optional mathematics education courses demonstrated higher personal expectancy and lower perceived costs. This suggests that a strong mathematical foundation or a personal affinity for the subject contribute to greater openness and confidence in implementing new instructional approaches. In line with this, Rach and Schukajlow (2024) report that students strongly interested in school mathematics were more willing to put more effort in mathematics tasks, suggesting that such interest may play a reinforcing role in shaping their motivational views.

The findings have implications for the design of teacher education and professional development programs. Tailoring programs to address the specificities of different teacher demographics could be crucial. For instance, training programmes could differentiate strategies by addressing the high expectations of pre-service teachers while encouraging more mature teachers to maintain elevated expectations for student success. Furthermore, the significant influence of academic background on teachers' perceptions underscores the importance of strengthening teachers' understanding of mathematics education during teacher training (Rach & Schukajlow, 2024). Encouraging pre-service teachers to take additional mathematics education courses and providing ongoing professional development for in-service teachers could potentially enhance their confidence and reduce perceived costs. Overall, while mathematical knowledge should be a central focus in professional development programs (Lada & Forbregd, 2022), it is crucial to also address motivational views or the interactions between knowledge and motivational views (Deslis et al., 2023). Demonstrating the benefits and feasibility of implementing authentic mathematical activities like LSI (Stylianides et al., 2022) through examples and hands-on experiences, such programs could help increase teachers' motivation and willingness to incorporate these activities into their classrooms (Eccles & Wigfield, 2002). A limitation of this study is the multiple comparisons problem arising from the large number of statistical tests performed. This increases the likelihood of Type I errors, meaning some significant results could be due to chance. While this issue is common in exploratory research, the findings should be interpreted with caution, and further studies are needed to validate these results. Future research could expand on our findings by exploring similar questions in different cultural or educational settings or employing qualitative methods. Gaining a more comprehensive understanding of how various factors influence teacher views can inform professional development programmes, ultimately contributing to the more widespread adoption of innovative teaching practices like LSI.

A sixth-grade student's first instance of mathematical proof

Merve Dilberoğlu[1], Erdinç Çakıroğlu[1] and Çiğdem Haser[2]

[1]TED University, Faculty of Education, Ankara, Turkey; merve.dilberoglu@tedu.edu.tr

[2]University of Turku, Finland

This paper presents findings from an individual teaching experiment study investigating the mechanisms behind a sixth-grade student's transitioning from the empirical to the deductive proof scheme. From the set of learning goals targeted throughout the ten-week teaching experiment, here we[1] report findings related to a particular learning goal – understanding "a first instance of mathematical proof". We introduce this concept as a major "goal understanding" in one's transitioning towards the deductive proof scheme. Using the constructs "intellectual need" from the DNR-Based Instruction in Mathematics and "reflective abstraction" from the Learning Through Activity (LTA) theoretical frameworks, we illustrate designing for a sixth-grade student's –Beren's– construction of such a first instance of her own. Findings of the study provide theoretical insight (rather than practical) into individual's learning of deductive proof, regardless of age or grade level.

Keywords: Deductive proof scheme, DNR-Based Instruction in Mathematics (DNR), Learning Through Activity (LTA), individual teaching experiments.

Introduction

The empirical proof scheme, using a limited number of confirming examples to validate a mathematical generalization, is pervasive among students, and does not fade away effortlessly as individuals learn about disciplinary ways of proving (Harel, 2008). This makes transitioning from the empirical to the deductive proof scheme a two-fold learning goal: eliminating the empirical proof scheme and promoting the deductive proof scheme. The first aspect was addressed in Stylianides and Stylianides's (2009) study, where the researchers introduced an empirically tested instructional sequence. Engaging in the task sequence, the participants of the study realized the limitations of empirical arguments and developed an intellectual need for a secure method of validating mathematical generalizations. When the forthcoming instruction demanded construction of a valid proof, the participants were not able to do so without the researchers' scaffolding. The participants showed no evidence of anticipating what a valid proof would look like. We explored this second aspect of the learning goal – how to promote learners' transitioning toward the deductive proof scheme after the elimination of the empirical one – with an individual sixth grade student. The broader study explored the processes by which an individual sixth-grade student may (1) come to recognize a deductive argument as an instance of mathematical proof for the first time and then (2) practice producing other instances of proper proofs to develop the character of the deductive proof scheme. Here we focus on the former aspect only.

[1] We present this work as part of the first author's doctoral dissertation. We respectfully commemorate the contribution of her recently deceased supervisor, Prof. Dr. Erdinç Çakıroğlu.

Defining the first instance of mathematical proof

The idea of spotlighting a first instance of proof in one's transitioning toward the deductive proof scheme is grounded in Duality Principle of the DNR-based instruction in mathematics (DNR) framework (Harel, 2008). DNR is an acronym for three instructional principles: *duality, necessity,* and *repeated reasoning*. Duality is a two-part principle referred to by Harel as "Duality I" and "Duality II," addressed in the below quote as parts (a) and (b) respectively.

> Duality principle: (a) Learners come with a set of ways of thinking, some desirable and some undesirable, that inevitably affect the ways of understanding we intend to teach them. (b) Learners develop desirable ways of thinking only through repeated application of proper ways of understanding. (Harel, 2021, p. 711)

Ways of understanding are cognitive *products* of particular *mental acts* through which mathematics is practiced, such as proving, modelling, or defining. *Ways of thinking* are the *cognitive characteristics* shared by the multitude of these products. Mathematics is the discipline consisting of *all the ways of understanding* and *the ways of thinking* that the mathematics community has accepted throughout history (Harel, 2008). *Mental act-way of understanding-way of thinking* is a generalization of the triad *proving-proof-proof scheme* (Harel 2008). From this perspective, one's proof scheme is her/his way of thinking associated with the act of proving, and the particular proofs she produces are her/his ways of understanding particular acts of proving.

Duality I implies that the learners in Stylianides and Stylianides's (2009) study did not have the deductive proof scheme. Neither the empirical, since now was eliminated, nor the deductive proof scheme, which was not yet constructed, did frame the participants' subsequent acts of proving. Duality II suggests that the learners develop the deductive proof scheme by repeatedly experiencing proper ways of understanding proofs. However, how one can recognize a proper proof as such without having the deductive proof scheme yet. This suggests the students must undergo a cognitive shift at some point from not recognizing to recognizing a mathematical argument, a product of their own or someone else's activity, as an example of a valid proof for the first time. We refer to this moment as the first instance of mathematical proof.

Recognizing the first example of mathematical proof as a proper member of the category without yet possessing the deductive proof scheme is no different than a case of Learning Paradox (Pascual-Leone, 1976) —a consequence of the constructivist notion of *assimilation*. According to Piaget's theory of *equilibration*, experiences new to the individual are assimilated into one's existing concepts and operations (one's existing cognitive schemes) only if they produce expected results for the individual's actions based on the individual's prior experiences. The unfitting experience, which is contradictory to the individual's existing assimilatory structures, creates a *perturbation* (a disequilibrating experience) in the individual's cognitive structures and – not necessarily, as discussed in Simon et al. (2004) – leads to an *accommodation*. Referring to a rearrangement of one's existing schemes, accommodation is the process that re-establishes the desired state of equilibrium.

As raised in Simon et al. (2004), a disequilibrating experience may stimulate a process of accommodation – in Stylianides and Stylianides's (2009) study, the cognitive conflict mechanism

results in such stimulation –, but it does not necessarily result in constructive reorganization in the desired direction (toward the deductive proof scheme in this case). One possibility for the solution to the learning paradox was postulated by Piaget (2001) as the process of "*reflective abstraction*." Simon et al. (2004) elaborated on the construct as the *learner's reflection on the activity-effect relationship*, which later, constituted the basis for the Learning Through Activity (LTA) research program. LTA aims to explicate the mechanisms of mathematics conceptual learning by studying individual students' transition from one conceptual state to another (from not recognizing to recognizing a mathematical argument as a proof, in the case of current study). The basis for studying conceptual change here is the close observation of individual students' goal-directed activities, engendered by purposefully designed task sequences that are also evolving as the research study progresses. Simon et al. (2018) defines *concepts* to be *researcher's constructs* that are articulated at the beginning of such a research process to be able to work on and progressively refine the "goal understandings" that the study aims to promote. Concepts that are constructed through a *coordination of actions* type of reflective abstraction are defined as "*CoA concepts*." A CoA concept is "a researcher's articulation of intended or inferred student knowledge of the logical necessity involved in a particular mathematical relationship" (Simon, 2020, p. 123). Such concepts include not only the objects but also the logical necessity of the relationships among them.

Based on the view of CoA concept as a researcher's construct, this study investigated whether CoA type of reflective abstraction could frame the study of an individual student's constructing of a conceptual understanding of a particular proof (proper way of understanding associated with the act of proving) for the first time through *abstracting from* her/his activity. The intended concept of this study can be viewed as understanding the logical necessity of the relationships involved in a particular deductive proof. The initial hypothesis of the study was that, in line with the LTA instructional design approach (Simon et al., 2018), an individual student, in response to a given task, would engage in a sequential activity that would result in a flowchart proof when completed. Reflecting on the result of her/his activity, the student would have a chance to realize that she indeed created a proof for a specific mathematical generalization. The following research questions guided the study:

> How does (or may) an individual student come to understand a deductive argument as an instance of mathematical proof for the first time? Can a coordination of actions (CoA) type of reflective abstraction explain the process of such learning?

Methods

The 6th grade student, Beren (pseudonym), participated in the ten-week teaching experiment study. She was selected for the study based on her competence in four operations, ability to express mathematical ideas, and willingness to learn mathematics. As the deductive structure of mathematical proofs were not explicit focus of middle school curriculum in Turkey, she had no previous interaction with mathematical proof. The broader teaching experiment study consisted of five major phases. Understanding a first instance of mathematical proof was the focus of the third phase, after the first two phases prepared the student for the conceptions needed in constructing the intended CoA concept. The first phase prepared the student about basic number theory concepts (such as modular structure, parity, and divisibility) to be coordinated at the third phase. The representation system for arithmetic

number patterns, ($kq+r$), called "general representation," namely the idea of using identical counting items and identical cups containing equal number of these items, was introduced here. The second phase challenged the student's empirical proof scheme by adapting Stylianides and Stylianides's (2009) task sequence including the Monstrous Counterexample Illustration. This phase triggered an intellectual need (Harel, 2008) in the student for learning about secure methods of proving.

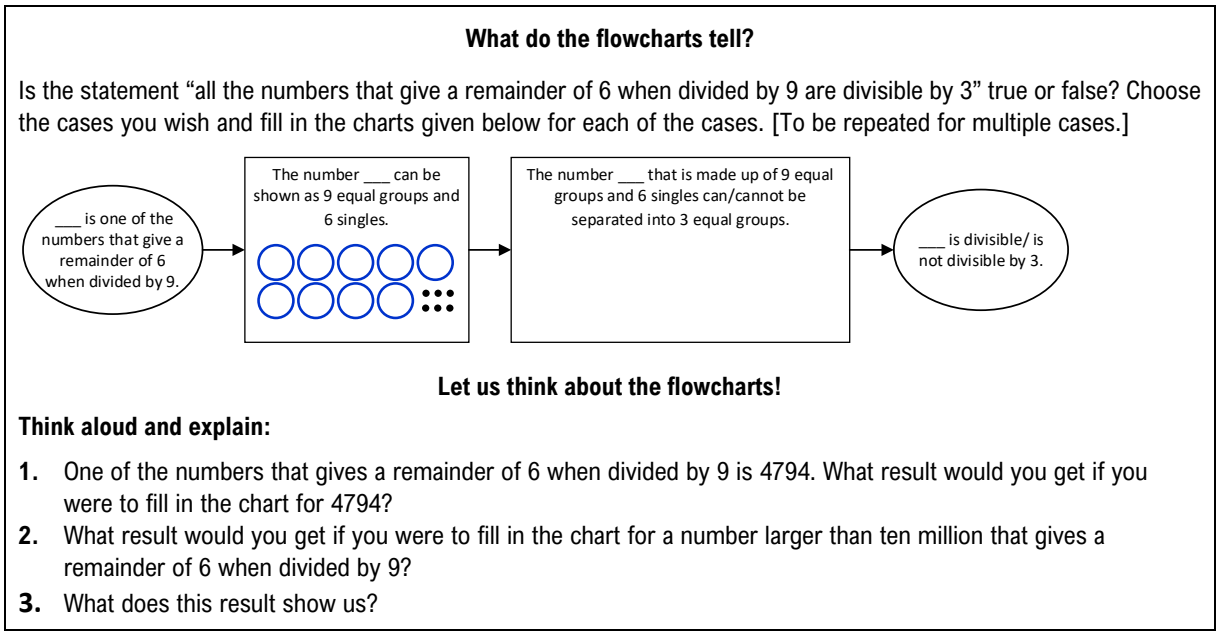

Figure 1: The modified task

The third phase consisted of two consecutive cycles, as the initial task design did not result in the intended learning. Both the initial task and the modified task (given in Figure 1) guided the student to carry out two consecutive actions sequentially to complete two distinct structures of flowcharts. In each case, reflecting upon flowchart activity, the student was expected to realize that the flowcharts indeed conveyed a new type of connected meaning beyond the distinct actions carried out, and this meaning was related to the goal of proving the conjecture being investigated.

While the activity elicited by the initial task started with constructing the general representation of a given arithmetic number pattern in a single flowchart, the modified task treated the elements of the pattern individually, in case-by-case flowcharts. The initial task failed to foster Beren's understanding of the structure *8k+4* as an *abstract structure* detached from the particular examples. Beren demonstrated a solid understanding of the one-to-one correspondence between the elements of the number pattern and the number of counting items contained in each of the cups for each of these elements. However, the intended shift of attention from seeing the representation *8k+4* as an expression of generality defining the set 12, 20, 28, 36, 44, 52, 60, 68, 76, 84, … had not been realized. Therefore, the modified task has built on the *operational* rather than *structural* origins of the concept of modular congruence (Sfard, 1991). The modified task guided the student to carry out the following two actions sequentially:

$A_{0a\ (modified)}$: Given a particular element of an arithmetic number pattern, identify its modular structure according to the given modulus n.

A_{0b}: Given a modular structure, make appropriate divisibility inferences.

As with the initial one, the modified task was expected to be the basis for the student's understanding of the logical necessity that the divisibility inference made about the particular modular structure is valid for all the numbers that share the same structure. Hence, the result of her activity ($A_{0a} \rightarrow A_{0b}$) is a proof to a particular theorem. Construction of the intended CoA concept was analysed based on the third-phase data by using the LTA theoretical account of conceptual learning (Simon et al., 2018). Any indications of understanding or lack of understanding of the deductive relations were captured through the observation of abstract structures revealed in students' thinking.

Findings

For the first case-by-case flowchart (see Figure 2) Beren selected the number 15. Thinking about the third box of the flowchart, her focus was on dividing the number 15 by 3, independently of its configuration in the general representation.

Beren: 15… Let me say this… Separable.
Researcher: How?
Beren: We separate five by five.

But then her focus shifted from the value of the number 15 to its specific form in general representation. Using the story, she had made-up previously in Phase 1, she drew 3 baskets with 3 cups and 2 singles in each, keeping an eye on the total number of cookies in every basket.

Beren: Christmas baskets again to be distributed among three persons. Inside these ones each (points to one of the cups) there is one. [The basket] consists of five. Others likewise. The number 15, one second, then, we should mark 'can be separated.' The number 15 is perfectly divisible by 3.

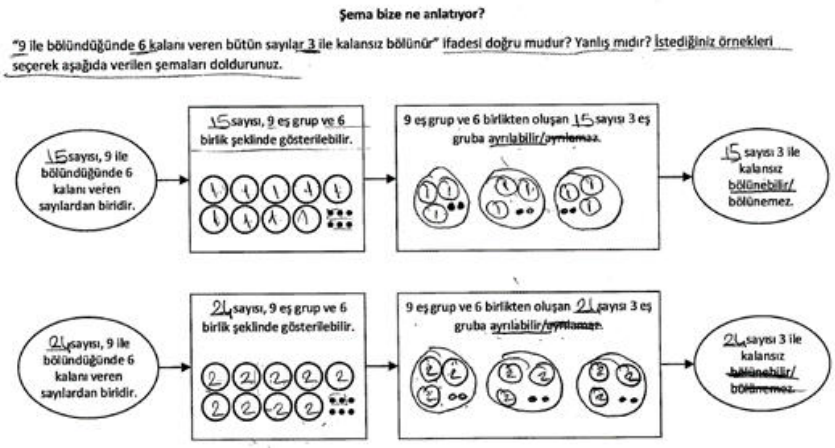

Figure 2: Beren's work on the case-based flowcharts for the numbers 15 and 24

For the second flowchart, she picked the number 24.

Beren: The number 24 that is made up of 9 equal groups and 6 singles can, cannot be separated into three equal groups. I am counting right now, 3, 6, 9, 12, 15, 18, 21, 24, it's ok (Her focus is again on dividing the number 24 by 3). (Drew three baskets.) Here (in the third step of the case 15) five (counting items) go in each (basket). How many go in here (in the case of 24)?

She first structurally mapped the third step look from the case of 15 to the case of 24. While doing this structural mapping, she demonstrated an instance of the intended abstract structure for the first time. That is, for Beren, 9k+6 instantly became a structure standing for itself, separated from the specific case of 24 being examined.

Beren: Three equal groups. Wait a minute, 3 okay. Same two of singles thing we will have. Two more will be in each of these (cups) and three of these (cups)… But it is not 24 then? (Probably thought each cup to contain a single cookie as in the previous case.)
Researcher: Why not?
Beren: No. Wait a minute. Whatever the number is. Okay I now understand (Seems to experience an a-ha moment). No matter what the number it is, my things here (points to the items in the second step) are the same. That means, again 3 cups and 2 single packs go in (each basket). Only the number inside the cup(s) changes. Okay, I got it. So, in total, this time, there will be […] 8 cookies.
Researcher: What is your decision? (When Beren came to marking the last box)
Beren: Can be separated. They all can be separated, in fact.
Researcher: What do you mean they all can be separated?
Beren: Well, think of it this way. You know, the number that is right here (Points to the number 24 shown in general representation as 9 groups of 2 singles plus 6 more singles), how can I explain it… It is not that the number 24 here when we actually look at it. I mean, you know it is (a thing) consisting of 9 equal groups and 6 singles.
Researcher: Yes.
Beren: It already. Well, let me say this way. This one is separable, in any way, it is separable into three equal parts and it is again three cups and two single packs. I can't put it into words but… is divisible by three.

Even if the intended abstract structure was observed in the second flowchart, the researcher encouraged Beren to work on further appropriate cases. She picked the numbers 33 and 42 for the next two flowcharts. Increasing the number inside the cups by one at a time, she consciously and purposefully recited the steps of the flowchart to match the same structure as in the first two ones. For each pick, she mentally did the division operation first (33:3 and 42:3) to check the result of the divisibility decision. She didn't seem as confident as she had just been when transitioning from the second to the third flowchart about the steps she was following. Only after making sure that the number selected was perfectly divisible by three, she drew three baskets in the third steps by rote, equally distributed cups and singles to each of the baskets and then marked the number of items in each of the cups to obtain the correct quotient (11 and 14). Then she considered choosing an "upper number" (üst rakam), as she put it. She selected 105 and calculated 11 items to go in each of the cups. This time she was about to make her decision without making the division operation 105:3. She attempted to reason based on the modular structure of the number 105 (refers to this structure as a "rule" in the below except). As she was not fully certain, Beren questioned whether the conjecture was a proven one or not. Unlike observed in the initial task, this time she ascertained herself by making a connection to the Monstrous Counterexample Illustration.

Beren: The number 105 […] can be separated. Why it can be separated? Because, in the end, it goes again with the same rule and all of them that go with this rule necessarily have to be. Well, it might not be proven, but I think it holds… It holds, isn't it? But wait a minute, it did hold, because that number… that day there was a number when I tried to read it, I couldn't read, starting with 30…. that in fact was a single number but I read as multiple numbers. Even if it goes up to those numbers, based on this thing (points to the step two), it already is divisible. Alright "divisible", that is it.

When she was asked to mentally run the flowchart activity for the number 4794 and a number that is greater than ten million, her reasoning was based on the same abstract structure again—the property of all the numbers in the conjecture domain.

Beren: You know this (step one) and this one (step two) already holds. This one (step three), as well. This one (step four) certainly holds as well. If, in here, one of them holds (points to the statement 'One of the numbers that give a remainder of 6 when divided by 9 is 4794.') […] again, divisible this is, because based on the digits (numbers) here (points to the configuration in box 2). Just I would have some trouble figuring out the number of cookies in each cup.

Beren: For a number greater than ten million […] I would again obtain the same result. If for example it was something around eleven million, again that number would be one of those numbers that gives a remainder of 6 when divided by 9. Again, that number can be shown as 9 equal groups and 6 singles. I just wouldn't know the number in the equal groups, well, which I would be able to find if I think and try.

She was certain of the truth of the conjecture. In the rest of the dialog, she used the expression "we prove" for the first time. Compared to her previous uses of the verb, where she attributed absolute certainty to an outside authority, here she expressed confidence in her decision.

Beren: After all, if we add 6 to one of the numbers that is a multiple of 9, it is already divisible by 3 without a remainder.

Researcher: Why?

Beren: We have already divided them into three here. And here we prove that it is divisible. And the reason is, well, for me there is not a reason for this. That just means all numbers that give a remainder of 6 when divisible by 9 can also be divided by 3 without a remainder.

Discussion

During her participation in the modified task, when Beren first detached the modular structure *9k+6* from the particular case being examined, the number 24, she also seemed to instantly have abstracted the logical necessity of the relationship whose correctness was being investigated. We interpret the two abstractions as having occurred simultaneously since the continuous data did not reveal any time lag in between. In Beren's expression, the two abstract structures appeared immediately after one another. First, she revealed an understanding of the structure *9k+6* as an invariant property of any and all of the numbers in the pattern "*15, 24, 33, 42, 51, 60, 69*, …" Then, she referred to this abstraction as the reason why the relationship between being a member of the pattern and being divisible by 3 was invariant.

Beren: No matter what the number it is, my things here (cups and counting items) are the same. (The first abstraction) That means, again 3 cups and 2 single packs go in (each basket). Only the number inside the cup(s) changes. (The second abstraction)

This marked the momentary abstraction of the intended logical necessity relationship. Beren utilized both abstractions together to explain why, in her words, "they (the elements of the pattern) all can be separated." However, this was only an instantaneous emergence of the intended structural understanding of the first instance of proof. While working on the subsequent case-based flowcharts for the numbers 33, 42, and 105, Beren did not maintain the logical necessity relationship that seemed to have been abstracted. Only after making a connection to the Monstrous Counterexample Illustration, while working on the case 105, the intended coordination of actions was completed.

This connection seems to have unexpectedly fostered a second reflection on Beren's way of thinking about the act of proving, leading her to relate the whole activity she engaged into the goal of proving. We speculate the twenty-six-digit number, from the Monstrous Counterexample Illustration, might have caused Beren to better envisage the extent of the conjecture domain to reflect on her abstraction as a *for all* argument (her way of understanding the particular relationship) and to reflect on her proof scheme (her way of thinking regarding the act of proving) to resolve the cognitive conflict she experienced previously in the second phase. Even though the intended learning took place only after introducing a modification to the initially designed task, Beren's learning from her activity provided supporting evidence for the initial hypothesis of the study, with a slight difference. Her abstraction of the intended logical necessity relationship was a result of the coordination of actions mechanism combined with her intellectual need for a secure method of proving.

A model-theoretic approach to didactic research on proof and proving in mathematics

Viviane Durand-Guerrier[1]

[1]University of Montpellier, France, IMAG, CNRS, UM, viviane.durand-guerrier@umontpellier.fr

Abstract – The model-theoretic approach developed by Tarski in the first half of the 20th century aimed at building a bridge between formal systems and reality, including mathematics. In this theoretical paper, we first present the main features of the model-theoretic approach, which we illustrate by presenting and discussing the axiomatic systems provided by Tarski for the foundations of arithmetic of real numbers. In the second part, we highlight and illustrate, on the basis of previous works, the value of a model-theoretic approach for didactic research on proof and proving in mathematics. This supports the claim that the model-theoretic approach developed by Tarski provides researchers with a logical framework for addressing critical questions about the dialectical relationship between syntax and semantics in proof and proving, from a didactic perspective.

Keywords: Didactics and epistemology of mathematics, model-theoretic approach to proof and proving, syntax, semantics, proof by interpretation.

Introduction

In a paper published in 2001, Hourya Sinaceur enlightened the fruitful contribution of Tarski to metamathematics:

> Tarski's specific contribution consisted in exploring the mutual relations between sentences and their mathematical models, showing that semantic analysis is furthered and not superseded by syntactic analysis and in weaving metamathematical and mathematical threads in a much tighter fashion than anyone had done before him. (Sinaceur, 2001, p.52)

This focus on the interplay between syntax and semantics and its relevance for clarifying the relationship between *truth* in an interpretation and *logical validity* was for us the main initial motivation for investigating the relevance of Tarski's perspective for didactic analysis. This relevance has been acknowledged in Durand-Guerrier (2008) for what concerns the relationship between truth and validity. It has been the logical background for much of our research since then.

In this theoretical paper, we first present the main features of the model-theoretic approach developed by Tarski in the first half of the 20th century (Tarski, 1994). We then illustrate this approach by presenting and discussing the axiomatic systems provided by Tarski for the foundations of arithmetic of real numbers. The second part of the paper is devoted to highlighting the value of a model-theoretic approach for conducting didactic research on proof and proving in mathematics.

All along the present paper, *logic* refers to *classical first-order logic* in which only variables that range over individuals are quantified, and the *excluded middle principle* holds.

Main features of a model-theoretic approach

As developed in Durand-Guerrier (2008, pp. 376–377), the initial step was done by Tarski with his definition of truth as "materially adequate" and "formally correct" (Tarski, 1983, p. 159). Tarski's

perspective was to bridge formal system and reality (the latter being either material reality, mathematical theory, or local theory): a proposition is true if it designates a state of things (Tarski, 1944). Although the term "model theory" appeared first in a publication in 1954, the model-theoretic approach was first developed in his book *Introduction to logic and to the methodology of deductive sciences,* first published in 1936[1].In the chapter VI of this book, *Methodology of deductive sciences*, Tarski introduced, by the example of the *miniature theory* of the congruence of segments, a method to associate to a given deductive theory a formal axiom system in which the statements of the initial deductive theory "become sentential functions containing as free variables those symbols by which the primitive terms have been replaced, and not containing any constant but those belonging to logic" (Tarski, 1994, p.117). This formal axiom system might then be reinterpreted using other *interpretation*s. In case the reinterpretations of all the axioms of the formal system are true, the new interpretation is a *model* of the axiom system. Of course, the initial given theory is a model of the axiom system. Then, Tarski proves an important result:

> Every theorem of a given deductive theory is satisfied by any model of the axiom system of this theory, and moreover to every theorem there corresponds a general statement which can be formulated and proved within the framework of logic, and which asserts the fact that the theorem in question is satisfied by any such model. (ibid., p.117)

This leads to what Tarski names *method of proof by exhibition of a model* or *proof by interpretation*. Let us consider the case where a sentence A in a deductive theory seems undoubtedly true, but we fail to find a proof.

> Thus, the conjecture arises that Sentence A simply cannot be proved from the axioms of the theory. In order to confirm this conjecture, we argue in the following way: if sentence A could be deduced from our axioms, every model of these axioms would satisfy the sentence; therefore if we succeed in describing a model of the axiom system that does not satisfies Sentence A, then we shall have obtained a proof that Sentence A cannot be deduced from the axioms [of the theory in question]. (ibid, p.116)

An elementary example of the construction of an axiom system and of the use of these two results is provided in the case of an item of the *Math Kangaroo* (In French *Kangourou des mathématiques*) in Durand-Guerrier (2008, pp. 377–379). This method of proof by interpretation can also be used to show that the Intermediate value property is not a theorem in the axiomatic theory of ordered fields with its natural topology (i.e., the topology generated by the open intervals). Indeed, $\mathbb{Q}$ with its standard order and the associate natural topology is a model of this theory but not a model of the property: it is true for certain pair (function, interval) and not for others. Adding an axiom of completeness provides a new axiomatic system for which $\mathbb{Q}$ with its standard order and the associate natural topology is not a model, while $\mathbb{R}$ with its standard order and the associate natural topology is.

[1] In this paper we use Tarski (1994), the fourth edition of the English version.

Tarski's axiomatic system for the foundations of arithmetic of real numbers

In chapter X of Tarski (1994), we find a presentation of an axiom system for the foundations of arithmetic of real numbers, which is based on an axiom system for groups developed and discussed in previous chapters (system A in the book). There are two ways to extend System A in this chapter. We will only present and discuss the first, which is sufficient for our purposes.

The new system A' contains four primitive terms: "$\mathfrak{R}$", "$<$", "$+$" and "1", and consists of nine axioms:

Axiom 1': If $x \neq y$, then $x < y$ or $y < x$.

Axiom 2': If $x < y$, then $y \not< x$.

Axiom 3': If $x < z$, *then there exists a number y such that* $x < y$ and $y < z$.

Axiom 4': If S and T *are any sets of numbers* (That is $S \sqsubseteq \mathfrak{R}$ and $T \sqsubseteq \mathfrak{R}$) *satisfying the condition:*

for any x *belonging to* S *and any* y *belonging to* T,

we have: $x < y$,

then there exists a number z *for which the following condition holds*:

if x is any element of S, and y any element of T, and

if $x \neq z$ and $y \neq z$, then $x < z$ and $z < y$.

Axiom 5': $x + (y + z) = (x + z) + y$

Axiom 6': *For any numbers* x *and* y *there exists a number* z *such that* $x = y + z$.

Axiom 7': If $x + z < y + t$, then $x < y$ or $z < t$.

Axioms 8': $1 \in \mathcal{R}$.

Axiom 9': $1 < 1 + 1$.

Figure 1. Tarski's first axiom system for Arithmetic of real numbers (Tarski, 1994, p. 202)

Axiom 1' to 4' concern the properties of the order relation. In chapter V (section 31, pp. 91–92) Tarski defines an order relation on a class K as a relation that is asymmetric, transitive and connected. Such a relation is also irreflexive. As an example, he mentions the relation *less than* that establishes an order in any set of numbers. This can also be expressed by *less than* is an ordering relation in any set of numbers, or by any set of numbers is ordered by the relation *less than*.

In the axiom system for the set of real numbers, Axiom 1' expresses that the relation is connected; Axiom 2' expresses that the relation is asymmetric.

It is the first occurrence in the book of axioms 3' and 4'. Axiom 3' corresponds to the law of density for the relation *less than* (a particular case of the law of density for a relation). Axiom 4' expresses the law of continuity for the relation *less than*. Tarski mentions that it is also named Dedekind's axiom. After defining a relation between two sets named "precedes", Tarski gives a very simple formulation of the axiom of continuity: "If one set of numbers precedes another, then there exists at least one number separating the first one from the second one". (p. 203)

In this form, this axiom captures our intuition of the continuum and fits the method developed by Dedekind in his essay "Creation of irrational numbers" (Dedekind, 1963).

In this axiom system (Figure 1), it is easy to prove the existence of a supremum for a bounded nonempty subset of the set of real numbers, a property of the set of real numbers which is often chosen as an axiom in French universities (another axiom often chosen is the convergence of Cauchy sequences), and then to prove that the intermediate value property holds in the ordered set of real numbers (with the standard order and the natural associated topology). Together with the bijection between the Cartesian product $\mathbb{R} \times \mathbb{R}$, and the plane (as set of points) with a cartesian coordinates system, this clarifies the back and forth between the algebraic and the geometrical register in Calculus (e.g. conjecturing the existence of solutions in some intervals in the graphical register, and then moving back to the algebraic register, using the intermediate value theorem to prove the conjecture).

While constructing this theory, Tarski uses his methodology of deductive sciences as mentioned in section VI of the book: the axioms are chosen to fit with our intuition of what should be true in the mathematical theory that we consider (here, the arithmetic of real numbers).

Then, this axiom system can be interpreted in a variety of mathematical domains, for example, in various sets of numbers. A question that could be raised is, do we really need to introduce Axiom 4', or would it be possible to derive it from the axioms 1', 2', and 3'? We know that it is not the case because of the incompleteness of the set of rational numbers that satisfies the System A", with all axioms of System A', except 4'. This is a proof by interpretation that Axiom 4' cannot be proved in the System A". The reverse question could also be raised: would it be possible to derive Axiom 3' from Axiom 4'? Here also, the answer is no; indeed, the set of natural numbers ordered by the standard order satisfies the System A"' composed of Axioms 1', 2', 4', 5' to 9' of System A', but does not satisfy Axiom 3': the standard order on the set of natural number is discrete, i.e. every element of the set of natural numbers has a successor; consequently, the following statement, which is the negation of axiom 3', is satisfied in the ordered set of natural numbers (with the standard order)

There exist at least two elements x, z such that $x < z$ and for any number y, $y \leq x \text{ or } z \leq y$.

This allows to point out the difference between dense non continuous (or incomplete) ordered set, such as the set of rational numbers or the set of algebraic numbers with the standard order *less than*, and dense and continuous (complete) ordered sets, such as the set of real numbers with the same standard order. Another interest of this axiom system is that it enlightens that discreteness, density, and continuity (completeness) are properties of order relations on a set, not of the set itself, given that different relations of order can be considered on a given set. There is research-based evidence that these two points are challenging for undergraduate students and secondary prospective teachers (Durand-Guerrier, 2016; Branchetti & Durand-Guerrier, 2023).

Value of a model theoretic approach for didactic research on proof and proving in mathematics

A fruitful theory for didactic analysis of mathematical activity

Logical matters are largely underestimated by teachers, as well in secondary school as at tertiary level, in particular concerning difference between novices and experts: an expert in a mathematical

field knows when it is dangerous to slack off the rigorous application of inference rules, while novices have to learn this at the same time as they acquire the relevant mathematical knowledge. These two aspects of mathematics cannot be learned separately. The back and forth between sentences and objects, syntax and semantics, interpretation and theory are at the core of mathematical learning (Durand-Guerrier & Arsac, 2005). From a didactic perspective, the model-theoretic approach developed by Tarski provides researchers with a logical framework for addressing questions about the dialectical relationship between syntax and semantics, which are critical in proof and proving, as emphasised by Weber and Alcock (2004). As Sinaceur (1991) states, for mathematicians, we consider that Tarski's construction of a definition of truth materially adequate and formally correct, and his project of bridging formal system and reality (including mathematical theories) provides an effective epistemology in mathematics education. This opens avenues for analysing mathematical activity and reconsidering the traditional assumption in mathematics education that there is a great distance between common sense and mathematical logic. In the following sections, we develop examples drawn from our own works to illustrate this fecundity

Fostering awareness of students of the role of theory in proof and proving in mathematics

As Mariotti (2006) points out, a theorem is a complex of a statement, a theory, and a proof of this statement in this theory. However, at secondary school and even in the first years of university, the theory is mainly left in the shadow. In other words, the logos bloc of praxeologies (Chevallard & Bosch, 2020) is most often reduced to technologies, which is likely to prevent students from being aware of the critical role of theory in proof and proving.

At the heart of the model-theoretic approach is a better understanding of the relationship between truth in an interpretation and logical validity in an axiomatic system: that is, accounting for the difference between a theorem and a statement that is considered true in an interpretation, but not provable in the corresponding axiomatic system. This was discussed in the 19th century by Bolzano (1817), who, unlike Cauchy (1821), did not accept proofs of the intermediate value theorem based on geometrical considerations, but looked for a proof in the theory of equations, where the statement was formulated. It was the first step that led to the creation of the sets of real numbers in the middle of the 19th century, bringing to the fore the issue of $\mathbb{Q}$-incompleteness versus $\mathbb{R}$-completeness. It is noticeable that this issue is almost never explicitly addressed in French curricula, since the set of real numbers is implicitly considered the reference set (i.e., the set of all numbers). Nevertheless, there is research-based evidence that students face significant difficulties when confronted with non-standard activities that require a genuine conceptualisation of the objects involved (Durand-Guerrier, 2016; Branchetti & Durand-Guerrier, 2023). Defining and proving are two intertwined practises that can be traced in the history of mathematics, and that we consider valuable for students to develop**.** In Durand-Guerrier (2022), we discuss this on the epistemological side in the case of real numbers and of infinity. Based on these studies, we argue that "emphasising the intertwining between *defining and proving* rather than the relationship between *definitions and proofs* opens new research avenues on students' practices at the secondary/tertiary transition". Durand-Guerrier and Tanguay (2018) highlight in the case of $\mathbb{R}$-completeness, "the importance of the way objects are defined towards molding the proofs, even when the approaches seem rather similar at first sight (e.g. defining real numbers as decimal expansions)" (p. 32**).** This highlights the importance of introducing undergraduates and future

teachers to activities that develop such practices, to raise their awareness of the importance of theoretical choices. In the case of completeness, beyond the issue of choosing definitions for objects, another challenge arises from the variety of possible axioms when moving to axiomatic systems of complete ordered fields (Bergé, 2010). An example of a multi-proof activity focusing on the Bolzano–Weierstrass theorem and designed to address this issue is presented in Durand-Guerrier (2024).

Dealing with incorrect proof of true statements

In addition to the well-documented reluctance of many students to engage with proofs of statements they consider obvious, there is also the difficulty of reconsidering an incorrect proof of a true statement. An example using the generalised mean value theorem is given in Durand-Guerrier (2008). More recently, we have provided an example (*Tilling by dominoes*) in a paper discussing logical issues at the interface between mathematics and computer sciences (Durand-Guerrier et al., 2019, pp.121–122). The problem is as follows: Given a rectangular grid (with integral dimensions), is it possible to tile it with dominoes (1x2 rectangles)? The answer is given by the theorem: *A rectangular grid can be tiled with dominoes if and only if its area is even.* A common (incorrect) proof of the above theorem given by students is the following: "a grid can be tiled by dominoes if and only if its area is $2k$ where k is the number of dominoes, which means that the area of the grid is even". Here, in Tarski's perspective, we can consider a kind of *miniature* theory whose domain is the sets of polyominos, a measure of area with the square as unit of measure; a domino is composed of two squares; its area is 2. An *axiom* (equi-decomposability of area): If an area can be decomposed into k subareas, then the measure of the total area is the sum of all the measures of the subareas.

Re-interpreting this miniature theory in the set of rectangular grids (a subset of the set of polyominos), the statement "*A rectangular grid can be tiled by dominoes if and only if its area is even"* is true. However, the above proof is incorrect. In fact, if the proof were correct, it should apply to any polyomino consisting of an even number of squares. It is easy to find a polyomino with an even surface that cannot be tiled with dominoes. This is a proof by interpretation, in Tarski's sense, that to prove the theorem for a rectangular grid, the miniature theory needs to be enriched.

This kind of argument can be used to convince students who have provided the above proof that it is not correct. In fact, it is an incomplete proof; it is necessary to prove that a rectangular grid (with integral dimensions) and an even surface can be tiled with dominoes, which may seem obvious to students.

Conclusion

In this paper, we intend to share with the audience how Tarski's model-theoretic approach has informed our research into proof and proving in general, and specifically in the case of the completeness/incompleteness of a set of numbers. However, this does not mean that this model-theoretic approach should be taught to undergraduate mathematics students or pre-service mathematics teachers. Rather, it is a conceptual framework to guide epistemological studies from a didactic perspective, as prolegomena to the design of didactic engineering (Artigue, 2020) aimed at

fostering proof and proving skills and, consequently, the conceptualisation of the mathematical objects at stake.

Justification not Proof as the Scope of Research: The RPA Model of Argumentation

Christian Fahse[1] and Tim Lutz[2]

[1]RPTU University of Kaiserslautern Landau, Germany; c.fahse@rptu.de

[2]University College of Teacher Education Tyrol, Austria

What kind of argumentation is shown when students try to convince an interlocutor in the context of division by zero? A grounded analysis of written argumentation leads to a classification into three groups: the RPA model. The empirically derived categories aim to provide insight (rich R-type), to imitate a mathematical argumentation (pseudo P-type), or to establish the reliability of the source of information (apodictic A-type). Attempts to proof are rare. While the R and A types are of obvious rationality, it remains an open question whether the P type follows a successful learning strategy. The empirical results are based on approximately 1,500 written texts on a special item that allows control and categorization by AI, a survey of argumentation skills at the level of learning groups, and a study of the quasi-longitudinal development of this competence.

Keywords: Argumentation, justification, discourse analysis.

Introduction

This is an exploratory study: How do students respond when asked to *justify* an opinion they hold? Will they show proofs or at least attempts to proof? A grounded analysis by inductive qualitative content analysis (QCA, Mayring, 2000) will deviate from the too narrow alignment to proof and decern any clusters. Moreover, this study does not have any particular interest in a theory of preliminary stages of proving activities, as there is already a substantial body of literature on this subject (e.g., Boero et al., 2010; Duval, 1991; Pedemonte, 2007). Instead, it focuses on the communicative purposes of any reaction to the stimulus "to justify" that is set by the task. Therefore, the main research questions of the study treated here are:

- (RQ1) What categories will be found?
- (RQ2) In what abundance?
- (RQ3) What is the quasi-longitudinal development, that is, the dependence on grade?

Due to the stimulus "to justify" and to connect this study to the existing literature, a review of definitions of the word field of "to justify" should be the first step. Three criteria are presented for the purpose of selecting appropriate definitions that will lead to the establishment of a special system of terms. The meaning of the terms for students is of importance and thus investigated, but not presented here. One of two long-term objectives of this study is to make a contribution to the monitoring of argumentation competencies on the level of learning groups, which is of interest for school development (see below). Another objective, not finished yet, is to provide a quantitative empirical review of the categories identified by Harel and Sowder (1998) in their influential paper, extending them beyond the scope of university students.

Theoretical background

There is considerable divergence in the literature with regard to the definitions of the basic notions in the conceptual field of argumentation (see Brunner 2014; especially the overview on p. 231). Even the term "proof" is not universally defined (Weber et al., 2022). Two factors contribute to the emergence of this ambiguity of terms and, consequently, of notions: The terms "argumentation", "justification", "explanation", and even "proof" are part of the everyday language register. As a result, there is a temptation to overestimate the degree to which others share one's concept images, especially, but not only, when translation is involved. Furthermore, the particular field of research requires a differentiation of the concepts in order to align them with the specific characteristics inherent to that field. To illustrate, if one is investigating university students, proof is a much more prominent feature and notions describing preliminary forms of proof would be useful. So, like in Fiallo and Gutiérrez (2017, p. 147), it is necessary to provide clear definitions of the terms used.

The literature contains a variety of argumentation typologies. It is possible to distinguish between argumentation and proof (Duval, 1991). Similarly, Tsamir and Sheffer (2000) differentiate between concrete and formal (algebraic) arguments, even with regard to division by zero. Following Pedemonte (2007) argumentations are based on a system of conceptions and related to conjectures either as "structurant" or as "constructive" argumentation. Furthermore, an argumentation may be classified as abductive, inductive, or deductive (Pedemonte, 2007, pp. 28–31). All these characteristics could be applied to our data set; however, as our study does not focus on proof, they do not adequately describe the variety of justifications found in our study. Harel and Sowder (1998) employ the term "proof schemes", which refers to "what the person offers to convince others" (p. 275). Apart from the choice of the identifier "proof", this fits well into the model of argumentation given below, aligning closely with our definition of justification, despite the criticism of this "subjective" approach by Weber et al. (2022, p. 66) as it "serves a psychological purpose", namely to convince. The classification scheme proposed by Harel and Sowder (externally conviction, empirical, and analytical proof schemes as superordinate categories; "analytical" is changed into "deductive" in Harel, 2008) will be compared to the findings of our study elsewhere. The proof scheme "external conviction" seems to be similar to our "apodictic" type (see below), but we do not identify the two terms to be able to discuss potential differences between our grounded found type and a rather theoretically structured proof scheme (second long term objective, see above).

It can be reasonably assumed that the majority of research concerning argumentation has been oriented towards the objective of developing effective pedagogical strategies for teaching especially proof, at least in a broad perspective. However, this article does not focus on proof per se due to both practical and theoretical considerations.

Firstly, it can be observed that proving activities are marginalised within the context of German schools. The national curriculum only makes reference to formal proofs as a particular instance on a continuum of argumentative activities, which also encompasses conjectures, plausibility arguments and empirical arguments (KMK, 2012). A survey of all 505 final examination tasks, published in the 2017-2024 "pool" of the national institute IQB indicates that the verb "to prove" was not utilized at all, whereas "to justify" was used 353 times (IQB, 2024). Thirty years ago, proof was by far more

prominent in classroom practice. The change may be attributed to several factors, including a higher percentage of students attending higher secondary schools, which has resulted in increased heterogeneity; a lack of constructive alignment, as cited above; the introduction of new subjects in the curriculum, such as statistics; and a resulting decline in the prominence of geometry, where the majority of proving activities had previously taken place. Secondly (and perhaps as a consequence), the data collected showed proofs to a limited extend, only. Thirdly, historically within our scientific community, the notion of proof was step for step expanded. Processes of exploring, of conjecturing (Boero et al., 2010), even of "inductive" proofs (Pedemonte, 2007) and other "informal reasoning" (Jones & Herbst, 2012) were also incorporated. The reason was to expand the scope, deepen the analysis (cf. Boero, 2017, argumentative activities in the "exploratory phase of proving"), and ensure greater relevance for existing classroom practice (cf. e.g. Fiallo & Gutiérrez 2017). Therefore, the defining feature of our study aligns with a broader developmental trajectory, on the one hand. On the other, here, argumentation is not taken as the antithesis to proof as proposed by Duval (1991), but rather as a generic term, with proof representing only one possibility among others.

In the following, definitions of the main terms are given in accordance with the following criteria: Firstly, they should be adapted to describe the data collected. Secondly, they should be consistent with the communication model employed and form a coherent system of concepts. Thirdly, they should be compatible with the language used in official documents related to the probe. In addition to these criteria, it would be beneficial to consider connections to existing didactical literature.

Following criterium three, **argumentation** has to be the generic term, encompassing proof, justification, explanation, and elucidation (KMK, 2012). It serves to settle or expand the shared content bases and rules of communication (Ger. "Rede" in the sense of Habermas, 1984). In the didactic literature, taking "argumentation" as generic term is found e.g. in Bezold (2009).

The communication model is a straightforward one (recurring among others to Habermas, 1984): Both the sender and receiver refer to a knowledge and communication basis, which they assume to be shared. The objects of justification are statements that are perceived as having varying degrees of plausibility by the two interlocutors. These degrees of plausibility are conceptualised as an ordinal structure, which models the attributed epistemic values. It is evident that this concept of argumentation is genuinely dialogic, encompassing the possibility that the receiver can also be an internal entity within the sender, or a universal audience.

Reasoning or **justification** represents a communicative reaction of the sender to a questioning of a statement by the receiver. The objective of reasoning is to increase the degree of plausibility of the statement under discussion by relating it to the basis of knowledge and communication that is assumed to be shared (Habermas, 1984).

A **proof** is constituted by a sequence of argumentative steps that rely on an accepted basis of statements, with the objective of establishing a complete logical chain of deductive steps (Duval, 1991). A mathematical proof is merely one method of justification among others, and its efficacy is contingent upon the mathematical abilities of the sender and receiver. For example, one student's proof step $7:0 = x \mid \cdot 0 \rightarrow 7 = 0$ may not be convincing to another student if the concept of equivalence transformation is not sufficiently understood. Weber et al. (2022) demonstrate that this extends even

to mathematicians, where the complexity of the proof, rather than the ability of the author, may necessitate supplementary inductive reasoning or socially constructed justifications.

An **explanation** (of "why", not "how" or "how to do") is an addressee-oriented justification with the aim of creating an "understanding".

These three different activities are not mutually exclusive but rather serve distinct purposes, namely plausibility, logical coherence, and understanding, which can be united. For instance, justifications may attempt to explain but may also just indicate reliable sources (see RPA model below).

The Study and method of analysis

Several items were pilot tested, each of which was assumed to evoke a variety of different types of justification (e.g. binomial formula, square root, statistical mean). The item presented here, division by zero, was chosen for a broader study because it showed the greatest variety of justifications. We asked the students to give the result of the division 7:0 and to "justify [their] opinion in a way that someone who doesn't know the answer is able to understand [the result]" (translation of the original task from German). The item was part of different tests administered to students in grades 7 to 13 in two secondary schools in Germany, as well as to pre-service teachers in their first lecture and in the middle of their studies, all in convenience samples (in fact, the study is being extended to 17 schools, but this part of the data is not yet available). Division by zero is covered in year 5 or 6. Different basic ideas about division are part of primary school education. The written responses of N=1442 students were analysed. In regard to the relative abundance of argumentation types, we report data from a subgroup of N=1185 students who did not take part in interventional courses.

The initial step of the analysis involved the application of a qualitative content analysis (QCA, Mayring, 2000) with inductive category development (grounded approach) to 365 texts from grades 7, 9, 11 and 13. Consequently, the student justifications were subjected to a multi-stage analysis. Initially, the texts were classified solely on the basis of their similarities, without any recourse to theoretical frameworks. Subsequently, the items were aggregated at an increasing level of abstraction, resulting in the identification of the various types of argumentation. To ensure reliability, a second step was conducted in which a pair of university students performed a separate "deductive category application" (Mayring, 2000, Section 4.2) using a coding manual describing the found types. The inter-rater reliability for this step was κ=.967 for the initial sample of N=365 texts. Further evidence on the reliability is provided by the accuracy of an AI classification by supervised learning, which achieved an accuracy of >0.93 (N=1442, size of evaluation sample 200). The AI tool (Lutz & Fahse, 2024), designed to assess argumentation skills, is currently available in German. A methodological decision that may appear surprising at first glance is that we do not assess the correctness of the responses. Our focus is on the capacity for argumentation, which we conceptualise as a construct that is not stochastically independent but nevertheless distinct from mathematical ability.

Results of the clustering by QCA (RQ1)

The QCA gives rise to three distinct types of argumentation, more specifically justification, forming the RPA model. Argumentations of a **rich (R-type)** nature are associated with an appropriate and well-structured mathematical domain, such as that pertaining to the distribution of quantities or

algebra (reversal of operations). The warrants employ basic concepts and are potentially useful even if the result may be erroneous. For example, "7:0=0 because no one gets an apple if there is no one to get any of the seven apples": This domain and the warrant are appropriate because they could lead to the insight that there is no answer to the question "How much does everybody get?" and this question is a correct potential modelling of division. There are operations – here the distribution, or more abstract, the change of representation. The rationale of this type is *to provide insight* (or, more seldom, a logical chain of arguments to check) *for a critical instance*.

The **P-type (pseudo-factual)** provides an answer that resembles a mathematical one; however, it is more concerned with appearing to be a genuine answer from a mathematics lesson than with offering insight or providing certainty for those who are critical. It employs unapt or poorly structured domains, sometimes fanciful (e.g., "All operations with 0 give 0" as an algebraic rule), and utilises only a limited number of operations. These cannot be improved to provide a rich answer, meaning they are essentially wrong. The rationale behind (why is it a justification?) is: "We do it always like this in mathematics much alike", the value is similarity.

In contrast to the first two types, which require a mathematical or content-based justification, the **A-type (apodictic)** provides reasons for the *reliability of the source* of the statement (information). There is no mention of mathematical domains or operations used for the warrants; instead, social authorities are referenced (in the broadest sense, including reference to the calculator or to the knowledge of the sender – "That's the way it is, I know it for sure.").

Results of the statistical analysis (RQ2, RQ3)

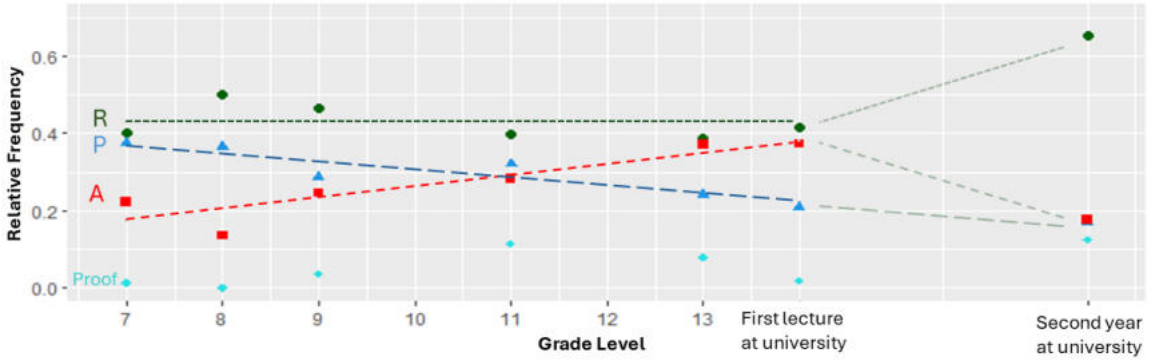
First and foremost, it is of interest to investigate the frequencies of the types in question (RQ2). In instances where more than one type is present, the cases are mapped in accordance with the rule "R before P before A". This rule, and perhaps the intention of the whole study, would be misunderstood if taken as a hierarchy of value between the three types, since the aim is to describe. On the contrary, the reason for the rule is logical: if a rich argument is presented, it achieves the objective of P, thereby rendering the attribution of P redundant. Furthermore, if R or P are identified in a text, the value of a mathematical justification is accepted, precluding the possibility of assigning A in a pure sense. It should be noted that all results are preliminary, as the study is still in progress.

With reference to Figure 1, which illustrates the quasi-longitudinal development (RQ3), it can be observed that Type R is about stagnating, P is descending, and A is demonstrating an increase. The most prevalent type is R, fluctuating about 40%. The other types are considerable, too, though they undergo changes over time. The proportion of P-type cases declines from almost 40% to about the half in opposition to the A-type, which roughly doubles from about 20% to almost 40% in the seven years. These two slopes observed for the initial 6 measurement times are significant, as indicated in Figure 1. The texts coded by "Proof" in Figure 1 (lower dots) are part of type R and comprise also texts only vaguely referring to multiplication as the inverse operation to division. Therefore, even when considering a favourable interpretation, there is a paucity of attempts to prove.

A comparison of the last two measurement times reveals a significant effect of the university, although it should be noted that only preservice teachers were included in the testing, here. They

obviously did significantly learn justifying but not proving in the same degree (the majority of them was preparing for primary school).

What is the effect of the teaching on argumentation in the various study groups? A total of 411 students belonged to 17 fixed study groups (only existing in grade levels 7 to 10, class sizes 19 to 29, mean 24.1). The prevalence of each type varies significantly with the different groups (Chi²-test in a log-linear regression with partialised grade, p<.001, D=81.1 for type R). The high value of the deviance indicates that the existing culture of argumentation within the study groups, implemented by different teachers, has a remarkable impact.



Number of students n=72, 88, 191, 78, 62, 518, 176 for grade 7 to university resp.. All cases with no answer to the division task were eliminated before. Linear model with slope significantly unequal 0 only for type P and A (t-tests, p=.009; .013 resp.).

Figure 1: Quasi-longitudinal development

Discussion

The study is limited by the use of convenience samples, which is somewhat mitigated by the sample size and the observation that the frequencies follow a satisfactory linear model. However, only the major trends are worthy of discussion in the following.

The substantial abundance of apodictic argumentation, a type of very poor justification that does not seek any understanding, could be irritating at first sight, particularly given its tendency to increase over time. It is, however, important to bear in mind that in communicative situations, the A-type perfectly fits the requirements of justification by increasing the plausibility of a statement. Thus, it is a pragmatic and sensible action, particularly well-suited in contexts such as engineering. In pedagogical practice, if the objective is to encourage an emphasis on comprehension, it would be both prudent and accurate to refrain from discrediting the A-type. Instead, it would be more beneficial to briefly address in class the various methods of enhancing plausibility, with an examination of the respective merits of each approach (plausibility independent of any mathematical ability of the interlocutors versus understanding and expanding networks of knowledge).

This recommendation relies on the communication model: The task presented to the student is to *justify* (which students do with appropriate rationality in R- and A-type), but we want them to *give* a mathematical justification instead. The latter is a request and does not serve the purpose of a justification in a real communicative situation. According to Habermas (1984), this confuses discourse (justifying) with communicative action (fulfilling a request). The teacher does not need to

be convinced as he/she is already aware of the veracity of the statement. Therefore, he/she cannot demand a proper justification other than in a simulated, purely artificial communicative situation. One implication for teaching would be to provide genuine problems (of pure mathematics or real contexts), where students attempt to convince each other and not a teacher.

What are the implications of this study? Firstly, it shows the relative frequency of the three types, indicating different ways of arguing that could, perhaps should, be discussed with students (without the abbreviations R, P, A): "Type A is appropriate when it is essential that the statement is true, for example in the context of engineering, or when the logical chain in a proof is completed by a mere reference to theorems known to be proven. Type R would be more appropriate in a different communicative setting, where the aim is to create understanding. The P type is only an imitation, but in mathematics similarity is meaningless: taking the double or the square root of 9 plus 16 seems to be similar, but the former is the double of 9 plus the double of 16, but the latter is not '3 plus 4'". The distinction between the two types A and R depends on the two interlocutors. If the proposition to which they are returning is understood and known by the receiver, no argumentation is needed at all, but only a reference. However, even in pure mathematics, the development of new theorems would be facilitated by a deeper understanding, which would lead to type R in line with our administrative regulations. In Germany, there is a consensus among didacticians and school authorities to cultivate overarching competencies such as argumentation and communication, conceptualised as a means of fostering comprehension in place of mere mechanical calculations. This suggests that formal operations should be accompanied by illustrative or explanatory activities (Ger. "Grundvorstellungen"). The extent to which a learning group has achieved this objective can be gauged in a relatively short time in the classroom using the item proposed here. The efficacy of the item is demonstrated by the markedly disparate frequencies observed at the learning group level, as well as the impact of an intervention, which is not discussed in this study.

Does the learning of mathematical argumentation through imitation (P-type) represent a futile pursuit or a valuable preliminary stage? In the field of foreign language pedagogy, the concept of inductive grammar is regarded as an effective and widely accepted approach to acquiring rules that are not too dissimilar from those encountered in mathematics. Our study indicates that the evaluation of type P in learning biographies is a relevant question for two reasons. Firstly, type P is a highly abundant type. Secondly, the instruction may play an important role, given the significant deviation observed across the different study groups. Nevertheless, the answer to this question is left to further research by longitudinal studies in the strict sense.

A framework for refutations to recipes and algorithms

Michael Fischer[1]

[1]University of Graz, Austria; michael.fischer@uni-graz.at

In many areas of mathematics, a systematic approach following a recipe or algorithm can be applied. Ideally, the individual steps, in the sense of a deductive structure of mathematics, should not only be mastered but also their validity should be justified through reasoning. In this way, conceptual knowledge can also be activated for procedural tasks. For this I adapt a framework developed for proofs and refutations to outline a task-based Lakatos-style intervention aimed at promoting conceptual argumentation. I accompany it with first results from an interview study.

Keywords: Lakatos, calculus, recipes, reasoning, argumentation.

Introduction

When mathematical proofs are addressed in the school curriculum, formal rigor is often not the primary focus (Meyer & Schnell, 2020). In late secondary education, there are several reasons for this, one being that many theorems in Calculus can only be proven in a traditional (often referred to as formal) manner, which is not feasible in the school context due to the lack of necessary mathematical tools. Argumentation in secondary education has therefore been identified by experts as an area needing further development (Sommerhoff & Brunner, 2021). In Calculus, an algorithmic approach or method-based recipe is often used instead, which includes tasks such as graphical differentiation (Fischer, 2024; Fischer & Krause, 2025). A common discussion in this context is whether such tasks are conceptual or procedural, with the latter allowing for the linear execution of a recipe (Sommerlade & Eichler, 2023), characterized by the sequential application of individual steps to complete a task. In practice, topics such as curve sketching are frequently criticized for being reduced to routine procedures, a tendency that has been further exacerbated by the widespread availability of function plotters, as already observed by Tall (1993) over 30 years ago. In the context of Calculus, Koichu (2008) therefore suggests focusing on the discovery of proofs by highlighting refutations. Lakatos (1976) views the handling of proofs and refutations as essential, emphasizing their role in the development of mathematical thinking. Based on his five heuristic rules, a framework for proofs and refutations has been established (Komatsu, 2016), which I adapt to recipes and algorithms. Following Komatsu (2016) this theoretical framework plays two roles interlinking research and practice, namely understanding and prescription (Komatsu, 2016).

Literature review and theory discussion

Argumentation and proof are essential components of authentic mathematics learning (Stylianides et al., 2022), yet the concept of reasoning and its relationship to these terms have so far been insufficiently clarified in the educational discourse. We use here the theoretical framework presented by Kirsten (2021, p. 26) for reasoning activities within Calculus. In this context, argumentation and proof are considered as subcomponents of reasoning, which overlap in pre-formal proofs. From a didactic perspective, pre-formal proofs can be often recognized as valid proofs, whereas in the context of university-level mathematics, they are often classified as argumentation (Jahnke et al., 2023).

While a proof may appear as a linear sequence of deductive steps, the actual process of proving follows a more intricate, non-linear line of thought, involving different phases of progress, exploration, adjustment, and revision. Lakatos (1976) described this process through five heuristic rules which were basis for a framework for proofs and refutations (Komatsu, 2016).

Lakatos's method of proofs and refutations is often criticized for its limited applicability but proves effective in specific mathematical domains, particularly in task design involving hidden assumptions (Stylianides et al., 2022). Many procedures and methods taught in schools often contain hidden assumptions or are presented in an incomplete form. A framework describing the structural activities when specific tasks lead to refutations of a naive recipe with a prescriptive nature could serve as a basis in creating task-based instructional interventions for the classroom, building on the ideas in Stylianides et al. (2022, p. 754). While frameworks for Lakatos-style proofing have been valuable for exploring pre-formal and formal proofs and refutations in the domains of arithmetic, algebra, and geometry (Komatsu, 2016; Larsen & Zandieh, 2008; Reid, 2002), to my knowledge no adaptation to the field of recipes and naive algorithms exists.

Research questions

Accompanying this, I address the following research questions: How can Lakatos' five heuristic rules be developed into a framework for recipes and can this framework be used as a prescription causing desirable behaviors in students, namely the use of conceptual knowledge when following recipes.

We present theoretical considerations based on the literature to develop the framework and demonstrate the application of it using an excerpt from an interview study to address the second question.

Model description of Lakatos' framework for recipes

In addition to proving, another form of argumentation in the classroom is "reasoning through the application of a procedure" (Jahnke et al., 2023, S. 374, own translation), which includes recipes and (possibly naive) algorithms. Similarities and differences between recipes on the one hand and theorems and their pre-formal proofs on the other can be outlined as follows, building on first suggestions in Fischer (2024a). Assumptions in a theorem ideally specify the minimal conditions under which the statement holds, making it clear that additional assumptions can restrict the validity of a statement. At the conclusion of the proof, based on premises, lemmas, and axioms, a mathematical theorem is deductively derived (Jahnke et al., 2023). Similar, assumptions in a recipe ensure its applicability to a task or a problem. Building on this, Weber & Tanswell (2022) argue that proofs and recipes are strongly related and that so-called recipe proofs are common in mathematical practice and in undergraduate mathematics textbooks (Tanswell & Inglis, 2022; Weber & Tanswell, 2022). Related, a recipe (or naive algorithm) consists of the process of applying individual steps, provided the assumptions on the input are met, until the output as the final product is achieved. Ideally, these steps are not merely followed procedurally; conceptual knowledge allows the users of the procedure to maintain some flexibility in the steps as well as to reflect on their correctness and justification (Oldenburg, 2022). A framework for recipes based on these similarities tells us which

parts of incidents one should focus on and how to construct a Lakatos-style activity in order to derive important actions based on conceptual arguments within the respective thematic field of the recipe.

For the reader's better understanding, we restate Lakatos-style reasoning, following Yang et al. (2023, p. 1): “First, a conjecture is constructed through conscious guessing (Phase 1). The conjecture is then tested using supportive examples (Phase 2). A proof may be constructed to further validate the conjecture (Phase 3). It is also likely that counterexamples emerge that refute the conjecture or invalidate the respective proof (Phase 4), leading to the refinement of the conjecture or proof (Phase 5). Still, it is important to note that Lakatos’ philosophy is more complex than this fivephase activity, highlighting also other important aspects, such as the crucial role of the interplay between defining and proving.” Additionally, a distinction is made between so-called local counterexamples (to a specific step in the proof) and global counterexamples (to the conjecture itself). Adapting this distinguishment to recipes, the former results in a modification of a recipe-step based on argumentation, while the latter leads to changes in the overall recipe, such as adjusting assumptions or incorporating additional steps.

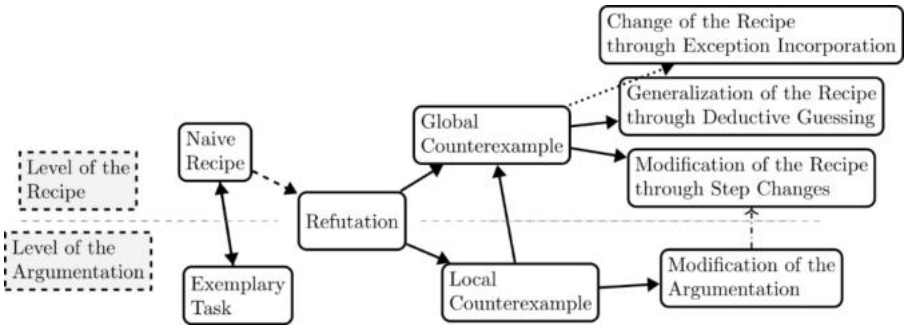

Figure 1: The framework from Lakatos, as presented in Komatsu (2016), adapted here for recipes.

Due to space limitations, it is not possible to present a complete adaptation of the framework in Figure 1. Instead, we primarily focus on Phases 4 and 5, which involve the identification of refutations, followed by a subsequent refinement of reasoning, the latter described in the original work by Lakatos (1976, p. 62) as the fourth heuristic rule: “If you have a counterexample which is local but not global, try to improve your proof-analysis by replacing the refuted lemma by an unfalsified one.”

Studies show that students often struggle to independently find counterexamples, but if they could do so, it would demonstrate a high level of conceptual understanding in the topic. Moreover, in the context of naive algorithms and recipes, students have often already received a proof by authority from a teacher or, for instance, an instructional video (Hanna, 1989), which they used exemplary multiple times. Therefore, this study design is created such that the refutations to students’ naive algorithms and recipes are presented by the interviewer respective the teacher after students developed their naive recipe (dashed line, Figure 1).

According to Weber & Tanswell (2022), the first two of the four levels of understanding a recipe involve executing a specific step of the procedure and understanding why that step can be applied. Similar to a refuted lemma in a proof, students must critically question the individual steps of the procedure when faced with a local counterexample. This occurs at an argumentative level in order to identify the step that is not properly applied or refuted. It is a central activity triggered by the local

counterexample, as this modification of argumentation may hypothetically form the basis for modifying the step, thereby leading to a modification of the recipe, adapted from Komatsu (2016). The latter occurs at the level of the recipe itself (dash-dotted arrow).

Additional Lakatos-style activities discussed in the context of math-education are “monster-barring” and “exception-barring” (Larsen & Zandieh, 2008; Reid, 2002). Adapted, the former refers to dismissing a counterexample on the grounds that it does not represent a true case application of the recipe or naive algorithm. The latter, termed “exception-barring”, refers to any response that modifies the recipe to tread the counterexample, without considering the recipe and its underlying reasoning (dotted arrow, Figure 1), it is therefore not a heuristic rule in Komatsu (2016). It may also include the addition of an extra step to handle exceptions (Larsen & Zandieh, 2008).

An explanatory episode

The data presented in the following originates from a task-based interview conducted as part of a research project focused on developing task design principles for argumentation in Calculus at the upper secondary level. Three interviews were conducted with first-semester mathematics students (BEd & BSc) using the Lakatos-style task sequence outlined below. Students were invited to bring a self-selected study partner to encourage observable communication within a group setting, as group interaction is closely linked to explanation and argumentation (Meyer & Schnell, 2020). These task-related interviews were recorded, transcribed, and examined according to the framework in Figure 1 following Mayring (2010). An important aspect of applying the framework is to analyze the students' argumentation in terms of its structural and content dimensions, as well as the processual aspects of their reasoning (Jeannotte & Kieran, 2017; Meyer & Schnell, 2020). The following excerpt serves primarily as an illustration of the proposed Lakatos-style intervention in Figure 1, rather than offering a comprehensive analysis of students' writing and cognitive processes during the task.

The initial task was to sketch the first derivative of a function represented by its graph f_1 (prompt: “Given is the graph of a function f. Draw the first derivative f'”) and then develop a recipe for this task (prompt: “Generalise the procedure just used as a general recipe”), explaining their steps with the help of the supportive example (Deslis et al., 2023). Accordingly, the interviewer then presented the students with a suitable counterexample f_2 to their recipe as illustrated in Figure 1 (dashed arrow), where solving this new task is ideally intended to lead to a revision of the recipe. Repeating this process subsequently leads to an iterative cycle of refining the recipe in a Lakatos-style activity (Deslis et al., 2023). Additionally, a pre- and post-test regarding reasoning in pre-formal proofs was conducted, results were discussed in Fischer (2024b).

The students first successfully draw the graph of the derivative. Then, referring to f_1' several times, they present their recipe which was summarised by the author as follows: M_1: Extrema of f become zeros of f', M_2: Inflection points of f become extrema of f', M_3: Determining the degree n of the polynomial f in order to deduce degree $n-1$ of its derivative f', M_4: Sign of the leading coefficient a_n of the polynomial to deduce the asymptotic behaviour of f'. Therefore, the graph of f_1' can be seen as a supporting example of their recipe, additionally the students explain M_3 and M_4 with an algebraic argumentation. The second task is again a 4th degree polynomial, but with a saddle point W, it leads to a discussion about a first sketch, traced with a finger, focussing on W.

S1: I have no idea whether this makes sense. Can this be an extremum?
S2: Yes, I just don't know. f' gives you the slope.
S1: I mean, the curvature changes. […]
S2: It [the slope] is negative, then it is zero and then it is negative again.
S1: Yes, we said that if the slope of the tangent is zero, - which is the case with the saddle point is zero, then it is also a zero, although it is not an extremum.
I: Shall we extend strategy?
S1: Yes, extrema in slope 0.
S2: When the slope is 0. [Word message almost simultaneously]

Student S1 initially does not use their recipe; the saddle point W can be viewed as a counterexample in her reasoning. Instead of relying on the recipe, she begins by making conjectures and examining other properties of the function, such as curvature, while searching for familiar similarities (Jeannotte & Kieran, 2017). Student S2 operates on the level of reasoning, classifying similarities between the saddle point and the extremum based on the slope of the tangent. Eventually, S1 agrees on an argument regarding the tangent slope, and together they sketch the derivative f_2' correctly. Despite the choice of words in the interviewer's question about extending the recipe, the students refine M_1.

Task f_3 is the graph of the normal distribution. The asymptotic behaviour should serve as a key sign here. Additionally, S1 and S2 face a problem at the beginning since f_3 is also not a polynomial.

S2: Oh man. Is it asymptotic [addressed to the interviewer]? Puh. So somehow with a fraction or, do you know what I mean? [addressed to S1]? Asymptote with fractions.
S1: Mm-hmm.
S2: I always associate them with fractions.
S1: Yes, but you don't have to.
S2: Yes, but I always associate them with fractions. [pause] But you can't see it as 2nd degree either.
S1: Hmm, but I have to say, I've never had to deal with a function that looks like this in school.
S2: Yes… [pause] So it must not take on any values that are negative, i.e. where $f < 0$. And it approaches the x-axis.
S1: But f' can still be 0.
S2: Yeahhh? [uncertain]
I: Let us just go through the steps?

The students initially focus on properties of the function that had not previously occurred, rather than applying their recipe. This only happens after prompting by the interviewer. The students later argue that M_3 and M_4 are not applicable for this task, it is solved correctly afterwards.

Discussion

The students begin by progressing through Phases 1 to 3. In the subsequent first excerpt, they recognize the saddle point as a counterexample. Their approach reveals a missing step for W in their recipe. The actions of S1 suggest that they are in Phase 4. Based on S2's response, however, the saddle point is subsequently treated as a local counterexample, leading to the identification and modification of the refuted step M_1 in their recipe. They do this based on an argumentative reasoning about the slope (Step 5). As a comparison, a second group of students S3 and S4, with a similar recipe, chose an alternative approach, commonly found in school books and online videos on the graphical differentiation task (Fischer, under review), treating saddle points as an exception and therefore a global counterexample. They added in the process an additional step. Contrary, S1 and S2 addressed

the conceptual relationship between a local extremum and a saddle point. Incorporating saddle points as exceptions removes the need for an argumentation based on the horizontal tangent slope, a fundamental concept of the derivative. In the following excerpt, the students work on the next item f_3, which presents a challenge. The horizontal asymptotes allow the students additionally to recognize that it is not a polynomial function. This leads to a metacognitive process. They do not resort to their usual recipe; this could be because they intuitively perceive f_3 as a global counterexample (Phase 4). However, rather than immediately resorting to "monster-barring", they begin with an information search and a sign analysis. They engage in a discussion about the mathematical content. Following the interviewers prompt they reason why they cannot execute steps M_3 and M_4, underlining the interpretation of f_3 as a global counterexample.

According to Tanswell and Inglis (2022), imperative forms and instructional statements are common in mathematical proof texts. This highlights both similarities and differences between proving activities and the application of algorithms and recipes, as I was able to outline based on the literature. Proofs are often structured like a recipe, relying on specific procedural instructions such as "take" and "choose" (Weber & Tanswell, 2022, p. 26). Similarly, recipes in school contexts frequently include hidden assumptions or are incomplete. However, the deductive nature of mathematics underscores that the steps of a recipe or algorithm can be understood or justified through reasoning. Building on this, reasoning about individual steps in algorithms, also an essential aspect of computational thinking, should take center stage in mathematics education and serves as another potential application of the framework (Oldenburg, 2022). Therefore recipes, when embedded in instructional tasks, provide opportunities for students to confront and resolve refutations, promoting conceptual understanding.

As outlined, the proposed framework aims to describe an intervention leading to a Lakatos-style investigation cycle, which we applied in the context of Calculus, where proving activities are often not feasible. Building on these ideas, I adapted a framework describing the structural activities when specific tasks lead to refutations of a naive recipe. It has a prescriptive nature and serves as a foundation for creating task-based instructional interventions for the classroom (Komatsu, 2016), aligning with the ideas in Stylianides et al. (2022, p. 754). This framework provides guidance on which parts of incidents to focus on and how to construct them to derive meaningful actions for conceptual arguments in the context of recipes (Komatsu, 2016). The importance of item selection must also be highlighted, as it plays a critical role in guiding students' reasoning. Refutations presented by the author were designed in such a way that students could easily identify a specific sign constituting it as a counterexample. The detailed task development process further underscores the need for additional exploration and research, particularly in teacher education. This is essential because the instructional approaches outlined in the literature can be challenging to apply in practice (Deslis et al., 2023; Stylianides et al., 2022; Yang et al., 2023).

Nonetheless, the results presented here are based on a single sequence of tasks in Calculus involving two first-year students. Yin (2009) suggests that individual case studies are justifiable when the case plays a critical role in theory development. In this regard, showcasing the process of students refining their recipe and modifying their reasoning, as described by the proposed framework, even in a single case, is significant. The results must now be further tested with additional items and in the classroom.

In this process, the students' reactions in dealing with counterexamples should be analysed to gain insights regarding prediction and generalization — two further roles in which theory acts as an intermediary between research and practice (Komatsu, 2016).

Investigating the relationship between negating competence and understanding proof by contraposition: A study with Indonesian undergraduate mathematics education students

Hapipi[1,2] and Andreas J. Stylianides[2]
[1]University of Mataram, Indonesia; hapipimath@unram.ac.id
[2]University of Cambridge, UK

Undergraduate mathematics students tend to have difficulties understanding proof by contraposition in which the concept of negation plays a significant role. Despite this significance, there is a lack of research investigating whether and how students' competence in negating statements is associated with their understanding of proof by contraposition. In this paper—which derives from a broader, ongoing study—we aimed to address this gap by analysing survey data from 87 fifth-semester undergraduate mathematics education students in Indonesia. The findings indicate a strong relationship between students' ability to negate statements–particularly conditional statements and single statements–and their understanding of proof by contraposition. These findings have significant implications for the teaching of proof by contraposition.

Keywords: Proof, negating competence, proof by contraposition, undergraduate mathematics.

Introduction

In addition to proof by contradiction (PBCd), proof by contraposition (PBCp) has been identified as another challenging indirect proof method for students (Antonini & Mariotti, 2008; Brown, 2017; Buchbinder & McCrone, 2020; Stylianides et al., 2004). Although research investigating students' understanding of PBCp is scarce compared to other proof methods, some issues regarding students' difficulties with this proof method have been identified: Students tend to lack adequate ways for validating contrapositive argumentation as a legitimate form of reasoning (Yopp, 2017, 2020). Also some students hold a "child logic" issue (Hoyles & Küchemann, 2002) considering that a conditional statement is equivalent to its converse, or that a contrapositive statement is the same as its inverse (Stylianides et al., 2004), thus failing to recognize that a conditional statement is equivalent to its contrapositive (Buchbinder & McCrone, 2020). Furthermore, students tend to find contraposition more challenging to understand in a symbolic form than in a verbal context (Stylianides et al., 2004). The inference method of justifying PBCp, known as modus tollens, is intuitively more challenging for students compared to modus ponens, which is one of the inference rules for direct proof (Antonini & Mariotti, 2008; Yopp, 2020).

Given that PBCp is based on the concept of negation, particularly as it starts by negating the conclusion of the given conditional statement, it is notable that no studies thus far seem to have investigated this relationship. In this paper, we take a step towards addressing this gap by focusing on the following research questions: *Does undergraduate mathematics education students' competence in negating statements associate with their understanding of PBCp? If so, in what ways?* This paper derives from a broader, ongoing study, and it is a continuation of our investigation of the role of students' negating competence in their understanding of indirect proof methods, which started with our investigation of this relationship in the area of PBCd (Hapipi & Stylianides, 2024).

Theoretical framework

Understanding proof

As discussed in Hapipi and Stylianides (2024), the concept of understanding in this study, rooted in the perspective of Baumberger et al. (2017), Sierpinska (2005), Skemp (2006), and Dewey (1971), denotes the profound ability to grasp meaning beyond mere recognition of facts. It entails an awareness of relationships, causes, consequences, and contextual intricacies within events or situations. To practically assess students' understanding of PBCp, this study adopts six criteria (Hapipi & Stylianides, 2024), drawing on the frameworks of Mejia-Ramos et al. (2012, 2017) and Anderson et al. (2001): (1) understanding the meaning of terms and statements, (2) evaluating the logical structure of statements and proof frameworks, (3) justifying claims, (4) summarizing using high-level concepts, (5) identifying modular structures, and (6) illustrating with examples.

Negating competence

Lin et al. (2003) explored four types of quantifying statements (all, some, only one, and none) in their study of students' understanding of PBCd, while Inglis and Simpson (2008) examined four types of conditional statements ($p \to q, \sim p \to q, p \to \sim q,$ and $\sim p \to \sim q$) in their study on conditional inference within the context of mathematical studies. Reflecting on this work, we defined negating competence as students' ability to negate a group of statements fulfilling the following three criteria, and we operationalized this definition in an instrument called the Negating Instrument (Hapipi & Stylianides, 2024). First, the statements encompass various types, as indicated by Lin et al. (2003) and Inglis and Simpson (2008). Second, the content of these statements aligns with participants' previous coursework, minimizing the likelihood that their ability to negate would be influenced by a lack of understanding of the statements. Lastly, the instrument includes the context of PBCd and PBCp when addressing conditional statements ($p \to q$), as negation can work similarly when dealing with PBCd and PBCp. Both proofs start by negating q; however, in PBCp, this is the only initial step, whereas in PBCd, it serves to simplify the negation of $p \to q$. The instrument captures this context by including statements asking students to negate $p \to q$ and separately to negate q and p.

Regarding the role of negation in the indirect proof methods of PBCd and PBCp, Hapipi and Stylianides (2024) reported that, in the context of PBCd, students' negating competence shows a significant association with their understanding of PBCd. Specifically, they found that students' competence in negating single or quantified statements significantly influences their understanding of PBCd. Interestingly, they also reported that students' ability to negate conditional statements did not show a significant link with their understanding of PBCd. Since PBCp applies exclusively to conditional statements, it would be worthwhile to investigate how students' understanding of PBCp relates to their ability to negate various types of statements.

The role of negation in PBCp

Given that PBCp is a proof method that demonstrates the truth of a statement by proving the truth of its (logically equivalent) contrapositive statement (Antonini & Mariotti, 2008; Thompson, 1996), the role that the notion of negation plays in this proof includes at least three aspects (Figure 1). First, at the beginning of the proof, PBCp starts by negating the conclusion of the conditional statement. Second, near the end of the proof, PBCp results in providing a statement that negates the premise of

the conditional statement. Lastly, at the conclusion of the PBCp, especially when distinguishing between negation, which contradicts the original statement, and the contrapositive, which is logically equivalent to the proved statement.

Steps of PBCp for a given statement $p \rightarrow q$	Logical structures of PBCp	Negation involved
Assuming the negation of the conclusion q is true	Assume not q	Negating the conclusion
This leads to producing a negation of the premise p.	leads to Not p is true	Resulting in negation p is true.
This results in producing a contrapositive statement for the given statement.	results in $\sim q \rightarrow \sim p$ is true	Contrapositive VS negation of conditional statement
As the given statement and its contrapositive are logically equivalent, this leads to the truth of the given statement.	hence $p \rightarrow q$ is true	

Figure 1: The logical structure of PBCp and the role of negation within it

Methods

This paper derives from a broader mixed-methods research study that employed survey and interview techniques to explore how undergraduate mathematics education students understand PBCd and PBCp, and their association with direct proof. Due to space limitations, in this paper we focus solely on relevant findings from the survey segment of our study. The study included 87 fifth-semester Indonesian undergraduate mathematics education students, all of whom had prior exposure to proof methods and proof-related tasks in their coursework. The participants completed two instruments in Indonesian: first, the Negating Instrument; second, the Understanding ContraProof (UCP) Instrument, which comprised six packets, three related to each of PBCp and PBCd.

UCP Instrument

The UCP Instrument, which we developed based on Mejia-Ramos et al.'s (2012, 2017) proof comprehension framework, comprised three components in each packet: a (mathematical) statement, its corresponding PBCp or PBCd, and questions that aligned with the six framework categories we mentioned earlier. Some of the contents related to PBCp were adopted from Brown (2017), while others were constructed, inspired by, or modified from Chamberlain (2017) and Mejia-Ramos et al. (2012). Four experts reviewed the instrument before it was piloted twice.

The questions within the UCP Instrument were presented in both open-ended and multiple-choice formats. Participants' responses to the open-ended questions were scored from 0 to 4. The scoring scheme was inspired by Stylianides (2019) and Stylianides and Stylianides (2009), where a score of 0 indicates a wrong answer with a wrong or no reason; 1 represents a wrong answer with a correct or partially correct reason; 2 signifies a right answer with a wrong or no reason; 3 indicates a right answer with a partially correct reason; and 4 signifies a right answer with a correct reason. Meanwhile, for the multiple-choice questions, a score of 1 indicates a correct answer, and a score of 0 is assigned for all other responses.

Negating Instrument

In the absence of an existing instrument or criteria for measuring negating competence in relation to PBCd or PBCp, this study developed one based on the three criteria mentioned earlier, under Theoretical framework. The instrument asked students to negate statements in the form of conditionals (CondS) and statements involving quantifiers (QuantS). It also required students to negate q and p within statements of the form $p \rightarrow q$ (SingleS). The content of these statements was drawn or adapted

from materials of courses that the students had previously attended, such as calculus, elementary algebra, number theory, logic and set, and real analysis.

Participants' responses were scored on a scale from 0 to 4, based on a scheme inspired by Stylianides (2019) and Stylianides and Stylianides (2009). A score of 0 denotes no response, 1 indicates an incorrect answer, 2 signifies an answer with a major mistake, 3 reflects an answer with a minor mistake, and 4 represents a correct answer. Figure 2 provides examples of coding for participants' responses negating the statement, 'If x is not a member of interval $[0,1]$, then $x^2 - x$ is positive'.

Students' responses and their translation	Scores	Notes
x bukan anggota interval [0,1] tidak x^2-x tidak positif x is not a member of interval [0,1], but $x^2 - x$ is not positive.	4	Correct answer
x bukan merupakan anggota interval [0,1] dan x^2-x negatif x is not a member of interval [0,1], but $x^2 - x$ is negative.	3	The participant wrote negative instead of not positive
Jika x tidak merupakan anggota interval [0,1] maka x^2-x negatif If x is not a member of interval [0,1], then $x^2 - x$ is negative.	2	A kind of negation but not proper and written in the wrong form, conditional form
Jika x merupakan anggota interval [0,1], maka x^2-x positif If x is a member of interval [0,1], then $x^2 - x$ is positive.	1	This is not negation. The premise is negated and expressed in wrong form
No answer	0	

Figure 2: Examples of coding for students' responses on the Negating Instrument

The instrument was piloted twice, demonstrating good reliability, as indicated by a Cronbach's alpha of 0.90 and an average interitem correlation of 0.41 (Acock, 2023). Results from confirmatory factor analysis, along with convergent and discriminant validity, also indicate the instrument met acceptability criteria (Hapipi & Stylianides, 2024).

Analysis

Participants' responses to the UCP and Negating Instruments were coded by the first author, referring to the predetermined key answers and coding scores. This process was conducted twice, a week apart, to ensure consistency. A student's individual understanding of PBCp was determined by averaging their score across six equally weighted criteria and then scaling the result by a factor of 10. Their negating competence was calculated by dividing their total score by the ideal maximum score and multiplying by 10. Correlation and regression analyses were then performed to examine the association between students' negating competence and their understanding of PBCp. The regression results do not show a causal relationship (Mehmetoglu & Jakobsen, 2017) between these two variables, but the theoretical framework in Figure 1 offers a basis on which to explain the findings.

Findings

Relationship between understanding PBCd and negating competence

Spearman's correlation was performed to explore the relationship between students' negating competence and their understanding of PBCp. Table 1 shows the summary results of the analyses.

Table 1 shows a strong correlation between students' ability to negate statements and their understanding of PBCp, with an overall correlation of $r(85) = .58, p < .001$. Moreover, students' competence in negating Conds, QuantS, and SingleS shows strong positive connection with their understanding of PBCp, with correlation coefficients of $r(85) = .41, p < .001$, $r(85) = .42, p < .001$, and $r(85) = .54, p < .001$, respectively. Additionally, students' ability to negate the conclusion and premises of statements specific to PBCp indicates a positive link with their understanding of the respective PBCp, with a correlation coefficient of $r(85) = .49, p < .001$.

Table 1: Correlation among negating competence and understanding PBCp

Categories	N	Understanding PBCp
All types of statements	87	0.58***
CondS	87	0.41***
QuantS	87	0.42***
SingleS	87	0.54***
Conclusion and premises of statements specific to PBCp	87	0.49***

* $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$

A significant positive correlation means that high scores on negating competence tend to be paired with high scores on understanding PBCp, while lower scores on one align with lower scores on the other. This association indicates that as participants perform better on negating statements, they are more likely to have a better understanding of PBCp as well. To further investigate these relationships, linear and multiple regression analyses were conducted, and their results are presented below.

Influence of negating competence on understanding PBCp

Regression analyses examined how students' competence in negating statements influences their understanding of PBCp. Table 2, column 1, shows that students' competence in negating statements significantly influences their understanding of PBCp, as indicated by the coefficient of 0.80 ($t = 6.73, p < 0.001$). The regression model is also statistically significant ($F(1, 85) = 45.29, p < 0.001$) and explains approximately 35% of the variance in students' understanding of PBCp (R-squared=0.35), with a low root mean square error (RMSE = 1.49). The model meets the assumption of linearity, as well as normality and homoscedasticity of residuals.

A multiple regression analysis examined how students' competence in negating specific statement types affects their understanding of PBCp (Table 2, column 2). The results show that students' competence in negating conditional (CondS) and single statements (SingleS) significantly influences their understanding of PBCp, with coefficients of 0.43 ($t = 2.34, p < 0.05$) and 0.36 ($t = 3.61, p < 0.01$), respectively. Meanwhile, students' ability to negate statements involving quantifiers (QuantS) has no significant effect, which seems to be understandable since PBCp, as illustrated in Figure 1, only works with conditional statements. Moreover, the model is statistically significant ($F(3, 83) = 15.15, p < 0.001$), explains about 35% of the variance in students' understanding of PBCp (R-squared = 0.35), and has a low root mean square error (RMSE) of 1.50. The model also satisfies the assumptions of linearity, normality and homoscedasticity of residuals, and no multicollinearity among the independent variables.

Additionally, students' ability to negate the conclusions and premises of statements proved using PBCp significantly affects their understanding of the respective PBCp, as shown by a regression analysis 0.39 ($t = 5.11, p < 0.001$) in Table 2, column 3. The regression model is statistically significant ($F(1, 85) = 26.10, p < 0.001$), with an R-squared value of 0.24, explaining about 24% of

the variance in students' understanding of PBCp, and it meets assumptions of linearity, as well as normality and homoscedasticity of residuals.

Table 2: Regression analysis results between negating competence and understanding PBCp

	(1) Understanding PBCp	(2) Understanding PBCp	(3) Understanding PBCp
Negating Competence	0.80***		
	(6.73)

Discussion and conclusion

This paper elucidates the importance of students' ability to negate statements for understanding PBCp. Working with negation during PBCp is crucial, as having a clear understanding of the concept of negation is required at least in three different stages of PBCp, as shown in Figure 1. Our findings indicate that students' negating competence, particularly negating conditional statements (CondS) and single statements (SingleS), contributed to their understanding of PBCp. Moreover, this study found that students' ability to negate the conclusions and premises of the conditional statements proven using PBCp significantly influences their understanding of the respective PBCp. These findings seem to be reasonable for two reasons. First, as noted in Figure 1, PBCp starts by negating the conclusion of the given conditional statement, so students' ability to negate the conclusion is essential for understanding the proof. Second, the ability to negate conditional statements presumably helps students distinguish between negation and the contrapositive of the conditional statement. Moreover, this competence

might ease students to follow the flow of PBCp as PBCp works with conditional statements. Therefore, these findings shed further light on aspects, in addition to those suggested by Hoyles and Kuchemann (2002), Stylianides et al. (2004), Buchbinder and McCrone (2020), and Yopp (2017, 2020), that could shape students' understanding of PBCp.

Interestingly, the significant effect of being able to negate conditional statements only appears on students' understanding of PBCp but not PBCd as reported by Hapipi and Stylianides (2024). On the other hand, negating quantifying statements which significantly affected students' understanding of PBCd (Hapipi & Stylianides, 2024) does not affect their understanding of PBCp. These findings seem to be important in the context of indirect proofs for three reasons: they confirm the importance of negating competence in PBCp and PBCd, clarify which type of statements are relevant to each proof methods, and highlight specific negating competence to emphasize when teaching negation in relation to PBCp or PBCd.

Despite the study's contributions, certain limitations and areas for future research remain. First, the UCP Instrument included only three statements with their respective PBCp, which may not fully capture students' understanding of PBCp across broader mathematical topics. Future research could benefit from a wider range of statements. Second, the Negating Instrument and its criteria need further testing in broader contexts, as they were developed and initially tested in this study.

Proving the rule for fraction multiplication: What kind of content knowledge is visible in preservice teachers' arguments?

Andrea Hofmann[1] and Trond Stølen Gustavsen[1]

[1]University of South-Eastern Norway, Norway; andrea.hofmann@usn.no

In this study, we investigate how preservice teachers construct written arguments for the rule for fraction multiplication after having worked with tasks designed in view of proof-based teaching. The aim was for the preservice teachers to explore fraction multiplication through paper folding and visual diagrams, and in this process develop content knowledge for fractions and competence in proving. We analysed written arguments of 28 preservice teachers in their fourth year of study. From our analysis we found that while most preservice teachers did not succeed in constructing a valid general argument or a proof, relevant content knowledge of fractions was visible in the arguments. We suggest that proof-based teaching can be a fruitful approach to facilitate the development of content knowledge for teaching both fraction multiplication and proving.

Keywords: Proving, proof-based teaching, fractions, teacher knowledge.

Introduction

Reasoning, argumentation and proving are central activities in the discipline of mathematics, but also in school mathematics. Proofs can have different roles, such as verification, explanation, systematization, discovery and communication (de Villiers, 1990). De Villiers (1990) emphasizes that proofs that explain are important for developing understanding for *why* a given statement is true. In Norway, there is an increased focus on reasoning and argumentation in school since the curriculum from 2020 (in short: LK20) includes "Reasoning and argumentation" as a core element (Ministry of Education and Research, 2019). Research suggests that it can be demanding for students to understand proof and proving, and that students often rely on examples in proving tasks and consequently provide empirical arguments and not valid general arguments (Aricha-Metzer & Zaslavsky, 2019). Additionally, research indicates that many students struggle with fraction tasks, which can constitute an obstacle since the learning of fractions and fraction operations is essential in further learning of mathematics (Siegler & Lortie-Forgues, 2017). Izsák (2008) suggests that "teachers' understanding of fraction multiplication (and division) is limited" (p. 100). Ball et al. (2008) discuss content knowledge that is necessary for a teacher to have. Stylianides and Ball (2008) argue more specifically that teachers' knowledge of proof is important and needs to comprise different aspects, such as "knowledge of situations for proving" (including "knowledge of different kinds of proving tasks") and knowledge of the logical and linguistic structures of proofs.

Since research points out the importance of content knowledge for teaching and difficulties that students might encounter with both fraction operations and proving, we wished to investigate preservice teachers' (PTs) knowledge within these two, more specifically, PTs' knowledge for proving the rule for fraction multiplication, and how reasoning and proving can be naturally integrated into the process of developing content knowledge. Utilising proof-based teaching (Reid & Vallejo Vargas, 2019), we engaged PTs in fraction multiplication tasks, with a goal for the PTs to further develop their reasoning skills and content knowledge for teaching the topic of fraction

multiplication (Izsák, 2008; Ball et al., 2008). In addition, as future teachers, they were supposed to reflect on how this kind of activity could be used with students in school.

The study reported in this paper is part of a larger project, where our aim is to develop proof-based teaching of fractions, both in school and in teacher education. In Hofmann and Gustavsen (2024), we analysed written work of 20 preservice teachers in the teacher education program for grades 1–7 in their first year of study. In the present paper, we extend the method of analysis in our previous short paper (Hofmann & Gustavsen, 2024) using a more detailed coding regarding aspects of fractions. Furthermore, we contrast our previous study by analysing a more advanced group of students. The PTs whose written work we analyse for the present paper, were in their fourth year of study and had chosen to specialize in mathematics education. One might expect that their skills in proving, reasoning and argumentation were developed further than the skills of PTs in their first year of study. Our research question is as follows: *How can we characterize advanced mathematics preservice teachers' arguments for the rule for fraction multiplication?*

Theoretical framework

Proof-based teaching

Proof-based teaching is a way of teaching where one seeks to integrate the learning of mathematical content knowledge into the learning of proving skills. One aim of proof-based teaching is that learners develop conceptual understanding in mathematics. One expectation in this way of teaching is that "the learners themselves conjecture and prove important theorems in mathematics" (Reid & Vallejo Vargas, 2019, p. 809). The proofs produced are expected to explain, as well as to verify the result (Reid & Vallejo Vargas, 2019). We use the definition of a 'proof' in school mathematics as in Stylianides (2007): A *proof* is a

> connected sequence of assertions for or against a mathematical claim, with the following characteristics: 1. It uses statements accepted by the classroom community (*set of accepted statements*) that are true and available without further justification; 2. It employs forms of reasoning (*modes of argumentation*) that are valid and known to, or within the conceptual reach of, the classroom community; 3. It is communicated with forms of expression (*modes of argument representation*) that are appropriate and known to, or within the conceptual reach of, the classroom community. (Stylianides, 2007, p. 291)

When preparing and implementing proof-based teaching of specific mathematical content, one needs to have in mind a 'framing theory' that "guides the development of teaching activities and their implementation in the classroom" (Reid & Vallejo Vargas, 2019, p. 809). The framing theory contains, among others, a 'tool-box' (can be compared to 'set of accepted statements' in Stylianides (2007)), and theorems that the learners are supposed to produce proofs of (target theorems) (Reid & Vallejo Vargas, 2019).

When we refer to a 'generic example', we use the concept as in Balacheff (1988), namely viewing an "object … as a characteristic representative of its class" (Balacheff, 1988, p. 219). In addition, we apply Reid and Vallejo Vargas (2019) in the sense that we require a "clarification that the example shown … is meant [to] be generic" (Reid & Vallejo Vargas, 2019, p. 811). Reid and Vallejo Vargas

(2019) express the opinion that "generic examples accompanied by explicit clarification of their intended generality are appropriate *forms of expression* at the middle school level" (p. 811), and Aricha-Metzer and Zaslavsky (2019) propose that the use of generic examples in the process of learning to prove can be productive.

Representations of fraction multiplication

Behr et al. (1983) proposed a model for the rational number construct comprising seven subconstructs, among those being part-whole, operator, measure and quotient. One way to introduce fraction multiplication is through the operator subconstruct, e.g. represented through paper folding (Wyberg et al., 2011). In this study, we focused on two representations that can be used for multiplication of two proper fractions: paper folding and drawings of grids. Paper folding can help students to visualize the process of fraction multiplication and to understand why the rule for fraction multiplication works (Wyberg et al., 2011). On the other hand, the use of manipulatives can also "interfere with their [childrens'] logical-mathematical thinking" (Behr et al., 1983, p. 108). Behr et al. (1983) also point out that the transition and interpretation from physical manipulatives (in this case paper folding) to symbolic representations (in this case grid with symbols) can be demanding for students.

Mathematical knowledge for teaching fraction multiplication

Ball et al. (2008) discuss content knowledge such as correct understanding of fractions as part of a whole. Izsák (2008) investigates mathematical knowledge for teaching fraction multiplication in depth and highlights the importance of teachers' knowledge of pedagogical use of drawings as representations in fraction tasks, of the operator subconstruct (multiplication as operator) and of change of unit in fraction multiplication. Izsák (2008) shows that, while the part-whole subconstruct of fractions is fundamental, in the operator subconstruct, when a fraction operates on another number, teachers must navigate several part-whole relationships to be able to produce drawings and explanations that can facilitate students' conceptual understanding of fraction multiplication.

Methods

The first author together with a teacher, conducted a teaching session of approximately three hours length in a master course in teacher education, in two classes separately. In this paper we focus on one class of PTs. The tasks in the session were designed in view of proof-based teaching of fraction multiplication, initially by the authors and three researchers, and then developed further in iterations by the authors and the teacher participating in the session. The PTs were in the primary and lower secondary school teacher education program (both grades 1–7 and grades 5–10, the majority from the grades 5–10 program), in their fourth year. All PTs were specializing in mathematics education in a five-year program culminating in a master thesis in either mathematics education (most of the PTs) or pedagogy. The master course the PTs attended included the discussion of theory and research literature on reasoning and proving. Our aim with the session was to introduce the PTs to representing fraction multiplication with paper folding and to initiate the process of proving the rule for multiplying two proper fractions. The PTs were 28 in total and arranged in groups of 3–4. The session started with a task where the PTs were asked to represent some fractions using paper folding. Then fraction multiplication was introduced as part of a part and exemplified with paper folding. In groups,

the PTs worked with the next two tasks, in which they were invited to fold and interpret several fraction multiplications and record the processes and the results (for that purpose we introduced tables on a whiteboard). The final task was answered individually. In this final task, the PTs were requested to give a proof of the rule for fraction multiplication. There was an emphasis on that the PTs' arguments should explain *why* the rule is true, using drawing and text. In addition, the PTs were asked to use variables to express a general argument. This task was framed in a way that it should be an argument given to a fellow PT, i.e. we view it in the context of a classroom community of PTs. In this session, we linked multiplication to the operator subconstruct, meaning that $\frac{a}{n} \cdot \frac{b}{m}$ is the same as $\frac{a}{n}$ *of* $\frac{b}{m}$ ($a \leq n,\ b \leq m$ and $n \neq 0,\ m \neq 0$). The statement (target theorem) that guided our development of the sequence of tasks and our analysis is the following: *Consider a grid with* m *equal columns and* n *equal rows. Assume that* b *of the columns are colored. In the restricted grid consisting of the* b *columns, suppose that* a *rows are colored once more. Then the part of the grid that is colored twice, is a representation of* $\frac{a}{n} \cdot \frac{b}{m}$ *and* $\frac{ab}{nm}$*, and thus these two expressions are the same.*

In the first part of the session, we used paper folding and coloring as one representation of grids and fractions. For the written task, we asked the PTs to draw a diagram, since utilising diagrams allows for a wider range of examples and a generalization, whereas using paper folding has limitations in that respect.

Analysis

We coded written arguments given by 28 preservice teachers in response to the final task described above. Since we were interested in the PTs' competence in developing a proof, we used the categories in Stylianides and Stylianides (2009) and adapted them to our setting, e.g. the "classroom community" in the definition of proof as in Stylianides (2007) is the class of preservice teachers: *proof* (according to Stylianides' (2007) definition of proof; use of generic example is included here; code M1), *valid general argument but not a proof* (deductive argument that applies "to all cases in the domain of the statement" (Stylianides & Stylianides, 2009, p. 239), but that for example is not "within the conceptual reach of the classroom community" (Stylianides, 2007, p. 291); code M2), *unsuccessful attempt for a valid general argument* (i.e. invalid or incomplete argument, but where an attempt of generalization was made evident; code M3), *empirical argument* (PT explained the truth of the statement in one or more examples, but did not make explicit an attempt to generalize; code M4) and *non-genuine argument* (non-mathematical or irrelevant argument, or the "response was potentially relevant but the relevance was not made evident" (Stylianides & Stylianides, 2009, p. 245); code M5). To supplement the codes M1–M5 in Stylianides and Stylianides (2009), we added the codes, "argument explains why the rule is true in a particular example", "uses generic example" and "uses variables to express generality". For instance, the codes "uses generic example" and "uses variables to express generality" can give us more detailed information about the arguments coded as M1, M2 or M3. In addition, we were interested in how aspects of content knowledge of fractions were reflected in the PTs' arguments, and we thus added the following codes for our analysis: "uses correct drawing", "refers to part-whole", "refers to operator" and "change of unit made explicit". The code "change of unit made explicit" was used when the PTs explicitly stated that when they take a fraction $\frac{a}{n}$ of a fraction $\frac{b}{m}$, the fraction they start with $\left(\frac{b}{m}\right)$ becomes the new whole. The code

"argument explains why the rule is true in a particular example" was added because we saw some (partial) explanations in arguments that were coded as M4 (empirical argument), while several arguments coded as M3 did not include sufficient explanations (i.e. this is an inductive code). We wish to emphasize that we do not view the categories M1–M5 as hierarchical. Both authors coded the written work of all the PTs independently, compared codes and discussed disagreements. Consensus was reached for all disagreements.

Findings and discussion

We coded the PTs' written arguments according to M1–M5 and aspects of content knowledge for teaching fraction multiplication as mentioned above. Our findings regarding the categories M1–M5 are presented in Table 1 below.

Table 1: The number of arguments in the categories M1–M5

M1	M2	M3	M4	M5
0	3	12	9	4

In all the three arguments that were coded as M2, variables to express generality were used. One of the three arguments included a generic example. The distribution of codes concerning content knowledge for teaching fraction multiplication is summarized in Table 2 below.

Table 2: The distribution of codes within content knowledge

	Correct drawing	Part-whole	Operator	Change of unit
Yes	14	8	15	6
Partially	11	12	4	5
No	3	8	9	17

These findings demonstrate that important aspects of knowledge of fractions were evident in many of the PTs' arguments, also those not coded as M2 (or M1). The three arguments that were coded as M2, all had codes "yes" or "partially" for correct drawing, part-whole and operator. Two of these mentioned explicitly a change of unit. Handling multiple units is a particular challenge in teaching fraction multiplication (Izsák, 2008).

To exemplify some of the categories, we discuss in the following the written arguments of two of the PTs, one coded as M2, and one coded as M3.

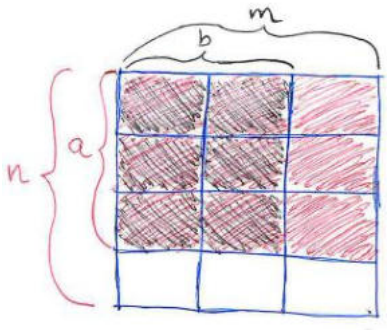

Figure 1: Reproduction of one PT's drawing, code M2

This PT started by explaining the multiplication $\frac{3}{4} \cdot \frac{2}{3}$ as taking $\frac{2}{3}$ of $\frac{3}{4}$. Since, by the definition we introduced, taking $\frac{2}{3}$ of $\frac{3}{4}$ is the same as $\frac{2}{3} \cdot \frac{3}{4}$, one could discuss commutativity of multiplication, but this was not the focus of our present study. The PT's explanations and the drawing with variables showed that this example is a generic example, as in Balacheff (1988). The PT also wrote the general rule $\frac{a}{n} \cdot \frac{b}{m} = \frac{a \cdot b}{n \cdot m}$ under the drawing. The drawing in Figure 1 is a good visualization of our target theorem. Change of unit was explicitly mentioned here, since the PT explained that one starts with four parts in the grid and then takes three parts of these four parts (representing $\frac{3}{4}$), thus "hiding the last part". The PT explained why $4 \cdot 3$ is the denominator in the product and that numerator times numerator is represented by the region that is shaded twice. The PT produced a valid general argument, but an explicit explanation of the product as part-whole is missing. We concluded that this proof attempt could not be accepted as proof in the classroom community of fellow PTs, and we coded it as M2, and not M1.

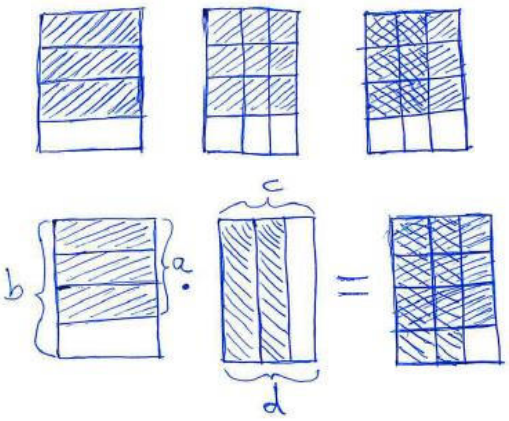

Figure 2: Reproductions of one PT's drawings, code M3

In the first sequence of drawings and explanations, the PT explained, although not in detail, why one can compute $\frac{3}{4} \cdot \frac{2}{3} = \frac{3 \cdot 2}{3 \cdot 4}$. Part-whole subconstruct was referred to in some places, operator subconstruct and change of unit remained implicit ("in the area already shaded, we wish to shade $\frac{2}{3}$"). In the next step, it becomes clear that the PT attempted to generalize, but the PT did not complete a general argument. In this context, it became evident that the example $\frac{3}{4} \cdot \frac{2}{3}$ is a generic example, although this was not made explicit. Next to the last drawing, the PT wrote the general rule $\frac{a}{b} \cdot \frac{c}{d} = \frac{ac}{bd}$. In the step towards a generalization (the last sequence of drawings in Figure 2), the PT represented the "overlap" ("placed on top of each other"), i.e. the PT shaded the part $\frac{c}{d}$ of the whole grid and $\frac{a}{b}$ of the whole grid, and thus did not use the operator subconstruct. We interpret the representation of c in the drawing as an error, since the PT demonstrated good knowledge of what c represents in the example.

Our analysis revealed that many of the PTs' arguments showed a limited understanding of generality. We also noticed that many of the PTs' arguments showed content knowledge of fractions, but that the explicitness and articulation of this knowledge varied across the arguments. As pointed out by Behr et al. (1983), the transition from paper folding to drawing diagrams might have been challenging for several of the PTs.

While we analysed and discussed our codes, we experienced some challenges. One challenge was to arrive at a conclusion regarding what could be included in the "set of accepted statements" (Stylianides, 2007) in this classroom community (of PTs), e.g. what kind of statements could be "taken-as-shared" (Stylianides & Stylianides, 2009), i.e. used without explicit reference or explanation. For instance, when something was discussed in the groups or in the whole class during the paper folding activity that preceded the PTs' written work, could the PTs use this in their arguments without explicit references? When we read an argument, it can be difficult to determine what is most likely understood by the PT that produced the argument and by the classroom community (of fellow PTs). In addition, the PTs could have had in mind a classroom community of students in school.

Compared to the written arguments of preservice teachers in their first year of study, analysed in Hofmann and Gustavsen (2024), we see that when it comes to referring to part-whole or operator subconstruct, there was no big difference. In both groups, the PTs mentioned the operator subconstruct more often than the part-whole subconstruct. There might be a natural explanation for this, namely in the session, fraction multiplication was several times referred to as taking a part of a part. When it comes to expressing generality, in percentages more PTs in year 4 than in year 1 used variables to express generality, while more PTs in year 1 compared to PTs in year 4 used a generic example. The latter might be due to the fact that the PTs in year 1 (Hofmann & Gustavsen, 2024) were guided more, and the use of a generic example might be facilitated to a higher degree through the sequence of tasks used.

Conclusions and further research

Our analysis revealed that there is a great variety among the PTs' written work. Many of the written arguments show a limited understanding of generality. On the other hand, most of the written arguments show content knowledge for teaching fraction multiplication (Ball et al., 2008; Izsák, 2008), even though they could not be categorized as proofs or valid general arguments. For instance, several of the empirical arguments (coded as M4) use the part-whole or operator subconstruct. In general, the arguments coded as M4 show a fair amount of knowledge. To produce this kind of argument, PTs could not just compute one or more examples, it required some argument, involving a visual representation or some context (if not linked to paper folding). We propose that proof-based teaching can be conducive to the development of PTs' mathematical knowledge for teaching, both within fraction multiplication and proving.

As we realized that many aspects remained implicit in the written arguments, we suggest that it might be fruitful to follow up the analysis of PTs' written work with task-based interviews to get insight into the PTs' thought processes. Video recordings of PTs giving explanatory arguments to students in school might also give insights. Building upon our observations from the coding process, where we perceived a need for expanded and more nuanced codes, we suggest further research employing a more detailed coding scheme, incorporating subcodes or "graded" codes, to enhance the depth and precision of our analysis. This more detailed analysis could provide important information for the further development of a more extended teaching sequence and deeper findings about to what degree and how proving competence and fraction competence are intertwined.

Pre-service teachers developing and using mathematical knowledge for teaching proof

Kasper Højbjerg[1]

[1]University College Copenhagen, Faculty of Teacher Education, Denmark; khch@kp.dk

This paper explores pre-service teachers' development of mathematical knowledge for teaching proof in a practice-based setting. Proof is challenging for both students and teachers but is crucial for meaningful mathematical learning. We design an instructional sequence based on core practices, tasking pre-service teachers with planning, implementing, and analyzing proving activities. Analyzing six presentations on the process, we select two cases of maximal variation to explain and illuminate how pre-service teachers report on and utilize mathematical knowledge for teaching proof. The results suggest that a minimum level of common content knowledge for proof might be necessary for developing other forms of mathematical knowledge for teaching proof. This highlights the need for further research into the relationship between categories of mathematical knowledge for teaching proof in relation to designing instructional sequences.

Keywords: Initial teacher education, Proof, Mathematical knowledge for teaching proof.

Introduction and background

Proving is a key mathematical activity that deepens understanding, generates knowledge, and should play a central role in students' mathematical education from the primary grades onwards (Stylianides, 2007; Stylianides et al., 2017). Stylianides (2007, p. 291) offers a classroom-specific definition of proof as a mathematical argument with the following characteristics:

1. It uses statements accepted by the classroom community (*set of accepted statements*) that are true and available without further justification;
2. It employs forms of reasoning (*modes of argumentation*) that are valid and known to, or within conceptual reach of, the classroom community; and
3. It is communicated with forms of expressions (*modes of argument representation*) that are appropriate and known to, or within conceptual reach of, the classroom community.

While this definition aligns with the traditional view of proof as a valid argument with true premises, appropriately represented, it adapts the components to the understandings within a specific classroom context (Stylianides, 2007). Research shows that students struggle to understand and use the concept of proof (Stylianides et al., 2016; Stylianides et al., 2017). Similar challenges are observed for teachers and pre-service teachers, who often share the same misconceptions as students (Stylianides et al., 2016; Stylianides et al., 2017). Buchbinder and McCrone (2020) suggest that "teachers themselves often lack the mathematical knowledge for teaching proof and hence are not disposed to support students to learn proving" (p. 1). However, there is little research on these teacher-related aspects (Stylianides et al., 2017). In a Danish context, Skott et al. (2020) show that pre-service teachers struggle with the concept of proof, often mistaking empirical arguments for proofs. We thus need to know more about equipping pre-service teachers with the knowledge and skills to competently teach proof, enabling students to benefit from their expertise (Stylianides et al., 2017).

Lesseig (2016) develops a framework of mathematical knowledge for teaching proof (MKT-P), building on Ball et al.'s (2008) framework of mathematical knowledge for teaching. The MKT-P framework consists of common content knowledge for proof (CCK-P), which includes the knowledge and ability to construct a valid proof; specialized content knowledge for proof (SCK-P), which includes the components (Stylianides' definition) and functions of proof; knowledge of content and students for proof (KCS-P), which includes knowledge of students' proof schemes (Harel & Sowder, 2007) and students' (mis-)conceptions of proof; and knowledge of content and teaching for proof (KCT-P), which includes knowledge of the relationship between instruction and proof schemes, questioning and other pedagogical strategies, such as talk moves (Kazemi & Hintz, 2014). Lesseig (2016) categorizes Stylianides' definition as SCK-P, but she classifies the ability to judge whether certain statements, representations, and arguments are within students' conceptual reach as KCS-P, illustrating the fluid boundaries of these categories.

This paper reports on an instructional sequence designed for initial teacher education to develop and/or reinforce pre-service teachers' MKT-P. Pre-service teachers presented their work from the sequence, and this paper analyzes those presentations to answer the following research question:

> (RQ) How do pre-service teachers utilize and report on different elements of MKT-P in their presentations, when focusing on isolating the three components of a proof (SCK-P) and combining these to an appropriate proof (CCK-P)?

The instructional sequence

The instructional sequence is based on *core practices as a pedagogy of teacher education* (McDonald et al., 2013). By adopting a practice-based, practice-directed framework, we acknowledge that "effective mathematics teaching requires teachers not only to have good mathematical knowledge but also to use that knowledge flexibly in supporting students' learning" (Stylianides et al., 2016, p. 342). The participating pre-service teachers are second-year students in initial mathematics teacher education in the Danish educational system. To enroll in initial mathematics teacher education, the students have passing grades from high school mathematics level B, where there is some focus on the construction and evaluation of proofs (CCK-P). In their first year of initial teacher education, they have studied various aspects of proof, including Harel and Sowder's (2007) proof schemes and proof construction and evaluation (CCK-P) in the contexts of number theory and geometry.

In the first unit of the instructional sequence, pre-service teachers worked in groups on the Josephus problem, which involves n people standing in a circle, eliminating every second person until only one remains. The task allowed multiple levels of proving activity, enabling pre-service teachers to engage at a level suited to their understanding—for example, proving that the survivor is never in an even position or, for $n = 2^m$ people, that the winning seat is always 1. Although no pre-service teachers reached this point, a double induction proof showing the general formula for the surviving seat with n people was a prepared possibility. The second unit focused on the content of Stylianides' 2007 article, specifically the definition of proof relating it both to Stylianides' examples and the Josephus activity. In subsequent units, the focus remained on Stylianides' framework, with groups of pre-service teachers conducting practice teaching of designed proving activities with classmates acting as students, which were then analyzed in the following units. All practice teaching, including

the Josephus activity, was recorded on video to support subsequent analyses. A Padlet was created for each group, containing all analyses of their taught proving activity. After these units, pre-service teachers had time to teach, observe, and analyze their proving activities in real classroom settings during practicum, under the guidance of the teacher educator. In a concluding unit, pre-service teachers orally presented a) the motivation for their proving activity, and b) a proof fitting Stylianides' definition, specifying the set of accepted statements, modes of argumentation, and modes of representation. The research question reflects that pre-service teachers were tasked with presenting on at least one aspect of SCK-P, the three components of a proof, and at least one aspect of CCK-P, the construction and presentation of a proof from the students' perspective.

Methods

The experiment is a teacher education design experiment (Cobb et al., 2003), focusing on designing an instructional sequence linked to specific learning outcomes and analyzing how these outcomes are reflected in pre-service teachers' presentations. The data consists of six recordings of pre-service teachers' presentations, each lasting around 35-45 minutes, with 20-25 minutes for the presentation and 15-20 minutes for questions and discussion. The recordings were initially viewed by the author, who timestamped sections where: a) pre-service teachers presented their proving activity, b) they presented a proof fitting Stylianides' definition from the students' perspective, or c) they addressed aspects relevant to their use of MKT-P. Subsequently, relevant timestamped sections were reviewed again, with a focus on the pre-service teachers' identification of three components in Stylianides' definition, as well as written or oral formulations of the student proof as a synthesis of these components. Based on this review, two of the six presentations were selected as cases of maximal variation (Flyvbjerg, 2006). The variation criterion was the extent to which pre-service teachers used CCK-P to present a valid proof from the students' perspective. Examining the differences in MKT-P utilization between two groups with contrasting performances on this aspect could provide valuable insights.

Analyses and results

Group A. This group provided a correct sketch of two valid methods to prove their chosen statement, though neither sketch was fully completed. This is well beyond how any other group utilized their CCK-P to present a valid proof from the perspective of the students. The group designed an activity for 6th graders, asking how many triangles with an area of 6 cm² can be made, where it is clear from context that the statement they want students to prove is that there are infinitely many. In their implementation, pre-service teachers had students create a table of different heights and bases that result in an area of 6 cm². They then continue this table with the possibility of dividing the base by two and doubling the height. In the presentation they orally report that "during the whole class discussion many students realized that the base was divided by two every time and the height doubled. In that way they realized that one could go on forever." In relation to this, another pre-service teacher comments, "as long as one of the accepted statements is that when dividing by 2 you never get 0". This demonstrates a good understanding of the logical structure of the proof (CCK-P), which relies on this fact. However, it also raises the question of why they did not include it as one of the accepted

statements from the start, especially given that the statements they did choose seem to provide background knowledge about triangles rather than directly supporting the proof.

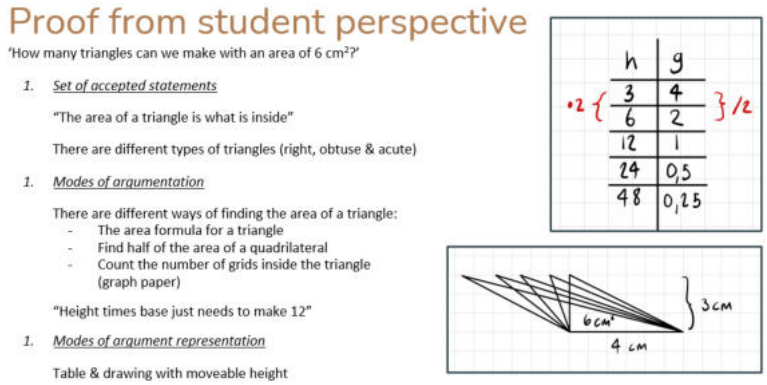

Figure 1: Slide from group A's presentation (translated from Danish)

The group effectively argues that infinitely many non-identical triangles can be generated, and that representing this through a systematic table is within students' conceptual reach. They emphasize the need to extend the table beyond the first few entries containing whole numbers, which reflects KCS-P, recognizing that students might have difficulties seeing the pattern continuing if only whole numbers are represented. They do not explain how we know that the new triangles are different from the previous ones, which is needed for the argumentation to be valid.

Group A also outlined another valid proof strategy using a triangle with a fixed base and a top point moving along an axis parallel to the base. They explain that as the top point moves, the area remains unchanged, demonstrating their grasp of the logical relationships (CCK-P) in a proof based on this fact. They did not explicitly address the fact that there are infinitely many possible positions for the top point or how this is known. Their chosen representations—a table and a drawing—align well with the envisioned proof, and they argue that both are appropriate for the classroom community.

Group A emphasized using talk moves to foster dialogue between students, but they did not specify the content of this dialogue, making it unclear how these moves supported students' engagement with proving or reflected pre-service teachers' KCS-P.

Group B. This group planned, taught, and reported on an activity for 5th graders. They never explicitly identified a statement to be proven, nor was it clear from the context what they expected students to prove. They did not present a proof, leading us to assess their use and possession of CCK-P as limited. The activity involved laying tiles around bushes, with eight tiles around the first bush and five more tiles for each additional bush. The phrase "valid forms of argumentation" (figure 2) is translated from the Danish *afslutningsformer*, a non-existent word. An introductory slide in their presentation states "The students were charged with proving a linear growth for a geometrical pattern," and the pre-service teachers orally use phrases such as "proving the activity" and "when we had to prove our proof." This may reflect confusion over terminology, but further analysis suggests that it might stem from pre-service teachers lacking a fundamental understanding of what a proof is and its role in mathematical reasoning. The pre-service teachers present the modes of argumentation as a *systematic enumeration of tiles*, relating to a form of argumentation that has been relevant

throughout the instructional sequence, as the examples from Stylianides (2007) use *systematic enumeration of all cases*. The context makes it clear that the pre-service teachers use the term without fully grasping its meaning, likely due to prior exposure. There is no systematic enumeration of tiles involved beyond simple counting, and without further explanation, it does not seem to be a relevant mode of argumentation either, as there is no given number of bushes for which we need to systematically enumerate the tiles. This suggests that the pre-service teachers have not developed sufficient CCK-P to produce or evaluate a valid proof in this context.

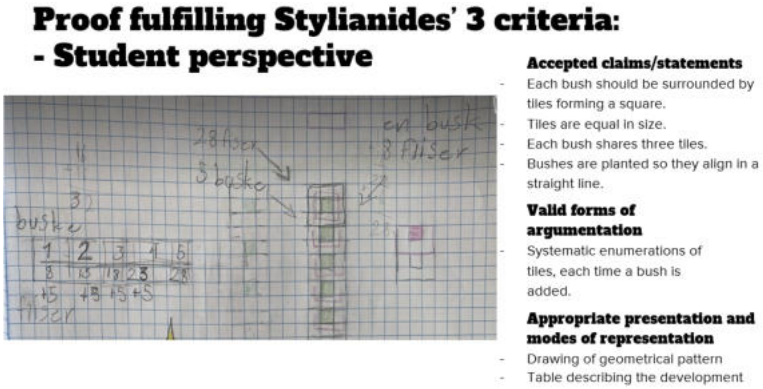

Figure 2: Slide from group B's presentation (translated from Danish)

The pre-service teachers approach the task as a problem-solving activity, focusing on guiding students to *discover* that the mathematical function $y = 5x + 3$ describes the relationship between tiles (y) and bushes (x), and we may note that in such a context, a crucial part of the process would be to count 5 tiles for each bush. In many other contexts, this would be a meaningful and rewarding mathematics activity. But in the given context, where pre-service teachers are tasked with developing proving activities, it is crucial to distinguish between finding an answer and moving beyond to prove that the answer is correct—something the pre-service teachers do not do.

Approaching the teaching activity through Stylianides' definition (SCK-P) did not help these pre-service teachers identify the lack of proving activity, likely due to their insufficient CCK-P. While the pre-service teachers identified relevant background statements and representations, it is unclear whether these elements were explicitly intended for proof construction or merely selected as relevant to the activity. Given that the pre-service teachers did not use Stylianides' definition to link these with a valid mode of argumentation to form a proof, the latter interpretation seems most plausible.

While Group B commendably emphasizes talk moves to foster communication, they provide no details on the proof-related content of the envisioned dialogue, leaving their use apparently disconnected from mathematical content and instructional goals.

General discussion and concluding remarks

Group B is more representative of the general difficulties pre-service teachers face with MKT-P. While 5 of 6 groups correctly identify a statement suitable for proving in their activities, their presentations reflect limited MKT-P, in particular CCK-P and SCK-P, as they generally do not isolate a valid mode of argumentation relative to which accepted statements and appropriate representations

can be singled out. Most pre-service teachers identify a set of accepted statements, though they tend to include background knowledge not directly relevant to the proof. And while they correctly identify the representations involved, it is not always clear whether they distinguish between representations used in the proof itself and those used in the lesson. Pre-service teachers often engaged superficially with Stylianides' components, particularly modes of argumentation, reflecting a lack of foundational understanding of valid proofs (CCK-P). When they struggle to identify the logical argumentation (CCK-P), they will naturally also face difficulties identifying accepted statements and representations used, as the logical structure of the argumentation is essentially a tying together of these. It is thus unclear if Stylianides' definition has helped the pre-service teachers. Instead, it might have led them to superficially focus on the content of the three components without engaging deeply with the nature of proof itself. This raises broader questions about the role of conceptual understanding in pre-service teachers' engagement with proof. While these challenges inevitably surface in classroom practice, they are rooted in the knowledge pre-service teachers bring to these situations.

Accordingly, this paper focuses on pre-service teachers' knowledge as distinct from their enacted classroom practices, though these are, of course, inherently interrelated. While what teachers do in classrooms is undeniably important, our focus here is solely on their development and utilization of MKT-P. This necessarily narrows our scope, as we consider pre-service teachers' classroom actions only to the extent that they reveal how they articulate and apply their MKT-P in their own reports. However, building on the example of Group B, it is reasonable to infer that if pre-service teachers' conceptual understanding of proof (CCK-P) is insufficient to the extent that students are not even presented with proving opportunities, then pedagogical strategies alone seem unlikely to compensate. Likewise, identifying students' misconceptions about proof (KCS-P) is likely to be difficult if pre-service teachers themselves hold similar misconceptions. Moreover, talk moves seem inefficient in eliciting proving (KCT-P) without a clear understanding of what needs to be proven and how.

Many groups of pre-service teachers focused on problem-solving rather than proving, which may reflect a limited understanding of the role and utility of proof in mathematics as a deductive discipline. Ball et al. (2008) define *horizon content knowledge* (HCK) as "an awareness of how mathematical topics are related over the span of mathematics included in the curriculum" (p. 403). Pre-service teachers' struggle may not only stem from the technical aspects of proving (CCK-P) but also from gaps in their own horizon content knowledge about the purpose and role of proof in mathematics. If pre-service teachers are unaware of the specific deductive nature of mathematics and the special role of proof, this could explain their focus on *problem-solving* over *proving*—they may not recognize a need for proof in the first place. While problem-solving and proving ideally occur together in teaching, there is a fundamental difference between finding an answer to a problem and moving beyond to establish with certainty that the answer is true given specific assumptions. If classroom mathematics primarily emphasizes the former, the nature and role of proof as a deductively valid argument may become unclear or even seem irrelevant. This, in turn, could likely impact the development of competencies for constructing and evaluating proofs (CCK-P), as pre-service teachers may struggle to see proof as essential to mathematical reasoning. Crucially, this issue is not confined to the pre-service teachers in this study but is embedded in their own mathematical education, often taught by teachers who might themselves lack a deep understanding of proof. This

could perpetuate a vicious cycle: when proof is not recognized as central to mathematical reasoning, it is neither emphasized in instruction nor meaningfully integrated in classroom practice. As a result, future teachers could enter the profession with the same limited appreciation of proof, reinforcing the gap between mathematics as a deductive discipline (HCK-P) and how it is taught. This is also closely linked to KCS-P and the proof schemes of pre-service teachers and students (Harel & Sowder, 2007), as a lack of appreciation for the purpose of proof—why it is needed and what it accomplishes—is likely to shape one's understanding of the concept of proof itself and what one accepts as such.

Future research should investigate whether empirical evidence supports such a hypothesized relationship between HCK-P and CCK-P. In light of this, future research should also further examine whether, as suggested by the analyses of this paper, a minimum level of CCK-P is necessary to support the development of other forms of MKT-P. If the framework of MKT-P has a hierarchical structure and certain types of MKT-P depend on foundational CCK-P, clarifying this structure can enhance our insight into how these domains interact and develop. Since all three components of Stylianides' definition—particularly *modes of argumentation*—seem to involve CCK-P, it could also be worth questioning whether categorizing the definition as SCK-P can be meaningfully upheld. If not, future research may need to adopt alternative frameworks, such as Buchbinder and McCrone's (2020), which introduces the category of *knowledge of logical aspects of proof* (KLAP), integrating core elements of both CCK-P and Stylianides' definition (Buchbinder & McCrone, 2020).

The instructional sequence reported in this paper does not appear to have significantly advanced pre-service teachers' mastery of MKT-P, likely due to their limited understanding of CCK-P—both at the outset and as developed during the sequence. This raises the crucial question of how to effectively integrate and balance proof components in initial teacher education. Given that MKT-P is directed at teaching in practice, giving up on practice-directed and practice-based instruction seems unwise. Rather than replacing practice-based instruction, a more effective approach could be to complement it with explicit proof-focused activities, such as elements from the instructional sequence in Stylianides and Stylianides (2022). This sequence fosters both an intellectual and pedagogical need for proof by engaging pre-service teachers in recognizing the limits of empirical justification and developing an operationally functional conceptualization of proof (Stylianides & Stylianides, 2022). Integrating such elements early in the instructional sequence could help pre-service teachers establish a stronger foundation in proof (CCK-P) before applying this understanding in practice-based settings. However, practice-based approaches, like the one reported here, can unintentionally divert pre-service teachers' focus. A review of Padlets containing pre-service teachers' practice teaching analyses highlights this issue: 17 of 56 points focus on talk moves, while only 9 address proof content or Stylianides' definition, with none addressing both. This suggests that while pre-service teachers are genuinely committed to fostering student collaboration and learning—an admirable and valuable emphasis—they tend to prioritize general teaching strategies over the content of proof. Talk moves are only an effective part of teachers' KCT-P when they directly support proving related dialogue—a challenge for pre-service teachers whose limited CCK-P may hinder their ability to identify and emphasize key proving concepts for students to discuss. More research is needed to explore how instructional sequences can better integrate proof-related teaching into practice-based approaches, ensuring that pedagogical strategies support rather than draw focus away from mathematical content.

Analytic and narrative perspectives on proof and proving in mathematics classrooms - a cultural comparative approach

Christine Knipping[1], Fiene Bredow[1], Takeshi Miyakawa[2], Hiroki Otani[3] and Yusuke Shinno[4]

Proof and proving are a complex endeavour in mathematics classrooms. Comparing such classroom ventures requires nuanced perspectives. From an analytic perspective, a structural, linguistic and functional angle permit the characterization of significant facets of the situation. To become more sensitive to cultural specifics in these situations, the tacit perspectives we hold as researchers are also important. The methodology of narratives allows the reconstruction of such tacit perspectives and the comparison of different views of the same situation. In our cultural comparative study, the comparison of different narratives of the same situations in German and Japanese classrooms inspired specifications for our theoretical framework. Analytic and narrative perspectives together enriched the cultural comparisons and the further development of the theoretical framework. In this paper, we illustrate this dialectic with regard to the evolution of our concept of structure.

Keywords: Argumentation, proof, comparative study, mathematics classrooms.

Introduction

Describing and comparing proof and proving activities in mathematics classrooms is challenging for several reasons. It is less obvious than one might believe, to agree on key aspects to look for. What constitutes a proof or proving is regularly discussed in mathematics education (e.g., Mariotti et al., 2018; Reid & Knipping, 2010). Researchers seem to not necessarily share the same epistemology (Balacheff, 2008), when talking about teaching and learning proof and proving in classrooms. Also, several studies conducted from a comparative perspective have shown the diversity of proof / proving and their role in different educational systems (e.g., Bergwall, 2021). Different cultural traditions and historically shaped conventions related to proof and proving in classrooms seem at stake. Describing these differences is not obvious (Reid, 2015). In a cultural comparative approach also language, its use and translations are an ongoing concern, which requires careful attention and reflection. In this paper the dialectic of analytic and narrative perspectives is the focus.

In our international collaborative research project on proof and proving in mathematics classrooms, several researchers are involved with research experiences in different national and cultural contexts. Aware of the above challenges, we wanted to develop together a refined cultural comparative approach for describing proof and proving in mathematics classrooms. We agreed to work together on this, both theoretically and empirically. Starting with a theoretical framework (Miyakawa & Shinno, 2021), which we describe in the next section, we focused on *structure*, *language* and *function*, to analyze similarities and differences of proof and proving activities in classroom situations at the middle school level. In the project and further collaboration, it also became obvious that we envisioned different perspectives, not only for the concept of *structure*, but also *language* and *function*. In this paper, we will focus on our concept of *structure* and how our view of it evolved towards a more multi-faceted understanding. It also occurred to us that our views of the classroom

situations were not only informed by our theoretical research backgrounds and foci, but also shaped by our cultural experiences of classrooms. Therefore, we started looking for a methodology that would allow us as researchers to capture our own different cultural views of the classroom situations we analysed. Such a reflective stance seemed critical to avoid confusing our own perspectives and prejudices with potential cultural differences in the classrooms. Our congruent and diverging views of the same classroom situations are the focus of this paper, not the classroom processes themselves.

The *methodology of narratives* (see Artigue et al., 2023), embedded in scholarly traditions of the Social Sciences (Connelly & Clandinin, 1985), seemed promising to us. Narratives, understood in this tradition as descriptive accounts of a series of related events or experiences, also called 'stories', are the starting point in this methodology. Comparing 'our distinct stories' about proof and proving in classrooms in form of narratives helped us to reveal the cultural underpinnings of our views.

> Narratives are more than just personal, individual stories, but imbricated in cultural and historical underpinnings. This means that comparing narratives allows us to reveal and understand this footing. (Artigue et al., 2023, p. 601)

Also, narratives bank on the resource of language and allow us to compare our languages about teaching and learning in mathematics classrooms. We became aware that the methodology of narratives could inspire our theoretical analyses and comparisons in the project. For these reasons, we decided to adopt the narrative methodology as complementary to our analytical approach. We sought not to conceal our tacit cultural views by an analytic perspective, but to reveal our tacit perception of processes in the classroom and to look at our tacit interpretation as complementary to our (further developing) multi-faceted theoretical framework. In this paper, we argue for such a multi-faceted cultural comparative approach, complementing analytic perspectives on proof and proving activities in mathematics classrooms by narrative accounts of these situations. We pursue the research question: How can narrative accounts of proof and proving processes in mathematics classrooms complement an analytic perspective and reconcile tacit cultural views?

Analytical perspective

Based on different theoretical perspectives of argumentation and proof in mathematics education (Mariotti et al., 2018; Reid & Knipping, 2010), Miyakawa and Shinno (2021) proposed to characterize proof and proving in a given institution by three aspects: *structure*, *language*, and *function*. The triplet allows us to understand cultural specificities of proof and proving in classrooms.

- *Structure* designates in this framework the organization of reasoning or arguments showing how different statements in a proof are connected.
- *Language* is understood as the semiotic representation (Duval, 2006) of arguments and reasoning structures, including gestures, diagrams, oral and/or written discourse.
- *Function* denotes the role which is attributed to a given proof or proving activity by the institution (e.g., verification, explanation, exploration, communication, or systematisation), and may not be restricted to these functions often mentioned in the literature.

How to analyse each of the three aspects, when characterizing proof and proving activities in classrooms, were still methodological and epistemological challenges. Characterizing the *structure*

of proof and proving, which is the focus of this paper, included in our initial theoretical framework reconstructing the *logical structure*. Particularly, it involved reconstructing the deductive steps, which led from starting statements, by the use of theorems/axioms/definitions, to conclusions in the class. Analysing the *logical structure* would include reconstructing the type of logic (e.g., propositional, predicate) which is employed, when statements and inference rules in a proof are applied (Durand-Guerrier et al., 2012). But, in many situations the presentation of proofs follows conventional styles rather than formal logical rules. So, reconstructing the *logical structure* has to acknowledge its more or less informal presentation, and include informally as well as formally presented logical structures.

Classroom practices are multi-faceted processes, where convincing others and negotiating a common argumentation basis may be important. Discourses with complex *argumentation structures* occur in classrooms, which are apparently different to the logic of deductive inference. Revealing these complex structures cannot be undertaken by means of logic alone, but requires a conceptualization of rationality related to the context of practice. Such a conceptualization has been introduced by Stephen Toulmin (1958), whose functional model of argumentation has been widely adopted in mathematics education. Reconstructing and comparing the *argumentational structures* of proving activities and their peculiar rationale in the classroom appeared to be insightful and complementary to a logical perspective. For revealing cultural differences in the organization of reasoning in class, we therefore decided to complement our analyses of the *logical structure* by analyses of *argumentation structures*.

Comparing logical and argumentation structures in different classrooms made it possible to reveal differences and similarities in proof and proving activities in classrooms. For example, an emphasis on an if-then structure in propositional logic in some of the Japanese classrooms occurred, while visual argumentations in some of the German classrooms were emphasised with less obvious *logical structures*. We further realized that our accounts and interpretations of the reasoning in the lessons diverged, beyond the structural differences we had found in these classes in terms of logic and argumentation. To better understand these disparities and our tacit diverging interpretations, we decided to capture our different points of views and to use the *methodology of narratives* (Artigue et al., 2023) for our cultural comparative approach. We characterize this methodology and our usage of it next, before we document the outcomes of this approach.

Methodology of narratives

In the Social Sciences narratives are defined as ‘distinct stories’ or descriptive accounts of a series of related events or experiences (Connelly & Clandinin, 1985). These ‘stories’ are acknowledged as a means to reconstruct tacit understandings of cultural events and experiences. Narratives of a situation are seen as more than personal stories, as these stories reveal an individual account of a situation related to a social and cultural background. Connelly and Clandinin (1985) also argue that individual’s narratives elicited by a setting expose the individual and cultural understanding and knowledge of a teaching and learning setting. Recognizing narratives as socio-cultural products and artefacts allows us to use these narratives for cultural comparative approaches (see Artigue et al., 2023). Narratives are deliberately not analytic, but foster a descriptive, eclectic and linguistically multi-faceted style. The intent is to reveal cultural underpinnings of the storylines, of the used language and linguistic styles, which are employed aside from a common research terminology or

professional language. This can help to reveal our tacit understanding of classroom teaching and learning of proof and proving, within and across cultural comparisons. This tacit understanding and revealing the cultural underpinnings of this understanding is the focus of this paper.

We adopted an approach that had been suggested by Artigue et al. (2017), in the context of the Lexicon project (Mesiti & Clarke, 2018). Stimulated by videos of Grade 8 mathematics classroom situations in Germany and in Japan, we split into different teams (German colleagues, Japanese colleagues, other colleagues) and each team produced their own narratives for each lesson. The foci of the lessons were proof and proving activities with a common topic: 'the sum of three consecutive numbers (is divisible by three)'. The narratives were team productions and besides the videos as stimuli, they also relied on transcripts of the lessons. The transcripts had first been produced in the original language of the lesson and then been translated into English; both versions were available to all teams. Different to Artigue et al.'s approach the teams only included researchers at this point, not teachers. Also, the focus was not (as in the Lexicon project) on our usage of professional language to characterize these situations, but had a focus on describing what 'proof' and 'proving' meant in the videotaped classroom situations. We therefore labelled our narratives as 'focused narratives'. The narratives included a general description of the context and progression of the lesson, followed by a description of what 'proof' and 'proving' meant and involved in the classroom situations. The intent of this approach was to capture descriptions of the situation to reconstruct our tacit interpretations.

The narratives were first written in the native language of each team, before they were translated into English, which was the language of communication in our international project. We did not want to lose specific linguistic characterisations and our reflections on them, when comparing the narratives. So, we regularly went back to the original versions of the narratives in our comparative analyses. As in the Lexicon Project, we consider language as an important resource that regulates individuals' experiences and interactions. Beyond an analytic approach, the narrative methodology also allowed us to capture and reflect our tacit use of language, when we described our experiences and observations of interactions. Comparing our descriptions in the narratives on what 'proof' and 'proving' meant in the videotaped lessons, helped us to become more sensitive for our own perspectives and how these might have been shaped by our cultural views on 'proof' and 'proving'. These intercultural comparisons and reflections also helped to distinguish our own interpretations from what teachers and students might mean by 'proof' and 'proving' in their conversations and interactions in the situation. This stimulated us to critically question, what we as researchers noticed in these classroom contexts and what we included in our theoretical perspectives.

Comparing our narratives on proof and proving

As researchers becoming aware of our tacit understandings of the classroom situations helped to see our different cultural perspectives on them. Comparing our narratives also made us aware that we 'naturally' commented on the triplet of the analytic framework. We will indicate how we described 'structures' in our narratives. This was obviously different from what we had done analytically.

The videos and transcripts stimulated us to describe the context and progression of the classroom lessons in concrete ways, characterizing the structure of proof and proving by their presentation and evolution, rather than their logical or argumentational structures. In the different narratives, we

described the intricate relationship of proof and proving, and we particularly discussed the role of the tasks and activities in class which were related with proof and proving. Cultural differences in our descriptions occurred, when it came to what we would consider as pre-activities or key activities for proof and proving in class. For example, generic-examples, figurative arguments with dot patterns or oral explanations in class, why 'the sum of three consecutive integers is three times the middle number', would be considered as proofs and proving by the German team, whereas the Japanese team would rather interpret these as a pre-proving phase, justifying a statement-in-action, from which later a symbolic proof with letters would evolve, which would prove the general statement.

Related to this, the German team's narratives described more activities as proving. Processes such as understanding, verifying, validating and justifying were all described as part of the proving activities in these narratives. In contrast, the Japanese team's narrative focused on the activities related to justifications and described the other processes as 'pre-proving activities'. Our researchers' tacit concepts of proving, as a footing of our descriptions, seemed different and leading our 'stories' on what counted as 'proving' in the classroom lessons. While the German team focused on 'proving' as a process with multiple functions, the Japanese team portrayed 'proving' rather as a process with one function, demonstrating the validity of a mathematical statement by generating a written proof, a product. Nevertheless, all teams described similar mathematical activities as characteristic for the classroom situations, specifically focusing the following: motivating the exploration of a statement, formulating the statement, looking for ideas how to justify it, formulate and present a general justification, applying or extending the statement in further activities.

Our narratives indicated that we as researchers interpreted the progression of these activities as different types of proof and proving patterns, which we saw as emerging in the classes. Comparing our different views in the narratives, we agreed to also compare our interpretations of the specific interplays of these activities, which seemed to constitute in our views different conventional styles of proof and proving in class. For example, we compared our descriptions of the Japanese lesson, when the students were engaged in pre-activities and were made familiar with a mathematical statement. We also compared how we described the teacher guiding the students through a written proof and agreed that this happened in a conventional form: 'introduction, contents, and conclusion'. We agreed across the teams that students' active engagement in proving seemed to happen later in application activities in the Japanese classrooms, where students were expected to replicate the pattern of the written proof they had seen in class. In the German classroom contexts, we saw together, despite our different views, an emphasis on the pre-activities, where students were actively engaged in justifying the statement for some examples. Together, we interpreted these activities now as establishing a common argumentative ground for generalizing the ideas of these example-based arguments, where using different representations for the arguments (figurative, generic examples, semi-paragraph) were encouraged. We agreed across the teams that no explicit conventional style for writing a proof was emphasized and found in the German classes. These comparisons made us aware that we needed to include an analysis of *didactical structures* in our theoretical framework (Shinno et al., 2024).

When comparing our characterisations of 'proof' and 'proving' in the narratives, we also realized that the foci of our interpretations were at times different and that we highlighted aspects, we had not specifically focused on in our analytical perspective.

We realized through the comparisons of our narratives and our discussions around these comparisons that our concept of structure of proof / proving referred to different 'objects'. The concept of structure refers to structures of (logical) products, when it comes to 'proof', and it refers to structures of argumentation processes, when it comes to 'proving'. These are different 'objects'. We also realized that there seem to be cultural differences in mathematics classrooms in this respect. We see a difference between the German / Japanese classrooms we analyzed: While in the German classrooms, 'proof' is not an object to teach, but a paramathematical concept (accompanied by activities), in Japanese classrooms 'proof' is an object to teach. This is clearly reflected in our narratives and comparing these made us aware of this tacit cultural underpinning.

In the German narratives, we found an emphasis on describing different mathematical approaches in the classrooms. For instance, for proving that 'The sum of three consecutive natural numbers is always divisible by 3', the narratives of the German team pointed out different mathematical approaches for the German classrooms. These narratives highlighted that first, the smallest number was represented by n and the sum was expressed and calculated as $n+(n+1)+(n+2)=3n+3=3(n+1)$. Then, a second approach was pointed out, where the middle number was represented by n and the sum was described as $(n-1)+n+(n+1)=3n$. The narrative of the Japanese team also noted these approaches, but the German narratives put more weight on this observation. These narratives highlighted that even though in both approaches the algebraic expressions were simplified and condensed, the justifications for the different approaches in class made obvious that their mathematical structures needed to be made explicit. Again, the comparisons of our different narratives pointed to the need of extending our analyses of the proof and proving activities in class. We decided to include an analysis of the mathematical content and the *mathematical structures* on which the proofs and the proving activities in class built.

Towards a cultural comparative approach

Comparing our narratives allowed us to not only become aware of our different cultural views of the classroom situations, but also that we had to come to an agreement on what we wanted to include, when analysing the structure of classroom practices of proof and proving. As argued above, our narratives made us aware that we needed to analyse the *logical* and *argumentation structures*, when analysing proof and proving as different objects in classrooms. Also, their *didactical* and *mathematical structures* needed to be analysed, closely related to proving as a process and proof as a product in the class. Acknowledging all these structures would help to characterize potentially different conventional styles of proof and proving in classrooms and their cultural contexts.

Structures of proof and proving activities in classrooms are also related to different functions that these activities have in classrooms. Defining these functions analytically is important. But, again the comparisons of our narratives indicate that the classroom situations are complex and our interpretations of activities and their role in these situations differ. While the narratives of the German team focused more on different functions of the (pre-)proving activities and proving as a process, the narratives of the Japanese team highlighted rather the progression of the lesson and focused on function and product, when looking at the written proof. Comparing and analysing this more closely,

will also help to come to a more nuanced analytical understanding of the concept of function, which has been discussed rather broadly in the mathematics education community so far.

Last, but not least, language and linguistic aspects require a closer look, analytically and pragmatically, through looking at the use of language in the classroom contexts. Looking at the semiotic representation of arguments and reasoning structures is analytically sound and well acknowledged in mathematics education as a way to analyse the register of language for proof and proving. But, what does this mean, from a pragmatic point of view? Our narratives might provide first insights related to this. As indicated above, the narratives of the German team interpreted the different representations of the general argument and their use as 'proofs' in the German classrooms. The narratives of the Japanese team on the other hand focused rather on the symbolic representation and its use in class, which was interpreted in this narrative as 'proof'. Our researchers' tacit concepts of proof not only shaped our narratives and what we considered as 'proof' in the classrooms, but also our focus on its meaning in the classroom practice. The comparison of our narratives indicates that looking at language from a pragmatic stance, and becoming aware of our cultural footing in this, might be worthwhile. In addition to a semiotic view, a focus on discourses and the pragmatic use of language in classroom contexts seemed necessary, which requires an extended theoretical and methodological approach.

Overall, we incorporated a narrative perspective to reflect our own tacit perspectives and epistemologies as researchers. This approach expanded our theoretical framework into a more multi-faceted one, as demonstrated in this article focusing on the evolution of our concept of structure. The narratives of German and Japanese researchers not only represent different views on the structure of proof and proving (e.g., logical, argumentative, didactical, and mathematical ones), but also differ in which aspects of the structure they emphasise. We propose to combine different theoretical and methodological approaches and perspectives to better understand and reconstruct cultural specifics related to proof and proving in classroom situations. As there is not enough space in this article, we will further elaborate on our networking approach of theories in future publications.

Recognising the situation for proving is not obvious

This paper investigates how visual perception and empirical experience influence recognising situations for proof. We examined the written works of 59 prospective math teachers on an open geometry problem based on a paper-folding task. This setting allows us to observe the cognitive process from problem identification to the formulation of conjecture and providing proof. The findings suggest that easily perceptible visual clues make it difficult to recognise the proof situation and may lead to a reliance on empirical argumentation. In contrast, situations with less perceptible clues tend to prompt the use of mathematical proofs to substantiate conjectures.

Keywords: Argumentation, mathematical proof, empirical proof scheme, paper-folding, perception of shapes.

Introduction

The knowledge teachers need to possess about mathematical proofs has been the subject of numerous studies. A. J. Stylianides and Ball (2008) have taken the initiative to complement teachers' knowledge of proofs with their understanding of the situations that require proving. The authors assert that teachers must possess the ability to recognise situations that require proof. When a mathematical problem's wording explicitly mentions proof or refutation, identifying a proof situation is simple. However, the student must first formulate mathematical relations when it comes to open tasks, such as situation-based problem-posing tasks. Students should be sure that their statement is only a conjecture that requires proof or refutation. However, various factors can influence students' identification of proof tasks. For instance, visual perception can override claims that require proof. Moreover, certain statements are straightforward to make visible through simple manipulation. The paper folding case investigated in this paper is a prime example of this phenomenon.

Paper folding is an appropriate medium for examining several questions on argumentation and proof (Mariotti et al., 2023), as well as the ability to recognise proof situations. First, paper folding frequently results in conjectures that are evident based on perception. On the other hand, manipulating geometric components can create a cognitive trap in which the learner accepts empirical reasoning as a conviction. This insight led to the research question in this paper: How do visual perception and empirical actions influence prospective mathematics teachers' ability to recognise situations requiring proof, and how do these factors shape their proof schemes?

The role of visualisation in the proving process has been examined in several studies (Biza et al., 2010). However, the literature rarely addresses the influence of visuality-driven intuition on mathematical activity. By investigating this phenomenon, our paper contributes to filling a research gap.

We draw on G. J. Stylianides (2009) conceptualisation of proof schemes to answer the research questions. This framework defines our coding system by distinguishing between empirical reasoning, rationale, and providing proof. By applying this perspective, the research links task design, based on paper-folding activities, to the broader goal of understanding how visual cues affect the recognition of proof situations and schemas.

Theoretical underpinning

Much research has been conducted on the factors that influence the argumentation process. Some of these factors depend on the circumstances under which the task is performed. For example, Dreyfus and Hadas (1996) argue that "Students' concept of proof, their appreciation for its need as well as for its roles, depends on the curriculum, on the activities students are asked to carry out, on the questions they are asked and on *how* they are asked these questions" (p. 1). In their experiment, Boero et al. (1996) reported that most seventh graders can produce theorems (conjectures and proofs) if, during the production of the conjecture, the student progressively works out their statement through intense argumentative activity. During the subsequent proving stage, they coherently link up with this process, organising some of the arguments generated during the construction of the statement into a logical chain. Intuition and perception can also influence proof-related activities. Mariotti and Pedemonte (2019) showed that when a conjecture is based on intuition or perceptual evidence, the proof process can involve a cognitive gap that learners sometimes find challenging to overcome.

The idea of *proof* in mathematics education has evolved over time; see (Hanna & Knipping, 2020) for more details. Following G. J. Stylianides (2009), in this paper, we define proof as a series of arguments, each accepted by the community, covering the key ideas needed to validate or reject a claim. As subjects in our research are prospective teachers for secondary mathematics education with strong mathematical backgrounds, the approach is also consistent with Hanna concept of "acceptable proof," i.e., "a normative concept that defines what is acceptable to qualified mathematicians" (1990, p. 6). On the contrary, the concept of *rationale* encompasses valid arguments for or against mathematical facts. However, in some respects, this is incomplete. In particular, an argument counts as a rationale rather than a proof if it does not explicitly refer to the accepted truths of a specific community; the argument is incomplete because it omits some of the necessary steps (G. J. Stylianides, 2009). *Empirical proof schemes* use physical evidence or sensory perceptions to prove, refute, or doubt hypotheses (Harel & Sowder, 1998). The paper folding process objectifies geometric shapes for instant sensory judgment. Moreover, rearranging the geometric elements by folding allows for experimental conclusions on geometric relations. However, using rigorous deductions to turn empirical argumentation into mathematical proof is sometimes challenging.

Method

Our research was based on the written homework of 59 prospective mathematics teachers (serial numbers S1-S59 in this paper). They have already completed introductory math courses, such as Euclidean geometry, and are assumed to have mathematical knowledge to mathematise the paper folding process. Data were collected in autumn 2020 and spring 2021.

The problem formulation is as follows:

From a sheet of A4 paper (ratio of sides is $1:\sqrt{2}$), cut the square with the maximum side as usual. Then, fold the two opposite vertices of the remaining rectangle to form a pentagon (Figure 1, left). Discover as many properties of the resulting pentagon as you can. It is unnecessary to list and prove properties that are true for all pentagons.

Figure 1 (right) shows the GeoGebra representation of the problem, which we will need to unify the notations in the future. For the sake of easy reference, we refer to the ADC' triangle as the "roof," MN will be the "base," D is the "top", and we refer to AMD and $C'ND$ triangles as "corner triangles." The folding line t is the perpendicular segment bisector of segment BD (diagonal of the rectangle), and C' is the reflection of C through t. The question of symmetry is whether vertices A and C' are symmetrical through the diagonal DB.

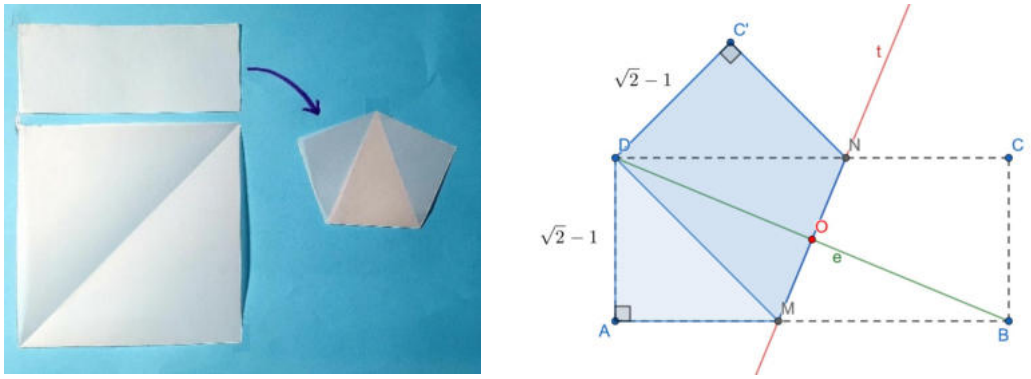

Figure 1: The problem representation: Paper folding (left); GeoGebra construction (right)

This open-ended task is a situation-based problem-posing task that simulates the complex process of mathematical activities. The geometrical problem has to be seen in a situation, mathematised, discovered and concluded with conjecture and proof or refutation.

We will only highlight two statements in this paper.

1. The pentagon is symmetrical.
2. The corner triangles are congruent isosceles right triangles, i.e., the pentagon has four equal sides.

The rationale behind the selection of these two properties is as follows:

Ad 1. We assumed that the pentagon's symmetry is an easily observable feature. Symmetry is one of the defining principles of form perception according to Gestalt psychology (Sternberg & Sternberg, 2012). In addition, brain research has suggested that humans are susceptible to symmetry. Bertamini and Makin (2014) asserted that the visual cortex processes symmetry automatically and sustainably. Therefore, we were intrigued to examine how students mathematically represent this visible characteristic, if they argue for it, and, if so, whether their argument extends beyond manipulative action.

Ad 2. Even though the isosceles triangles are symmetrical, they appear as parts of the pentagon in this situation. Therefore, the pentagon must be mentally or physically split into parts to deal with these triangles. For example, some students used backlit photographs to make this separation evident

(Figure 2, left). Although the two triangles at the corners are visible, in their photo, S58 only stated that they were congruent but did not claim that they were isosceles triangles. Thus, we assume that it is harder to perceive that the corner triangles are isosceles, but one is naturally curious about the length of these sides. We are interested in whether this researcher's attitude and interest will lead to a flawless mathematical investigation and proof.

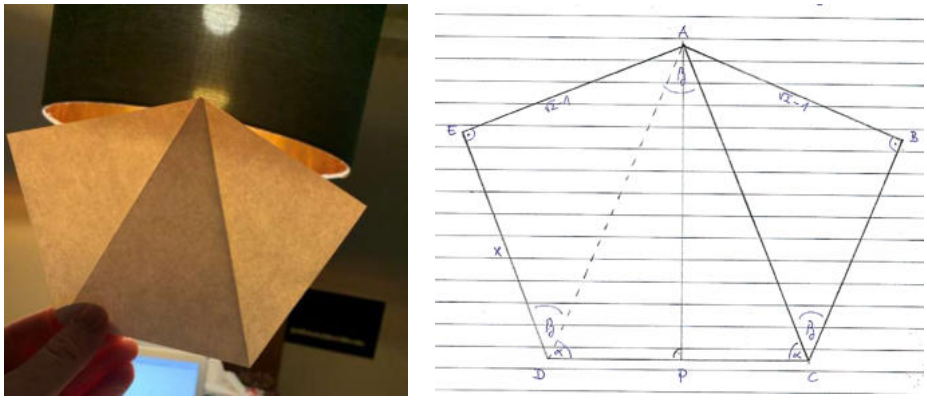

Figure 2: Problem representations: a photo included S58 in their work and a typical drawing (S41)

The two authors independently judged the proof schema for the student contributions, and we closed cases of disagreement by consensus.

Results and discussion

The high proportion of students identifying the pentagon as regular (10 of 59 students, 16.9%) was unexpected. We identified a lack of conceptual clarity regarding regular pentagons for four students. Moreover, a misinterpretation of the task also appeared, as six students did not refer to the folding situation. We excluded these students from further analysis, leaving a sample of 49.

Forming conjectures

Consistent with our hypothesis, most students (46 of 49 students, 93.8%) identified symmetry, whereas slightly fewer (39 of 49 students, 79.6%) formulated a statement for the corner triangle's property. However, the treatments for these properties differ significantly. Studying the students' figures, we can observe that the axis of symmetry is usually included in their figure, while the indication for the equal sides is usually not. A typical example is shown in Figure 2 (right). This figure captures the properties that follow from the folding: right angles, the length of the sides that make up the roof, and the corresponding alternate angles, which are marked in the drawing by β. The ED segment, a quantity to be calculated, is denoted by x. However, the axis of (assumed) symmetry is also included in the drawing. The student clarifies this in the explanation of the drawings:

S41: The pentagon is axially symmetrical. The axis of symmetry is the line connecting the midpoint of the DC side to vertex A.

This student will later calculate x using the Pythagorean theorem using the relation $AD = 1 - x$, but will no longer deal with symmetry.

Argumentation and proof schemes

Folding, i.e., applying the *empirical proof scheme,* can be used to argue for both properties. The elements of the original figure can be rearranged manually, making the claims convincing. This is obvious in the case of symmetry; see Figure 3 (left). Regarding the corner triangles, the folding shown in Figure 3 (right) is the most straightforward. From this fold, conclusions about the angles can be drawn, namely, the angles of corner triangles at the top are congruent, and they give a right angle together, so we have angles of 45°.

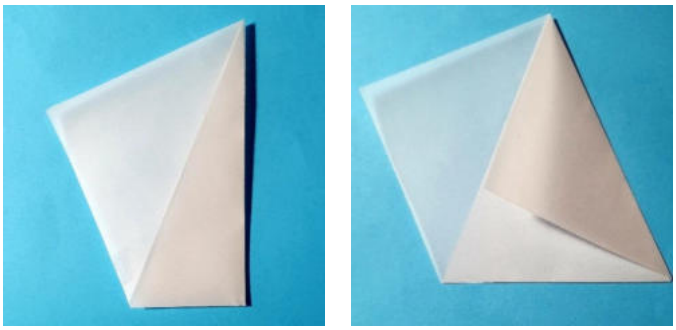

Figure 3: Demonstrating the symmetry (left); the acute angle of the corner triangle (right) with fold

To *prove* the properties of corner triangles, one can apply the Pythagorean theorem, as shown in Figure 5.

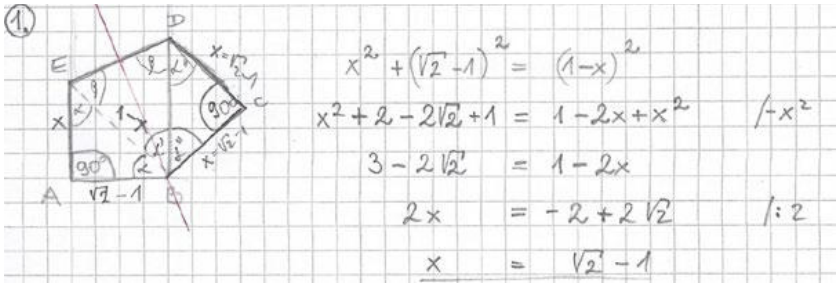

Figure 4. Drawing and calculation by S13

All of the work arguing for the pentagon's symmetry was incomplete to a greater or lesser extent, leaving it somewhere between proof and rationale. In four cases, however, the students' assumed and expected geometric knowledge easily compensated for missing arguments. We recalled these students' arguments, aligning their texts to Figure 1.

S50: AMD and $C'ND$ are congruent isosceles right-angled triangles with vertex D common and $DM = DN$. Thus, the shape is symmetric with respect to the angular bisector of the MDN angle.

Despite the student's proof's lack of details, it aligns with the group's expected geometric knowledge, as congruent triangles can be transformed into each other by the composition of axial reflections, and in the geometric situation under consideration, a single axial reflection is sufficient; see, for example, Theorem 19.9 of the textbook (Martin, 1975).

Student S33 made similar arguments. Their proofs necessitate a deeper understanding of abstract concepts of congruence and isometry in geometry.

S35: The two angles on the segment MN are equal. The two sides joined at the base are also equal. Thus, $AMNC'$ is a symmetrical trapezoid; in conclusion, the pentagon is symmetric.

The missing step in the proof is that the axis of symmetry of the trapezoid, which is the perpendicular bisector of the segment AC', has vertex D on it because it is equidistant from both A and C'.

S3: The two angles lying on the segment MN are equal. The two sides lying on the base are also equal. The roof's two sides are equal, with two opposite right angles. (These are all due to the way the folding is done.) Therefore, the resulting pentagon is axially symmetric.

S3's argument was similar to that of S35, but this student referred to the symmetric construction of the pentagon from two components. A possible necessary completion is that reflecting one side of the pentagon to the segment bisector of MN yields the other side. This reasoning is an example of the transformational argument (Simon, 1996): S3 dynamically imagines constructing the pentagon in successive steps. S3 starts at the base's endpoints and symmetrically builds the pentagon's two halves. Thus, the pentagon is not a static end state but the result of successive construction steps.

No rationale-type argument for corner triangles has been identified. Regarding symmetry, the most common example of the rationale is that the pentagon's symmetry follows the symmetry of the triangle *MND*, as shown in S16 work:

S16: I started with the isosceles triangle MND. The segment connecting the vertex D to the midpoint of the MN side divides the MND triangle into two congruent triangles. The straight line connecting points D and O is the axis of symmetry for both the triangle and the pentagon.

The argument's obvious flaw is that it does not examine whether A and C' are symmetric along the MND symmetry axis. This missing part of the proof presumably results from some mentally performed thought processes supported by visual perception.

Table 1 categorises the reasoning types students use when identifying properties of the pentagon.

Table 1. The types of reasoning used in the study

	Proof	Non-Proof argument		False argument	No argument	Sum
		Rationale	Empirical			
Corner triangle	17	0	7	2	13	39
Symmetry	4	6	5	0	30	45

After analysing the different types of argumentations, we were surprised that many students failed or missed clarifying the properties of the corner triangles. When examining the work of students who lacked an argument, we observed instances where the isosceles right triangle was held in a "typical position," i.e., with a horizontal hypotenuse (Figure 6). Some research suggests that typical positions, such as horizontal hypotenuse in our case, aid geometric shape recognition (see Chapters 3 and 8 of

Sternberg & Sternberg, 2012). Interpreted in this way, this result also supports our hypothesis that decisions based on visual perception adversely affect the recognition of the proof situation.

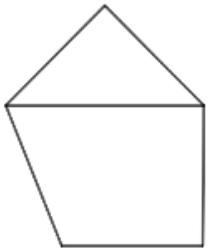

Figure 5. The isosceles right triangle in a typical position based on the photo by S8.

Conclusion

Both problems had many students who did not argue their claims. Visual perception contributed to certainty in both cases. This finding highlights the difficulty of transitioning from observable evidence to formal, deductive proof or even recognising the "need for proof" situation. Moreover, we identified a notable disparity in the treatment of corner triangle properties, where formal proofs were more prevalent. This disparity suggests that students found it easier to apply concrete, formal-symbolical mathematical methods, such as applying the Pythagorean theorem, rather than dealing with more abstract concepts, like symmetry.

Contrary to our expectations, the empirical proof scheme did not dominate any problems. Perhaps the reason may be that the teacher candidates were aware that the manual activity is not proof. As S21 notes, "By folding, an *informal deduction* can be used to prove that we have obtained an axially symmetric pentagon" [italicised by the paper's authors].

The pedagogical impact of the results presented in this article is achieved by reflecting on the experience gained during the task performance and evaluating it in the form of a meta-discussion with teacher candidates. Investigating this aspect is beyond the scope of this article and presents a topic for future research.

A series of mathematical induction activities to promote de-ritualization processes

Latifah Mustofa Lestyanto[1] and Kirsten Pfeiffer[1]

[1]University of Galway, Ireland; l.lestyanto3@universityofgalway.ie

In this paper, we suggest including opportunities for de-ritualization in teaching and learning activities of mathematical induction. De-ritualization is a term used in commognition theory which refers to the process of moving away from ritualized routines towards explorative routines in learning. This process plays a key-role in learning. After introducing the concept and theoretical background of de-ritualization we present a literature review on teaching and learning mathematical induction. Based on these ideas and findings, we developed a series of teaching and learning activities with the aim to advance de-ritualization and ultimately undergraduates' understanding of mathematical induction. We will outline this series and exemplify how they have potential to advance de-ritualization processes.

Keywords: De-ritualization, commognition, mathematical induction, teaching and learning activities.

Introduction

Commognition theory offers a socio-cultural view of mathematics teaching and learning, which has been emerging in recent years. In this theory, de-ritualization is a valuable process which can promote an understanding of concepts as it shifts the focus from repetitive, rule-based learning to a more dynamic, exploratory approach (Sfard, 2018). The main goal of this paper is to propose a sequence of teaching and learning activities to promote de-ritualization of mathematical induction. Teaching and learning activities, here, mean suggestions for tasks and teacher inventions.

We focus on mathematical induction (MI) because it is a powerful proving technique to improve problem-solving, persuasive argumentation, reasoning, creativity, mathematical thinking, and enabling mathematical communication (Güler, 2016). The application of mathematical induction tackles a wide range of mathematical problems, from proving fundamental identities and inequalities to establishing the correctness of algorithms and recursive structures. It is particularly valuable in developing theoretical foundations of computer science (Baker, 1996), which became very popular in recent years. Apart from its mathematical significance, Stylianides et al. (2007) argued that inclusion of proof methods is important in teacher education programs to provide them with insights into mathematical practice. They argue that in particular mathematical induction promotes conceptualization of preservice teachers' conception of proof and logical thinking. This paper presents a series of teaching and learning activities of mathematical induction promoting de-ritualization processes which we are planning to implement with a group of mathematics undergraduate students in Malang, Indonesia.

Theoretical background

De-ritualization in commognition theory

Commognition, a term that was first introduced by Anna Sfard, combining two words "communication" and "cognition", focuses on the social and discursive nature of thinking and learning. This theoretical framework views learning as a process of becoming fluent in a specific discourse, characterized by unique language or *keywords* (for instance, “three,” “triangle,” “set,” or “function”), *visual mediators* (e.g., numerals, algebraic symbols, and graphs), *routines (*repetitive patterns characteristic of the given discourse), and *endorsed narratives* (in mathematics, theorems, definitions, proof methods and computational rules, among others) (Sfard, 2008). Thinking as a form of communication is the basic assumption in this approach, and learning mathematics means participating in this special form of communication (Sfard, 2018).

Commognition theory in mathematics education examines how learners transition from everyday language to specialized mathematical discourse. Key processes include *ritualization*, where learners focus on procedures, and *de-ritualization*, where conceptual understanding and logical reasoning become the primary focus (Lavie et al., 2019; Sfard, 2007). Through this lens, thinking is conceptualized as the internalization of communicative processes (Sfard, 2018), and the classroom functions as a space where learners collaboratively develop and negotiate mathematical understandings (Sfard, 2008; Yackel & Cobb, 1996).

In commognition theory, ritualization and de-ritualization in the routines are important for meta-level learning. Ritualization is often the initial stage of meta-level learning, where learners imitate expert performances before they can fully understand the usefulness and success of their own actions, while in de-ritualization, learners start to actively participate in discourse, making persistent efforts to figure out the purpose and applicability of the discourse (Lavie et al., 2019; Sfard, 2018). These two parts of routines should be provided by teachers’ actions to achieve learning goals. Nachlieli and Tabach (2019) introduced two notions of opportunities to learn (OTLs) which identify and explain teaching goals: *ritual-enabling* OTLs, and *exploration-requiring* OTLs. The former OTLs are the teachers’ actions that primarily focus on practising established procedures and mimicking previously learned examples, and the latter OTLs are the ones that encourage students to engage in more active and independent learning (Nachlieli & Tabach, 2019). Exploration-requiring OTLs are considered crucial for developing a deeper understanding of mathematical concepts, fostering problem-solving skills, and promoting mathematical communication. However, these two OTLs are equally important as they can contribute to shifting students' focus towards exploration and problem-solving (Nachlieli & Tabach, 2019).

De-ritualization in teaching and learning of mathematical proof and the role of teachers

Several characteristics of de-ritualization have been discussed by Lavie et al (2019). These characteristics include flexibility, bondedness, applicability, agentivity, objectification and substantiability. In context of mathematical proof, according to Karavi et al. (2022), *flexibility* refers to presenting multiple approaches to the same proof, demonstrating that there are different paths to the same solution. *Bondedness* describes the links between conceptual understanding and the formal execution of steps in a proof. *Applicability* means how a specific proof strategy or concept can be applied in other mathematical contexts, showing broader relevance beyond the immediate problem. *Agentivity* refers to the extent to which students take an active role in the proving process, rather than

passively following algorithms. *Objectification* is the ability to treat mathematical concepts as objects that can be manipulated, rather than just procedures to be executed. Finally, *substantiability* is the degree to which students can provide meaningful explanations for each step in a proof, grounded in their conceptual understanding.

To obtain characteristics of de-ritualization, teachers play a crucial role in the classroom (Karavi et al., 2022; Valenta & Enge, 2022). Valenta and Enge (2022) provide a practical framework for achieving this, suggesting six practises to support students: (1) introducing new routines and guiding the interpretation of tasks, (2) promoting proving tasks that require exploration, (3) encouraging clear communication and challenging informal arguments, (4) facilitating the shift from empirical arguments to deductive reasoning, (5) emphasizing the significance of justification, pattern recognition, and the development of strategic knowledge, and (6) aiding students in recognizing structures, developing clear reasoning, and connecting various mathematical concepts.

Literature review on teaching and learning of mathematical induction

Mathematical induction is a powerful tool for proving patterns, identities, and algorithmic correctness, yet it remains a challenging topic for students (Baker, 1996; Telloni & Malara, 2021). Telloni and Malara identify four key difficulties: *logical*, *conceptual*, *technical*, and *psychological*. Students often misunderstand the sequence of logical implications that connect the base step to the induction step because they see the variable n simply as a generic fixed number, and do not reflect on the role of quantification. Many also struggle with algebraic manipulation. These challenges suggest that students frequently engage with induction as a procedural routine rather than a conceptual process. From a commognitive perspective, this reflects a ritualized mode of learning that hinders deeper understanding and flexible application.

Recent studies have proposed strategies to enhance students' conceptual understanding of mathematical induction. Telloni and Mallara (2021) identified four key activities: *exploration* and *conjecturing*, *small group work*, *proofs* and *refutations*, and a *role-playing game*. These activities encouraged students to generalize from patterns, collaboratively prove implications, analyze flawed arguments to grasp the structure of Principle Mathematical Induction (PMI), and teach peers to reflect on their understanding. Conducted with Computer Engineering sophomores in Italy, the study showed improved comprehension of PMI, especially in handling its complexity and appreciating its explanatory power. Students also developed stronger linguistic, argumentative, and reflective skills. The authors suggest this approach benefits not only students but also pre- and in-service teachers due to its focus on higher-order goals and argumentation beyond technical proficiency.

Relaford-Doyle and Núñez (2021) introduced visual proofs to investigate students' understanding of mathematical induction. Participants, both MI-trained and untrained, created tutorial videos explaining visual proof to a hypothetical audience, followed by reflective interviews. The study found that while MI-trained students had procedural knowledge, they often lacked conceptual depth, especially when applying induction across different representations. MI-untrained students struggled

with foundational concepts, such as the nature of natural numbers. The authors recommend incorporating visual proof into instructions to promote deeper conceptual understanding.

De-ritualization of mathematical induction: reframing teaching and learning activities

Based on the theoretical considerations above, we propose a sequence of teaching and learning activities consisting of three sessions, each 100 minutes long, to promote de-ritualization of mathematical induction. Table 1 illustrates our proposed sequence of teaching and learning activities. We propose two key shifts in the framing of teaching and learning activities. First, we advocate for reducing the scale of ritual-enabling OTLs that overly focus on the procedural aspects of induction proofs. Secondly, we propose incorporating exploration-requiring OTLs that foster deep engagement with the various roles of proof, such as verification, explanation, systematization, and discovery. Below we describe three of our suggested activities in detail (oral presentation and reflection from Session I, proof evaluation and peer review from Session III). We will explain how these activities have potential to support de-ritualization in mathematical induction.

Table 1: Teaching and learning activities

Session I (Introduction to MI)	Session II (Consideration of base cases)	Session III (Consideration of nature and features of MI)
(1) Students explore a visual pattern individually, discuss and make a conjecture about the sum of the first n natural numbers in groups.	(1) Students recall what they have learned in Session I.	(1) Students explain individually in writing for each of the steps in MI why they are necessary.
(2) Instructor explains the idea of MI using visual analogies (not showing an example proof).	(2) Students identify base cases for three example statements.	(2) Proof evaluation exercise (see below for detail)
(3) Students work in groups to prove their conjectures from (1).	(3) Class discussion about importance of careful consideration of base cases.	(3) Proof construction exercise.
(4) Presentation and reflection (see below for detail).	(4) Students work in groups to outline their strategies or proof ideas to prove one of the statements from (2). (5) Group work: students develop their ideas from (4) into formal proofs.	(4) Peer review activity (see below for detail)
(Closure Activity) Students discuss and summarize what they have learned in Session I.	(Closure Activity) Students summarize what they have learned in Session II.	(Closure Activity) Students summarize what they have learned in Session III.

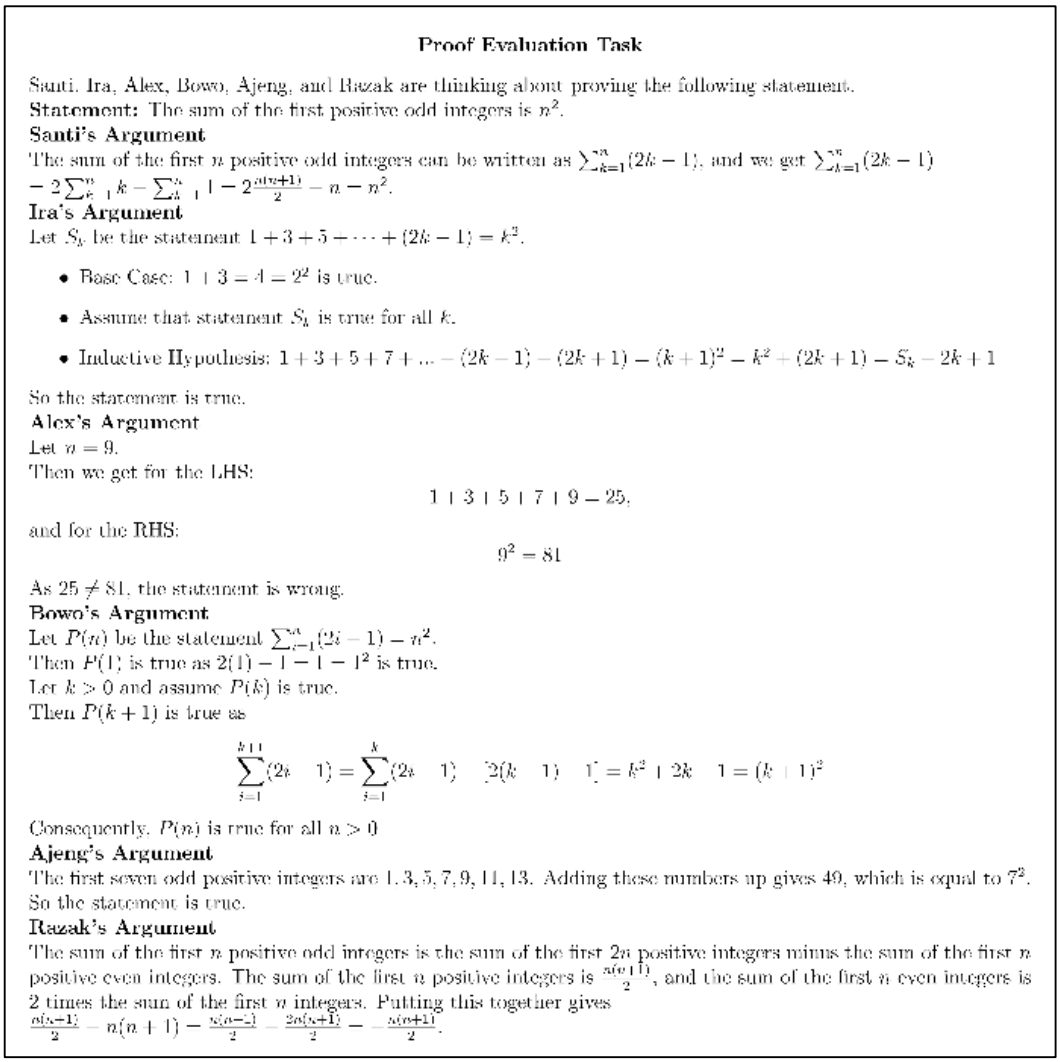
Inspired by Kontorovich & Greenwood (2023), we include oral presentation and reflection activities. After students prove their conjectures and plan their presentations in groups, some delegates present their proofs. This activity involves students writing and explaining their proofs without much interaction with the rest of the class during the presentation. Presenting their ideas allows students to validate and refine their proofs in a public setting. This activity encourages students to engage in practices similar to those of the mathematics community (Kontorovich & Greenwood, 2023). When students present their proofs, they take ownership of their reasoning process. Students move beyond ritualized execution to communicate the reasoning behind the base case, inductive assumption, and inductive step, which is the essence of de-ritualization. After presentations, students engage in a posteriori reflection to discuss the presented proof. The instructor then provides feedback, highlights any issues, and offers suggestions for improvement. These reflection activities help deepen students'

understanding of the concept of mathematical induction. By discussing their proofs, students see different perspectives and approaches, which is enriching their learning experience, and encouraging them to think critically about their work and the work of others. Reflection activities in Session I prepare students for the more advanced collaborative tasks of proof evaluation and peer reviewing in Session III.

For the proof evaluation task, students will be presented with a variety of approaches to prove a statement, of different nature with some of them being flawed, see Figure 1. Students are instructed to collaboratively: a) observe and compare the arguments, b) rank the arguments in order of their preference and include some comments to explain the ranking, c) include comments about the arguments, and d) find any errors in the arguments and advise to resolve the errors. As suggested by Pfeiffer & Quinlan (2015a), the six arguments provide a sufficient variety of different approaches to provoke learning and discussion about the nature and features of mathematical proof and about the process of proof evaluation. In our proof evaluation task, Santi's argument and Razak's argument are sufficient to prove the statement, but not using mathematical induction. Ira's argument has several errors: the base case is wrong, too much is assumed, S_{k+1} is used in an effort to prove it, and S_k is used as a value. Alex's argument interprets n incorrectly as the last odd number to be added in an effort to provide a counterexample. Bowo's argument is a valid proof using mathematical induction. Ajeng's argument is an example and does not prove the statement.

There is no "right answer" for the proof evaluation task. Incorporating a request for students to rank the proofs according to preference encourages them to evaluate the subjective qualities of each proof and recognizes the diversity of mathematical perspectives (Pfeiffer & Quinlan, 2015b). By ranking the different proposed arguments, students consider and discuss criteria that make a good proof. This activity encourages students to reflect on purposes of mathematical proofs, including how they establish truth and enhance understanding. When students discuss and compare arguments in the task, they gain insight into the structure and function of each step in mathematical induction and the importance of these steps, why these steps are missing and what happens if any part is missing, incorrect, or unclear. By critiquing flawed arguments, students may notice cases where induction is misapplied, such as incorrect base case and overextending the assumption which can make the argument invalid. By comparing different arguments, students see that there may be multiple valid ways to approach and prove statements. Proof evaluation activities address several goals of de-ritualization, to enhance students' understanding of mathematical induction, to foster their critical thinking, and to encourage a more exploratory and reflective approach to mathematical reasoning.

When implementing a proof evaluation task, the instructor has multiple roles (Pfeiffer & Quinlan, 2015b). One is to supply the students with a selection of proposed proofs that is varied and appropriately challenging. This is similar to one of practices suggested by Valenta and Enge (2022), namely aiding students in recognizing structures, developing clear reasoning, and connecting various mathematical concepts. Other roles for the instructor are to facilitate a discussion without fully directing it, to assess the students' work and to consider useful feedback to provide to the group or to individuals. Additionally, the instructor should consider other responses based on their assessment of the students' understanding and competence in mathematical proof.



Proof Evaluation Task

Santi, Ira, Alex, Bowo, Ajeng, and Razak are thinking about proving the following statement.
Statement: The sum of the first positive odd integers is n^2.

Santi's Argument

The sum of the first n positive odd integers can be written as $\sum_{k=1}^{n}(2k-1)$, and we get $\sum_{k=1}^{n}(2k-1)$ $= 2\sum_{k=1}^{n} k - \sum_{k=1}^{n} 1 = 2\frac{n(n+1)}{2} - n = n^2$.

Ira's Argument

Let S_k be the statement $1+3+5+\cdots+(2k-1)=k^2$.

- Base Case: $1+3=4=2^2$ is true.
- Assume that statement S_k is true for all k.
- Inductive Hypothesis: $1+3+5+7+\ldots-(2k-1)-(2k+1)-(k+1)^2-k^2+(2k+1)-S_k-2k+1$

So the statement is true.

Alex's Argument

Let $n=9$.
Then we get for the LHS:

$$1+3+5+7+9=25,$$

and for the RHS:

$$9^2=81$$

As $25 \neq 81$, the statement is wrong.

Bowo's Argument

Let $P(n)$ be the statement $\sum_{i=1}^{n}(2i-1)=n^2$.
Then $P(1)$ is true as $2(1)-1=1=1^2$ is true.
Let $k>0$ and assume $P(k)$ is true.
Then $P(k+1)$ is true as

$$\sum_{i=1}^{k+1}(2i-1)=\sum_{i=1}^{k}(2i-1)+2(k+1)-1=k^2+2k+1=(k+1)^2$$

Consequently, $P(n)$ is true for all $n>0$

Ajeng's Argument

The first seven odd positive integers are $1, 3, 5, 7, 9, 11, 13$. Adding these numbers up gives 49, which is equal to 7^2. So the statement is true.

Razak's Argument

The sum of the first n positive odd integers is the sum of the first $2n$ positive integers minus the sum of the first n positive even integers. The sum of the first n positive integers is $\frac{n(n+1)}{2}$, and the sum of the first n even integers is 2 times the sum of the first n integers. Putting this together gives $\frac{n(n-1)}{2}-n(n+1)-\frac{n(n-1)}{2}-\frac{2n(n+1)}{2}-\frac{n(n+1)}{2}$.

Figure 1: The proof evaluation task

The peer review exercise is scheduled after students prove the statement " For all $n \geq 1, n \in \mathbb{N}$, $1+4+7+\cdots+(3n-2)=\frac{n(3n-1)}{2}$ " collaboratively in groups. Students exchange their proofs with those from other groups for peer review. This task includes writing the other groups' proof idea, to justify whether all steps of the proof are correct, and to give feedback to the other groups. We choose peer review because it encourages students to articulate their understanding and critique their peers' work constructively. As far as we know, this approach is relatively rare in teaching mathematical induction. The activity reinforces students' ability to identify and correct errors, a skill that helps them internalize the structure of induction proofs. According to Telloni and Mallara (2021), the process of validating another student's proof forces them to think through the logic step-by-step, which justifies their own understanding. Writing constructive feedback also helps students think about proof-writing as a communication skill, which is another novel aspect for mathematical induction lessons. According to characteristics in Karavi et al. (2022), peer review tasks naturally

encourage key features that support de-ritualization such as bondedness, helping students make connections between different mathematical ideas within the proof, and agentivity, promoting the active role of students as evaluators and creators of mathematical arguments, thus enhancing their agency in the discourse. Lavie et al. (2019) emphasize that de-ritualization involves changes in students' routines, where their focus shifts from mimicking established methods to actively constructing and validating mathematical arguments. Peer review activities encourage such shifts by requiring students to justify critiques and suggestions, promoting deeper engagement with the proofs.

In the peer review activity, the instructor's role is to facilitate collaboration and open dialogue. The instructor demonstrates how to evaluate proofs constructively, focusing on logical structure, clarity, and reasoning. This practise aids students in recognizing structures, and developing clear reasoning as suggested by Valenta and Enge (2022).

Closing Remarks

Karavi et al. (2022) claimed that the scholarly exploration of instructional approaches aimed at fostering students' de-ritualization of mathematical proving practices remains underexplored. While some alternative approaches (Relaford-Doyle & Núñez, 2021; Telloni & Malara, 2021) emphasize conceptual understanding and student involvement in mathematical induction learning, these studies do not specifically explore de-ritualization in the teaching and learning of this material. In this paper, we address this gap and propose a series of teaching and learning activities to promote de-ritualization of mathematical induction. Going forward, we plan to implement these teaching and learning activities with a group of first-year mathematics undergraduate students at Universitas Negeri Malang, Indonesia, and to use commognition theory to identify de-ritualization processes and to analyze their effect on students' learning and understanding of mathematical induction.

Debating the machine: Mediations and truth

Amedeo Matteucci[1], Francesco Saverio Tortoriello[1] and Ilaria Veronesi[1]

[1]Department of Mathematics, University of Salerno, Italy; amatteucci@unisa.it

In this paper, we examine the relationship between disciplinary debate and mathematical discussion. The advent of generative AI has revolutionised the field of education, bringing about changes that are both profound and irreversible. A key skill that will become increasingly necessary for students in the future is the ability to evaluate AI-generated output. We have previously introduced an activity model—rooted in Engeström's Expansive Learning theory—designed to address this need. In this study, we focus on the dialogical components of the model, particularly discussion and debate, analysing their similarities and differences in light of the concept of mediation, with special attention to the role of teachers.

Keywords: Debate, artificial intelligence, mediation, discussion, argumentation.

Introduction

Pierre Rabardel begins one of his most renowned works (Rabardel, 2002) with a joke. The joke goes that in the cockpits of future airplanes, there will only be two seats: one for a human and the other for a dog; the dog's job is to prevent the human from touching the controls; the task of the human is to feed the dog. With the advent of powerful Artificial Intelligence Large Language Models (AI LLMs), there's a chance that in the aircraft of the future there will be no seats at all, and that risk will not only concern airplanes. In fact, the real risk in an AI-dominated future is not the one depicted in many apocalyptic science fiction movies featuring killing machines: the AI will not make us dead, although it may make us irredeemably lazy. But this scenario—featuring a humanity uncritically, irreversibly, and completely abdicating its decision-making role—is not inevitable.

AI is essentially a guessing machine, a piece of software that tries to give you an answer as close as possible to answers that were given to similar questions (Tao, 2024). So, how is it possible to use a tool that is very powerful yet not entirely reliable? We should devise a way to independently check its answers. Speaking of mathematics, in academic research one possibility is to pair the AI LLM with a proof assistant software (Tao, in print), but in an educational setting this might not be a viable solution. As optical illusions—such as the Müller-Lyer illusion, the Zöllner illusion, the Poggendorff illusion etc.— in challenging intuitive understandings of space and shapes, are useful in letting students understand the necessity of formal geometric reasoning and proofs, the very fact that AI-generated answers to mathematical questions—whether theorem proofs or problem-solving procedures—might look right even if factually wrong can let students understand the need for a consideration of the correctness of the solution itself. The difference between these two situations is that in the first case the subject of this pondering are properties of a mathematical object, in the latter case we are talking about the properties of an argument or a chain of arguments.

Mechanically copying patterns does not generate understanding, as Searle's Chinese Room thought experiment predicted and generative artificial intelligence tools have confirmed. This is especially evident in mathematics, aligning with the belief that mastery of mathematics does not consist merely of knowing certain definitions and possessing procedural skills (cf. Baccaglini-Frank et al., 2017). However, since Plato's era, explanatory dialogue has been regarded as a crucial tool for

preventing the pitfalls of false knowledge and highlighting the non-mechanical and non-imitative nature of knowledge (cf. Piazza, 2020), hence the idea of using dialogical activities to problematise the assessment of AI-generated answer in class. One of the difficulties in orchestrating such an assessment with students is that—unlike what happens in ordinary mathematics teaching—when dealing with AI, teachers cannot act as experts holding institutionalised knowledge: in this regard they are on the same level as their students. Nor can they make up for it with training courses, because the current rapid development of the AI sector makes it impossible to bridge this gap in a timely manner. Our research group has already begun investigating the possibility of applying dialogical methods, including debate (Matteucci & Tortoriello, 2023), to the evaluation of AI-generated answers (Matteucci et al., 2024a; Matteucci et al., 2024b). Notably, while most classroom activities in formal educational contexts that can be classified as debates consist of competitive debates (Akerman & Neale, 2011), unless otherwise stated, we will use the term 'debate' to mean disciplinary debate and metamathematical debate in particular—that is, briefly, a debate focused on the hows and whys of doing mathematics (for more details cf. Matteucci & Tortoriello, 2023). With this distinction clarified, we now provide context and details on applying debate to AI answer evaluation.

Theoretical framework and outline of the proposed model

The dystopian scenario hinted at in the introduction above can be considered the eventual limit outcome of what Rabardel (2002) called the technocentric approach: a perspective where human involvement in technological systems is seen as secondary or even undesirable, therefore characterising human activity as a mere residue. The antithetical approach to the technocentric approach, which is the anthropocentric approach, "places human activity at the heart of analysis and thus allows the reversal necessary so as to speak of things in terms of people" (Rabardel, 2002, p. 5). Of course, Rabardel writes about human activity in a highly technological environment—he is no luddite—where humans have to interact with tools, tools that—to use Rabardel's terminology—are no mere artefacts, i.e. objects considered independently of their use, but instruments—that is artefacts that have been integrated into human activity and have acquired a specific function through their use. In short, an instrument is an artefact—physical or symbolic—in use, mediating the users' interactions with their environment, helping them achieve their goals.

Rabardel's notions of artefact and instrument originate from the concept of cognitive artefact by Donald Norman. In the book where this concept is expounded, Norman (1993) also describes the difference between experiential and reflective cognition. As their names imply, the first is based on experience, immediate, intuitive, it is used in routine situations that do not require analytical thinking; the second one involves conscious thought and reasoning, it is used in planning, learning or problem-solving situations. Of the dangers that can arise in an activity that misunderstands the above difference, Norman says that the one that "poses the greatest peril today is that of experiencing when one should be reflecting" (1993, p. 27)—incidentally, this is exactly the risk we hinted at in the introduction. In building upon Norman's concept of cognitive artefact describing how an artefact can become an instrument, Rabardel (2002) also introduces the concepts of instrumentalization and instrumentation: the first refers to the process by which an artefact is modified or adapted to better fit the users' needs within an activity, while the second describes how

users develop the necessary cognitive and operational schemes to effectively use the artefact as an instrument.

Phase	Sub-phase	Description
Chatting	1. Problem Selection	The teacher selects a mathematical problem to be solved by the AI.
	2. Problem Input	The teacher inputs the problem into the GAI chatbot, requesting detailed explanations of the steps used to reach the solution.
	3. Solution Distribution	The teacher sends the problem along with the AI-generated solution to the students.
Discussing	4. Critical Review	Students critically review the solution at home, following a predetermined list of criteria: correctness, completeness, effectiveness, generalizability, clarity, understandability.
	5. Classroom Discussion	Students discuss their assessments in class under the teacher's supervision to establish consensus on the conformity of the solution to the aforementioned criteria.
	6. Motion Drafting	The teacher drafts precise debate motions based on the unresolved controversial issues from the discussion, using the metamathematical motions' taxonomy.
Debating	7. Debating	Students, divided into teams, debate the motions prepared by the teacher according to a specific protocol.
	8. Debriefing	The teacher debriefs the students on the debate results, highlighting strengths and weaknesses in reasoning and argumentation.
	9. Final Discussion	Students and teacher discuss the lessons learned from the debate and debriefing, concluding with a metacognitive reflection.

Table 1: Model of the proposed activity

Expanding on Rabardel's work about instruments and their genesis, Bartolini Bussi's theory of semiotic mediation (Bartolini Bussi & Mariotti, 2008) delves deeper into how instruments become instruments of thought in educational settings. She argues that instruments are not just objects or symbols but are embedded within a broader semiotic system where meaning is co-constructed through interaction. In this framework, the teacher plays a crucial role in guiding students' use of tools, helping them transitioning from external, concrete interactions with artefacts to internal, abstract mathematical reasoning. This process of semiotic mediation, therefore, explicitly links the development of cognitive schemes to the communicative and social dimensions of learning in the classroom, within a Vygotskian framework.

Speaking of Vygotskian frameworks, it is useful for our purposes to underline the difference between action and activity, as exemplified by Engeström and Sannino (2017) expanding on an example by Leont'ev:

> In a tribal hunt, for example, certain participants chase the game away, toward other participants who wait in ambush and kill the game. These two groups perform different actions (chasing, killing) in the collective activity of hunting. The half-life of an action is finite; an action has a definite beginning and an end. A collective activity, on the other hand, reproduces itself without a predetermined endpoint by generating seemingly similar actions over and over again. Yet there is continuous and at times dramatically discontinuous change in the activity. The very idea of expansive learning is built on this theoretically consequential *distinction between action and activity*. Expansive learning is movement from actions to activity. (p. 105)

Building on this distinction, we already proposed an activity model, built up on dialogical actions, designed to foster students' critical engagement with AI-generated solutions to mathematical questions, shifting focus from product-oriented learning to process-oriented understanding (Matteucci et al., 2024a; Matteucci et al., 2024b). In our usage, the term "dialogical" refers to any interaction between subjects that involves an exchange of responses with a back-and-forth dynamic. While such interactions are typically conceived as oral exchanges, they are not in principle limited to this form and may also occur in written formats, such as digital chat. The aforementioned model is summarised in Table 1.

In this model, the overall activity—*Tätigkeit*, to use the German word that best conveys the meaning of activity as collective interaction aimed at achieving a collective goal, instead of simply being busy with something to do (Radford, 2021)—involves the use of different "dialogical tools" that can be considered instruments in Rabardel's meaning. These instruments are both discussions, in subphases 5 and 9, and debates, in subphase 7. Debates are to be intended as metamathematical debates (Matteucci & Tortoriello, 2023; Giangrande & Matteucci, 2021), but how are they related with the discussions? Moreover, can these discussions here be considered compatible with the concept of "mathematical discussions" described by Bartolini Bussi (1996)? Because while the latter entail facilitating students' construction of object meanings through the use of signs, in this particular case, the meanings we are considering—e.g. the clarity of a proof—are not those of mathematical objects *per se*, nor is the presence of corresponding signs for them guaranteed.

Thus, the question we are posing is: how can discussions in the proposed activity model be properly understood in relation to debate? And what is the role of teachers in this context?

Protocols, dialectics, and teachers

According to Bartolini Bussi (1996), in a Vygotskian approach, the social construction of knowledge in classroom activity:

> is realised, on the one side, by the format of discussion, that gives value to joint activity in mathematical experience and, on the other side, by the systematic recourse to tools for semiotic mediations [...] hence mathematical discussion and semiotic mediation seem to be the two sides of a same coin both theoretically and experimentally (pp. 37–38)

The overall process can be conceived as an iteration of "didactical cycles" (Bartolini Bussi & Mariotti, 2008) each of which consists of: a) activities with artefacts, b) individual production of signs, c) collective production of signs; step c) is where mathematical discussion plays a crucial role. In this respect, if one examines the model in Table 1, one can see a parallel between its first phase, subphase 4, subphase 5 and steps a), b), c) above. There is one important difference, however. In the case discussed by Bartolini Bussi and Mariotti the teacher exploits the semiotic potentialities of the use of a given artefact to foster the students' move towards the learning of the properties of a given mathematical *object*, while in our model it is the properties of a mathematical *process* that teachers and students are interested in.

If one considers metamathematical debate as a tool of semiotic mediation, one can also draw an additional parallel between the aforementioned steps a), b), c) of the didactical cycle and subphases 7, 8, 9 of the model in Table 1. It is important to recognise that, also in this case, the intended mediation is different. To explain how this latter mediation is also different, consider that in the framework of Bartolini Bussi and Mariotti (2008), teachers mediate between students and mathematical knowledge using artefacts as tools of semiotic mediation. This mediation is typically intended as a bridge between the personal meanings of the students and the institutionalised meanings of mathematics as an academic discipline, and this evolution of signs, with respect to the students, towards mathematical signs is akin to the institutionalization process as found in Brousseau (2006). Conversely, in the case of the mediation during debate and debriefing actions in subphases 7, 8, 9 of the model, this mediation does not focus primarily on the abstract mathematical objects that can be found in the various branches of institutionalised mathematics. It mediates, instead, mainly between the personal experience that students have of debates and discussions (intended in a broad sense) and debate as a regulated dialectical practice. It also mediates between students' personal beliefs about how and why they engage in mathematics and the reflections on the how and why one does mathematics, according to the professionals' practice, that is the object of the so called philosophy of mathematical practice (cf. Mancosu, 2008).

The differences between these kinds of mediations and the typical mediations of mathematical discussions, and also the differences of these two kind of mediations between themselves allow us to further clarify the status of metamathematical debate—and disciplinary debate, understood in a broad sense—versus both competitive debate and mathematical discussion. First, although competitive debate can exist in isolation as a 'team game', disciplinary debate differs from it primarily because it is necessarily embedded within a broader activity—exactly as, to elaborate further along the lines of Leont'ev's example, although archery as a sport can exist in isolation, archery as a real life practice makes sense only within a broader context (e.g. hunting, war). Second, debate not only does not overlap with the concept of mathematical discussion but, in fact, within the discussion/tool dichotomy illustrated in the previous quotation by Bartolini Bussi (1996), it takes on the role of a tool. In which way can debate act as a tool or, to use a more precise term, as an instrument? Since debate, as we said above, can mediate between both the beliefs about how disputes are conducted and how and why mathematics is done, it does this with respect to its two constitutive aspects, respectively: 1) protocol, 2) dialectic.

A protocol is the set of rules that governs how a debate is conducted. It contains indications related to timing, speaking order, rules of engagement, cross-examination, moderation. Although teachers

will mainly act as moderators during the debate, their role in devising, adapting, and enforcing the protocol will in turn create the action that shall act as a mediating tool with respect to the belief about how disputes are conducted. Dialectic is a mode of argumentation theory that starts, typically, from probable premisses, instead of principles or axioms, and differs from both demonstrative reasoning—insofar as the latter is based only on deductions from certainties—and rhetoric—which does not rely exclusively on rationality but also on authority and emotion, the famous Aristotelian triad of *logos*, *ethos*, *pathos*. Keeping track of the structure of the proposed arguments during debate, and comparing their relative effectiveness, teachers will be able to prepare a debrief (subphase 8) that along with the debate proper (subphase 7) will be the tool mediating the conclusive reflection of the whole activity (subphase 9).

Speaking again of the role of teachers, we see that while in competitive debate they act mainly as moderators, here their role as mediators is paramount throughout the activity as a whole. This is due to the peculiar nature of the disciplinary debate described above. Plato, in the seventh book of The Republic, already warned about the risks of the uncritical use of dialectic by the youth, especially when done for amusement rather than in the pursuit of truth (Plato, 2013). Here, the teacher does not simply act as a referee but as a guarantor—not of the final results, which by their very nature cannot be institutionalised à la Brousseau, but of the intentionality of the entire activity in the search for truth, understood as the collective result of a process of applying mutually agreed-upon criteria of rationality to ongoing open questions.

Conclusions and perspectives

With this paper we aimed to better situate debate within the landscape of research in mathematics education, elucidating its status *vis-à-vis* other established dialogical practices—i.e. dialogical discussion. It emerged that disciplinary debate is not only non-conflatable with mathematical discussion, but also serves as an essential complement for it in contexts where *lato sensu* metamathematical issues are to be addressed.

Moreover, we contributed to clarifying the role of teachers in disciplinary debate, underlining the fact that they act not only as 'judges'—as it is customary in competitive debate—but also as mediators, and the mediations they are enacting are typically different from what usually happens in the majority of mathematical discussions as there is no single institutionalised reference to aim for. The emphasis in the previous sentence is on the word "single". The point being that, while there is a single right answer to the question about, say, what is the sum of the internal angles of a triangle in Euclidean geometry, there is no single codified right answer to questions such as: what is the most explicative proof of Gauss' formula for the sum of the first n positive integers or what is the worst error one can make in solving a quadratic inequality. Nonetheless, the fact that there is no single institutionalised answer does not mean that there are none—even institutionalised.

After having answered the questions about the relationship between discussion and debate and what is the role of teachers in this context, we are now poised to shift our focus toward briefly exploring the broader implications and future avenues of inquiry that these results envisions.

We recently completed the design of a pilot experiment (Matteucci et al., 2024b), which will be conducted in a secondary school next autumn. This pilot test aims to evaluate the feasibility and

effectiveness of our proposed model and will take place within the framework of the Liceo Matematico (Mathematical High School) research project (Rogora & Tortoriello, 2021).

Empirical testing, of course, is not the only perspective opened by the present work. There is still room for theoretical research, starting from these conclusions. Topics that deserve to be studied include, for example, how to link the concept of instrumental genesis to debate seen as a tool, and how to detail the selection and refinement of its protocol through the processes of instrumentation and instrumentalisation (Rabardel, 2008). Also, considering the specific application of the proposed model to the evaluation of AI-generated answers to mathematical questions and not only the more general application of metamathematical debate, another issue worth researching is modifying the model to include the analysis of how to modify the prompts to obtain better results and, eventually, delegate the first phase of the activity to the students themselves.

In his famous paper titled "On Proof and Progress in Mathematics," William Thurston, discussing what he considered the ultimate goal of mathematicians' work, wrote: "What we are doing is finding ways for *people* to understand and think about mathematics. The rapid advance of computers has helped dramatize this point, because computers and people are very different." The advent of generative AI has made this goal even more relevant. We maintain that the activity proposed in our model is a small step towards achieving it.

Proof awareness and students' proof evaluations

Andreas Moutsios-Rentzos[1] and Vassiliki Mantziou[2]

[1]National and Kapodistrian University of Athens, Department of Pedagogy and Primary Education, Athens, Greece; moutsiosrent@primedu.uoa.gr

[2]First Directorate of Secondary Education of Athens, Athens, Greece

In this paper, we introduce the construct of proof awareness conceptualized as a complex affective system including also meta-affective dimensions about experiencing proof: self-efficacy, views, certainty, and emotions. As an exemplar, we operationalize this theoretical perspective to investigate the proof awareness of high school students (Grade 10) in Greece as they evaluate different proving statements in an algebra task. Indicative results of the empirical study are discussed.

Keywords: Proof awareness, affective system, high school, algebra.

Setting the scene

Proof appears to be the validity gatekeeper of modern mathematics. Notwithstanding the fact that school mathematics qualitatively differs from the mathematics discipline, proof holds a central role at school, even as a potentiality. Considering the complexity that mathematical proof entails and the complex mathematics classroom system, researchers have investigated aspects of the students' conceptualisations of proof and their divergences from the desired qualities. For example, considering the validation function of proof (Zaslavsky et al., 2012), the students face difficulties discerning the complex relationship between mathematical verification, which is based on a theoretical framework, and common-sense verification, which is based on empirical confirmation (Mariotti, 2006), thus being sceptical about the way that a deductive proof secures the lack of counterexamples (Chazan, 1993). The students appear to strive to realise the need for producing a proof, or even when they do, they are uncertain about the logical process to follow, the steps they need to perform, whether they have successfully completed it, or, in cases that they may construct an institutionally acceptable proof, they may remain unsure about the generalization of a proof or whether further empirical checks are needed (Herbst & Brach, 2006). Considering the fact that the learning outcomes of an educational system is strongly related to the assessment process (Boud & Falchikov, 2007), the students appear to experience a chasm between proofs they believe will receive better grades and proofs that the students themselves would adopt (Healy & Hoyles, 2000; Moutsios-Rentzos & Korda, 2018).

Raising awareness about crucial aspects of mathematics practices is essential to developing crucial qualities of mathematical thinking. Moreover, a central goal of mathematics teaching is to improve and enhance students' awareness concerning the types of arguments and proofs that are acceptable for validating various statements (Tabach et al., 2010). Following these, in this paper, we introduce the notion of proof awareness and we discuss aspects of an empirical study investigating the proof awareness of Grade 10 students when evaluating proving statements about an algebraic task.

Towards a conceptualisation of proof awareness

The importance of teachers' awareness in the teaching and learning mathematics has been stressed by various researchers (Mason, 1998; Potari, 2022). Mason (1998) notes that awareness is "a complex

concept comprising both conscious and unconscious powers and sensitivities which enable people to act freshly and creatively in the moment" (p. 243). Mason continues by drawing upon Gattegno (1987) to identify three levels of awareness:

> *awareness-in-action* (the powers of construal and of acting in the material world); awareness of awareness-in-action, or *awareness-in-discipline*, which enables articulation and formalisation of awarenesses- in-action, and is closely linked to one form of shift of attention; awareness of awareness-in-discipline or *awareness-in-counsel*, which is the self-awareness required in order to be sensitive to what others require in order to build their own awarenesses-in-action and -in-discipline. (Mason, 1998, p. 256)

Thus, the role of *attention* is crucial in one's being aware of something and qualitatively differs from one's perceptual and/or mental ability to perceive something. For example, a medical doctor may draw life-saving conclusions that a non-medically trained person cannot, although both apparently experience the same perceptual reality. Thus, awareness may be linked with the phenomenological notion of *intentionality*, which refers to "the conscious relationship we have to an object," thus implying that every "intending has its intended object" (Sokolowski, 2000 p. 8). Following these, *noema* (the phenomenologically described given object) is differentiated from *noesis* (the intentional activity). Hence, awareness may be conceptualized as an intending activity, as the experienced lifeworld is determined by the ways the intending being is related with the intended object.

Learning has also been strongly linked with the affective domain. For example, emotions have been found to be related with mathematical achievement and learning (Kleine et al., 2005). Thus, awareness is associated with the interaction between cognitive and emotional aspects, grounded in one's beliefs, abilities, and level of understanding (Hannula et al., 2004). Considering the interplay of conscious and pre-conscious affective states in learning situations, Malmivuori (2001) emphasised the role of self-regulation and self-motivation and the dynamic links between affective arousal and states and cognition within specific social mathematics learning situations. Regarding proof and proving, Selden et al. (2010) distinguish emotions from feelings ("with the former being physical and the latter being mental," p. 202) and they suggest that nonemotional feelings play an important role in the students' behavioural schemas ("habits of mind, that appear to drive many mental actions in the proving process," p. 199) when they are engaged in a proving process.

Furthermore, learning mathematics within a school environment is largely a goal-oriented activity, related with the results of the assessment process (e.g., grades). Skemp (1979) posited a theory about goal-directed thinking identifying two 'realms of consciousness': a) actuality, the "environment in which our physical actions and activities take place" (p. 21), and b) inner reality, the person's 'mental realm' of "individual experiences [...] which can also take place independently of sensory input from actuality" (p. 21). He argues that "many, perhaps most, of our actions are systematically directed toward bringing about goal states" (p. 105). Skemp explicitly discusses the role of emotions as they "give information about progress, or ability to progress, relative to goal states and anti-goal states" (Skemp, 1979, p. 18) set by an individual. Focussing on proof, Moutsios-Rentzos (2009, 2015) drew upon Skemp's theory to propose a topological organisation of the multidimensional affective and cognitive broader and task-specific processes operating in an exam-type proving question situation

to identify and give meaning to the links amongst: general affective/thinking learning dispositions (such as attitudes or cognitive styles), domain-specific affective/thinking learning dispositions (such as mathematics attitudes or mathematics learning style), and actual task-specific affective/thinking experiences (such as emotions or thinking strategies).

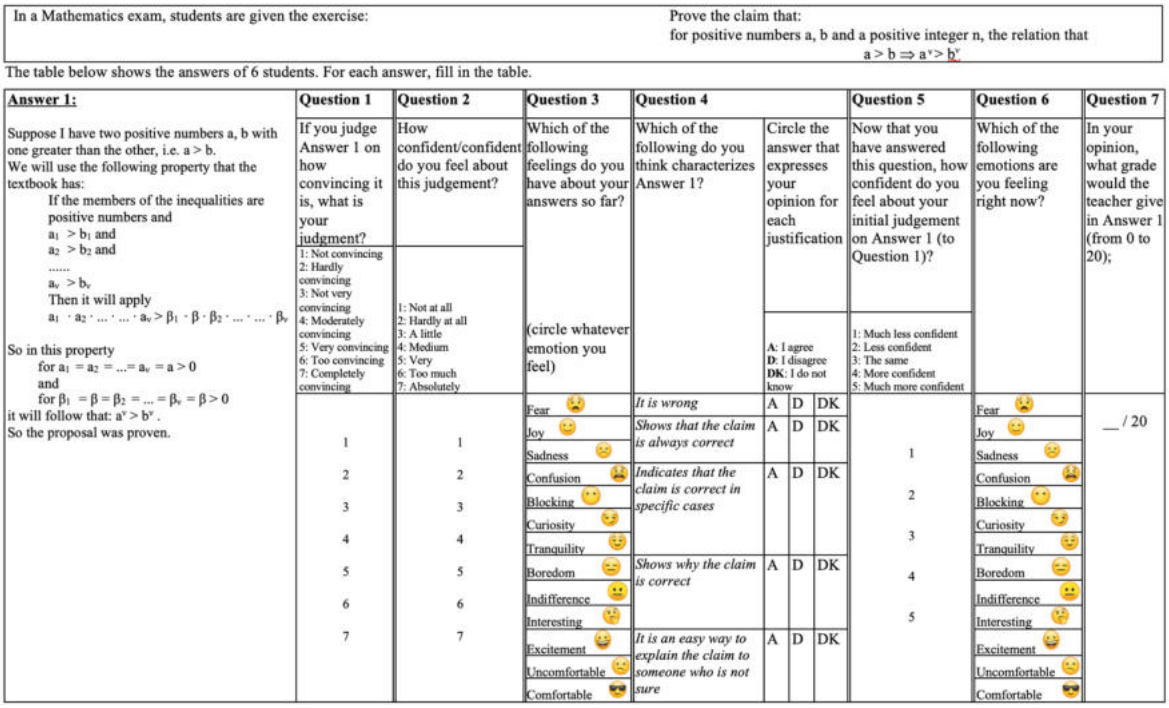
Following these, *proof awareness* is conceptualised as a partially hierarchical, complex affective system (Pepin & Roesken-Winter, 2015), with *proof self-efficacy* representing an overarching wholistic affective positioning about proof, whereas *views*, *certainty,* and *emotions* about proof are situated and given meaning in relation with this positioning. Proof awareness includes meta-affect referring "to affect about affect, affect about and within cognition about affect, and the individual's monitoring of affect through cognition (thinking about the direction of one's feelings) and/or further affect" (DeBellis & Goldin, 2006, p. 136). The meta-affective dimension of proof awareness includes, for example, views about expressed views, as well as emotions about views and emotions.

Considering proof self-efficacy, Bandura (1986) defines self-efficacy as "people's judgments of their abilities to organize and perform actions required to achieve defined forms of proof" (p. 391). In relation to mathematics, Hackett and Betz (1989) state that "mathematical self-efficacy is a casual, on a particular problem, assessment of an individual's confidence in his or her abilities to perform successfully on a particular activity or problem" (p. 262). Following these, we posit that proof self-efficacy refers to the extent that one believes that the proof influences mathematics learning and who also have confidence in their proving abilities. Furthermore, views refer to a 'softer-wired' construct than beliefs in terms of their temporal stability (Goldin, 2002; Hannula, 2012). Hence, we conceptualise views about proof to include one's views about proof, as well as his/her views about specific (claiming to be) proving statements, produced or evaluated by this person. Emotions may refer to two inter-related, complementary notions of an *affective reflex*: a state of alertness as a bodily reaction to a stimulus (Oatley & Jenkins, 1996), and/or a socially situated, and mentally processed affective reaction towards a situation (Hannula, 2012). In our perspective, proof awareness includes the affective reflex towards a proving situation (e.g., proof evaluation.). Moreover, drawing upon the notion of intentionality, in our conceptualisation of proof awareness, we explicitly include the *audience* of the proving statement (Moutsios-Rentzos, 2009; Segal, 1999) and the context within which is situated, as the *goals* of the proof-related situation may radically differ. For example, students' proof awareness may differ in a high-stakes situation (such as exams) from a non-threatening situation (such as a research interview). Finally, in line with Mason (1998), we identify three levels of the students' proof awareness: proof awareness-in action, proof awareness-in-discipline, and proof awareness-in-counsel.

Operationalizing the theoretical perspective to an empirical investigation

In order to operationalize this perspective, a study was conducted in April (towards the end of the school year) with 59 students (N=59) attending Grade 10 in a public high school in Greece. Data were collected through questionnaires and follow-up interviews (two weeks after the questionnaires), structured in line with the questionnaire with four students (two average and two above average, as identified by their teacher). The questionnaire was organised in two sections: one focusing on the students' affective relationship with mathematics, whilst the second section focused on proof

awareness in proof evaluation of specific proving statements. In this paper, we concentrate only on proof awareness and on aspects of the respective conducted analyses.



In a Mathematics exam, students are given the exercise:

Prove the claim that:
for positive numbers a, b and a positive integer n, the relation that $a > b \Rightarrow a^v > b^v$

The table below shows the answers of 6 students. For each answer, fill in the table.

Answer 1:	**Question 1**	**Question 2**	**Question 3**	**Question 4**			**Question 5**	**Question 6**	**Question 7**
Suppose I have two positive numbers a, b with one greater than the other, i.e. a > b. We will use the following property that the textbook has: If the members of the inequalities are positive numbers and $a_1 > b_1$ and $a_2 > b_2$ and ..... $a_v > b_v$ Then it will apply $a_1 \cdot a_2 \cdot \ldots \cdot \ldots \cdot a_v > \beta_1 \cdot \beta \cdot \beta_2 \cdot \ldots \cdot \ldots \cdot \beta_v$ So in this property for $a_1 = a_2 = \ldots = a_v = a > 0$ and for $\beta_1 = \beta = \beta_2 = \ldots = \beta_v = \beta > 0$ it will follow that: $a^v > b^v$. So the proposal was proven.	If you judge Answer 1 on how convincing it is, what is your judgment? 1: Not convincing 2: Hardly convincing 3: Not very convincing 4: Moderately convincing 5: Very convincing 6: Too convincing 7: Completely convincing	How confident/confident do you feel about this judgement? 1: Not at all 2: Hardly at all 3: A little 4: Medium 5: Very 6: Too much 7: Absolutely	Which of the following feelings do you have about your answers so far? (circle whatever emotion you feel)	Which of the following do you think characterizes Answer 1?	Circle the answer that expresses your opinion for each justification A: I agree D: I disagree DK: I do not know		Now that you have answered this question, how confident do you feel about your initial judgement on Answer 1 (to Question 1)? 1: Much less confident 2: Less confident 3: The same 4: More confident 5: Much more confident	Which of the following emotions are you feeling right now?	In your opinion, what grade would the teacher give in Answer 1 (from 0 to 20); __ / 20
	1 2 3 4 5 6 7	1 2 3 4 5 6 7	Fear Joy Sadness Confusion Blocking Curiosity Tranquility Boredom Indifference Interesting Excitement Uncomfortable Comfortable	*It is wrong*	A	D	DK	1 2 3 4 5	Fear Joy Sadness Confusion Blocking Curiosity Tranquility Boredom Indifference Interesting Excitement Uncomfortable Comfortable	
				Shows that the claim is always correct	A	D	DK			
				Indicates that the claim is correct in specific cases	A	D	DK			
				Shows why the claim is correct	A	D	DK			
				It is an easy way to explain the claim to someone who is not sure	A	D	DK			

Figure 1: Investigating proof awareness in proof evaluation (Answer 1)

Regarding the level of proof awareness, in this study, we mainly focus on proof awareness-in action and, in specific, on proof evaluations (and not, for example, on proof producing). Considering proof awareness and proof evaluation, first, the students completed the Proof Self-Efficacy Scale, which was constructed in line with Bandura (2006), drawing upon Hackett and Betz (1989) and May (2009). Subsequently, they completed a questionnaire investigating their views about proof (Moutsios-Rentzos & Korda, 2018). Considering proof evaluations, the students were provided six answers to an algebra task that they were asked to evaluate (see Figure 1). Drawing upon the types of proof that the students encountered during Grade 10 in Algebra, upon Balacheff (1988), upon Duval (2006) and upon Moutsios-Rentzos (2009) the following six types of answers were provided: Answer 1 (deductive, correct, expected mathematical language in Algebra; see Figure 1), Answer 2 (deductive, incorrect, expected mathematical language in Algebra), Answer 3 (deductive, correct, natural language), Answer 4 (crucial symbolic experiment, expected mathematical language in Algebra), Answer 5 (naïve empiricism, expected mathematical language), Answer 6 (geometrical, expected mathematical language in Geometry). In line with Moutsios-Rentzos and Korda (2018) and with proof awareness as conceptualized in this paper, the students were asked for each of the six answers the following (see Figure 1): to evaluate how convincing this answer is, to provide a degree of their certainty for their evaluation, to identify their emotions about this evaluation, to identify their views about whether this answer satisfies different functions of a proof (cf. Healy & Hoyles, 2000), to re-evaluate their certainty about their initial evaluation, to re-identify their emotions about this evaluation, and to provide their expectation about the grade that the teacher would assign to this

answer. At this point, it should be noted that we acknowledge the literature investigating basic emotions (e.g., Moutsios-Rentzos & Kalozoumi-Paizi, 2017), but for the purposes of that study, we considered only the students' emotions as communicated by their conscious choices. Upon completion of their evaluations about the six tasks, the students were asked to re-consider all the answers to *comparatively* re-evaluate them, to justify their choice, to state their certainty about this choice, and to identify their emotions at that stage (see Figure 2). The latter part is attempting to also explore the students' second level of proof awareness: proof awareness-in-discipline.

Of the previous answers, which would you choose in a Mathematics exam?

	Question 1	**Question 2**	**Question 3**	**Question 4**
	Mark your choice with✓.	Why did you choose this answer? Explain your view.	Now that you have answered this question, how confident do you feel about your initial choice? 1: Much less confident 2: Less confident 3: The same 4: More confident 5: Much more confident	Which of the following emotions are you feeling right now?
Answer 1			1 2 3 4 5	Fear Joy Sadness Confusion Blocking Curiosity Tranquility Boredom Indifference Interesting Excitement Uncomfortable Comfortable
Answer 2				
Answer 3				
Answer 4				
Answer 5				
Answer 6				
None of the 6				

Figure 2: Investigating proof awareness in comparative proof evaluation

Indicative results and concluding remarks

For the purposes of this paper, we consider only two of the research questions posed in the broader study: a) How is proof awareness (as conceptualized in this study) manifested in first-year high school students? b) What is the relationship between this awareness and different types of proofs and proof arguments?

Considering views and certainty, the results of the quantitative analyses revealed that the students appear to favour deductive incorrect proof (27%) and naïve empiricism (21%) as the most convincing. Moreover, they seem to be certain about their choices (more than 70% positive certainty for all the provided answers). The situation did not appear to change in the respective meta-affective dimension, when they were asked to re-consider their evaluations. It is noted that this was after the students stating that the answer: a) 'deductive-correct-expected' is correct and it explains, b) 'deductive-incorrect-expected' is correct, it holds true in some cases, and it explains, c) 'deductive-correct-natural language' is undecided whether it is correct or not, it holds true in some cases, and it explains, d) 'crucial symbolic experiment' is correct, it holds true in some cases, and it explains, e) 'naïve empiricism' is correct, it holds true in some cases, and it explains, and f) 'geometrical' is correct, it always holds true, and undecided whether it explains or not. Interestingly, the situation changed when the students considered exams: they chose 'naïve empiricism' (27%) and 'geometrical' (21%),

followed by the three deductive proofs sharing the same percentage (14%). Considering the students' emotions and meta-emotions, these did not appear to change across the different phases of the study. Moreover, they were mainly 'comfortable', 'calm' and 'curious' after their interaction with each answer. However, 'blocking' was also prevalent in students' responses for two deductive answers: 'deductive-correct-expected' and 'deductive-correct-natural language'. Consequently, the students appeared to experience a low degree of proof awareness-in action, since they did not hold appropriate views about proof—views associated with positive emotions and high degrees of certainty.

The results of the qualitative analyses partially confirmed these findings, as the students appeared to radically reposition themselves about certainty when during the interview they comparatively re-consider the answers. This also resulted in their reporting more negative emotions about their proof evaluations (e.g., uncomfortable, confusion). Hence, it appears that the comparative proof evaluations within a dynamic communicational context (such as the interview) allowed the students to question their affective positionings. It may be argued that this situation disturbed the equilibrium of the interviewees' affective system, thus allowing for the potentiality of developing more appropriate qualities of proof awareness. However, the fact that such a process entails negative emotions and lower degree of certainty requires delicate teaching decisions. Ongoing research focusses on engineering appropriate teaching designs that may identify the students' proof awareness and to constructively disturb the equilibrium towards obtaining desired proof awareness qualities.

Overall, in this paper, we concentrated on introducing the construct of proof awareness as a complex affective system. As an exemplar, we also presented a way of operationalising these ideas in an empirical study and we discussed aspects of the obtained results, with the purpose to show the potential gains of this theoretical perspective. We argue that raising the students' proof awareness may allow us to tap into important till now invisible aspects of teaching and learning mathematics.

The use of generic examples in students' conjecturing processes

Julia Niederquell[1] and Leander Kempen[1]

[1]University of Greifswald, Institute for Mathematics and Computer Science, Greifswald, Germany

Julia.niederquell@uni-greifswald.de

In this paper, we focus on the use of generic examples in students' conjecturing process from the perspective of promoting mathematical reasoning in school mathematics. For this purpose, we propose the ECJ-model by dividing the conjecturing process into several subprocesses. A case study was used to gain initial insights into how learners cope with generic examples in a conjecturing process and to what extent they make use of its generic idea to justify their conjectures. Results indicate that the role of the generic example differs significantly between the different groups. The study thus considers initial approaches to the potential of generic examples as a scaffold for the transition from conjecturing to justification. By this, we highlight the relevance for further research on the effect of generic examples in mathematical reasoning.

Keywords: Conjecturing process, generic example, school mathematics, mathematical reasoning.

Introduction

In several national standards, the authors call for mathematics education to promote mathematical reasoning in everyday mathematics classes, and also the OECD highlights mathematical reasoning as an integral part of mathematical literacy (c.f., Kultusministerkonferenz, 2022; OECD, 2018). Accordingly, there is a need to offer broad fields of application for mathematical reasoning in daily school mathematics by focusing on different skills. One of these subskills is making and checking conjectures. Developing conjectures is a central component of and closely related to mathematical reasoning processes (Hsieh et al., 2012). Several international studies have shown that conjecturing has become important in teaching mathematics (Cañadas et al., 2007). However, it does not seem clear how to guide learners in their conjecturing processes so that they can subsequently verify their conjectures mathematically (ibid.). In particular, it is unclear how the transition from conjecturing to justification should be organized (Morselli, 2006). It is already known from research that generic examples can be helpful in starting a justification process and can be a fruitful element of proving processes at the school and university level (Kempen & Biehler, 2019). For the process of conjecturing and proving, the use of examples has already been highlighted in the case of university students (e.g., Morselli, 2006). However, it is still an open question how learners can benefit from generic examples during conjecturing processes.

Theoretical Background

According to Reiss and Ufer (2009), 'mathematical reasoning' includes exploring and checking activities that can be labeled as 'conjecturing'. The term conjecturing comprises activities in which "a regularity to be formulated as a (plausible) conjecture is sought or a given conjecture [...] is checked and, if necessary, adapted or corrected" (ibid., p. 157; authors' translation). Making conjectures provides a basis in that arguments or approaches can already be made for later proof production (Kirsten, 2021). Boero et al. (1996) stressed that a lack of engagement with a conjecture from the

outset can create additional obstacles in the proving process. According to the literature, a conjecture is a logical statement whose truth is not yet certain (a.o., Fischbein, 2002). “Along with this idea, conjecture is a statement concerning all the possible cases, based on the empirical facts, but with the doubtful elements.” (Sutarto et al., 2018, p. 1). However, conjectures are constructed in the course of a process. Fischbein (2002) describes the “conjecturing process [...] as the mental activity in constructing conjecture based on the possessed knowledge” (in Sutarto et al., 2018, p. 1). Connected to this, Hsieh et al. (2012, p. 288) “regard the process of proving in the classroom as a process of justifying a conjecture”. There are already several models that describe the activity of conjecturing in more detail, as Cañadas and Castro (2007) do for cases of inductive reasoning in seven stages: (1) Observing cases, (2) Organizing cases, (3) Searching for and predicting patterns, (4) Formulating a conjecture, (5) Validating the conjecture, (6) Generalizing the conjecture and (7) Justifying the generalization. To focus on the activity of conjecturing in the context of mathematical reasoning, a model was developed that represents the essential activities of exploration (E), conjecturing (C), and justification (J) as a process. The activities of the ECJ-model, shown in Figure 1, were refined by the seven stages of Cañadas and Castro (2007) so that the model allows a more focused view and classification of possible conjecturing processes of learners. Here, we focus especially on the transition from conjecturing to justification. As an additional element to support the transition to justification, a generic example has been included in the model.

This model is intended to provide a focused view and classification of a possible learners’ conjecturing process. As conjecturing is considered here as part of a wider reasoning process, the third activity justification is also modeled, but is not the focus of the empirical research presented in this paper. The generic example was meant as a scaffold to ease the transition from conjecturing to justification. As one can see in Figure 1, the generic example is placed at the transition from conjecturing to justification to use the general idea in respective examples as a starting point for such activities.

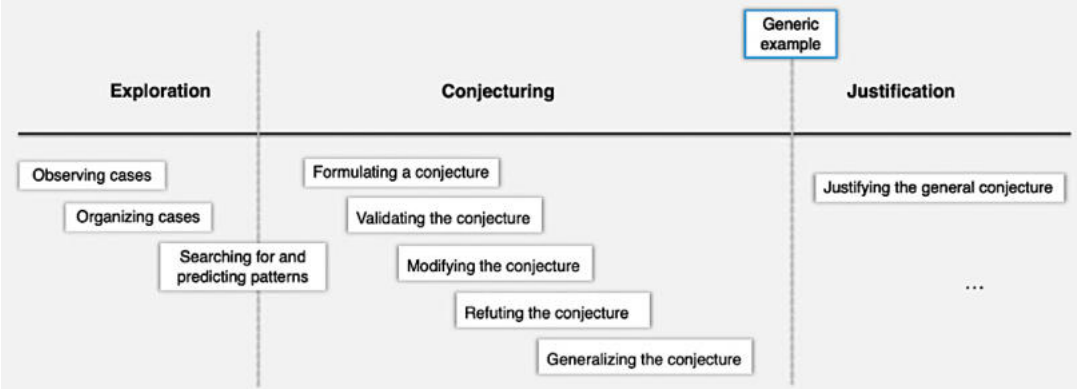

Figure 1: ECJ-model

Generic examples have been shown to be a fruitful element of proving processes at the school and university level (e.g., Kempen & Biehler, 2019). They allow learners to engage with the key ideas of a (generic) proof in an intuitive and familiar context. Potential obstacles such as the requirement for completeness of generality, formalism, and symbolism are not yet taken into account (Leron &

Zaslavsky, 2013). This can make it much easier to start an argumentation process and smooth the transition to a more formal proof structure. Our definition of a generic example is based on Mason and Pimm (1984), who define a generic example "as an actual example […] presented in such a way as to bring out its intended role as the carrier of the general" (ibid., p. 287).

Empirical Insights

Conjecturing activities are highlighted in various national mathematics standards and play an important role in mathematics education. For example, the German educational standards explicitly call for the formulation of conjectures (Kultusministerkonferenz, 2022). Similar activities around conjecturing can, for example, be found in Swedish curricula (Bergqvist, 2005). It is, therefore, surprising that an exemplary analysis of tasks on quadratic functions in German textbooks showed that although conjecturing tasks are relatively common, they are rarely embedded in reasoning processes (Niederquell & Kempen, 2024). Also, Bergqvist (2005) described that although tasks related to the wider competence mathematical reasoning are required, they are rarely found in Swedish textbooks. These findings seem problematic, as it has been shown that teachers follow the textbook very closely when designing lessons (Lepik et al., 2015). Therefore, it could be challenging for teachers to select appropriate tasks or problem situations to develop the ability to make conjectures. Furthermore, it did not seem clear how to guide learners in their conjecturing process so that they can justify their conjectures mathematically (Cañadas et al., 2007). This question (a.o.) led Morselli (2006) to investigate the use of examples in conjecturing and proving in elementary number theory. The results of her study showed that examples can help to discover patterns but are often considered insufficient for later proof productions. Students without a mathematical focus rely more on numerical examples and explain their justification verbally. The study showed that university students' mathematical background and their understanding of examples significantly influence their approach to proof. The use of generic examples as a didactic tool for learning to prove and respective research on it has increased in the last decades. Discussing or independently generating a generic example can help to initially convince oneself of the truth of a statement. Leron and Zaslavsky (2013) claimed that the benefits of generic examples are not about the explicit example itself but the process of using it. Based on the theoretical and empirical aspects described above, the question arises as to how learners make use of generic examples in conjecturing processes.

Research Questions

It has been shown above that there is a need for further research in the area of conjecturing processes, especially in school mathematics. It is still an open question to what extent generic examples can be a fruitful tool for the transition from conjecturing to justification. Therefore, our research questions focus on the use of generic examples in students' conjecturing processes: *(1) How do learners use a given generic example in a conjecturing process? (2) How does the use of a generic example influence learners' conjecturing process?*

The Learning environment

We chose the content of quadratic functions to engage students in conjecturing activities. This topic was chosen to widen the scope of activities around mathematical reasoning beyond the classical

domains such as geometry or elementary arithmetic (a.o., Furinghetti & Morselli, 2011). We used a conjecturing task on the rate of change of quadratic functions to gain initial insights into learners' process of conjecturing.

Kaya is a passenger in Tim's car and complains that he doesn't keep his distance when he speeds up. They both learned a rule of thumb at driving school to calculate braking distance, in which x is the speed (in km/h) and f(x) is the braking distance (in meters):

$$f(x) = \frac{x^2}{100}$$

Now, the two of them are discussing how the braking distance changes as the speed increases.

Figure 2: Central task in the learning environment

In the context of the braking distance of a car, the learners are guided through a complete conjecturing process. The tasks are formulated and arranged according to the model illustrated in Figure 1. The learners should first explore the pattern of quadratic change and increasingly generalise it as they progress. After the learners have generated several examples and made initial conjectures towards a generalization, they are asked to conjecture how the assumed behavior of change can be described in general. When they have completed this task, the interviewer first asks if this is their final answer. They are then given the generic example shown in Figure 3 and asked to explain whether it fits their conjecture and how far it applies to all possible cases.

$$f(40) = \frac{40^2}{100} = 16$$

$$f(2 \cdot 40) = \frac{(2 \cdot 40)^2}{100} = \frac{2^2 \cdot 40^2}{100} = 2^2 \cdot \frac{40^2}{100} = 2^2 \cdot 16$$

Figure 3: The generic example

Learners should then justify whether and why the generic example fits each of their conjectures. Finally, they are asked how confident they are that their general conjecture (which they made before the generic example came in) holds. They tick this on a six-point scale from "very uncertain" to "very certain" and are asked to state the reasons for their choice. The generic example was integrated into the learning environment to provide the initial impulse for respective justification processes. In Figure 3, the number two, marked in green, represents the general factor k, which we wanted the learners to identify. The speed 40 can also be considered a generic moment, as every number (possible speed) can be placed here. Finally, the whole equation can be regarded as generic, as respective manipulations can be performed in every case, i.e., the "two" and the "forty" could be replaced by any numbers (factor of change and speed).

Methods

A case study was conducted with three pairs of two students for the initial research. The learners, four females and two males, were fifteen years old and in the ninth grade of a grammar school. They had

already covered the topic of quadratic functions in the school year and thus should be familiar with the basic aspects of quadratic functions. Their previous performance in mathematics is considered average by their teacher. This case study aimed to gain initial insights that would enable a deeper understanding of individual, complex thinking processes. Since we still lack (empirical) insights about the use of generic examples in conjecturing processes, a degree of flexibility was required. Therefore, a deliberately small sample was used for the first laboratory study in order to capture the unique characteristics of each conjecturing process and consider them individually. The detailed observations of the three pairs were meant to generate new hypotheses about the use of generic examples in conjecturing and reasoning processes that will provide an approach for further, possibly larger, studies (Yin, 2018).

For research purposes, the learners were filmed in a laboratory setting while working in pairs in the learning environment. An interviewer observed the work and only intervened if the learners could not continue without help. The video and audio recordings were then transcribed. The transcripts were analysed using a qualitative content analysis (Mayring, 2014) with regard to the research questions above.

Results

Group 1: Tanja & Paula

Tanja and Paula started their exploration by generating different examples. As can be seen in Figure 4, they organized the three different cases (doubles, triples, quadruples) and observed patterns of quadratic change. The learners generalised each as a 'rule' to predict the pattern. This led Paula to move on to the activity of conjecturing. She formulated their first conjecture:

Paula: Our conjecture is: [...] how often you multiply the speed [...], the number is then squared.

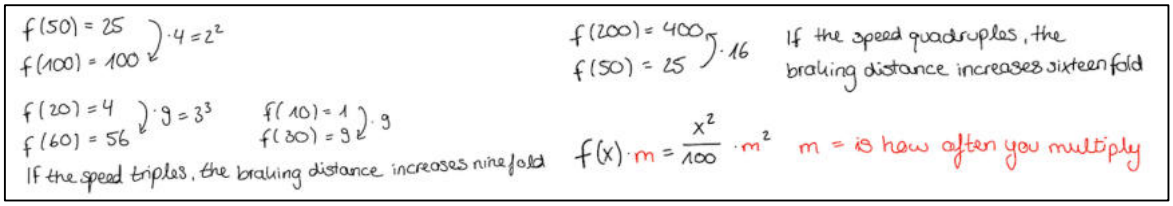

Figure 4: Conjecturing process group 1

Without being prompted, Paula and Tanja wrote their conjecture using algebra (see Figure 4, below). They validated their formula with two examples and signalled to the interviewer that they were sure that their general conjecture always held. Then, the interviewer handed out the last part of the learning environment with the generic example. Tanja and Paula immediately identified the marked “two” as the factor of change and recognised the generic character of the factor in the sense of a variable. They then discussed the structural similarities between the factor of change in the generic example and the factor they had labelled “m” themselves (Figure 4, at the bottom).

Tanja: I think we just did it like this [...] (*adds a bracket to* $f(2 \cdot (40))$ Because we wrote it on the outside [...] But then, yes, the new x would be an 80, so that works, too.

[...] In the end, it just means that our conjecture was correct. We just wrote it down differently.

As can be read in the transcript excerpt, they added a bracket around the 40. They argued that although their formula was written differently, it was just as correct because both formulae expressed the previously established 'general conjecture'. The similarities they discovered strengthened their confidence in their own conjecture. To justify their conjecture, they used the generic example and equated a term from their example with a term from the generic example. With this ‘true’ result, they confirmed that their formula must always be correct and, therefore, had no need for further investigation. The generic example thus represented a certain 'authority' for them, the validity of which was transferred to their conjecture by equating it with a concrete example.

Group 2: Maja & Gwen

Maja and Gwen began their exploration by generating different examples and searching for a pattern. They repeatedly looked at the local change between several concrete values and found some patterns. They formulated various conjectures, but when they tried to validate them, they always realised that these were not always valid. Therefore, they switched several times between the exploration and conjecturing activity. By analysing a table of several examples, they ruled out linear growth and finally formulated a supposedly general conjecture (see Figure 5).

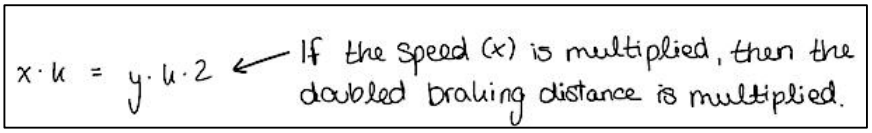

Figure 5: General conjecture group 2

Although they formulate their conjecture in general terms, they know that it does not apply in all cases. However, even when comparing it with their examples, they couldn’t identify precisely where the error was. The interviewer handed out the last part of the learning environment with the generic example. After Maja and Gwen had received the generic example, they were immediately able to explain the given equation. Finally, they recognised their mistake and the actual rate of change in relation to squaring.

Gwen: That squares itself [...] then we had it wrong somehow. [...]
Maja: Well, I mean, it still fits for the first step, because 2 squared is two times two. That's what we had. But it doesn't work after we have another point, you know?

When comparing the computations with the generic example, they recognised why their conjectures did not work. In this process, the generic example served as a stimulus for modifying the conjecture.

Maja: You have f(k times x). That's what's in front (*points to* $f(2 \cdot 40)$), because the green is always k; that's the factor. Later, Maja and Gwen went back to generalizing a conjecture and formulated the rate of change. They used the generic example to write down a general formula, which can be seen in Figure 6.

However, these students were not able to proceed to the activity of justifying the generalization and to reason why their conjecture (or the given generic example) applies to all possible cases. In the end, they were unsure whether their formula really always holds. The results of the third group are not

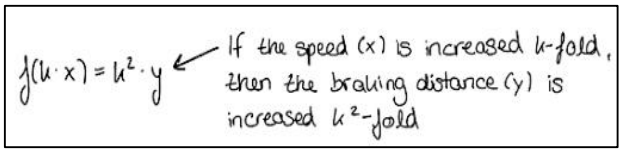

Figure 6: Revised general conjecture group 2

presented here in detail because the generic example had almost no relevance for these learners. They just noted it and then said this was just another way of solving the question. Although the generic example contradicted their conjecture, they were still sure that their conjecture was correct.

Conclusion

The results provide initial insights into how learners use a given generic example in a conjecturing process and how it influences their conjecturing process. The role of the generic example in the different conjecturing processes turned out to be very different. The analysis of Tanja's and Paula's conjecturing process shows first indications that generic examples can, in principle, serve as an *initial impulse for the transition to justification*. They actively engaged with the generic example, discussing general structures and using these structures as arguments for generalization. The situation was quite different for group 2, who had problems with the conjecturing process and could not state a general conjecture that they felt was always valid. The generic example *helped them modifying their conjecture*. As Group 3 showed, the generic example can also have *no (noticeable) effect*.

Final Remarks

The ECJ-model was helpful in describing learners' work in our learning environment and specifying the moment in the process when the generic example came in. The analysis of the results provided initial insights into the use of a generic example in a conjecturing process. It was shown that the generic example takes on different roles and thus has various influences on the further course of the process. It turns out that learners can benefit from active engagement with generic examples in the conjecturing process, for example, by encouraging discussion and the use of general structures as arguments for generalization and justification.

Overall, these initial findings on the different roles of generic examples in the conjecturing process provide a substantial starting point for further research. It seems especially interesting to investigate the extent to which a generic example can support or stimulate the transition to mathematical proof and the extent to which it influences learners conviction about the validity of conjectures.

Enhancing pre-service mathematics teachers' justification abilities: Impact of a brief intervention on real numbers

Mehdi Parsinia[1] and Benjamin Rott[1]

[1]University of Cologne, Faculty of Mathematics and Natural Sciences, Institute of Mathematics Education, Cologne, Germany; mparsini@uni-koeln.de

This study examines the development of justification abilities in the context of real numbers among pre-service teachers (PSTs). A comparative analysis was conducted between Grade 12 students (n=36) from a Cologne Gymnasium and an equal number of final-semester Masters of secondary PSTs at the University of Cologne. Initial results revealed comparable performance between groups, with PSTs showing modest advantages in proof construction but lower performance in applications. A short-term intervention with PSTs (n=20) yielded significant improvements across all areas, with overall performance increasing from 47.9% to 80.8%. Analysis employed Toulmin's model of argumentation, supported by strong internal consistency measures (pre-test $\alpha = 0.83$, post-test $\alpha = 0.87$), demonstrating that focused intervention can significantly enhance both reasoning abilities and conceptual understanding.

Keywords: Justification ability, pre-service teacher, mathematical logic.

Introduction

Mathematical justification abilities are fundamental to effective mathematics teaching, particularly in the context of real numbers where conceptual understanding intersects with formal reasoning. Recent research indicates a concerning gap between pre-service teachers' (PSTs) theoretical knowledge and their ability to construct and evaluate mathematical arguments (Stylianides & Stylianides, 2017). This gap is critical as teachers' capacity to understand and explain mathematical concepts significantly influences their ability to make mathematics reasonable and accessible to students (Ball & Bass, 2003). In German secondary schools, this challenge is particularly evident in the teaching of real numbers, where procedural fluency often takes precedence over conceptual understanding and justification skills. The Standing Conference of the Ministers of Education and Cultural Affairs (KMK) has emphasized this issue through their Mathematics Standards Agreement (KMK, 2022), calling for enhanced focus on mathematical logic and reasoning in teacher preparation programs.

The observation that PSTs' justification abilities often do not significantly exceed those of secondary school students raises fundamental questions about current teacher preparation effectiveness. While PSTs typically demonstrate competence in formal proof construction, their ability to apply mathematical reasoning in practical contexts and effectively communicate mathematical concepts remains problematic. This study addresses these challenges by examining the impact of targeted interventions on PSTs' justification abilities in the context of real numbers. By focusing on the development and evaluation of specific interventions, this research contributes to both theoretical understanding of mathematical justification development and practical improvements in teacher

education programs, particularly in bridging the gap between formal mathematical knowledge and its practical application in teaching contexts.

Literature Review

Research in mathematics education has increasingly emphasized the importance of justification abilities, particularly in the context of teacher preparation. The literature reveals several key frameworks and approaches that have been developed to understand and analyze mathematical justification processes, especially in relation to proof and proving activities in mathematics education. Stylianides and Ball (2008) highlight the importance of teachers' knowledge about proof and their ability to engage students in proving activities. Their research emphasizes that effective mathematical tasks should incorporate multiple aspects of reasoning, including pattern recognition, conjecture formation, and formal proof construction. More recent work by Stylianides et al. (2017) synthesizes research on teaching and learning of proof, suggesting that supporting teachers' development of proof competencies requires attention to both content knowledge and pedagogical approaches. Hemmi, Lepik, and Viholainen (2013, p. 374) observe that "the role of proof and proving in school mathematics is often marginal, and explicit requirements for students' proof-related competences are rare." Their comparative analysis of national mathematics curricula in Estonia, Finland, and Sweden demonstrates that proof and proving occupy a peripheral role, with explicit expectations for students' proof-related competences seldom articulated. The importance of addressing these gaps in teacher preparation is underscored by research showing that teachers' own comfort and facility with mathematical justification significantly impacts their ability to foster these skills in their students (Lo et al., 2008). Pre-service teachers often struggle with constructing and evaluating mathematical proofs, particularly when dealing with abstract concepts—a challenge compounded by limited exposure to formal proof techniques during their own secondary education. However, research indicates that carefully designed interventions can successfully bridge the gap between procedural fluency and conceptual understanding, especially when focusing on connecting intuitive understanding with rigorous mathematical reasoning.

Despite this, the existing literature reveals a critical gap in our understanding of how teacher preparation programs develop justification abilities compared to secondary education outcomes. While studies document that teachers often struggle with proof construction (Lo et al., 2008), there is limited empirical evidence comparing PSTs' actual performance with that of advanced secondary students on equivalent tasks. This comparison is crucial because it can reveal whether teacher education programs are effectively building upon students' existing mathematical reasoning foundations or merely maintaining similar competency levels.

Research Questions

The study was guided by the following research questions:

1. How do advanced secondary students and pre-service mathematics teachers compare in their ability to justify mathematical statements about real numbers?
2. To what extent does targeted intervention improve PSTs' ability to apply logical reasoning and construct valid mathematical proofs, particularly in the domain of real numbers?

These questions underscore the study's focus on the potential long-term effects of educational practices that prioritize procedural knowledge over conceptual understanding and logical reasoning, as well as the effectiveness of an intervention aimed at improving justification skills.

Methods

The study employed a two-phase research design, beginning with a comparative analysis followed by a targeted intervention specifically for pre-service teachers. In the initial phase, we conducted a comparative analysis between two distinct groups: 36 Grade 13 students from a Gymnasium in Cologne, North Rhine-Westphalia, Germany, and 36 pre-service secondary school mathematics teachers (PSTs) in their final semester of Master's studies at the University of Cologne. All participants completed a written test comprising 10 carefully designed items organized into four questions. These items were specifically designed to evaluate the participants' ability to apply their knowledge in justifying mathematical statements within the context of real numbers, requiring them to demonstrate logical reasoning, construct mathematical proofs, and use counterexamples effectively. Following this comparative analysis, the study transitioned to its second phase, focusing exclusively on the PST group. Based on the initial assessment results, we developed and implemented a targeted intervention specifically designed to address gaps identified in the PSTs' justification abilities. This intervention consisted of two intensive 90-minute workshops that focused on developing mathematical reasoning skills and proof construction abilities within the context of real numbers. The workshop design was informed by the specific areas of difficulty identified in the initial assessment, particularly focusing on enhancing PSTs' capacity for mathematical justification and proof construction. To evaluate the effectiveness of this PST-specific intervention, we administered a post-test to the intervention participants. Due to train strikes in Germany during this period, the post-test sample size was reduced to 20 PST participants, which was noted as a limitation of the study. The assessment of intervention effectiveness employed paired t-tests to compare pre-test and post-test scores within the PST group, providing a statistical measure of improvement in their justification abilities. This focused analysis allowed us to quantify the impact of the intervention specifically on the target group of pre-service teachers, while maintaining the broader comparative context established in the initial phase of the study.

Test Construction and Intervention

The assessment methodology integrates multiple theoretical frameworks to create a comprehensive evaluation system for mathematical reasoning and justification abilities. At its foundation lies Toulmin's Argumentation Model (2003), enhanced by recent developments in mathematics education research, particularly Stylianides et al.'s (2017) work on proof teaching and learning, and Knipping's (2008) adaptation for mathematics education. The evaluation employs a four-level Structural Completeness Scoring Framework (0-3 points), designed to capture increasingly sophisticated levels of mathematical argumentation. At Level 0 (No Structure), responses lack coherent mathematical argumentation, typically showing only calculations without explanation and no clear mathematical claims. Level 1 (Basic) responses demonstrate elementary argumentation with isolated mathematical claims and minimal supporting evidence, as exemplified by statements like "The sum of a rational and irrational number is always irrational because irrational numbers can't be written as fractions."

Level 2 (Developing) responses show emerging sophistication through connected mathematical claims and partial evidence, such as "When we add a rational number to an irrational number like π, the result must be irrational because π is irrational and can't be written as a fraction. Adding doesn't change this."

At Level 3 (Complete), responses demonstrate full mathematical argumentation including clear claims, comprehensive evidence, and well-structured logical warrants. A representative Level 3 response would be: "Consider a rational number r and an irrational number x. Assume their sum s is rational. Then $s = p/q$ for some integers p, q. This implies $x = s - r = p/q - r$, which can be written as a fraction, contradicting x's irrationality. Therefore, s must be irrational." The assessment comprises four distinct components: Mathematical Classification (12 points), Proof Construction (3 points), Concept Explanation (3 points), and Mathematical Applications (12 points), totaling a maximum possible score of 30 points. The scoring process involves initial evaluation using the 0-3 framework, followed by weighting based on component maximum points, enabling standardized comparison across different components while accounting for their relative complexity.

The framework's effectiveness was demonstrated through pre- and post-intervention comparisons, where pre-intervention responses typically scored at Level 1, showing basic claims without proper support, while post-intervention responses often reached Level 3, demonstrating complete argument structures with clear logical progression. Comparative analysis revealed no significant differences between PST and high school student performance, suggesting potential gaps in teacher preparation programs. However, the framework successfully captured improvements following targeted interventions, demonstrating its utility in measuring the development of mathematical reasoning abilities. This refined assessment system provides a robust tool for evaluating mathematical reasoning development, particularly valuable for teacher preparation programs and intervention assessment, while maintaining high standards of reliability and validity in measuring mathematical argumentation skills.

The intervention program was designed as a focused, two-session workshop series, with each session lasting 90 minutes. The design emphasized active learning principles and progressive skill development, allowing participants to build confidence while developing deeper mathematical understanding. The first session focused on developing robust conceptual understanding of real numbers through multiple representations and hands-on exploration. Participants began by examining the geometric interpretation of real numbers using dynamic geometry software, which allowed them to visualize and manipulate representations of both rational and irrational numbers on a number line. This visual approach helped bridge the gap between intuitive understanding and formal mathematical concepts. The session then progressed to exploring different representations of real numbers, including decimal expansions, fractional forms, and geometric constructions. Through guided discovery activities, participants investigated the relationships between rational and irrational numbers, examining properties such as density and completeness of the real number system.

Building on this foundational understanding, the second session concentrated on developing proof strategies and justification techniques. The session began with an introduction to direct proof methods, where participants learned to construct step-by-step logical arguments using definitions and

previously established theorems. This was followed by exploration of indirect proof strategies, including proof by contradiction and contraposition. Participants worked through carefully sequenced examples that demonstrated how to identify key properties needed for proofs and how to structure mathematical arguments effectively. Special attention was given to the construction and verification of counterexamples, as this skill had been identified as particularly challenging in the initial assessment. Throughout both sessions, participants alternated between individual work and small-group collaboration. Each new concept was introduced through carefully designed tasks that progressed from simple applications to more complex problems. For example, when working with irrational numbers, participants first proved the irrationality of $\sqrt{2}$ using a traditional proof by contradiction, then progressed to proving the irrationality of other square roots and finally to proving statements about operations with irrational numbers. It also incorporated regular opportunities for reflection and discussion, with participants sharing their reasoning strategies and receiving feedback from both peers and instructors. These discussions were structured using Toulmin's argumentation framework, helping participants identify the key components of effective mathematical arguments. The instructors modeled appropriate mathematical language and proof techniques throughout, emphasizing the importance of precise communication in mathematical justification.

The intervention concluded with a synthesis activity that brought together the conceptual understanding developed in the first session with the proof techniques learned in the second. Participants worked on complex problems involving real numbers that required both deep conceptual understanding and sophisticated proof techniques. This culminating activity helped reinforce the connections between different aspects of mathematical reasoning while providing participants with a model for integrating these skills in their future teaching practice.

Results

We begin with comparison of the responses of Master student versus High School students for each question on the test. The comparison revealed several interesting patterns:

Table 1: Masters students pre-test vs. high school students

Question	Masters Pre-Test	High School	Improvement	Effect Size	p-value	t-statistic
Q1	55.8%	52.5%	+3.3%	$d = 0.28$	0.183	$t = 1.35$
Q2	57.2%	44.7%	+12.5%	$d = 0.43$	0.312	$t = 1.02$
Q3	52.8%	45.6%	+7.2%	$d = 0.31$	0.428	0.428
Q4	32.5%	41.4%	−8.9%	$d = -0.38$	0.198	0.198
Overall Mean	49.6%	46.1%	+3.5%	$d = 0.25$	0.226	0.226

The table revealed nuanced patterns in mathematical reasoning abilities. For Question 1, PSTs demonstrated marginally better performance (55.8% vs 52.5%), with a small effect size and non-significant difference. The most notable difference appeared in Question 2 where PSTs achieved

57.2% compared to high school students' 44.7%, showing a moderate effect size. Similarly, Question 3 showed a small advantage for PSTs (52.8% vs 45.6%) but with substantial variability. An interesting reversal occurred in Question 4, where high school students demonstrated stronger performance (41.4% vs 32.5%), with a moderate negative effect size. This difference, while not statistically significant ($p = 0.198$), suggests potential gaps in PSTs' ability to apply mathematical concepts practically. The overall mean scores show a small advantage for PSTs (49.6% vs 46.1%), but the non-significant p-value (0.226) suggest this difference is not practically meaningful. The high Cronbach's alpha values for both groups (PSTs: 0.83, High School: 0.81) indicate good internal consistency in the assessment measures. The intervention produced substantial improvements across all assessment areas:

Table 1: Master Students pre-test vs. Master Students post-test

Question	Pre-test	Post-test	Improvement	Effect Size	p-value	t-statistic
Q1	51.7%	82.5%	30.8%	$d = 0.89$	$p < 0.001$	$t = 4.86$
Q2	55.0%	85.0%	30.0%	$d = 0.88$	$p < 0.001$	$t = 4.73$
Q3	53.3%	80.0%	26.7%	$d = 0.82$	$p < 0.001$	$t = 4.52$
Q4	31.7%	75.8%	44.1%	$d = 1.18$	$p < 0.001$	$t = 5.94$
Overall Mean	47.9%	80.8%	32.9%	$d = 0.94$	$p < 0.001$	$t = 5.12$

The intervention demonstrated substantial and statistically significant improvements across all assessment areas, with overall performance increasing from 47.9% to 80.8%. This comprehensive improvement indicates a significant enhancement in mathematical competency across all measured dimensions. The most dramatic improvement was observed in Question 4, where performance increased to 44.1%. This substantial gain was accompanied by the largest effect size, indicating that the intervention was particularly effective in developing students' ability to apply mathematical concepts in practical contexts. Question 1 showed similarly impressive gains, with overall performance increasing from 51.7% to 82.5%. This improvement in foundational mathematical reasoning abilities suggests that the intervention effectively enhanced students' basic conceptual understanding and analytical skills. The strong effect size indicates that these improvements represent meaningful practical advances in student capability. Question 2 and Question 3 demonstrated robust improvements of 30.0% and 26.7% respectively, both with strong statistical significance ($p < 0.001$) and large effect sizes. The improvement in Question 2, indicates enhanced ability in formal mathematical reasoning, while the gains in Question 3, from 53.3% to 80.0%, suggest improved capacity to articulate mathematical concepts clearly. The intervention also demonstrated strong internal consistency in post-test ($\alpha = 0.87$) which showed increase in internal consistency compare to the pre-test. This increase suggests that the intervention not only improved performance but also led to more consistent demonstration of mathematical reasoning abilities.

Discussion and Conclusion

This study investigated the development of mathematical justification abilities among pre-service teachers (PSTs) and the effectiveness of targeted intervention in enhancing these abilities. Our research addressed two key questions: comparing PSTs' justification abilities with those of advanced secondary students, and evaluating the impact of targeted intervention on PSTs' mathematical reasoning skills. Addressing our first research question, the findings reveal a concerning gap in teacher preparation. Despite their advanced mathematical training, PSTs demonstrated no significant advantage over high school students in mathematical justification tasks involving real numbers. This finding is particularly concerning when considering that PSTs represent a highly selected subset of former high school students who demonstrated strong mathematical aptitude and chose to pursue advanced mathematical studies. Given their academic trajectory, including successful completion of university-level mathematics courses and selection into competitive teacher preparation programs, one would reasonably expect PSTs to significantly outperform average high school students in mathematical reasoning tasks. The absence of such performance differences suggests that current teacher preparation programs may not be effectively building upon PSTs' existing mathematical strengths to develop the specialized reasoning and justification abilities required for effective mathematics teaching. In fact, high school students occasionally outperformed PSTs, particularly in tasks requiring logical reasoning and proof construction. This unexpected pattern suggests that current teacher preparation programs may not effectively develop these crucial mathematical competencies beyond high school level understanding. The comparable performance between groups ($p > 0.05$) raises important questions about the structure and focus of current mathematics teacher education programs. In response to our second research question, the intervention program demonstrated remarkable effectiveness in enhancing PSTs' justification abilities. The most substantial improvements were observed in proof construction (58.7% improvement) and applications of real number properties (59.9% improvement), areas that initially showed the weakest performance. Analysis through Toulmin's Argumentation Model revealed qualitative improvements in participants' ability to construct mathematical arguments, with enhanced use of warrants and backing to support their claims. The intervention particularly strengthened PSTs' abilities in classifying numbers (23.3% improvement) and explaining mathematical concepts (22.8% improvement), demonstrating growth in both procedural and conceptual understanding. These findings have significant implications for mathematics teacher education. The initial comparison results suggest that current preparation programs need to place greater emphasis on developing advanced justification abilities. However, the significant improvements observed after the intervention indicate that these skills can be effectively developed through targeted instruction. The success of our brief intervention, demonstrated by substantial gains across all measured areas ($p < 0.001$), suggests that similar approaches could be valuable additions to mathematics teacher education curricula, particularly in developing proof construction and logical reasoning abilities. This study provides compelling evidence that while current teacher preparation programs may not adequately develop mathematical justification abilities, targeted interventions can effectively address this gap. The strong effect sizes observed across all areas ($d = 0.82$ to 1.18) indicate practically significant improvements in PSTs' mathematical reasoning capabilities. As mathematics education continues to emphasize logical reasoning and proof

skills, ensuring that teachers are well-prepared to develop these abilities in their students becomes increasingly crucial.

Some limitations should be noted, including the reduced post-test sample size due to external factors and the short duration of the intervention. Future research should examine the long-term impact of such interventions, their transfer to classroom practice, and their application across different mathematical domains.

Acknowledgment

The authors would like to express their deepest gratitude to Professor Elena Nardi for carefully reading the paper and providing invaluable comments.

Studying the role of synergy between paper folding and a Dynamic Geometry Environment in upper secondary students' conceptualization of conditional statement and proof

Aliki Perivolari[1] and Giorgos Psycharis[1]

[1]Department of Mathematics, National and Kapodistrian University of Athens, Greece;
aperivolari@math.uoa.gr

This paper reports a research study focusing on the contribution of the synergy of a manipulative artefact (paper folding) and a Dynamic Geometry Environment (DGE) to the conceptualization of the conditional statement and proof during 10th grade students' engagement with construction-proof tasks. Under the combined use of Mathematical Working Spaces and the Theory of Semiotic Mediation the analysis highlights the particular contribution of the synergy of paper folding and the DGE in the formation and validation of conjectures, in understanding the logical dependencies between premises and the conclusion of a conditional statement, and finally in proving.

Keywords: Synergy, paper folding, dynamic geometry environment, conditional statement, proof.

Introduction

Proving and conjecturing have attracted much research interest over the years. The literature is replete with studies that focus on the role of Dynamic Geometry Environments (DGE) in students' conceptualization of these mathematical concepts. According to Mariotti (2012), with the dragging modality of a DGE the user can act upon the drawing while all the properties defined by the construction are maintained. Observing the simultaneity of invariants of a robust construction during dragging is likely to contribute to the understanding of the conditional links of a conditional statement. Specifically, the invariants referring to the single steps of the construction correspond to the premises and the invariants that appear as the consequences of the former correspond to the conclusion of the conditional statement (Mariotti, 2012). This dynamicity of the dragging combined with the measuring tool are considered to promote the transition from the exploration phase, characterized by conjectures, to the proving phase (Sinclair & Robutti, 2013). Furthermore, the investigation of different instances of the construction is claimed to support the generalization of propositions and their proof (Komatsu & Jones, 2020). Parallelly, one can find in the literature studies about the potential of manipulative artefacts, such as paper folding, to contribute to exploring geometric ideas and to discovering mathematical relations (Wiles, 2013). According to Hsieh et al. (2012), interaction with paper folding has the potential to promote the discovery of the logical steps necessary in a proof, thus supports understanding of the proving process.

In recent years, there has been intense research interest on the interplay of two artefacts of different nature. Mariotti and Montone (2020) introduced a new research field by defining the *synergy* of a duo of artefacts. Synergy is the combined effect of using different artefacts, where their interaction creates interconnected signs and meanings. This occurs when references to both artefacts form relationships between their respective signs, which can be organized to semiotic chains, i.e. evolution paths describing the move from personal situated meanings towards shared de-contextualized mathematical

meanings (Mariotti & Montone, 2020). Within this new research trend, among the few related studies, there is one (Valori et al., 2022) that examines the interplay between paper folding and GeoGebra during students' engagement with construction-proof tasks. The results confirm the value of using different artefacts to support students' coordination of operative and discursive apprehensions of the figures. However, this study focuses on the nature of students' argumentation rather than on the proof per se. This paper aims to fill the gap in the existing literature regarding the conceptualizations of conditional statement and proof arising during students' interaction with both paper folding and DGE (i.e. Geometer's Sketchpad, GSP) from the perspective of synergy. The research question is formulated as follows: What is the role of synergy between paper folding and the use of a DGE in upper secondary students' conceptualization of conditional statement and proof?

Theoretical framework

Our theoretical framework consists of the combined use of Mathematical Working Spaces (MWSs) (Kuzniak & Richard, 2014) and the Theory of Semiotic Mediation (TSM) (Bartolini Bussi & Mariotti, 2008) as a tool of design and analysis. According to MWSs, to grasp the mathematical work of individuals confronted with mathematical activities, it is necessary to take into account an epistemological plane which is related to the mathematical content and a cognitive one related to the reasoning of the individual. The evolution of mathematical work occurs progressively through the bridging of these planes, a process which takes place through three interrelated geneses; *semiotic (sem)*, *instrumental (ins)* and *discursive (dis)*. Semiotic genesis associates signs with the process of visualization and explains the dialectical relationship between syntactic and semantic perspectives on mathematical objects. Instrumental genesis reveals the connection between artefacts and the construction processes that contribute to the completion of the mathematical task. Finally, discursive genesis of proof refers to the process through which properties and results organized in the theoretical system of reference become available for mathematical reasoning and discursive validations.

On the other hand, TSM allows the study of the interaction of three categories of signs in the process of conceptualizing conditional statement and proof: artefact, pivot and mathematical. Artefact signs refer to the context of the use of the artefact and the associated meanings are personal, strictly related to the subject's experience with the artefact. Mathematical signs refer to the mathematical context and are associated with mathematical meanings. Pivot signs are bridges between the artefact and mathematical signs and can refer to the activity with the artefact and the mathematical context. The evolution of meanings can be organized into semiotic chains that highlight the process of meaning-making through the transformation of signs and the transition from meanings associated with the artefact to mathematical and de-contextualized meanings. In this study, we consider paper folding and GSP as two MWSs and we use this framework to analyze their semiotic, instrumental and discursive dimensions. The concept of semiotic chain contributes to the analysis of the connections between the MWSs through the study of the transitions from one dimension to the other and the evolution of meanings from empirical to more mathematical ones.

Methods

Participants and data

This case study involved two groups, Group 1 (S1, S2) and Group 2 (S3, S4) of students around the end of the 10th grade and the main criterion for the selection was their interest in geometry. The small number of participants aligns with the in-depth investigation of the case study method, while working in groups may foster the evolution of signs (Bartolini Bussi & Mariotti, 2008). There was a first meeting with each group in order to become familiar with GSP followed by three meetings (lasting $5\frac{1}{2}$ hours with Group 1 and $6\frac{1}{2}$ hours with Group 2) in each of which the students worked on one of the three tasks. The role of the teacher (first author) was mainly to encourage, where necessary, the emergence of pivot signs and to facilitate discussion. Data include audio, video and screen recordings, worksheets and sheets of paper with students' creases and folds.

Tasks

Task 1 first asks students to fold an A4 sheet according to the instructions given (Figure 1) and then formulate a conjecture about the final shape. The expected conjecture is that the resulting shape is an equilateral triangle, which they are asked to validate working only with the folded paper. Then, through the identification of properties and relations of the creases, students have to entirely construct the same structure step-by-step in a robust manner (preserving properties during dragging) in GSP by selecting appropriate tools. In this phase it is expected that students' mathematical interpretation of the signs of the paper folding will encourage a more deductive reasoning. The completion of the robust construction in the GSP is followed by the request to validate the conjecture also in the digital environment. Finally, a formal proof of the conjecture is requested, in which the mathematical meanings and properties emerged through the synergy of the two MWSs are expected to be exploited.

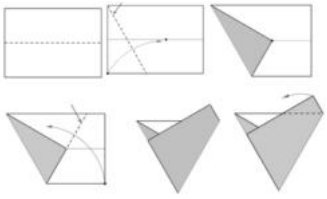

Figure 1: Folding instructions for Task 1

Tasks 2, 3 introduce some new aspects to the objectives of Task 1. Task 2 (Figure 2) involves the emergence of contradictory results on the screen and on the folded paper. While the expected conjecture in the folding paper is that the resulting shape is an isosceles triangle, the completion of the construction in GSP leads to a scalene. The contradiction arises if the premise of maintaining the ratio of the dimensions of the rectangle to those of the A4 sheet is not considered. This procedure aims at understanding the logical dependence of the premises and the conclusion of a conditional statement.

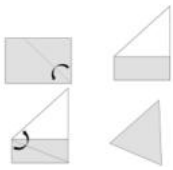

Figure 2: Folding instructions for Task 2

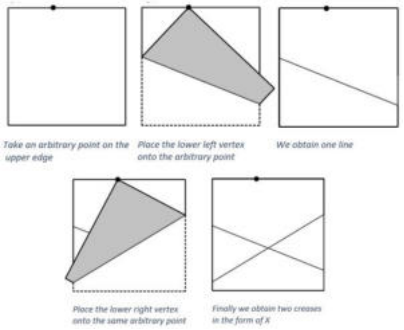

Figure 3: Folding instructions for Task 3

The particular element of Task 3 (Figure 3) is the notion of generalization. After some repetitions of the folding steps (with a different initial arbitrary point), students are asked to formulate a conjecture about the intersection points of the X-lines. They are expected to observe that these points lie on the perpendicular bisector of the upper and lower side of the square. The request to represent the construction in the GSP and to

investigate the conjecture is expected to lead to investigation procedures of invariant properties. Dragging will play a crucial role in generating multiple pairs of X-lines and in observing general properties. In addition, Task 3 invites groups to prove their conjecture in the particular case where the arbitrary point coincides with one of the square's vertices and in the general case. This process is expected to contribute to further understanding of the general-particular distinction through the need to change the proving path. In this task, too, the logical connection of the conclusion from the premises is expected to become evident on an empirical and a strictly mathematical level.

A priori analysis

We distinguish two MWSs "Paper folding" and "GSP", each of which offers different possibilities for students' work at its three dimensions. However, the focus of the research is the synergy between them. After the completion of the constructions in the paper folding, a continuous interplay between the dimensions of the two MWSs is expected to emerge and be evident in students' constructed meanings. In particular, during the transfer of the construction from the manipulative to the digital artefact, the work in the semiotic and instrumental dimension of the "Paper folding" and the empirical interpretation of the creases, is likely to be followed by the discovery of properties and invariant relations. This way the preceding semiotic and instrumental work may be mobilized in the "GSP". During the evolution of this process, the transition from personal to mathematical meanings is expected through the transformation of the students' conceptualization of signs. The cooperation of the discursive dimensions of the MWSs is expected to become apparent while exploring mathematical meanings related to the conditional statement and methods of validating conjectures and proving them. Episodes of synergy are also expected to occur in instances of contradictory results between the two MWSs and during the investigation of particular and general cases.

Method of analysis

After the transcription, the open coding method (Strauss & Corbin, 1998) was used, and codes were assigned in relation to the dimensions (semiotic, instrumental, discursive) of each of the MWSs. Then, additional codes were developed to characterize the categories of signs (artefact, pivot, mathematical). In the next step, episodes of synergy were identified and organized in semiotic chains to show the move from one MWS to the other, and the evolution of meaning generation. In these chains the transition from one sign to the adjacent stems from students' work in particular dimensions of a MWS. Finally, the episodes were categorized into four groups based on their contribution to the conceptualization of specific elements or processes related to the conditional statement.

Results

An episode from each one of the four groups is presented to illustrate the progressive conceptualization of the conditional statement and proof. Each episode brings to the fore a specific component of the conditional statement (premises, conditional links and conclusion) and the proof.

Conceptualizing the premises of the conditional statement

In all three tasks, after completing the folds and formulating a conjecture, the challenge of a robust construction in the GSP brought out episodes of synergy between the two MWSs in the students' attempt to attribute a mathematical meaning to the folds and the relationships between them.

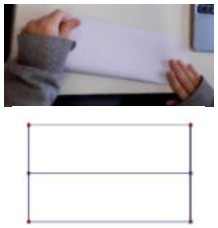

Figure 4: Student's work on paper folding and GSP

Achieving this goal led the groups to early premises and logical connections of the conditional statement. The following excerpt is from Group 1's engagement with Task 1, in which students attempt to conceptualize the first fold (Figure 4).

S1: It's the midline (a line halfway between two parallel lines).
Researcher: Why?
S2: If I fold it, they fall on top of each other.
S1: Yes that... these sides are equal.

Initially, the students working on the semiotic dimension of paper folding visualize the first fold (*artefact sign*-paper folding) and refer to it as "midline" (*mathematical sign*). When asked to justify this conjecture, they activate the instrumental dimension and folding again along the first crease, they observe that the upper and lower sides coincide (*pivot sign*-paper folding). They interpret this visual and haptic fact as symmetry (*mathematical sign*) of the sides and, finally, they justify their claim by observing the resulting equalities. This instrumental and discursive dimension of the MWS of paper folding subsequently directs their work in GSP, as they identify those properties of the sign (1st crease) that will allow it to be represented in GSP. Using appropriate commands (*pivot sign*-GSP), students construct the perpendicular bisector of the right and left sides of the rectangle, enriching the initial meaning of the midline, thus activating the instrumental and discursive dimension of the GSP. In summary, the synergy revealed premises related to the first crease, and in particular to the properties of the midline and the perpendicular bisector. However, these premises were ultimately not explicitly exploited by the students in the final proof.

Semiotic chain: 1st crease (artefact sign-paper folding) $\xrightarrow{ins\ (paper\ folding)}$ properties of 1st folding (pivot sign-paper folding) $\xrightarrow{sem\ (paper\ folding)}$ midline/symmetry (mathematical sign) $\xrightarrow{ins-dis(GSP)}$ selection of tools in GSP (pivot sign-GSP) $\xrightarrow{sem\ (GSP)}$ construction of midline from the middle points of the sides (artefact sign-GSP) $\xrightarrow{dis}$ early premises of the conditional statement (mathematical sign).

Conceptualizing the conditional links of the conditional statement

During the investigation of the contradictory results in the folding paper and GSP in Task 2, groups were led to a deductively questioning of the premises and to the conceptualization of the conditional links. The contradiction led Group 1 to generate correspondences both between the signs and the actions they were carrying out in the two MWSs. Specifically, the students first worked at the instrumental dimension of the GSP where they utilized dragging and measuring to identify instances where the triangle becomes isosceles (*pivot sign*-GSP), as they expected. This work activated the instrumental dimension of the paper folding as the students repeated the same folds on sheets of different dimensions ("manipulative counterexamples") (*pivot sign* -paper folding), discovering that only the sheets that are similar (*mathematical sign*) to A4 lead to an isosceles triangle. The comparative observation of the "manipulative counterexamples", led students to identify the necessary mathematical relationship for the desired conclusion, namely the perpendicularity of two segments (Figure 5, purple). This synergy supported the discursive genesis of meanings related to the dependence of the conclusion from the premises.

Semiotic chain: different visual feedback from the two MWSs (artefact signs) $\xrightarrow{ins\ (GSP)}$ dragging to obtain an isosceles (pivot sign-GSP) $\xrightarrow{ins\ (paper\ folding)}$ manipulative counterexamples (pivot sign-paper folding) $\xrightarrow{sem\ (paper\ folding)}$ similarity (mathematical sign) $\xrightarrow{dis\ (paper\ folding)}$ different dimensions lead to different shapes (pivot sign-folding) $\xrightarrow{dis}$ different assumptions lead to different results (mathematical sign).

Figure 5: "Manipulative counterexamples"

Developing conclusions and strengthening of the conditional links of the conditional statement

In Task 3, the students in Group 2, to test the conjecture that the intersection points of the X-lines lie on the perpendicular bisector of the two opposite sides of the square, apply two validation methods in the paper folding and two in the GSP, which are related to each other. S3, having already made 4 repetitions of the folding procedure of the task with different initial arbitrary points, in order to reject the fact that it is by chance that the intersection points are collinear, makes one more repetition (*artefact sign*-paper folding) (Figure 6). Correspondingly, this group activated in GSP the trace (*artefact sign*-GSP) of the intersection point (Figure 6). The synergy of the instrumental dimensions of the MWSs seemed to favor students' conceptualization of the locus as a set of infinite points with a common property. Another validation method was to produce a new crease (*artefact sign*-paper folding) along the line through which the intersection points seem to lie, to check whether this line (the crease) is the perpendicular bisector. Similarly, working at GSP, S4 states that to confirm that the intersection points of the X-lines are on the perpendicular bisector (*mathematical sign*) they can construct this object (*artefact sign*-GSP) and then check whether the intersection points are indeed points of this line by utilizing the dragging. The synergy in this case led to the perception of the locus as a whole, i.e. as an object or a static structure bearing certain construction properties. The chains of meaning composed due to the connections of the validation methods contribute - in addition to highlighting different aspects of a mathematical concept – to the strengthening of the constructive and ultimately logical dependencies of the premises with the conclusion.

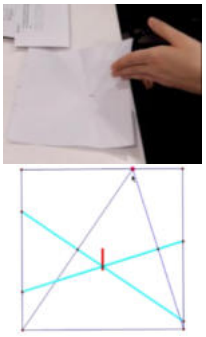

Figure 6: The intersection on paper and the trace at GSP

Semiotic chain 1: production of a new pair of X-lines (*artefact sign*-paper folding) $\xrightarrow{ins}$ trace (*artefact sign*-GSP) $\xrightarrow{dis}$ perpendicular bisector as a locus (mathematical sign). Semiotic chain 2: crease along the perpendicular bisector (artefact sing-paper folding) $\xrightarrow{ins}$ construction of the perpendicular bisector and dragging (artefact sign-GSP) $\xrightarrow{dis}$ perpendicular bisector as an object (mathematical sign). These semiotic chains express the reinforcement of the conclusion and the conditional links of the conditional statement and the enrichment of the notion of the perpendicular bisector.

Proof of the conditional statement

Students' experience stemming from the synergy of the manipulative and digital artefact revealed geometric properties and relations between signs and consequently helped them to identify the necessary components of proof. Combined with their known propositions and theorems, the revealed geometric relations structured their proofs. For example, students of Group 1, in order to prove that the triangle ABC (Figure 7) is isosceles in Task 2, utilized the geometric relationships they discovered through synergy. In a previous phase, the students proved empirically (equality as coincidence) by folding that the three triangles are equal (Figure 7), and the justification of equality was given a mathematical character when transferred to the digital environment. The equality of triangles 1, 2 was justified by exploiting a property of a diagonal of a rectangle and the equality of 1,3 was justified through symmetry which was expressed in GSP by exploiting the reflection tool. Through the logical relation "if a=b and b=c then a=c" the students justified the equality of triangles 2, 3 and finally the equality of angles ACB and CAB and recalled their well-known proposition about the equality of adjacent angles in an isosceles triangle. The semiotic chain is: equality of triangles 1,2,3 through the folding and the properties of creases (pivot sign-paper folding) $\xrightarrow{ins/dis(paper\ folding)}$ geometric relations of symmetry and properties of the rectangle (mathematical sign) $\xrightarrow{dis}$ justification of equality of the angles ACB and CAB/definition of isosceles (mathematical sign) $\xrightarrow{dis}$ proof.

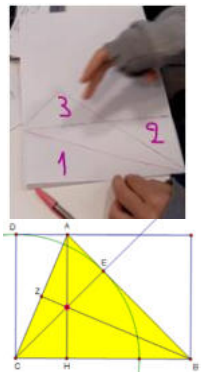

Figure 7: The Task 2 with folded paper and GSP tools

Conclusion

The analysis highlighted the contribution of the synergy of the two MWSs to the students' conceptualization of the conditional statement. The visual and haptic experience offered by paper folding activated the semiotic and instrumental dimension of this MWS, resulting in students' empirical attribution of mathematical meanings to the folds and the discovery of relations related mainly to symmetry (e.g., equality of segments and angles). The same two dimensions of GSP were activated by the request to represent the construction in GSP which led the students to search for appropriate commands and through this to develop meanings (e.g. for the midline). Moreover, in Tasks 2 and 3 the dynamic nature of GSP (dragging, trace) promoted further the exploration of contradictory results. A closer look at the emerging semiotic chains reveals that the synergy of the semiotic and instrumental dimensions of the two MWSs resulted in the interplay of their discursive dimensions and the discovery of the premises and conditional links of the conditional statement. For example, in Task 2 S1 and S2 exploited the manipulative counterexamples and dragging and provided a mathematical explanation of the source of the contradiction. In addition, the easy manipulation of the paper and the dynamicity of the GSP with their immediate feedback helped students to find methods to validate their conjectures and thus make the role of synergy more evident. For instance, in Task 3 the strengthening of conditional links and the generalization of a conjecture (i.e. perpendicular bisector as a locus) was promoted through the synergy of multiple paper foldings (different arbitrary points) and the subsequent activation of trace in GSP. Summarizing, the above episodes illustrate how the emerged meanings were utilized by the groups during the proving process. Specifically, the synergy contributed to the rich conceptualizations of the signs, the logical

dependencies between premises and conclusions and the students' use of a variety of propositions and theorems of Euclidean Geometry in structuring their proofs (e.g. the isosceles triangle in Task 2). This research contributes to the gap in the existing literature regarding the role of synergy in the conceptualization of conditional statement and proof and demonstrates that the combined use of MWS and TSM is an effective theoretical tool in revealing the aspects of the contribution of synergy in this context.

How do children in primary school prove?

Melanie Platz[1]

[1]Saarland University, Faculty of Mathematics and Computer Science, Saarbrücken, Germany;
melanie.platz@uni-saarland.de

A learning environment that allows the discovery of the assertion 'the sum of three consecutive numbers is three times the middle number' was tested with eight primary school children (grades 3 and 4) in clinical interviews. The interviews were analyzed on the epistemic actions recognizable in the proving activities using Abstraction in Context, and proof levels and indications for the further development of the learning environment were derived. The construct 'block towers' was used by a minority of children but led to proofs by generic example. The justifications of the children using the other construct, 'placeholders', remained empirical.

Keywords: Primary education, content-visual proving, reasoning, instruction support.

Introduction

By embedding proving at the center of children's mathematical experiences, they have more opportunities to engage with mathematics in depth and see it as a meaningful activity. In addition, they will not only be better prepared in secondary school to engage in proving, which they see as a natural extension of their earlier mathematical experiences but will also be more able to reason mathematically in a disciplined way (Stylianides, 2016, p. 10). In particular, content-visual proving can be implemented at the primary level (Peterßen, 2012, p. 20). A content-visual proof (Blum & Kirsch, 1991; Wittmann & Müller, 1988) is based on some concrete, visually perceptible object used to prove something general. Through trained observation, this can be understood as an object of a more general nature, whereby the more general aspect of this example must be mentally recognized to provide a content-visual proof. A verbalization must occur so that what is initially subjectively found to be universally valid can be socially shared and possibly recognized by others (Wittmann & Ziegenbalg, 2007). Proving can be realized within the framework of learning environments of the 'best quality' (Wittmann, 1998, p. 337), so-called substantial learning environments. According to Wittmann (1998, p. 339), a substantial learning environment is open in principle. Merely, the key information that the teacher gives at the beginning of each phase is determined, and further interaction with and among the pupils remains open. Concerning content-visual proving, the question arises of how such key information can look and how open the further interaction should be to stimulate a proving activity.

This paper presents the current state of development of a learning environment for content-visual proving. The learning environment is created using Design Science Research (Drechsler & Hevner, 2016) around a task that allows the discovery of the assertion 'the sum of three consecutive numbers is three times the middle number' and is tested with primary school children in clinical interviews (Wittmann, 1998) by students who have been specially prepared. This paper looks at which constructs primary school pupils use for reasoning to draw conclusions for the further development of the learning environment. Abstraction in Context (AiC) provides a model of nested epistemic actions to investigate learning processes on a micro-analytical level that lead for the learner to new constructs

(e.g., concepts, strategies, etc.). The central theoretical element of AiC is the dynamically nested epistemic action model, according to which the emergence of a new construct is described and analyzed based on three observable epistemic actions (RBC model): *(R–recognizing)* identifying situationally relevant knowledge constructs, *(B–building with)* combining known constructs to solve a local problem and *(C–constructing)* developing new constructs (Dreyfus & Kidron, 2014).

The Learning Environment

The design of the learning environment is based on the following design principles (Platz, in review) formulated in the manner of van den Acker (1999): If you want to design a learning environment for proof at the primary level, then you are best advised to

(1) awaken the need for proof right from the start by
   a) embedding the tasks in a historical context (Krauthausen, 2018) or a story (Kothe, 1979), as this can reduce the rejection of the tools used and create experiences of relevance.
   b) allowing the children to discover the assertion independently (Krumsdorf, 2015), as this increases the children's motivation.

(2) awaken the need for proof concerning generalizing by
   a) repeatedly asking 'why' questions (Krauthausen, 2001, p. 105) because we get what we accept (Higgins, 1998) – and if we settle for less, children will only give us that.
   b) the application of the concept of 'Big Numbers' (Martin & Harel, 1989), as this can help children detach themselves from empirical testing (Krumsdorf, 2015).

(3) as a learning guide, to be a reliable source of information, and to support and supplement the children's activities with suitable, not too far-reaching impulses (Wollring, 2008), namely by
   a) taking up the children's previous experiences and ideas and not directing them too strongly but instead building on their ways of thinking (Selter & Spiegel, 1997).
   b) giving the children time (Krauthausen, 2001).
   c) well preparing the implementation by identifying possible solutions/ sources of error in advance (Wollring, 2008).

The tasks within the learning environment are as follows:

Table 1: Tasks in the learning environment and corresponding design principles

Task	Design Principle(s)
Today, you will become a maths detective: a tricky case must be solved.	(1) a)
Solve the tasks. a) $2 + 3 + 4 =$ $3 \cdot 3 =$ b) $3 + 4 + 5 =$ $3 \cdot 4 =$ c) $7 + 8 + 9 =$ $3 \cdot 8 =$ What do you notice?	(1) b)
Why is this so? Give reasons!	(2) and (3)

Research Questions

In this paper, the following research questions are targeted: *RQ(1) Which epistemic actions are recognizable in the proving activities of primary school children? RQ(2) Which consequences can be drawn for the further development of the learning environment?*

Methods and procedures for collecting and analyzing data & obtained data

A multiple case study (Yin, 2018) was conducted using qualitative data collection and analysis methods. Clinical interviews (Selter & Spiegel, 1997; Wittmann, 1998) were used for data collection. Conducting a clinical interview, in which only the key questions are defined, and the requirement is to follow the children's thinking, is analogous to classroom management when implementing a substantial learning environment (Wittmann, 1998). However, as these do not coincide with the routines of maths lessons and, therefore, a teaching reference can be established more in terms of content, only limited conclusions can be drawn for implementing proving in maths lessons. Nevertheless, the data collected can provide information about the teaching and learning processes, thought processes, and learning progress. On the other hand, they help evaluate and revise the learning environments to organize teaching and learning processes even more effectively (Wittmann, 1998, p. 339). Although group interviews have certain advantages (Selter & Spiegel, 1997, p. 106), the decision was made in favor of individual interviews to avoid the disadvantages of group interviews like the dominance of individual children, loss of information, the heterogeneity of the group and mutual reinforcement, which would make it difficult to keep track of the individual children's approaches (Selter & Spiegel, 1997, p. 106).

In the seminar 'Mathematics didactic research: proving in primary school' in mathematics for the primary school teaching profession at Saarland University (Germany), students were prepared in the summer semester of 2022 for conducting the clinical interviews. They were trained to consider the design principles mentioned above. In the interviews, besides pencil and grid paper, the children were offered clamping blocks and the 'Steinchen-Applet' (Platz, 2020a). The children were free to decide which materials they wanted to use. The interviews were videotaped and transcribed. The visual and text material was analyzed using qualitative content analysis (Mayring, 2015). A category system was developed in the seminar based on theory (cf. Platz, 2020b) and is further developed inductively using the material. The analysis focussed on constructs developed independently by the children. Eight clinical interviews were conducted with 3rd and 4th graders from Saarland and Luxembourg. Balacheff's (1988) generally recognized levels of proof are used to classify the solutions: *(1) 'proof' by naive empiricism* (some arbitrarily selected concrete examples are verified), *(2) 'proof' by crucial experiment* (concrete examples are used, however, these are typical examples that allow for generalization), *(3) proof by generic example* (structural mathematical properties are stated with reference to a characteristic case that exemplifies a whole class of cases) and *(4) proof by thought experiment* (a reference is made to structural mathematical properties, but completely independent of concrete examples). Proofs on *levels 3* and *4* can be regarded as valid (Balacheff, 1988).

Results

RQ1

Firstly, ideal-typical exemplary substantive and illustrative proofs are presented (a priori analysis, Tables 2 and 4), followed by a description of the particular aspects of the constructs and possible difficulties. The ideal-typical reasoning contexts are each a content-visual proof, as the reasoning on the image works with logical arguments. Still, the warrants are not drawn from the formal system but from images, reality-related considerations, or similar (Meyer & Prediger, 2009). Therefore, the justification consists of a chain of correct conclusions based on non-formal premises (Blum & Kirsch, 1991). The reasoning can consequently be considered valid, as the operations are generally executable, regardless of the specific examples used to demonstrate them (Wittmann, 2014, p. 226). The structure of the tables is as follows: in row 1, we have the prerequisites *(C_1)*; in row two, the proof idea or the 'trick' *(C_2)*; in row three, the generalization, which makes it a valid proof *(C_3)*.

Table 2: Blocktowers (subconstructs C_1-C_3 and classification in the RBC-Modell)

C_1: Three consecutive numbers can be represented as three towers of blocks (cardinality, *R*), where the second number has one block more than the first, and the third has one block more than the second (predecessor and successor, *B*).	C_2: Putting the top block of the third number on the first number creates a rectangle with a side length of 3 and another side length of the middle number (constancy of the sum, opposing change, *B*). So, for this example, the sum of three consecutive numbers is three times the middle number (in this case, 4) (addition as union of sets, multiplication as continued addition, *R*).	C_3: Extending or shortening the towers still leads to three consecutive numbers; the sum is always three times the middle number (*C*).	
Table 3: Explaining and visualizing the generality of the values

Pupil: Um (...) from 103, one goes to 101. So and so. *(draws an arrow on the top of the blocktower)*  Interviewer: That means you've already drawn 100 boxes here? Pupil: So (...) that I don't (...) have to do so much, I draw something that (...) that it still goes on. *(draws three arrows on the bottom)* […] Interviewer: And for other numbers with the same distance? Pupil: Then it works like this. Interviewer: Always? Pupil: Always!	
Table 4: Placeholder (subconstructs C_1-C_3 and classification in the RBC-Modell)

C_1: Three consecutive numbers can be represented as numerals (numeric notation, predecessor and successor, *R*).	3, 4, 5
C_2: If the summands 3 and 5 are changed in opposite directions (both to 4), the sum remains constant (constancy of the sum, opposing change, *B*). Using the definition of multiplication as continued addition leads to 3·4. So, for this example, the sum of three consecutive numbers is three times the middle number (*R*).	3+4+5 = (4-1)+4+(4+1) = (4-1+1)+4+4 = 4+4+4 = 3·4
C_3: This procedure works no matter which consecutive numbers we choose (*C*).	(□ -1)+□+(□+1) = (□-1+1)+□+□ = □+□+□ = 3·□

Among others, Krumsdorf (2015, p. 192) and Stylianides (2016, p.131) report on the 'blocktower'-construct (Table 2). In the study, two children, 3rd and 4th grade, used this construct. Both justified by verifying a statement by referring to the structural properties of mathematics using a general example (*level 3,* Balacheff, 1988). Particular in the solutions was the visualization of the generality of the values (C_3): starting from big numbers (*principle (2) b)*) the 4th-grader used arrows for visualizing the generality of the values (Table 3, left). The 3rd-grader used clamping blocks and visualized generality by adding or removing the three upper blocks arranged in the form of stairs (Table 3, right).

Among others, Krumsdorf (2015, p. 192) reports on the 'placeholder' construct (Table 4). Six children's solutions can be assigned to this construct, whereby only two children (both grade 4) used placeholders for their arguments. One child said the following *(C_2)* but did not explain why this works no matter which consecutive numbers are chosen *(C_3)*: "You must take one from the largest number and add it to the smallest, and then multiply the number in the middle by three." The others (one 3rd- and three 4th-graders) used a set visualization, which reminds of the visualization in Dilberoğlu et al. (2022, p. 162) and showed a cardinal understanding of the numbers (see Fig. 1). All children justified empirically: five with crucial experiment (*level 2*) and one by naive empiricism (*level 1*).

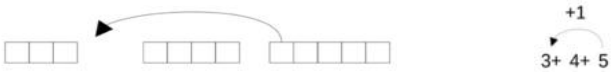

Figure 1: cardinal visualization

RQ2

As the sample is very small, no generalizable statements can be made. However, indications for the optimization of the learning environment can be found. The two children who used the construct 'blocktowers' (Table 2) successfully constructed a proof by generic example. Whereas the six children who used the construct 'placeholders' (Table 4) found the proof idea but did not express any generalization. The fact that children do not express a generalization and remain on C_2 (like in the 'placeholder'-construct) does not mean that they do not understand that their procedure works no matter which consecutive numbers are chosen. One problem could be that the pupils are required to generalize without knowledge of the algebraic language (Akinwunmi, 2012). Furthermore, the generalization may be so evident for the child that it prevents the linguistic effort (Freudenthal, 1978,

p. 262). Additionally, the transition from arithmetic to algebraic thinking (Steinweg, 2013) could cause difficulties here. To support pupils, the negotiation for a common argumentation basis is important, and that the children learn proving, e.g., by conducting a proof that follows a known pattern (Fischer & Malle, 1985; in our case, this could be proving the assertion that 'the sum of five consecutive numbers is five times the middle number' after the pattern for proving such assertions was learned). It is necessary to reflect justifications with pupils: they must learn which justification is accepted or rejected when and why, i.e., which requirements are demanded of a justification (Peterßen, 2012, p. 348). This was not stimulated in the learning environment (Table 1). Therefore, in the project's next step, authentic pupils' solutions will be reenacted and provided as short videos that can be used in the learning environment. To discuss the videos with the pupils, the interviewer can guide the pupils through stages with increasing metacognitive demands (Platz, 2022).

Conclusion

In this paper, the proving activities of eight primary school children (grades 3 and 4) were analyzed to determine which epistemic actions are recognizable in the proof activities of primary school children *(RQ1)*. Based on the results, consequences for the further development of the learning environment were drawn *(RQ2)*. The presented learning environment is rather not suitable for regular teaching, as the attention required from the teacher for the individual child (Wollring, 2008) is too extensive. Nevertheless, targeted further development of mathematical reasoning skills in primary school mathematics teaching seems to be possible in principle (Bezold, 2009; Peterßen, 2012; Vogt, 2020). In the next step, a concept for establishing a culture of justification in the classroom will be developed, including the reenacted video scenes created in the project. This way, justifications in themselves and their respective persuasiveness can be made the subject of teaching (Platz, 2022).

Acknowledgments

I thank all the participating children and students for their outstanding work!

Evaluating arguments: the role of goals and interlocutors

Marta Saccoletto[1]

[1]University of Eastern Piedmont; marta.saccoletto@uniupo.it

Argumentations may serve different functions in mathematical classrooms, such as explaining, verifying or convincing. We believe that considering the function arguments serve in the classroom could influence students' conception and evaluation of arguments. This work aims to investigate students' evaluation of written arguments in two situations: to explain a problem resolution to a peer and in a class test. To this purpose, a questionnaire was administered to nineteen 11th-Grade students at the end of a teaching experiment. The analysis of the students' answers shows that students choose different arguments in the two situations investigated and take into consideration both the interlocutors and the function that the arguments serve in the two situations.

Keywords: Argumentation, explanatory function, probability, upper secondary school.

Introduction and theoretical framework

Mathematics Education researchers investigate argumentations from different perspectives (Mariotti, 2006; 2022), in which different goals, or more precisely, different *functions* of argumentation can be recognised. For example, research conducted by Boero and colleagues, within the framework of Cognitive Unity (e.g. Boero et al., 1996), emphasises the use of argumentation to promote the development of mathematical proofs, particularly focusing on supporting the validity of a claim. The research of Harel and Sowder (1998) delves into personal conviction and the persuasive power of arguments. Studies by Krummheuer (1995) and by Yackel and Cobb (1996) highlight argumentation as a tool to facilitate learning in the classroom, stressing its connection to the learning process. Finally, in Cusi, et al. (2017) argumentation is conceived both as a mean to "make the process visible", thus providing insights into students' thought processes, and as a learning objective in itself. Drawing on the research on functions of proof (e.g. de Villiers, 1990; Hanna, 2000), in Ferrari and Saccoletto (2023) we took into consideration different functions that arguments and argumentations might serve in mathematical classrooms, such as verifying, explaining, or convincing. We believe that the function of the argument plays a role in its production or evaluation, and, in classrooms, the *explanatory function* is particularly crucial. We see that the explanatory function as relational and, therefore, dependent on the interlocutor (Ferrari & Saccoletto, 2023; Stylianides et al., 2016).

To examine the explanatory function of arguments and argumentation, in Ferrari and Saccoletto (2023), we discussed the introduction of a theoretical framework based on the perspective of Mercier and Sperber (2017), related to the investigation of the social evolution of reasoning. According to Mercier and Sperber (2017), arguments and argumentation are developed primarily for social purposes. People produce reasons mainly to justify their claims, actions, or points of view to others. In doing so, they adhere and negotiate norms of what is considered reasonable, and they make their reasoning available for questioning while also asserting their right to question the reasoning of others. In their perspective, interlocutors play a crucial role. They state that "a good argument consists precisely in displaying coherence relationships that the audience can evaluate on their own" (Mercier & Sperber, 2017, p. 195). Coherence relationships should link interlocutor's knowledge and beliefs

to the speaker's claim. Although Mercier and Sperber do not explicitly characterise these coherence relationships, they emphasise the influence of context in producing and evaluating reasoning. In a mathematical classroom context, the links between the speaker's claim and the audience's knowledge and beliefs can take various forms. For example, theorems or propositions are commonly accepted to justify a mathematical result.

Interlocutors influence arguments and argumentative processes. In classroom to enhance the explanatory function of argumentation, we think peers should be the primary interlocutors. However, students also produce arguments directed at the teacher, particularly in evaluative contexts. Interlocutors and argumentative functions are interrelated. This paper investigates which written argument students prefer to justify a problem resolution in two different situations, which differ both for the interlocutors and the function of argumentation:

- explaining the problem resolution to another peer,
- during a class test.

The aim of this work is to study whether students choose different arguments and to reflect on the characteristics of the selected argument(s). Moreover, students' motivations for the selected argument are analysed to understand whether students' choice are influenced by the different interlocutors and or by the different functions.

Method

In the school year 2022-2023 we carried out a teaching experiment in an upper secondary school classroom of 19 students of a "Liceo Scientifico" (a high school with a curriculum that places particular emphasis on scientific disciplines such as mathematics). The mathematics teacher of the classroom was involved in the research group. The teaching experiment lasted from the beginning of March to the middle of April (approximately 40 hours). The activities were carefully designed with the dual aim of fostering argumentative practice and introducing students to probabilistic thinking. No probability concepts had been introduced in the classroom before the teaching experiment. Students were involved in the resolution of different problems related to the classic theory of probability and in discussion about the solution of the problems (see Ferrari and Saccoletto, 2023 for an example of an historical problem used in the activity). During the discussions students were generally asked to explain to others their solutions and to justify them. Explaining and justifying one's reasoning primarily occur in small-groups or whole-class discussion, where peers were the main interlocutors. The aim of the activities was not to convince others at all costs to agree with one's own ideas, but to foster sharing, understanding, and supporting collective learning. With this purpose, students were prompted to understand others' ideas and perspectives, and to elaborate on the rationale behind their choice. The explanatory function of argumentation was at the core of the activity, with peers as the primary interlocutors.

Among the final activities of the teaching experiment, we administered a questionnaire to students, which is at the centre of this paper. Eighteen out of nineteen students participated in the questionnaire.

In the questionnaire we presented students with a problem similar to those they had previously encountered in classroom activities. The problem, translated in English by the author, was:

According to an ISTAT[1] survey, in Italy, 34% of people (male or female) aged three or over engage in at least one sport. Among those who practise a sport, 60% are male, while among those who are sedentary, that is, those who do not engage in any physical activity, 40% are male.

a. *What is the probability that a randomly selected person aged three or over is female and engages in at least one sport?*
b. *What is the probability that a randomly selected person from the total population (aged three or over) is male?*
c. *A person aged three or over is randomly selected from the total population, and it is known that they are male. What is the probability that this person is sedentary?*

Three different solutions followed the problem: Carlotta's, Enrico's and Diletta's solutions. The solutions were created ad hoc by the author of the paper and discussed with the teacher of the classroom. All the solutions could be acceptable according to the classical probabilistic approach, but they comprised different arguments to sustain the results. Particularly, they differ in the visual representation used in the text: Carlotta's and Enrico's solutions primarily employ visual representations, namely a table and a tree diagram. Diletta's solution is strongly characterized by the use of formulas and theory recall. Tables, tree diagrams and formulas were all encountered and learned by the students in classrooms activities.

Below, we present the author's translation of the three solutions. We are aware that translation may affect the texts, however we think major differences are still recognisable.

Solution 1 (Carlotta's)

Table 1: Table of Carlotta's solution

	Engage in at least one sport	Sedentary	Engage in at least one sport or sedentary
Males	0.34•0.6=0.204	0.66 • 0.4=0.264	0.468
Females	0.34•0.4=0.136	0.66 • 0.6=0.396	0.532
Males and Females	0.34	0.66	1

a. The probability that the person is female and engages in at least one sport is 0.136, i.e. 13.6%.
b. The probability that the person is male is 0.468, i.e. 46.8%.
c. The probability that the person is sedentary, given that they are male, is $0.66 \cdot 0.4 : 0.468 = 0.564$, i.e. 56.4%

Solution 2 (Enrico's)

[1] ISTAT is the Italian National Institute of Statistics.

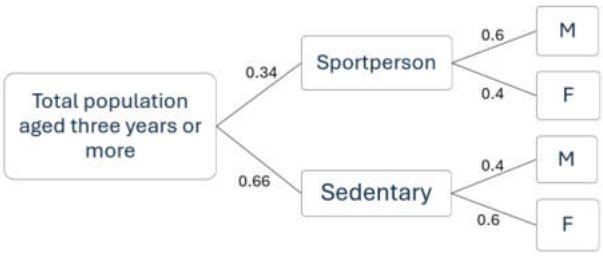

Figure 1: Tree Diagram of Enrico's solution

a. The probability that the person is female and engages in at least one sport is $0.34 \cdot 0.4 = 0.136$, i.e. 13,6%.
b. The probability that the person is male is $0.6 \cdot 0.34 + 0.4 \cdot 0.66 = 0.468$, i.e. 46.8%.
c. The probability that the person is sedentary, given that they are male, is $0.66 \cdot 0.4 : 0.468 = 0.564$, i.e. 56.4%

Solution 3 (Diletta's)

a. If among those who practice sports, 60% are male, then 40% are female. Let M denote being male, F denote being female, S denote being sedentary, and *NS* denote being non-sedentary. Then: $P(F \cap S) = P(F) \cdot P(S) = 0.4 \cdot 0.34 = 0.136$, i.e. 13.6%
b. The probability of being male is given by the sum of the probabilities of the two mutually exclusive events $M \cap S$ and $M \cap NS$. Then: $P(M) = P(M \cap S) + P(M \cap NS) = P(M) * P(S) + P(M) \cdot P(NS) = P(M) \cdot P(S) + P(M) \cdot (100\% - P(S)) = 0.6 \cdot 0.34 + 0.4\% \cdot 0.66 = 0.468$, i.e. 46.8%.
c. The probability that the person is sedentary (NS), given that they are male (M), is a conditional probability. $P(NS \mid M) = P(M \cap NS) : P(M) = (0.4 \cdot 0.66) : 0.468\% = 0.564$, i.e. 56.4%.

At the end of the questionnaire, students were asked to choose an argument to explain which solution they would employ to explain the problem resolution to other students and which one they would use in a class-test. In addition, students were required to carefully justify their choices. The two situations involve different interlocutors (peers and the teacher) and serve different functions (explaining to someone who does not know the resolution and validate one's results, showing one's reasoning to the professor in an evaluative context). Through this questionnaire, we aimed to explore whether students' choices were different in the two situations and the reasons for the various choices. Students' answers were analysed qualitatively using thematic analysis (Cohen et al., 2018) in order to identify the reasons behind students' choices.

Results

Sixteen out of eighteen students chose Enrico's solution as the most suitable for explaining the resolution of the problem to another student. One student selected Carlotta's solution, and one chose Diletta's.

From the analysis of students' justifications, it emerges that students value the graphical aspect: Enrico's solution is considered the easiest to understand, thanks to the tree diagram, which enables the steps to be visualised. Carlotta's solution is seen as less clear and intuitive, although the graphical

element is generally appreciated, while Diletta's solution is regarded as the least comprehensible. For example, two students state:

> [S6] I chose Enrico's solution because, in my opinion, it is the easiest to understand. Even visually, you immediately grasp the procedure to follow to reach the solution. I find it to be an intuitive and immediate method for understanding the problem. I excluded Carlotta's method because I find it harder to understand and less immediate than the previous one; it's easy to misread the table. In my opinion, the third method helps the least in understanding the problem because it develops the process purely through laws without explaining or providing a different visual perspective of the problem, as the other two methods do. […]

> [S18] I think Enrico's solution is the most suitable because it uses an effective graphical representation (a tree diagram), making it easier to explain the problem and helping classmates understand it (as they have a reference point to follow). While Diletta's solution is correct and justified in all steps (using proven formulas), it could be a bit harder to understand, as some might not grasp why a certain formula is being used or may not fully comprehend it. Carlotta's solution also uses a graphical representation (a table), but I find it less effective and harder to understand compared to the tree diagram.

The diagram is also positively evaluated as it allows calculations to be performed more quickly or explained more effectively.

> [S2] […] If I had to explain it to someone for the first time, drawing a tree diagram on how the exercise is structured would be extremely effective, as all the data would be easily noticeable and would allow me to explain how to calculate the percentage (40% or 60%) of one of the two initial percentages given (34% and 66%).

> [S3] Because the diagram helps to reach the solution more quickly […].

Finally, students emphasize the accessibility of Enrico's solution, which is considered easier to understand by a greater number of people and accessible without requiring specific knowledge. For instance, two students state:

> [S9] The second response explains the problem's resolution even to those who do not have an intuition for probability, thus making it easier for a wider variety of people to comprehend compared to the other two methods. The third response is a translation of the solution into mathematical language, and if one does not master it, it becomes difficult to draw the path to the solution […].

> [S11] I chose Enrico's explanation simply because it is a very simple and understandable explanation – meaning everyone will be able to grasp it. […] Personally, I am not a mathematician, but I enjoy maths. I say this because I couldn't quite understand Diletta's explanation of the problem, as it is based solely on mathematical language […].

To sum up, the focus is on comprehension, intuitiveness, ease of performing or explaining the calculations, and the accessibility of the solution.

Regarding the in-class test, twelve students indicated Diletta's solution as the most appropriate, five chose Enrico's solution, and one selected Carlotta's. Among the five students who chose Enrico's solution, two noted that although they would choose Enrico's solution, their professor would likely prefer Diletta's. Among the twelve students who indicated Diletta's solution, four stated they would probably add Enrico's tree diagram to help them solve the problem.

The analysis of students' justifications indicates that students focus on the use of formulas and symbolic language. Diletta's solution is generally considered the most formal among the three solutions:

> [S9] The first and second might be more intuitive, but they are informal. The third is academic and formal, as it uses fundamental probability laws. Moreover, it helps to generalise the resolution for these kinds of problems.

Additionally, students consider the use of formulas and symbolic language to be the most appropriate way to validate a result:

> [S8] Diletta's solution, while a bit less immediate than the others, is the only one that directly refers to the theory demonstrated in class, and therefore cannot be questioned […].

> [S6] I would choose the third because it appropriately justifies the method and the calculations used through established theorems, while the other two methods do not use theorems or laws but are simply based on diagrams that help to understand the problem. However, the calculations are not supported by formulas, as I believe they should be in a maths test, because formulas increase the validity of the response.

Finally, Diletta's solution is considered the most appreciated by the professor:

> [S11] […] it [Diletta's solution] is also the preferred method of writing for all professors, meaning our teachers want us to reach this kind of interpretation of the problem.

> [S10] I would use Diletta's response because it contains the formulas that our professor requires. However, I would also include a tree diagram to help with the calculations.

Student 10 is an example of someone who would use the tree diagram to solve the problem but still chose Diletta's solution as the most appropriate for a class test. The usefulness of the tree diagram in solving the problem is the most common reason students give for selecting Enrico's solution in an in-class test, as these answers show:

> [S12] I find it much easier to represent problems with tree diagrams, so I chose this solution. However, in a test, the professor would probably also want to understand the process, so I would likely use the final solution to describe everything.

Discussion and conclusion

The analysis shows that students' preferences differ in the two situations investigated: Enrico's solution is generally considered the best to explain the problem resolution to a peer, while Diletta's solution is the most appropriate in a class-test. In other words, there is not a "best argument" to support the result, but arguments are evaluated according to the situation which is influenced both by

the interlocutor and the function of the argument. From the analysis of students' motivation of the answers, it emerges that their choices are influenced both by the interlocutors and by the function. In the following we try to distinguish the two variables; however, we recognise a strong link between the two. First, in motivating their choices students take into consideration the interlocutor. For instance, they think about what the interlocutor might (not) know. This is in line with the perspective of Mercier and Sperber, in which the *knowledge of the interlocutor* are to be considered when developing an argument. Enrico's solution is generally considered more accessible than Diletta's, as the latter contains formulas and a symbolic language that not all might be familiar with. In this sense a tree diagram is considered a way of displaying *coherence relationships* more approachable than Diletta's discursive solution to explain to a peer. Conversely, when the teacher is the main interlocutor students prefer formulas and symbolic language, without doubting the knowledge of the teacher. Moreover, in a class-test, students think about what an interlocutor might prefer. For example, students state "It is also the preferred method of writing for all professors" or "It contains the formulas that our professor requires", highlighting the importance of adapting the texts to the interlocutors. These answers might be considered from the point of view of the pragmatic linguistic (e.g. Sperber & Wilson, 1995), in which Mercier and Sperber's (2017) perspective is rooted: students choose the text that, in their view, is the most suitable for communicating with a teacher, their intention is likely also to show they master symbolic and technical language. Moreover, in giving reasons students adhere or negotiate norms of what is reasonable (Mercier & Sperber, 2017). Thus, the norms established in the classroom, such as the *didactic contract* (Brousseau et al., 2020), likely influence these answers. Second, students take the function of the argument into account. On one hand the visual representations used in Enrico's and Carlotta's solutions are positively evaluated to explain, as they help illustrate calculus and problem resolution steps. On the other hand, formulas are considered the best way to validate a statement and to show the own knowledge of probability theory. However, some students choose Enrico's solution for the class-test, as it is the way they solve the problem they are most comfortable with.

Being able to take into account the interlocutor and the function of arguments is in line with competencies related to argumentation framed in literature, such as the competence framework of Niss (2003) and the *argumentive competencies* by Kuhn (1992).

The influence of the interlocutor(s) and of the function of the argument point out the importance of considering linguistic aspects of the argument. We are currently further investigating the characteristics of explanatory arguments drawing on the Theory of Relevance (Sperber & Wilson, 1995), which we believe will be useful in better characterising text differences and in deepening the analysis conducted.

Using *FullProof* to develop geometrical reasoning and proof skills within a practicum course for preservice teachers

Ruthmae Sears[1], and Orly Buchbinder[2]

[1]University of South Florida, Faculty of College of Education, Tampa, Florida, USA; ruthmaesears@usf.edu

[2]University of New Hampshire, USA

This paper describes the technological pedagogical content knowledge (TPACK) specific to proof of three prospective secondary mathematics teachers (PSTs) who worked with FullProof - the innovative AI-style tool for writing geometry proofs. The PSTs were introduced to the tool to develop their ability to facilitate instruction, promote geometrical reasoning and proof-writing, and strengthen their TPACK. Two mathematics teacher educators (MTEs) co-taught the course. Data were collected via four video-recorded lessons. The results suggest that the use of FullProof-mediated learning experiences aided in strengthening the PSTs' TPACK knowledge and enhanced their confidence in teaching geometrical proofs. The results illustrate how FullProof can support the development of PSTs' TPACK about proof in geometry and highlight the role of MTEs in facilitating PSTs' learning.

Keywords: Future teachers, geometry, reasoning and proof, technological pedagogical content knowledge.

Introduction

There is a need to develop preservice teachers (PSTs) and in-service teachers' proof skills to support students learning how to prove. The use of technological tools during instruction can afford opportunities for individuals to explore concepts, shift the foci of what individuals attend to, impact what is learned and by whom it is learned, strengthen connections, support knowledge construction, and provide intelligent support (Hoyles, 2018). In recent times, advancements in artificial intelligence resulted in technological tools that can support students in proof writing and validating the accuracy and completeness of the proof. *FullProof* is a digital platform specifically developed to help students advance their proof-writing skills in Euclidean Geometry. Hence, we sought to examine how *FullProof* can be used to develop PST's technological pedagogical content knowledge (TPACK) about proof and proving, with the support of two mathematics teacher educators. The overarching research question for this study is: *How does the use of FullProof in a secondary mathematics education practicum course affect PSTs' TPACK knowledge about proof in geometry?*

FullProof – the innovative tool for supporting proof writing

FullProof is a digital platform developed to advance proof-writing skills in Euclidean Geometry. It holds a vast collection of proof problems at high, medium, and low difficulty levels. Each problem is accompanied by a static figure whose angles and segments become highlighted when pointed to; they can also be marked. Students write proofs in the two or three-column format by typing statements or equations and choosing supporting justifications from the menu of theorems and definitions. For

example, in Figure 1, it is given that $\overline{DE}$ is a midsegment of ΔABC. The length $BF = (1/2)FC$. The segment $\overline{AF}$ intersects $\overline{DE}$ at a point G and the segment $\overline{BE}$ at a point O. Prove that $\overline{BO} \cong \overline{EO}$. If students do not know how to proceed, the software provides hints. *FullProof* also checks the completed proof and provides line-by-line feedback indicating correct, partially correct, or incorrect steps, as well as a hint into the nature of the mistake.

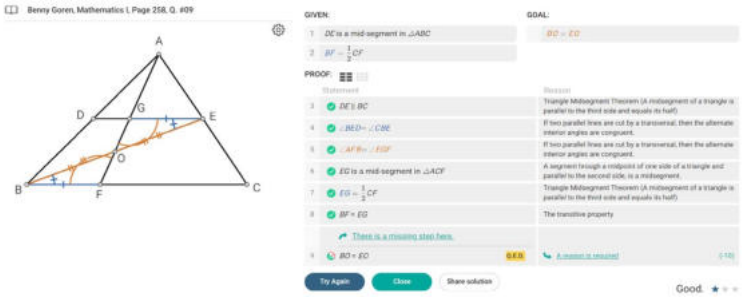

Figure 1: Sample solution in *FullProof* and the feedback provided by the software

The unique feature of *FullProof* is that it allows for multiple solution paths as long as the proof is mathematically correct. For example, the proof in Figure 1 can be completed by relying on congruent triangles or using centroid properties. Correcting their mistakes and resubmitting solutions allows students to improve their proofs, which makes *FullProof* a valuable formative assessment tool.

Theoretical Perspective

The Technological Pedagogical Content Knowledge (TPACK) framework (Mishra, 2019) is the theoretical lens used for this study. TPACK has been widely used to conceptualize the integration of technology into mathematics teaching and the various facets of teacher knowledge involved in this integration. The TPACK framework (Figure 2) comprised three knowledge domains: Technological (TK), Pedagogical (PK), and Content (CK), and their intersections. The TK domain involves teachers' familiarity with various technological tools and the ability to integrate these tools into mathematics instruction effectively. The PK domain considers teachers' ability to create effective learning environments to support student mathematical learning and engagement. Teachers' CK provides robust mathematical knowledge (Mishra, 2019). In the context of teaching geometry, CK considers the teacher's knowledge of geometric concepts, theorems, and modes of argumentation and proving, including their ability to write geometry proofs. Similarly, PK implies promoting a culture of proving in the classroom by designing learning opportunities to construct proofs, strengthen students' ability to communicate their arguments, and evaluate the arguments of others. TK involves knowledge of technological tools that can support students' proof processes.

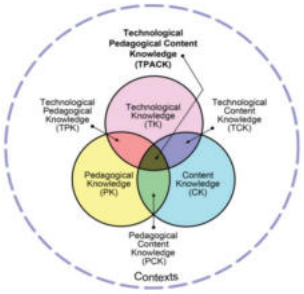

Figure 2. TPACK Framework (Mishra, 2019, p. 77)

Intersections between and among knowledge domains can occur. Teachers draw on their Technological Pedagogical Knowledge (TPK), i.e., the combination of TK and PK, when they consider how particular technological tools can support (or constrain) students' understanding of geometry concepts or developing certain geometry skills and how to structure students' experiences with technology to aid their learning. Similarly, Technological Content Knowledge (TCK) enables teachers to understand how geometry content is represented through a particular technological tool and what affordances it provides to communicate mathematics.

Method

We conducted an exploratory study in a university practicum course for PSTs enrolled in a secondary mathematics education program in the southeast region of the United States. Data were collected via a video recording of lessons and analyzed using thematic analysis. In the subsequent sections, additional information is provided about the course context, data collection, and analysis employed.

Course context

The practicum course is taken the semester before PSTs complete their final internship. The course met virtually for 2 hours and 45 minutes weekly for a 15-week semester. Three PSTs participated in the course. For the course, the PSTs were required to engage in clinical experiences for at least 60 hours. They were assigned to teach geometry lessons in which they integrated technology and strengthened students' reasoning and proof skills. The first author (MTE1) of the paper was the course instructor, the second author (MTE2) led the discussions devoted to learning how to use features of *FullProof* and participated in the sessions in which the PSTs reported on their use of the *FullProof* in their classrooms.

Participants

There were three PSTs in the practicum course who were in the 18-25 age group. The PSTs were in the fourth year of their undergraduate program, having typically completed coursework in Calculus, Discrete mathematics, Number theory, Geometry, History of mathematics, and Statistics. They also would have completed a course on technology and methods of teaching secondary mathematics. Pseudonyms are used to refer to the three PSTs (Alpha, Beta, and Gamma).

Data collection and analysis

Data were collected via recording of virtual class meetings in Fall 2023. One session was devoted to an overview of *FullProof* (August 31, 2023), and three sessions (September 7, 14, and 26, 2023) were allocated for PST to teach with *FullProof* and reflect on the enacted lessons. During the first session, MTE2 provided an overview of *FullProof*, and MTE1 provided insight into how the tool could support the teaching and learning of proof in geometry, with consideration given to evidence-based teaching practices. The preliminary training sought to aid PSTs in becoming comfortable with the tool, to increase the likelihood of using the tool to teach proof, and to support students' ability to prove. Both MTEs supported the discussion focusing on geometrical content knowledge. For the subsequent lessons, PSTs were required to engage with *FullProof* and teach their fellow classmates a 30-minute lesson using it. The mathematics teacher educators (MTEs) emphasized the domains of TPACK during their facilitation and supported PSTs in developing a conceptual understanding of the geometrical concepts, reflecting on effective pedagogical practices for helping the development of proof skills and familiarizing PSTs with varied features of *FullProof*.

The video recordings of the sessions ranged from 60 minutes to 90 minutes. They were transcribed for the analysis. The didactical discourse of the PSTs and the MTEs was analyzed using thematic analysis (Braun & Clarke, 2012), referring to the domains of the TPACK Framework, particularly referring to the focus on mathematics, pedagogy, and the role of technology. The roles of the two MTEs in facilitating learning and the nature of the didactical discourse among the PSTs and the MTEs were also examined. The data was subsequently organized by emergent themes.

Results

In the subsequent sections, we provide evidence supporting the outcomes of our analysis, which suggest that *FullProof* positively affected PSTs' TPACK knowledge regarding the teaching and learning of geometrical proofs. The MTEs played an essential role in supporting PSTs' development of TPACK knowledge and engaging in reflective practices. The MTEs modeled how to develop complete geometrical proofs and made explicit connections to the intersection of TPACK, where the tool created opportunities to reflect on pedagogical approaches such as questioning strategies. Productive struggles emerged as PSTs reflected on why their statements were incorrect and experimented to find solutions. The PSTs used *FullProof* to illustrate statements and reasons and make connections between steps. The immediate feedback provided by the *FullProof* system validated the accuracy of PSTs' progression in constructing proof and enhanced their comfort level. We organize this section to provide insight into how the domains of TPACK and intersections among them were attended to.

Technological Knowledge

Providing adequate training on *FullProof* and its features supports the likelihood that PSTs would actually use it within their practice. Thus, the first session focused on having PSTs become familiar with the tool features and elements. MTE2 noted that as PSTs explore the tool, they may notice a few instances of differences in notation since the tool was developed outside of the US. She said, "You will be able to... poke around and try it out... But you might see some things that are a little bit different

than the American notations." Nonetheless, the PSTs acknowledged the tool was generally user-friendly and helped clarify how to write proof. For instance, Alpha said: "I found it kind of simplified it for me, where I was like, oh yeah, I do remember this from high school. And it helped break certain ideas down back to me […] instead of having just definitions thrown at me, it kind of broke it down in a way of, oh, that's how I do this in a proof again!" (August 31, 2023). Similarly, Gamma indicated, "I felt like a good word to describe it [*FullProof*] is intuitive. I feel like it was pretty easy to follow along with how to use it. Um, and I think it gave good feedback and hints. […] Honestly, I wish that I had it when I was learning how to do proofs because I still struggle with proofs to this day. Because I didn't have stuff like this" (August 31, 2023).

The PSTs also shared strategies to utilize the tool with each other. For instance, the vignette below illustrates a PST sharing a shortcut in labeling angles with a peer.

Gamma: I don't know if this will help you with the type typing part, but instead of having to type out B, F, D, or whatever, you can also click on the angle if that makes it easier for you as the person typing.
Beta: I had no idea. Oh, my goodness. I love it. (October 26, 2023)

Thus, the PSTs were becoming proficient with the use of *FullProof,* such that they could help each other rather than rely solely on the MTEs for support.

Pedagogical Knowledge

As PSTs explored geometry proof, the MTEs pressed them to reflect on pedagogical considerations that can impact student learning outcomes. The importance of PCK in teaching proof was emphasized to ensure the proof task maintained cognitive rigor during enacted lessons. Throughout the lessons, MTE 1 frequently asked the PSTs to share how they knew learning occurred, saying: "What would be your evidence of [student] learning based on working through the problem? How did you know they learned anything?" (October 26, 2023). Beta responded by identifying mathematical objectives related to how interior angles and alternate interior angles can be used to structure the proof, which was among the goals for learning.

The PSTs also frequently reflected on practices that can promote reasoning and potentially address students' misconceptions. For instance, Gamma talked about how they "tend to encourage productive struggle […] try questions that probe for reasoning. […] because that's just an important part of making sure that the students are actually understanding" (September 14, 2023). The MTE1 further encouraged Gamma to engage in self-reflection on what students are "looking for" when trying to construct a proof. The PSTs' awareness of how to question and support productive struggle is critical to ensuring that students can actively engage in the proof process in a meaningful way. It also helps to ensure they can address misconceptions that may arise relative to a concept and to proving theorems. Therefore, to promote the development of pedagogical knowledge, PSTs were encouraged to reflect on their instructional decisions and the extent to which they would support learning.

The MTEs encouraged the PSTs to consider the implications of projecting their perspectives about proof onto their future students and think like teachers. MTE1 said: "Reflect on what knowledge you need to support your students. What knowledge will students need? And how do you bridge this

knowledge that you need to help your students make sense of it?" Similar sentiments were shared by Gamma, who noted, "... So I always like to start proofs with asking what do we know and what's our goal? So, we kind of have a sense of direction" (September 14, 2023).

During the lessons, consideration was also given to the learning experience. The following vignette illustrates a PST reflection on their experience. The PST indicated that their peer facilitation of the proof catalyzed productive struggle as they questioned whether the justification for the concluding statement in the proof was required.

MTE 1: Okay. Now, so you were the teacher [Beta]. Now I'm going to ask the question to the learner. …what was your learning experience that [Beta] was facilitating? Because we want to talk about the experience of the teacher, which may not necessarily be that of the learner. What was happening as [Beta] engaged in this space? What were your thoughts?

Gamma: Um, I thought that [Beta] was doing a good job at letting us have the productive struggle and giving us the space to try things when we weren't sure if uh, on the last line we had to put, reasoning. [Beta said,] Well, let's try it with and without [justification] and see if it's considered correct [by *FullProof*]. Because I personally struggle with the proper way to write certain proofs. So that is something … I don't know if that's correct, and I never really get to check both ways.

The PST response suggests that the support offered emphasized providing reasoning and multiple ways of writing the proof despite initially struggling with it.

Content Knowledge

The analysis revealed that PSTs' initial CK of proof was lacking. All three of them admitted that they had not encountered proofs extensively besides brief exposure in a geometry course in high school and at the university. The PSTs were uncomfortable with the idea that, as teachers, they would need to teach geometry proofs. For example, Beta said about the lesson plan they needed to write for the practicum: "I was scrolling through the standards […] I saw the proofs, and I [said], "I'm getting away from that. I do not want to touch that because just the idea of teaching it, and I mean, at least how I remember it in high school, is just so frustrating." The other two PSTs shared similar thoughts and feelings, saying things like "It has been a while since I've used geometric knowledge," that proofs are "scary," and "intimidating" (Alpha and Gamma, August 31, 2023).

As PSTs engaged with *FullProof* as students and then attempted to use it to teach each other various proof problems, they gained more competence in proving; consequently, their confidence in their ability to teach proof (with *FullProof*) increased. For example, Alpha appreciated that the tool allowed for multiple proving paths, saying that "forcing" teachers' way of thinking onto students will "make them [students] miserable." Instead, teachers can utilize *FullProof* to "build on their logic" (October 26, 20203).

The PSTs also sought to provide a rationale for how they constructed a proof with *FullProof*. For example, in the vignette below, Alpha explained how they constructed the proof in Figure 3.

Figure 3: Proof involving an angle bisector (Benny Goren, Geometry 1, page 241, Q.#06)

> … what I did for *FullProof*, the first thing I immediately went for was looking at the goal and breaking down what I needed to do with the goal. So, I knew I needed to find three different items to prove that these two triangles would be congruent. […] So, I looked into, […] try and use one of the various theorems, like Angle-Side-Angle and all that. Uh, the first thing I then went from there is to look into the givens. So I noticed that since we know that AC bisects the angle BAD […] I was able to go ahead and say that the angle ∡BAC is congruent to the angle ∡CAD, and ∡ACB, is congruent to the angle ∡ACD from being bisected. Uh, then from there, I looked at the triangle, and I noticed that since they share AC… So, it took me a bit to remember it was reflexivity as it says. But then, from there, I was able to get that since I knew I have two angles and a side, I could say the Angle-Side-Angle congruence theorem. I would say I definitely would want to define more stuff (Alpha, September 7, 2023)

This vignette shows the PSTs utilized theorems and definitions to justify the proof constructed related to congruent triangles and indicated PST's desire to provide additional information.

The Intersection of Various Domains of TPACK

The instructional dialogues often promoted the intersection of various TPACK knowledge domains. For instance, the overlap between technological and content knowledge became evident through didactical discourse in which the tool helped PSTs reflect on appropriate mathematical vocabulary and logical progression of proofs. *FullProof* helped PSTs remember definitions, visualize concepts, and probe for understanding. The following vignette illustrates the intersection of TK and CK. In the dialogue, the PST realized that *FullProo*f was not crediting the response of bisector, since the word should be perpendicular.

> Beta: ... I was just, I was just meaning that they were, that they were perpendicular and
> MTE 2: Perpendicular. Exactly. That's why the word bisector is not appropriate there. That's why the software is totally ... alerting.
> Beta: Okay, that makes a lot more sense. I don't know why I kept saying bisector. (September 7, 2023)

Thus, the tool supported the PST in using the correct terminology.

Discussion and Conclusion

Our study relates to the broader issue of how to prepare preservice teachers to teach proof, which has been consistently shown to be hard for teachers to understand and be able to teach. We focus on the

intersection of geometry and technology in this space. We also acknowledge the role of MTE in promoting PSTs' reflection on their didactical discourse and in supporting the development of PSTs' TPACK and proving competence. Our findings have implications for teacher preparation programs that support the development of PSTs' proof skills. Given that the PSTs acknowledged their fragile understanding of proving, the use of *FullProof* mediated the learning of geometrical content and writing proofs. The didactical discourse that the MTEs facilitated during the lessons supported PSTs in making sense of the content and encouraged them to apply their enhanced TPACK knowledge in their future classrooms. The immediate feedback offered in *FullProof* contributed to PSTs' confidence in writing proofs. This feature of the tool also contributed to rich discussions as to why the progression across proof steps was logical. It also emphasized the need to know appropriate theorems and definitions that can support claims made, thereby enriching PSTs' content knowledge. Finally, the vignettes shared illustrated questioning strategies MTEs could employ to have PSTs reflect on how to teach proof and support their future students in learning to prove. The co-teaching approach utilized by the MTEs provided opportunities for students to gain multiple insights and reflect on how they can emulate similar practices with their collaborative teacher during their clinical experiences.

In closing, this study provided insights into how MTEs within a practicum course intentionally sought to develop PSTs' proof skills. It illustrated that once PSTs become familiar with the features of *FullProof*, the tool could be used to mediate learning opportunities and support PST's development of TPACK, which is needed to support the teaching and learning of proof in geometry. The ability to adjust the level of difficulty of tasks posed could promote differentiated instruction. PSTs utilized *FullProof* to assess the accuracy of their proof and the justification for the reasoning provided. This helped the PSTs to conceptualize how to write a proof that progresses from a given to a concluding statement logically and on the suitability of mathematical definitions and theorems to be included in proofs about congruent triangles. Furthermore, the use of *FullProof* promoted scaffolding and students' engagement with geometry. Therefore, the study has implications for how technology can be used to enhance the teaching and learning of proof in geometry. Nevertheless, future studies are needed to examine further co-teaching efforts to support the development of teaching proof in teacher preparation programs.

Exploring how affect-related constructs predict students' proof construction competence in algebra and geometry

Gabriel J. Stylianides[1], Andreas J. Stylianides[2], Ling Zhang[3], Dimitrios Deslis[2] and Jisoo Seo[1]

[1]University of Oxford, UK; gabriel.stylianides@education.ox.ac.uk

[2]University of Cambridge, UK; [3] Chengdu University, China

Research suggests that proof construction, an important proof competence, is not an isolated cognitive construct but rather may relate with certain affect-related constructs including students' productive disposition beliefs towards proof construction. Yet there is a scarcity of research on how proof construction competence may relate with such beliefs. In this paper, we take a step towards addressing this research gap. Based on preliminary analysis of survey data from 226 secondary students in England, we report an empirically-based and theoretically-meaningful model depicting how certain student beliefs concerning proof construction (affect-related constructs) predict, in isomorphic ways in algebra and geometry, students' proof construction competence (cognitive construct). Implications for research/practice and limitations are discussed in light of these findings.

Keywords: Proof construction, affect, beliefs, cognition, secondary mathematics, algebra, geometry.

Introduction

Proof construction is challenging for students, attracting considerable research attention (for a review, see Stylianides et al., 2017). Some research showed a connection between proof construction and affect-related constructs such as the *value* students place on this activity (Weber et al., 2020). Yet the field still lacks an empirically-based and theoretically-meaningful model depicting possible relationships between students' cognitive and affect-related constructs in the area of proof construction. While existing research recognizes the intertwined nature of cognitive and affect-related constructs, understanding their relationship is crucial not only within specific mathematical topics/areas (Jacobson et al., 2018), such as proof construction, but also across content domains (e.g., algebra, geometry) that may influence variably proof-related behaviour (Dawkins & Karunakaran, 2016). We recognize the potential bidirectional relationship between affect-related and cognitive constructs. Due to space constraints, we limit our exploration in this paper to the following questions: *Do certain student beliefs concerning proof construction (affect-related constructs) predict students' proof construction competence (cognitive construct)? If so, what model describes these relationships, and how does this model vary (if at all) by the content domains of algebra and geometry?*

Prior research and theoretical framework

Several theoretical frameworks have addressed the relationship between cognitive and affect-related constructs for mathematics students and teachers. Some frameworks used "knowledge" broadly to encompass both cognitive and affect-related constructs including beliefs (e.g., Ponte & Chapman, 2008). Others viewed "knowledge" as a cognitive construct separate from beliefs, acknowledging its intertwined nature with beliefs (e.g., Jacobson et al., 2018). We align with the latter perspective, though we do not associate knowledge exclusively with an individual's cognitive domain, choosing instead the notion of *(proof construction) competence* as our focal cognitive construct.

Proof construction competence (cognitive construct)

General proof competence comprises several constituent competencies including proof construction, our focus herein, and others like proof evaluation and proof comprehension (Stylianides et al., 2017). By *proof construction* we mean the activity to develop a proof to a given or a self-generated statement. The outcome of this activity is an argument for the truth or falsity of the statement that a teacher or a researcher can judge against a specified standard of proof to measure the prover's competence in proof construction. Several hierarchical frameworks have been developed to categorize students' constructed arguments for *true* statements (e.g., Harel & Sowder, 2007; Stylianides & Stylianides, 2009); the categorizations range from non-proof arguments, including *empirical arguments*, to arguments qualifying as proofs. In contrast, there is a scarcity of frameworks to categorize students' constructed arguments for *false* statements (Stylianides et al., 2017), posing methodological challenges in achieving a holistic measurement of proof construction competence.

Productive disposition beliefs towards proof construction (affect-related constructs)

Among the various perspectives on beliefs, we follow Jacobson et al.'s (2018) notion of *productive disposition beliefs* defined as topic-specific affect-related constructs with empirical links to students' mathematics learning. Productive disposition encompasses malleable beliefs, attitudes, and emotions (Jacobson & Kilpatrick, 2015) that extend beyond cognition. Thus, we distinguish between cognitive and affective constructs concerning proof construction, while acknowledging they are interrelated, interdependent, dynamic, and malleable (Jacobson et al., 2018). The literature is broad in terms of the objects of belief, or the scope of the mathematical content about which an affective evaluation is made (Jacobson et al., 2018). Some studies address beliefs related to mathematics in a general sense, others focus on specific mathematical domains, or even narrower topics such as teachers' beliefs related to teaching the topic of multidigit addition and subtraction (Jacobson et al., 2018). The latter perspective suggests a relationship between cognitive and affect-related constructs that is dependent on the mathematical topic or domain. This perspective forms the basis for our research, which investigates task-based beliefs specific to proof construction in algebra and geometry.

Diversity in the literature on beliefs also concerns their role in an individual's behavior. Some view them as "predispositions to action" (Rokeach, 1968, cited in Leatham, 2006, p. 92) while others argue that they "must be inferred from what people say, intend, and do" (Pajares, 1992, p. 207). Our research departs from dichotomous perspectives and is based on the premise that beliefs are held with varying degrees of conviction that can be task- or topic- dependent (Jacobson et al., 2018). Furthermore, we posit that beliefs about proof construction can be self-reported and related to proof construction competence in a dialectical manner (Saleh et al., 2023). Productive disposition beliefs comprise multiple affective traits that influence mathematical competence in a particular task or topic (Jacobson & Kilpatrick, 2015), in our case, proof construction. In the framework of *productive disposition beliefs towards proof construction* that we use in our study, we consider five core beliefs.

The first two, *anxiety* and *value,* derive from Jacobson et al.'s (2018) framework and describe, respectively, how students feel when engaging in proof construction ("I feel nervous when I try to answer questions like this one") and how much they value it ("It is important for me to be able to answer questions like this one"). Anxiety and value are often overlooked in proof construction

research. Yet there is evidence that anxiety can negatively affect students' performance on geometric proof construction tasks (Shimizu, 2022), while the value an individual perceives in obtaining high levels of conviction can influence their proof construction competence (Weber et al., 2020).

The previous two, alongside the third belief, *self-concept of ability*, derive from Jacobson et al.'s (2018) framework; they are all based on the expectancy value theory (Eccles & Wigfield, 2002) and were connected to proof construction by Weber et al. (2020). Self-concept of ability is similar to, but distinct from, *self-efficacy beliefs*, our fourth focal belief, also deriving from Jacobson et al. (2018). A main distinction between self-concept of ability and self-efficacy beliefs is that the former embodies a past-oriented perception while the latter denotes a future-oriented conception of one's ability to construct a proof (Bong & Skaalvik, 2003). Particularly, self-concept of ability refers to how good one believes they are engaging in proof construction ("I am good at answering questions like this one"), while self-efficacy is associated with the amount and length of effort one might expend on a task ("If I try hard, I can figure out questions like this one"), indicating an individual's confidence in their ability to overcome factors that could make proof construction difficult.

The fifth productive disposition belief, *self-evaluation beliefs*, derives from our prior research (Stylianides & Stylianides, 2009) and concerns students' beliefs about whether their arguments meet the standard of proof ("I have proved that my answer is correct"). Specifically, we found these beliefs could distinguish individuals based on their awareness of the mathematical quality of their arguments, thereby exhibiting different levels of understanding of proof. *Self-evaluation beliefs* are likely related with *self-concept of ability* and *self-efficacy beliefs*: students' subjective evaluations of their proof constructions in specific tasks (self-evaluation beliefs) may be related with their perceptions about how good they think they are at responding to proof construction tasks (self-concept of ability) and their perceptions about the role of effort in responding to such tasks (self-efficacy beliefs).

Methods

The findings are part of our ongoing analysis of data we collected from a survey study with 226 Year 10 students (14–15-year-olds) in England. The students responded to one or both of the algebra and geometry versions of the Reasoning-and-Proving Instrument (Stylianides & Stylianides, 2022b). This is a newly developed instrument that addresses several important competencies in the area of reasoning-and-proving including proof construction. Its two versions, one in algebra and the other in geometry, were designed to be isomorphic. The instrument is literature-based and has passed three rounds of review and revision, including two rounds of expert validation each with three mathematics education experts in the area of proof, and a review regarding clarity of instructions and age appropriateness by four experienced teachers.

Student participants and procedure

The instrument was administered to the students by their teachers. The students were of variable mathematics achievement, as determined by school data. We asked the teachers, if possible, to administer both the algebra and geometry tests, specifying a different order of administration per half teachers. If administering both tests was not possible, teachers gave half of their students each test, alternating the tests between students sitting next to each other.

Data

Students responded to 3 or 6 proof construction tasks if they took one or both tests, respectively, enabling the measurement of their *proof construction competence*. Additionally, they responded to 5 Likert-scale questions, ranging from 1 ("Strongly disagree") to 7 ("Strongly agree"), after each task, addressing students' *productive disposition beliefs towards proof construction* using the statements we presented earlier. Each test included two tasks with statements with undisclosed truth values (one true and one false), and one task where students had to generate (through conjecturing) the statement to be proved. We discarded the data from participants who did not respond to any of the corresponding Likert-scale questions for a specific affect-related construct in the survey, across the six proof construction tasks. In total, data from 198 students were included in the analysis.

Coding

For *true* statements, a non-zero mark was assigned only when students recognized the statement as true or generated the expected statement themselves through conjecturing. The actual mark was based on Stylianides and Stylianides's (2009) 5-level categorization of arguments for true statements, ranging from 3 (non-genuine argument) to 7 (proof). For *false* statements, a non-zero mark was assigned only when students recognized the statement as false. The actual mark was based on a new 5-level categorization that we developed, ranging from 3 (non-genuine argument) to 7 (refutation by counterexample or a valid general argument). The first 40% of the responses to proof construction tasks were coded independently by the last two authors with an inter-rater agreement (Cohen's kappa) of 0.71 to 1.00 in the different categories of the coding scheme; disagreements were discussed and resolved. The researchers then each coded independently half of the remaining data. Instances where a second opinion was needed were coded also by others within the team; disagreements were resolved through discussion. *Anxiety responses to the Likert-scale questions were reverse-scored.*

Analysis

Confirmatory Factor Analyses (CFA) and Structural Equation Models (SEM) were conducted with Mplus 8.3 using the MLM estimator (maximum likelihood estimation with robust standard errors). The Full Information Maximum Likelihood (FIML) estimation was used to handle missing data (roughly 35.6%, missing at random [MAR] caused by participants taking only one of the tests as it was one of the options we gave to the teachers).

We carried out the data analysis in four steps. First, a particular construct (e.g., proof construction, anxiety) in algebra/geometry was defined by its mean score across the three tasks in algebra/geometry. Second, descriptive and correlational statistics among variables and covariates were conducted. Following observation of the strong associations among *self-concept of ability*, *self-efficacy beliefs*, and *self-evaluation*, we ran CFA with a one-factor, a two-factor, and a three-factor model to identify an acceptable measurement model. Finally, the structural model with possible paths was specified and evaluated, exploring whether/how students' affect-related constructs predicted students' *proof construction competence*, hereafter referred to as PCC.

Findings

Table 1 presents descriptive statistics and correlations among the observed variables. PCC in algebra was significantly associated with all the *affect-related constructs* in algebra (marked in orange) but not in geometry. Similarly, PCC in geometry was significantly associated with all the *affect-related constructs* in geometry except for anxiety (marked in purple) but not with all the *affect-related constructs* in algebra. This indicated that the paths of *affect-related constructs* predicting PCC may differ by the content domain. Also, *self-concept of ability*, *self-efficacy beliefs*, and *self-evaluation* were correlated (marked in red), some of which strongly. Regarding *value* (marked in blue), we found *value* in algebra was more strongly associated with *self-concept*, *self-efficacy,* and *self-evaluation* in algebra as compared to the same constructs in geometry. A similar pattern was observed in regard with *value* in geometry. *Anxiety* was associated with certain constructs; for instance, *anxiety* in algebra was significantly related with *self-concept* in algebra and *self-evaluation* in algebra, but significantly negatively associated with *value* regardless of the content domain (marked in green).

Notes: ***p<.001, **p<.01, *p<.05; [1]PCC: proof construction competence; SC: self-concept of ability; SEF: self-efficacy beliefs; SEV: self-evaluation beliefs; VAL: value; ANX: anxiety. [2]Subscripts: a (algebra) and g (geometry).

Considering the strong associations among *self-concept of ability*, *self-efficacy beliefs*, and *self-evaluation,* we used CFA to examine if these three facets of self-related constructs could be empirically explained/encapsulated as a singular, dual, or triple entities in PCC in algebra/geometry by testing a one-factor (M1), a two-factor (M2), and a three-factor model (M3) (see Table 2). The results of the three models indicated that M2 provided the best fit, suggesting that there were differences in students' *self-perceptions* about PCC across content domains (algebra and geometry).

Once an acceptable *self-perceptions* measurement model was established, we moved onto the structural part of SEM, where the *affect-related constructs* were specified and examined in predicting PCC (Table 2). Based on M2, the *self-perceptions* model predicting PCC in algebra and geometry (M4) was first specified with a good fit (*Chi-square/df* =1.676 < 3, *CFI*=0.977 > 0.95, *TLI*=0.965 > 0.95, *RMSEA*=0.058 < 0.06). This indicated that *self-perceptions*, predicted by *self-concept of ability*, *self-efficacy beliefs* and *self-evaluation*, empirically and positively predicted *proof construction*, in both algebra and geometry. Then, in M5 and M6, we successively added the constructs of *value* and *anxiety*, which served as the exogenous variables predicting *self-perception*, which, in turn, predicted PCC in algebra and geometry. We accepted M6 as the final (at this point of our ongoing analysis) structural model shown in Figure 1. Most of the model fit indices in M5 and M6 were good (Table 2). In the final structural model M6, the path in algebra showed that *value* and *anxiety* positively predicted *self-perception* ($\beta = .419, p < .001$; $\beta = .439, p < .001$, respectively), which was loaded by *self-concept of ability*, *self-efficacy beliefs*, and *self-evaluation*, and in turn positively predicted PCC ($\beta = .449, p < .001$). *Value* in algebra negatively predicted *anxiety* ($\beta = -.283, p < .001$). The path in algebra was the same as the path in geometry. Also, we found that each construct in algebra was significantly associated with the respective construct in geometry (e.g., $r_{\text{value}} = .748, p < .001; r_{\text{anxiety}} = .674, p < .001; r_{\text{self-perception}} = .569, p < .001; r_{\text{proof-construction}} = .667, p < .001$).

Table 2: Model fit statistics for the CFA and SEM models

Model	Description	χ^2	df	χ^2/df	CFI	TLI	$RMSEA$
CFA							
One-factor (M1)	SCa+SCg+SEFa+SEFg+SEVa+SEVg	101.2	9	11.2	0.805	0.674	0.227
Two-factor (M2)	SCa+SEFa+SEVa, SCg+SEFg+SEVg	21.979	8	2.747	0.970	0.944	0.094
Three-factor (M3)	SCa+SCg, SEFa+SEFg, SEVa+SEVg	70.171	6	11.695	0.864	0.660	0.232

M5	M4, +VAL	88.201	32	2.756	0.907	0.872	0.094
M6	M5, +ANX	108.197	48	2.254	0.914	0.884	0.080

Note: Acceptable model fit:1< χ^2/df<3, CFI>0.9, TLI>0.9, RMSEA<0.1.

Discussion

The roles of content domain and affect-related constructs in students' proof-related behavior have been proposed in prior research (Dawkins & Karunakaran, 2016; Weber et al., 2020) but were not systematically explored. Our preliminary analysis of survey data we collected from secondary students in England yielded an empirically-based and theoretically-meaningful model depicting how certain student beliefs about proof construction (affect-related constructs) predict, in isomorphic ways in algebra and geometry, the student participants' PCC (cognitive construct). Specifically, PCC is positively predicted by students' self-perception (a new construct loaded by students' self-concept of ability, self-efficacy beliefs, and self-evaluation beliefs), which is positively predicted by students' value and anxiety. Since the identified model did not differ by content domain, similar implications apply to algebra and geometry for the student participants in our study.

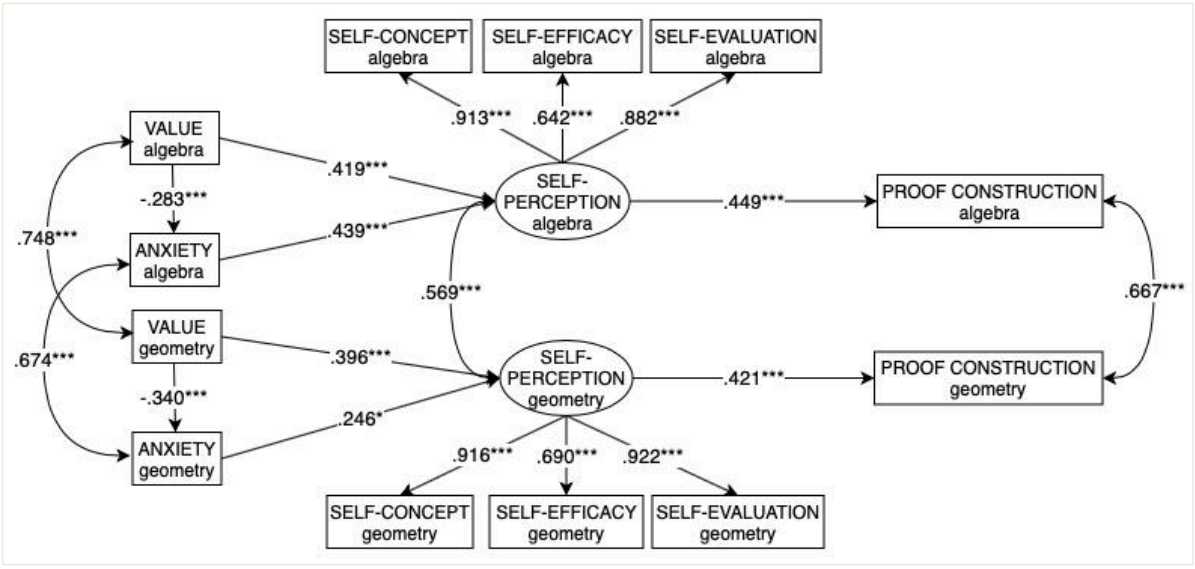

Figure 1: The final (at this point of our ongoing analysis) structural model (M6)

A limitation of our study is that we did not examine the students' prior knowledge and experiences in algebra and geometry. This information is crucial for interpreting our findings, as variations (or the absence thereof) across content domains could be influenced by students' variable experiences with these domains, not only during the year the study was conducted but also throughout their earlier education. Another limitation is that the study included students from a single cultural context, making it uncertain whether the specific model we identified would be applicable in other countries or even in schools located in different regions within England.

The above suggest important directions for future research to more systematically explore the role of the following factors in students' PCC: students' backgrounds in different domains (algebra, geometry, and beyond) and the broader cultural context. In our ongoing research, we are exploring another direction for which we have the required data: whether the relationship between affect-related and cognitive constructs is bidirectional. Irrespectively of this, our identified model supports the argument that instruction in the area of proof construction should consider not only students' cognition (as is typically the case) but also their affective worlds. For example, instruction can help students recognize the value of proof construction by fostering in them an *intellectual need* to learn about proof in general or proof construction in particular (Stylianides & Stylianides, 2022a).

Reasoning and proving opportunities related to Thales' theorem in selected lower secondary textbooks from four different regions

Kinga Szűcs[1] and Mária Slavíčková[2]

[1]University of Erfurt, Faculty of Education, Erfurt, Germany; kinga.szuecs@uni-erfurt.de

[2]Comenius University in Bratislava, Slovakia

In light of the central role proofs should play in mathematics classrooms, this study examines how Thales' theorem, as one of the main theorems in lower secondary geometry, and its proofs are presented in the narratives of textbooks from the Czech Republic, Hungary, Slovakia, and Thuringia. We also analyse the volume and quality of tasks requiring reasoning and proving (R&P) in those textbooks, whose class level differs from 7 to 9 due to varying regional curricula. Our study highlights the diversity of teaching R&P in distinct educational administrations that were once very similar.

Keywords: Proof, secondary school mathematics, textbook research, geometry, Thales' theorem.

Introduction

Because proofs are a central concern within mathematics (Hanna & Barbeau, 2008), mathematics-education researchers and educators agree that reasoning and proof (R&P) should play a significant role in mathematics classrooms (Stylianides, 2009; 2014). However, the implementation of R&P in mathematical classrooms can be challenging (Buchbinder & McCrone, 2022) and the contexts in which proof and proving are taught worldwide differ greatly in terms of curriculum requirements, student age levels, teacher expertise, and other factors (Jones & Herbst, 2012).

In mathematics classrooms, not only do textbooks have an important function as being mediators between the educator and the students, but they also play a key role during classroom activities (Fan et al., 2013) and are crucial in offering students opportunities to engage in R&P (Stylianides, 2009). Therefore, to provide adequate and consistent learning opportunities in mathematics education with regard to R&P, it is of extraordinary importance to investigate how R&P are implemented in existing mathematics textbooks (Stylianides, 2014). In the next section, a short summary of the broad-spectrum national and cross-national textbook research related to the treatment of R&P will be given.

Before the political changes in 1989, the political, educational, social, and economic structures, and efforts for uniformity were paramount for more than four decades in Czechoslovakia (now, the Czech Republic and Slovakia), Hungary and in the German Democratic Republic (now, the new German states: States of Thuringia, of Saxonia, of Saxony-Anhalt, of Brandenburg and of Mecklenburg Western Pomerania). Since 1989, countries have adopted democratic tendencies in all aspects of social life and today they determine their own educational systems independently. Since today in Germany, all states have an individual educational system, tendencies in countries such as Czech Republic, Slovakia or Hungary are comparable with German results on the state level. Thus, in our study, we focus on selected textbooks from those countries as well as from one of the new German states (Thuringia) and aim to detect the opportunities to enhance R&P. Note that differences related to limited mathematical topics have already been discovered between Slovakia and the Czech Republic (Novotná & Slavíčková, 2023) as well as between Thuringia and Hungary (Szűcs, 2023).

Theoretical framework

Reasoning and proving in mathematics textbooks

Research on textbooks with a focus on R&P opportunities for students has become more comprehensive in the last few decades (Fan et al., 2013; Wong & Sutherland, 2018). However, the studies show a wide variety not only in terms of the applied frameworks, but also about the school level and mathematical topic under investigation. Hence, the results depict a high level of diversity.

As an illustration, researchers point often out that the treatment of R&P in textbooks can differ from country to country and from region to region. To give an example, Hoyles et al. (2003) showed that all students in Japan are expected to construct challenging proofs for a wide range of statements related to 2D- and 3D-diagrams. In contrast, in Baden-Württemberg (one of the 16 German federal states) only students in grammar school are expected to face proofs. Further, the focus in Baden-Württemberg's textbooks is mainly on proofs related to the Pythagorean theorem and proofs are treated very much top-down in the textbooks under investigation. Meanwhile, the study by Hoyles et al. (2003) also revealed that in French textbooks students are strongly guided to construct a formal, deductive proof and the focus is on straightforward applications of well-specified knowledge.

According to Wong and Sutherland (2018), a strong variation in the ratio of R&P tasks to all tasks in the textbooks can be detected from study to study. In their review chapters, the authors point out that R&P opportunities in different textbooks vary considerably from 3.7% to 77%. These findings are in line with some recent results: Hong and Choi (2018) compared geometry lessons in secondary school textbooks and found that R&P tasks are more dominant in American textbooks (40%) than in Korean textbooks (20%), for instance. Similarly, Szűcs (2023) examined 23 upper-secondary textbooks from three different German federal states and Hungary related to the law of sines. Her findings suggest that the proportion of R&P opportunities vary between 0% and 87%.

With respect to analytic frameworks, one of the most prevalent schemes is that of Thompson et al. (2012), which not just offers a way of categorising the tasks in textbooks on a conceptualised level but also incorporates the investigation of the proof provided in the narrative part of those textbooks. Their framework encompasses four categories for inspecting the narrative as follows: general justification (GJ), specific justification (SJ), left to the student (LT) and no justification (NJ), as well as seven types of exercises for categorising the tasks: make a conjecture (1), investigate a conjecture (2), develop an argument (3), evaluate an argument (4), counterexample (5), correct or identify a mistake (6) and principles of proof (7). Thompson et al. (2012) developed and implemented their framework to analysing tasks in algebra. Szűcs (2023) adopted this framework to examine tasks in trigonometry and added a new category: (8) investigate a premise. Likewise, besides some other modifications, Otten et al. (2014) extended the framework of Thompson et al. (2012) by coding the statements stated in the narratives using the categories general (g) and particular (p).

Moreover, because geometry traditionally offers numerous opportunities to R&P (Otten et al., 2014), when investigating textbooks, geometry is one of the most preferred mathematical areas. To give an example, Stylianides (2009) examined grades 6-8 secondary school textbooks and found that most of the tasks offering R&P opportunities require either a non-proof argument (60 %) or a proof (19 %).

Consistent with those results, Otten et al. (2014) investigated six geometry textbooks series and detected that about 13 %–25 % of the R&P tasks involve the construction of a proof while about 36 %–54 % of the R&P tasks require to develop a rationale but not necessarily a proof. They also included the study of the textbook narratives and found that general statements are dominant in the narratives, whereas particular statements are prevalent in exercises. Using the same analytical framework, Hong and Choi (2018) compared geometry lessons in five secondary textbooks from the United States and Korea. Similar to the results of Otten et al. (2014), Hong and Choi's (2018) findings suggest that general statements are more common than particular assertions in both American and Korean textbooks. On the other hand, students in the United States have more opportunities for constructing a proof (29 % *of all R&P tasks*) than in Korea (0 % *of the tasks engage in R&P*), while Korean learners are more frequently asked to evaluate an argument (60 %) than American students (45 %). In our paper, we aim to contribute to this research by providing new insights into how textbooks from four regions offer students R&P activities and different types of proofs in geometry.

Thales' theorem (angle inscribed in a semicircle theorem)

According to Alsina and Nelsen (2011), there are two different theorems in geometry called Thales' theorem, one of them states that the angle inscribed in a semicircle is a right angle if its vertex lies on the circumference. In lower secondary geometry classrooms, this theorem is one of the most important theorems students have to face: It not only allows learners to construct tangent lines to circles (French, 2008) and other geometrical objects (Posamentier et al., 2009), it also offers them a far-ranging tool to solve a wide variety of geometrical problems and to prove theorems in elementary geometry. Therefore, in this paper we focus on this theorem, and we will refer to it as Thales' theorem.

Thales' theorem can be proved in different ways: It can be derived as a special case from the inscribed angle theorem (proof A), which states that the angle subtended at the circumference of a circle by an arc is half the angle at the centre subtended by the same arc (French, 2008; Jacobs, 1992). Moreover, a widespread approach (proof B) resorts to the strategy of bisecting the triangle inscribed in a semicircle into two isosceles triangles and makes usage of the interior angle sum theorem in triangles. This approach is found in The Elements of Euclid (book 3, proposition 31) and was adopted by Alsina and Nelsen (2011), French (2008) and Wellstein and Kirsche (2009), for instance. Another approach (proof C) was taken by Gonzalez-Velasco (2001), who, by using point reflection, complemented the triangle in question to a rectangle and concluded that the triangle has a right angle.

It is noteworthy that the converse of Thales' theorem also holds: The hypothenuse of a right-angled triangle is one of the diameters of its circumcircle. As with Thales' theorem, there is a variety of proofs for its converse, too. To illustrate, Wellstein and Kirsche (2009) took an approach which was converse to proof B and proved the converse of Thales' theorem by using isosceles triangles (proof D). They also provided a proof (proof E) by contradiction. Additionally, another approach which is converse to proof C uses the strategy of point reflection, this (proof F) was taken by Alsina and Nelsen (2011).

Research Questions

Because of the prominent role proofs play in mathematics, they should take an essential part in mathematics classrooms, too (e. g. Stylianides, 2009; 2014). Therefore, we aim to investigate the

implementation of R&P in lower secondary mathematics education in the four above-mentioned educational administrations since we are familiar with their curricula, frameworks, teachers, and textbooks. To comprehend the underlying reasons and motivation for learning activities related to proofs, in this paper, similar to that by Szűcs (2023), we will use the term "proof-related-reasoning" in the sense of the work by Thompson et al. (2012) and we take this to mean a wide range of learning opportunities (GJ), (SJ), (LT) and (1)-(8) by that. The following questions led to the study presented in this paper: (RQ1) How does the treatment of proof related to Thales' theorem differ in the textbooks across the four distinct educational administrations? (RQ2) How does the volume and the quality of R&P opportunities for learners vary across those textbooks?

Methods

The sample of our analysis presented in this paper contains three currently accredited and widely used textbooks that entail the topic of Thales' theorem from each of the following four educational administrations: the Czech Republic, Hungary, Slovakia, or Thuringia. Note that, due to curricular differences, the class level varies from 7 to 9 across the 12 textbooks under investigation (the full list of the textbooks in the sample can be downloaded from here: https://www.uni-erfurt.de/fileadmin/fakultaet/erziehungswissenschaftliche/Mathematikdidaktik/Szuecs_Kinga_list_of_analysed_textbooks.pdf. In the following, the textbooks are labelled by CZ1-CZ3, HU1-HU3, SK1-SK3 and by TH1-TH3.

In accordance with Otten et al. (2014), in each lesson that included Thales' theorem, the statement of the theorem as well as of its converse was coded by using the categories (g) and (p). In addition, consistent with Thompson et al. (2012), the proof of Thales' theorem as well as of its converse was categorised by using the codes (GJ), (SJ), (LT) and (NJ). The type of the proof provided in the textbook for both Thales' theorem (proof A-C) and for its converse (proof D-F) was also registered. Further, following Sevinç et al. (2022), and Novotná and Slavíčková (2023), for coding the proving activities addressed to students in the textbooks' narratives, the categories pupils make a conjecture (mc), perform (pe), follow instructions (fi) and use previous knowledge (pk) have been used. In the same way, based on Thompson et al. (2012) and Szűcs (2023), all the tasks in the lesson except review exercises, were investigated according to the categories (1)-(8). To do so, the exercises requiring proof-related reasoning were tagged as R&P-tasks and mapped to exactly one of those categories. Excerpts from the coding manual can be found in Table 1. Further, the number of all tasks was determined and the ratio of R&P-tasks to all tasks was calculated.

Results

Treatment of Thales' theorem and its proof in the textbook narratives (RQ1)

Our analysis of the textbooks revealed several key findings about the teaching of Thales' theorem and its converse. For example, both the theorem and its converse were consistently generally (g) stated across all textbooks. However, while general justification (GJ) of Thales' theorem can be found in all the textbooks under investigation, the justification of its converse varies strongly across the textbooks even within one educational administration. Therefore, no main tendency related to the justification of the converse could have been identified in those regions. Similarly, while the textbook narratives

consistently provide proof B except CZ1, which uses point reflection (proof C) for proving Thales' theorem, when it came to proving the converse, there was a diversity of approaches depending on the region. In textbooks from the Czech Republic as well es from Thuringia only proof E was found, whereas proof D and proof F are present in Hungarian textbooks. Moreover, in none of the textbooks from Slovakia was a proof for the converse of Thales' theorem given.

Table 1: excerpts from the coding manual

Cat.	Definition	standard example
(1)	Learner is asked to generate a conjecture either in general (e. g. about an arbitrary triangle) or of a specific case (e. g. about a specific triangle).	Draw the points A(-2|1) and B(4|1) in the coordinate-system. Where do all the points P lie for which the lines AP and AB are perpendicular? (TH3, p. 101, exercise 2)
(2)	A conjecture or assertion is stated. Learner is asked to determine if it is true or false and provide a rationale. The question does not necessarily use the word conjecture.	Three different points A, B, C lie on the circle k(S, r) such that the center of the circle lies on the segment AB. Mark the false statements: a) Segment AB is the diameter of the circle. b) Angle ABC is right. c) Triangle ABC is isosceles. d) Segment SC is half of segment AB. (SK3, p. 33, exercise 9)
(3)	Learner is asked to provide a proof of a statement, either about a general or a specific geometrical object.	Draw in a circle two different diameters AC and BD. Reason that the points A, B, C and D are vertices of a rectangle. (TH1, p. 126, exercise 16a)
(4)	Learner is asked to determine whether an argument that is stated is valid or not.	Construct the tangent lines to the circle $k(S, r = 2.5\ cm)$ passing through the point R if $\|RS\| = 8\ cm$. Vendulka thought like this: "Given: $k(S, r)$ and R. Tangent $t \perp ST$, ΔSTR is right-angled, and SR is its hypothenuse." Is her thinking correct? (CZ3, p. 54, exercise 4)
(6)	A faulty solution to a problem or an invalid argument in stated. The learner is told there is a mistake and asked to determine the error in the reasoning or to correct it.	Pepa has drawn tangent lines from point Q to circle k, T_1 and T_2 are the points of tangency. The figure did not go too well for him. Draw your own figure and decide whether the line segment T_1T_2 passes through the midpoint of the line segment SQ. (CZ1, p. 25, exercise 10c)
(8)	Learner is asked to identify impacts if premises are changed or, in order to reach a specific impact, to find necessary premises.	The hypothenuse and the height perpendicular to the hypothenuse are given. Construct the triangle. Investigate the conditions of the solvability. (HU3, p. 156, exercise 6)

Additionally, notable differences in the explicitness of the expected student activities were detected. While most textbooks clearly outline those activities, TH3 has only implicit instructions, and all Hungarian textbooks lack proving activities in the narrative entirely. The expected student activities also vary across regions: Textbooks from the Czech Republic focus on (pe) targeting proving statements, while textbooks from Slovakia and Thuringia emphasise (mc). Particularly in Slovakian textbooks, we observed guiding activities (fi) that refresh previous knowledge (pk) and encourage students to use this knowledge by evaluating their conjecture related to Thales' theorem.

Volume and quality of R&P-opportunities in the textbooks' exercises (RQ2)

In our study, the ratio of R&P tasks to all activities in the textbooks varies from 19.61 % (TH1) to 100 % (HU1) (Table 2). The observed strong variation of the data is in line with the results of Wong and Sutherland (2018) and the findings of Szűcs (2023). However, the average ratio of R&P tasks in the regions under investigation (Table 2) offers a picture similar to the results of Hong and Choi (2018): Thuringian students have, on average, approximately 30 % less R&P opportunities than learners in the three other places under investigation (ca. 59 % - 70 %).

Table 2: Ratio and average ratio (in %) of R&P tasks in the textbooks under investigation

CZ1	CZ2	CZ3	HU1	HU2	HU3	SK1	SK2	SK3	TH1	TH2	TH3
61.2	54.55	61.54	100	46.67	29.41	57.89	81.82	70.00	19.61	51.28	28.57
59.10			58.69			69.90			33.15		

Our data suggest that most R&P tasks in all the analysed textbooks require either making (1) or investigating a conjecture (2) or developing an argument (3) (Figure 1). Note that the ratio of tasks involving the development of an argument (3) to all R&P tasks is primarily in Czech Republic (55 %) and in Slovakia (65 %) comparable with the results of Otten et al. (2014) and of Stylianides (2009).

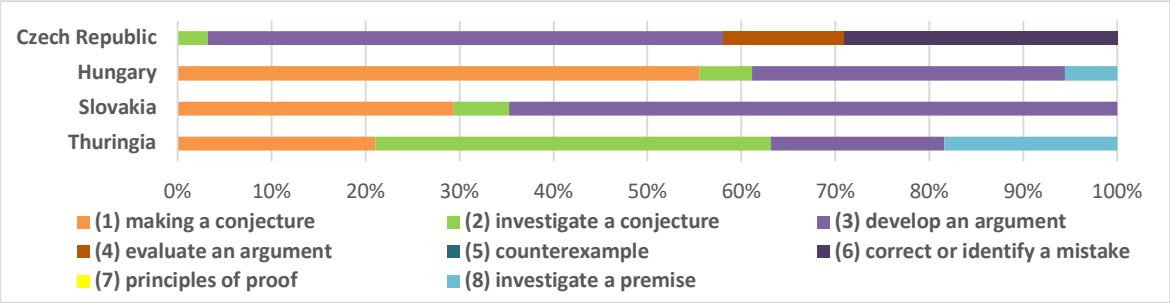

Figure 1: Identified expected students' activities in the textbooks under investigation

Interestingly, we found that tasks instructing students to investigate a premise (8) were present only in Hungarian and Thuringian textbooks, while tasks which involve evaluating an argument (4) or identifying/correcting a mistake (6) appeared exclusively in textbooks from the Czech Republic (Figure 1). Compared with the results of Hong and Choi (2018), the ratio of tasks instructing students to evaluate an argument (4) to all R&P tasks is low (13 %). Further, we did not find any R&P task which requires giving a counterexample (5) or applying the principles of a proof (7).

Conclusions

We found that there is a uniformity in stating Thales' theorem and its converse as well as in proving Thales' theorem across all analysed textbooks. However, students' opportunities to improve their R&P skills vary from region to region. Although students in Hungary have no opportunity for proof-related reasoning in the textbooks' narratives, which is similar to the top-down treatment of proofs in Baden-Württemberg (Hoyles et al., 2003), a high ratio of exercises offers learners R&P activities. In contrast, learners' R&P opportunities in Thuringia are limited in terms of both the volume and the quality of the tasks. Further, as in French textbooks (Hoyles at al., 2003), the emphasis on guiding activities towards the evaluation of conjectures in Slovakian textbooks enables students to create deductive proofs. The facts, that activities in the narratives of Czech textbooks require proving statements and a high ratio of R&P tasks asks students to develop an argument suggest that they are, similarly to Japanese learners (Hoyles et al., 2003) expected to construct challenging proofs. Thus, we conclude, that related to students' engagement with mathematical proofs, varying educational philosophies and underlying teaching strategies currently exist in the four examined educational administrations.

Collaborative problem solving to foster higher-order thinking skills in mathematics: A systematic literature review[1]

Haydeé Ceballos[1,2], Theo van den Bogaart[2], Jeroen Spandaw[3], Stan van Ginkel[2] and Paul Drijvers[1]

[1]Freudenthal Institute, Utrecht University, The Netherlands; m.h.ceballos@uu.nl

Keywords: Collaborative problem solving, higher-order thinking skills, systematic literature review.

Introduction

Collaborative problem solving in mathematics lessons may promote higher-order thinking skills (HOTS). However, clear design guidelines for these activities are lacking (Han et al., 2021). Through a systematic literature review, we aimed to identify optimal features for peer group mathematical problem solving such as task selection, ideal group size, and effective group work procedures that can effectively foster HOTS. The research question is: What are the key design features of CPS tasks that promote HOTS and how do communication challenges impact their effectiveness?

Theoretical framework

HOTS in mathematics involve reasoning, mathematical thinking, and metacognition (Makmuri et al., 2021). We use the following definitions in our review: (a) *reasoning*: the process of drawing conclusions in order to achieve goals, thus in forming problem-solving and decision-making behaviour (Leighton & Sternberg, 2004), (b) *mathematical thinking*: a complex blend of thinking processes that involve creating strategies for solving problems, recognizing patterns, making conjectures, and forming and validating arguments and proofs (Stacey, 2006), (c) *metacognition*: the ability to monitor and control one's own thoughts, approach to the problem, choice of strategies to find a solution, or self-questioning about the problem; hence, it can be defined as thinking about thinking (Goos, 2002).

Methods

A systematic review using a language-based machine learning technique (van de Schoot et al., 2021) identified 45 empirical studies on collaborative mathematics problem solving. One reviewer screened the articles, so no consistency measure was calculated, but the iterative approach ensured consistent prioritization. The PRISMA-guided search focused on HOTS, CPS, and mathematics in secondary and tertiary education. The selected articles were analysed using Sandoval's model (2014).

Results and conclusion

In the empirical studies discussed in the reviewed articles, the authors formulated specific conjectures, which, when incorporated into the design, were expected to trigger mediating processes that would lead to the desired outcomes. Our review identified a variety of tools, task structures, and

[1] Link to the poster: https://ap.lc/DGzgm.

participant configurations that are frequently associated with the promotion of HOTS during CPS in mathematics education. Commonly used settings included small group work and educational contexts at the secondary and tertiary levels. The most frequently addressed mathematical subjects were geometry and algebra. Regarding task characteristics, exploratory and inquiry-based learning using technology, along with open-ended problems, emerged as particularly prominent approaches. Additionally, several communication challenges that often impede the development of higher-order thinking are identified. In conclusion, this research underscores the importance of high-quality communication for successful CPS and the development of HOTS. By establishing classroom norms that encourage meaningful discussions (Littleton & Mercer, 2013), teachers can foster "sociomathematical norms" (Yackel & Cobb, 1996), thus creating a learning environment where dialogue drives growth and supports all students.

Is it possible to assess the impact of proof assistants on undergraduate students' proofs? Preliminary results

Clara Sisco[1] and Cécile Ouvrier-Buffet[2]

[1]Laboratoire de Didactique André Revuz, Paris Cité University, France; clara.sisco@etu.u-paris.fr

Keywords: Proof, undergraduate students, theorem prover, proof assistant, test.

Introduction

My PhD, started in February 2024, proposes to investigate students' conceptions and difficulties with proof at the secondary-tertiary transition and the potential impact of theorem provers in mathematics classes. This work is part of a larger national project APPAM (Les assistants de preuve pour les apprentissages mathématiques) about "proof assistants for mathematics learning" (14 researchers in didactics, mathematics, and computer sciences from 9 French universities). The need to develop new ways of teaching proofs that consider "theorem provers" has been demonstrated since 2020 (e.g., Hanna & Knipping, 2020). Originally, a theorem prover is a tool used by mathematics researchers designed for the verification of mathematical proofs. In recent years, interactive theorem provers have been developed with different interfaces but with no systematic didactic analysis of the impacts on students' proofs. They are called proof assistants (PAs). In a PA, a set of definitions, lemmas, theorems, etc. is provided, and the aim is to progress through the proof step by step. A PA checks the correctness at each step. The examples of PAs being used with undergraduate students remain rare and isolated but promising (e.g., Kerjean et al., 2022). In particular, there is no large-scale study of the impact of PAs on students' mathematical learning about proof. In this context, this poster presents preliminary results from a quantitative pilot study that addressed the following research question: How can the potential impact of using PAs on undergraduate students' proofs be assessed?

Methods

In February 2024, 135 freshmen from the University of Strasbourg, majoring in mathematics and computer science, completed a pre-test. During the following months, the students attended ten hours of class dedicated to the use of a PA, with this constraint: half of the students followed the course on Verbose L∃∀n (writing code interface developed by P. Massot), while the other half followed the course on D∃∀DUCTION (point-and-click interface developed by F. Le Roux). Finally, 47 of them passed a post-test in June 2024. Unfortunately, among them, a large majority followed the course with Verbose L∃∀n. This imbalance in our data does not allow us to make a comparison of the effects of one PA compared to the other. The pre- and post-tests consisted of three parts, this poster is about the first one. The students did not have access to computers, they were asked to write a "simple" proof (not treated in classes) with accessible concepts similar to existing large-scale studies (Stylianou et al., 2015): the sum of two odd numbers is even (pre-test) and the product of two odd numbers is odd (post-test).

Results and concluding remarks

Our analysis grid of the data starts from the typology proposed by Balacheff (1987) and then develops a detailed description of the objects introduced, the words or symbols that accompany them, the mathematical knowledge that is mobilised and the arguments and conclusions that are made explicit by the students. Toulmin's model, reinvested by Pedemonte (2002), was used for this last part, as well as other criteria and frameworks coming from the literature in education about proof that will be presented in the poster. Qualitative and quantitative analysis with excerpts emphasize students' proving practices and obstacles. In particular, we point out a local phenomenon in the post-tests: the expression of arguments that allow conclusions becomes less frequent. Besides, the formalism in students' productions evolves. Nevertheless, it remains difficult to affirm that PAs have an impact on the students' understanding of the mathematical concepts involved: some students still formalise the sum of two odd integers using the sum of one odd integer with itself. Then, this pilot study gives not only first results on students' proofs, but also an operational grid to analyse students' proofs before and after PAs sessions with pre- and post-tests. It also underscores the strong need of interviews before and after classroom sessions using PAs (designed with the didactical engineering framework) in order to study the evolution of students' proving processes.

Introduction

WG02 is dedicated to research on the presentation and discussion of recent developments in the teaching and learning of arithmetic, numbers and their operations. At CERME14, we retained themes established in previous CERMEs, while also expanding the scope by introducing new topics. Thus, we included, among others, aspects such as conceptual understanding and procedural skills, number and structure sense, problem solving and problem posing, innovative teaching and learning approaches in arithmetic, and the potential use of digital tools.

Our group received 34 submissions — 30 research papers and 4 posters. Of these, 22 papers and 2 posters were accepted for presentation. These contributions were thoroughly discussed both in plenary sessions and in smaller breakout groups. Ultimately, 21 papers and 1 poster will be included in the conference proceedings. The group's work was structured around both whole-group and small-group discussions, and the sessions were organized according to five key themes that emerged from the submitted contributions: (i) *Rational and real numbers* (4 papers), (ii) *problem solving and posing* (4 papers, 1 poster), (iii) *numbers and their operations* (4 papers), (iv) *place value and representations* (3 papers), and (v) *difficulties and understanding in learning arithmetic* (5 papers).

Theme 1: Rational and real numbers

While rational numbers remain a central theme for this group, only a few papers on the topic were submitted to this CERME. *Jérome Proulx* focused on the conceptualization of percentage with the aim of refining its understanding through both theoretical reflections and empirical findings. He reviewed various conceptualizations discussed in the literature which he synthesized into a conceptual frame. This frame was then applied in a case study to investigate students' understanding of percentage highlighting three perspectives on percentage. *Diana Herreros-Torres, Maria T. Sanz, Carlos Gómez-Ferragud, Hélia Oliveira* and *Renata Carvalho* working with Grade 4 students found that the concept of 'fraction as operator' remains a considerable challenge for students. The students engaged with mathematical problems across two contexts —continuous and discrete— and through arithmetic and graphical approaches. The findings suggest the importance of integrating multiple representations to improve students' understanding. *Maria T. Sanz, Carlos Valenzuela García, Sofia*

Peregrina, Emilia López-Iñesta, Francisco Grimaldo, and *Daniel Garcia-Costa* presented an exploratory study focusing on ratios and percentages aiming to evaluate students' performance using software that implements the tree graphs method. The results indicate that tree graphs facilitated students' understanding and improved their performance, particularly in problems involving ratios. The last paper in this group concerns real numbers. *Virginia Garrido-Adame, Olimpia Figueras* and *Minerva Martínez-Ortega* presented a design-based research project focused on developing number sense in the context of real numbers. Using a framework that outlines abilities related to number sense in real numbers, they designed the 'Broken Key' activity and implemented it with twelve students aged 15 to 18. The authors were interested in exploring which number sense abilities students employed while working on the 'Broken Key' tasks. Their findings suggest that the activity effectively activated specific number sense abilities.

Theme 2: Problem solving and problem posing

This is a relatively new theme within the group, which has seen a growing number of submissions over the last two CERMEs. *Mónica Arnal-Palacián* and *Nuria Begué* explored the criteria preservice teachers use to evaluate a 6th-grade student's incorrect solutions to two additive tasks and the levels at which they justify their assessments. Their decision-making criteria fell into three categories: the problem's semantic structure, the use of materials, and the use of diagrams. Overall, the level of their responses was below the required level. *Eszter Kónya* emphasized the need to shift attention from numerical solutions to examining the methods and procedures used during problem solving. She highlighted the significance of identifying and using the arithmetic structures embedded in word problems to solve them. Working with upper primary students she found that certain tasks can effectively be used as a starting point for working with arithmetic structures particularly when the task solution is followed by whole classroom discussion. *Karolína Mottlová* investigated how 5th-grade students approach atypical word problems known as "Fidgets," which are distinctive in that they lack an explicit question. The study revealed that students most frequently employed a Guess-Check-Revise strategy, drawing on mathematical, contextual, and linguistic cues to formulate, test, and adjust their guesses —either systematically or at random. In their poster presentation, *Waqas Bin Sarfraz, Dave Hewitt* and *Ian Jones* shared a study involving two second-grade students using an educational app called 'Stick and Split' to solve multiplication problems. They identified four distinct strategies: known or derived multiplication facts, a two-step multiplication model, skip counting, and trial-and-error grouping. Additionally, one paper in this key-theme focused on problem posing. *Ioannis Papadopoulos* investigated how preservice teachers — with and without problem-solving experience — posed open problems from a closed one. Both groups predominantly interpreted open problems as having multiple solutions and formulated them by keeping the original problem and task environment unchanged or slightly modified. However, those with problem-solving experience demonstrated a clearer understanding of the distinction between open and closed problems.

Theme 3: Numbers and their operations

The four papers in this key-theme explore various aspects of all four operations. *Timo Flückiger* and *Elisabeth Rathgeb-Schnierer* examine the flexibility of Grade 3 students' mental calculation, with a particular focus on how they recognise features of addition and subtraction problems. The results

showed significant differences in both the number and types of problem characteristics the students recognised, largely influenced by the specific structure of the problem. One commonly identified feature was "crossing the ten boundary". *Michael Gaidoschik, Myriam Burtscher* and *Heidi Pechlaner* presented an ongoing teaching experiment, designed to support primary students to understand both partitive and quotative division. The results give evidence that after the first cycle of the experiment, most students were able to comprehend and articulate the dual nature of division. *Éva Fülöp, Hoda Ashjari, Marie Fredriksson* and *Angelika Kullberg* reported on an one-semester intervention focused on teaching two-digit subtraction in Grade 2 and discussed the impact of this intervention on students' learning. Following the intervention, the students demonstrated an increased ability to explain their answers and began to adopt sequential strategies. In the final paper of this key-theme *Sandra Gleißberg*, *Klaus-Peter Eichler* and *Moritz Seibold* investigated German students' mastery of basic multiplication and division facts from the end of Grade 2 to the end of Grade 3 using timed tests. Although overall performance improved by the end of Grade 3, only 42% of the participating students achieved the expected level of mastery, with significant variation across classes.

Theme 4: Place value and representations

Within this key-theme, two papers directly explored aspects of place value while a third one examined a manipulative functioning as a linear representation of number position —also relevant to place value understanding. In their study, *Gerald Wittmann* and *Katja Lenz* validated a test instrument designed to assess German fourth graders' conceptual understanding of place value for numbers larger than one thousand, up to one million. The test focuses on translating pictorial representations into numerals and incorporates non-standard representations and a variety of task types. *Mia Lene Ransiek* and *Thomas Rottmann* investiagted Danish and German second graders' understanding of place value through tasks involving translation between different number representations. Although both languages use inverted number word structures, German students exhibited more inversion-related errors, while Danish students struggled more with irregular tens-related errors. The study shows that additional features of number word formation also seem to play a significant role in influencing these types of error. The third paper, co-authored by *Sarah Hopkins, James Russo, Jane Hubbard, Anne Roche* and *Janette Bobis* examined how to encourage the use of retrieval-based solutions instead of the counting strategy in simple addition through a case study involving a ten-year-old student. The intervention focused on a novel manipulative, the "Keyboard," which visually displays the linear arrangement of numbers. The results showed that after the intervention, the student showed a significant decrease in reliance on minimal counting strategies and a growing use of strategies based on retrieval or derived facts.

Theme 5: Difficulties and understanding in learning Arithmetic

This key-theme is broad and concerns difficulties relevant to (i) the transition from primary to secondary school, (ii) the criteria for evaluating the quality of a student's solution to an arithmetic task as being good or high, (iii) the transition from the real word of quantities to numerical expressions, (iv) the perception and understanding of linearly increasing number patterns, and (v) conceptual and lexical understanding of arithmetic in the context of learning difficulties. More specifically, *Volker Ulm, Annalisa Steinecke* and *Moritz Zehnder* investigated students who, in the

transition from primary to secondary school, have severe difficulties in learning arithmetic. Their findings underscore the challenge faced by the education system in establishing effective structures to identify these students, accurately diagnose their specific difficulties in a differentiated way and provide appropriate support. *Linda Devi Fitriana, Zoltán Kovács* and *Christiyanti Aprinastuti* emphasized hands-on activities by investigating how paper-folding tasks can reveal preservice primary school teachers' number sense skills. Through tasks that offered the chance to explore number patterns, the participants demonstrated their capacity to move from physical to mathematical forms, identify numerical relationships, and intuitively recognize sequence patterns. *Robert Gunnarsson* and *Ioannis Papadopoulos* presented an ongoing study exploring the conventions of what is required for a student's solution to an arithmetic task to be good, or even of high quality. According to 21 secondary school teachers and mathematics education researchers, a high-quality solution must meet three key criteria. It be mathematically correct, it employes an efficient solution strategy and must be communicated transparently — particularly in terms of the syntax of the written expression and its adherence to necessary mathematical conventions. *Darina Jirotková* and *Jana Slezáková* working with Grade 2 and 3 students, analyzed their solutions to a problem involving numerical patterns. They classified the solutions into seven categories according to the accuracy of the answers across various fragments of the pattern in a given task. This classification enabled them to formulate three distinct levels of students' perception and understanding of linearly increasing number patterns. *Charlotte Rechtsteiner* and *Michaela Scheffknecht* focus on children with specific learning difficulties in mathematics. To support the development of conceptual and lexical understanding in arithmetic they employed general Why-explanations as an efficient means. In this paper they followed a Grade 3 student who received supplementary weekly lessons aimed at stimulating general Why-explanations. Their findings indicate that the formulation of general Why-explanations was essential for developing (flexible) calculation competences.

Some concluding remarks

At CERME14, TWG02 participants had the opportunity to engage in productive small- and whole-group discussions on various aspects of arithmetic across all educational levels, with a focus on both teachers and students. This year's well-balanced mix of early-career and experienced researchers significantly enriched the conversations. Discussions emphasized shared interests, such as analyzing students' strategies rather than merely judging the correctness of their answers, deepening our understanding of students' thinking, enhancing learning through appropriate learning environments, and exploring the connections between arithmetic operations. These discussions also laid the groundwork for extending the current work by exploring cultural influences on teaching and learning, examining student competencies and misconceptions more closely, developing alternative instructional approaches, and incorporating interdisciplinary perspectives into arithmetic. Additionally, we recognize the importance of addressing emerging areas in arithmetic, such as patterns involving irrational numbers and the role of arithmetic in STEM education—topics that will be reflected in the upcoming call for papers for CERME15.

Preservice teachers' decision-making: an empirical study using additive problems

Mónica Arnal-Palacián[1] and Nuria Begué[1]

[1]University of Zaragoza, Faculty of Education, Zaragoza, Spain; marnalp@unizar.es

The aim of this paper is to identify the categories on which a preservice teacher (PST) relies when describing decision-making in relation to the resolution of an additive problem, as well as to identify a gradation in the characterisation of this decision according to the chosen category. The study sample consisted of 63 PSTs. They were given a task consisting of two additive problems presented together with a resolution by a child in the 6th grade of Primary Education. Among the results, we found that PSTs take into account in their decision-making the semantic structure of the problem, the use of materials and the use of diagrams, although not in all cases with the same level of precision. In the case of the use of diagrams or drawings, more general decisions are made, while in the case of the semantic structure, the comments are much more precise and elaborated.

Keywords: Decision-making, additive problems, preservice teachers, semantic structure.

Introduction

The literature emphasises the need for teachers to acquire skills and competencies for their classroom practice, which should begin during their initial training. Specifically, Jacobs et al. (2010) describe a theoretical framework, professional noticing of children's mathematical thinking, as a set of interrelated skills, including decision-making based on understanding the child's response.

Stahnke et al. (2016) conducted a systematic review of 60 studies focused on the perception, interpretation, and decision-making of pre-service (PST) and/or in-service teachers (IST). Half of the analysed articles aim to examine at least decision-making, with only five articles focusing solely on decision-making with samples of IST. The results show that decision-making is very challenging for PST. Additionally, the review highlights the limited research focused on decision-making among PST samples, which justifies the need to design studies that seek to identify the criteria on which decision-making is based and the inherent difficulty in doing so. Therefore, we designed an instrument which presents two different additive problems, along with an incorrect solution provided by a primary school student. The assessment instrument requires the PST to describe the reasoning behind their decision-making in order to support the student's learning process in response to this type of problem. The literature highlights the difficulties that students face in carrying out these actions, and we expect a varying level of description depending on their ability to articulate the use of each category. Therefore, the aim of this study is to identify the categories used in describing the type of decision made by the PST and to establish a gradient in the characterisation of the decision according to the selected category. Additionally, the additive problems correspond to different semantic structures, as described in the methodology section. This task variable allows us to explore whether the decisions related to the categories depend on the type of semantic structure.

Theoretical Framework

In the resolution of arithmetic problems that can be solved using addition or subtraction, different classifications have been proposed based on their semantic structure (Carpenter & Moser, 1982; Riley et al., 1983), with the most commonly used being the distinction between transformation, combination, and comparison (Riley et al., 1983). Refining this categorisation further, there is a combination of these categories that results in six semantic structures (Vergnaud, 1982): a) State-State-State (SSS), b) State-Transformation-State (STS), c) State-Comparison-State (SCS), d) Transformation-Transformation-Transformation (TTT), e) Comparison-Transformation-Comparison (CTC), and f) Comparison-Comparison-Comparison (CCC).

The choice of each of these categories impacts the difficulty in solving these problems (Carpenter & Moser, 1982). Despite the existence of these categories, not all of them are presented in the same way or with the same frequency in primary education classrooms (Arnal-Palacián et al., 2023). The difficulty of arithmetic problems, particularly additive ones, can also be explained by the consistency of the language used. For instance, addition is often associated with words like 'increase', 'add', 'more than', etc., while subtraction is linked to terms like 'decrease', 'take away', 'less than', etc. (Orrantia et al., 2005). This inconsistency in language is determined by the position of the unknown in the problem for each of the previously mentioned semantic structures.

In relation to the research, we propose the following research question: Are there differences in decision making provided by PST to student answers to additive problems that allow descriptive levels to be established?

Methods

The intentional sample consisted of 63 PSTs enrolled in the course *Didactics of the Natural Number*, which corresponds to the first Mathematics Education course in their undergraduate degree in Primary Education. The task proposed consisted of two additive problems, each accompanied by a solution provided by a 6th-grade primary school student (11-12 years old) (Figure 1 and Figure 2).

You have 1600 red chips on the table. If you have 900 more chips than your friend Cristina, how many chips does your friend Cristina have?

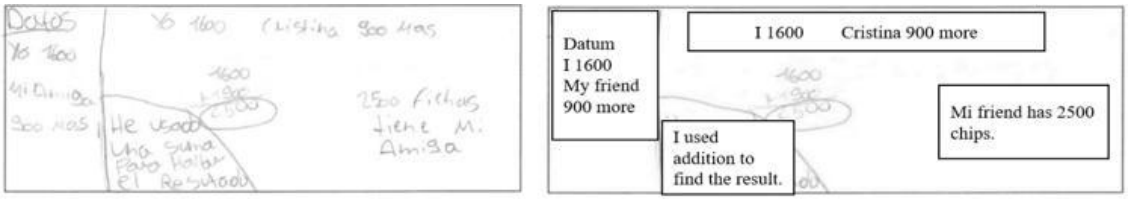

Figure 1: Statement of Problem 1 and Response from the Primary School Student

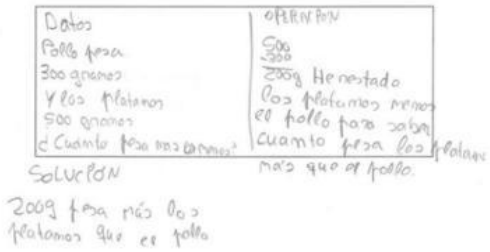
The chicken weighs 300 grams more than the cake, while the bananas weigh 500 grams less than the cake. How many grams more or less does the chicken weigh compared to the bananas?



Datum
Chicken weighs 300 grams and the bananas 500 grams.
How much more or less does it weigh?

OPERATION

I subtracted the bananas minus the chicken to find out how much more the bananas weigh than the chicken.

SOLUTION
The bananas weigh 200 g. more than the chicken

Figure 2: Statement of Problem 2 and Response from the Primary School Student

The PSTs were assigned the following task: "*Describe the decisions you would make to help the student, if necessary, to progress in their understanding*". The task was presented as a class activity to be completed individually, after receiving instruction on solving and creating additive problems. Therefore, the students were familiar with the categories of analysis described below.

The analysis variables considered were semantic structure, with manipulatives, and the use of diagrams or images. Problem 1 corresponds to an SCS structure, in which an additive comparison relationship is presented between two known quantities. Problem 2 corresponds to a CCC structure, in which each datum of this semantic structure reports the comparison relation that is established between two unknown quantities. In our case, we do not know the amount of mass of the chicken and the pie, but the comparison between those unknown quantities. Therefore, the statement provides information about the positive and negative comparison that is established between the unknown quantities of mass of the chicken with respect to the cake, and the bananas with respect to the cake. Therefore, the question aims to determine the additive comparison that is established between the unknown mass quantities of the chicken and the bananas. Despite the fact that the operations involved in solving these problems do not pose a challenge for students of these ages, as Arnal-Palacián et al. (2023) state, SCS problems have hardly been present in their textbooks, and CCC semantic structure problems have not been presented.

Therefore, PSTs were expected to have this category to explain their decision-making. Moreover, this change in semantic structure has implications for the difficulty of each problem. This explains why the characterisation of this category for Level 3 - levels presented below - differs according to the type of problem. Specifically, a student making a Level 3 decision for Problem 2 identifies the need to work with additive situations corresponding to Problem 1 (SCS). Additionally, the use of manipulatives is considered a potential decision-making factor due to its importance in establishing connections between ideas, concepts, and procedures as a teaching and learning tool (Hodgen et al., 2018). Finally, diagram or pictorial representation is taken into account, as these tools allow for the analysis of a verbal problem (Ramos et al., 2016) by organising and relating its data (Hershkovitz &

Nesher, 2003). The established categorisation is shown below, and student responses are shown in the next section to exemplify the levels defined for each category:

Semantic structure

- Level 0. No mention is made of the semantic structure.
- Level 1. The semantic structure is only mentioned, without any additional information.
- Level 2. It is specified that other problems with the same semantic structure could be used.
- Level 3. It is specified that other problems with the same semantic structure could be used, also specifying a progression in the degree of difficulty.

With manipulatives

- Level 0. No mention is made of the use of materials.
- Level 1. The use of materials is only mentioned, without any additional information.
- Level 2. The use of materials is mentioned, and, additionally, the materials are determined in a specific way: objects or balance.
- Level 3. The use of materials is mentioned, the materials are specifically identified, and it is further specified that their incorporation requires changing the size of the number.

Diagrams/Images

- Level 0. No mention is made of the diagrams or images.
- Level 1. The diagrams and/or images are only mentioned, without any additional information.
- Level 2. Diagrams and/or images are mentioned, and, in addition, one is presented.
- Level 3. Diagrams and/or pictures are mentioned, one is presented, and how to manage their use with the student is explained.

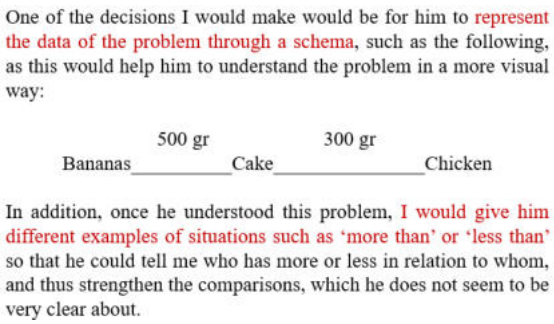
Results

The decision-making made by the PST for Problem 1 resulted in the following results: 26.5% made decisions, but none of the categories were considered, 53.1% dealt with one of the categories, 9.3% with two, 4.9% with three, and 6.2% did not respond to the requested task. Among these decisions, 23.8% attended to the learner with the help of a diagram or drawing, 23.8% took the material into account, for example, PST#32 refers to the use of paper balls to construct the quantity associated with the data in the statement. Finally, 36.5% attended to the semantic structure.

> PST#32: I would re-read the problem with the child and do *a visual example with paper balls* and smaller numbers.

In relation to the results of Problem 2, the analysis of the results shows that 27.4% of the PSTs do not provide an answer that corresponds to a decision-making categorisation. On the other hand, the majority of the sample, 40.6%, refers to one of the indicated categories, while the percentage of PSTs

referring to two or three categories takes the value of 16% (Figure 3) and 2.9%, respectively, and 13.1% do not respond to the requested task.



One of the decisions I would make would be for him to represent the data of the problem through a schema, such as the following, as this would help him to understand the problem in a more visual way:

500 gr 300 gr
Bananas Cake Chicken

In addition, once he understood this problem, I would give him different examples of situations such as 'more than' or 'less than' so that he could tell me who has more or less in relation to whom, and thus strengthen the comparisons, which he does not seem to be very clear about.

Figure 3: PST #48. Two decision-making processes addressed: diagram and semantic structure

As can be seen in PST#59 answer and Figure 3, both PSTs address decision making in which the use of diagrams is taken into account. However, the level of development of each of them is different, being more advanced in the second case. For this reason, the analysis is completed by classifying each type of decision identified according to its level (Table 1). This analysis shows that PSTs are able to provide better decisions for the case of *materials*, in the case of Problem 1, and for the *semantic structure*, for Problem 2. However, despite finding a sufficiently high number of comments for the *diagram* category, this decision-making hardly contains any reflection on what kind of diagram to use or how to manage it with the learners.

Table 1: Number of PSTs at each level for each category and proposed problem

Level	Level 0		Level 1		Level 2		Level 3	
Category	Probl. 1	Probl. 2	Probl. 1	Probl. 2	Probl. 1	Probl. 2	Probl. 1	Probl. 2
Semantic Structure	41	44	0	0	21	15	1	4
Use of materials	48	51	3	8	1	3	11	1
Make a sketch or pictorial representation	48	37	13	21	1	3	1	2

Level 0 is the predominant level in both problems for each of the categories considered. Given the objective of the study, we focus the analysis on the rest of the levels.

The highest number of Level 1 decision making is concentrated in the case of making diagrams or pictorial representations to help solve the problem, while Level 2 could be linked to decisions made with semantic structure and Level 3 is dominated by the use of materials.

Level 1. The results in Table 1 show that for this level, a similar tendency is identified in both problems. At this level, most of the PSTs cite the diagram or pictorial representation, without offering any type of decision for this level in the case of the semantic structure. In the case of Problem 1, most of these comments at this level concentrate on the presentation of a diagram or drawing. The type of decision making for the latter case are of the following type: "I would propose to the student to make a new reading with the help of a teacher that would allow him to understand more precisely and the question and, in addition, if necessary to make a small drawing that would allow him to observe what he should do more easily" (#20), "I think that the easiest way to understand the problem is to use drawings, using them makes it easier for the student to understand" (#25), "I think I would advise him/her to make a drawing or a scheme so that the data of the problem can be appreciated in a more visual way" (#35) or "I would help him/her to make a scheme of the statement" (#59).

In the case of Problem 2, we find similar answers in which the drawing or diagram is mentioned, where the difference lies in who assumes the task of making the drawing or diagram, as can be identified from the answers shown, "And finally, I would help this student above all with a representation through drawings that he makes..." (#19); "I would make a more visual diagram of the weight of the three elements..." (#57); "the student could be encouraged to make a scheme to see more clearly the comparisons that are made,..." (#63).

Level 2. Most of the PSTs provide information regarding the semantic structure at this level for both problems. The decision-making they propose, depending on the problem, is described below:

In the case of Problem 1, 91% of the PSTs that belong to this level for one of the three categories are for the semantic structure. Some of the decisions made by the PSTs were the following: "I would do State-Comparison-State problems with the student to improve his understanding progressively" (#9), "We would do different SCS problems in which the word 'more' also appears but the word 'more' has to be subtracted and the word 'less' has to be added so that the student understands that it is not the same" (#59) or "I would focus on helping the student to improve his/her understanding in relation to the terms 'more than' and 'less than' so that he/she does not associate 'more' always with addition and 'less' always with subtraction and can do the problems without making mistakes" (#55).

In the case of Problem 2, they correspond to answers indicating that the same semantic structure of the problem presented is being worked on, for example, "we could do is to put smaller data and numbers, offering them a material and context close to the child. But, not modifying the semantic structure". (#1), "I would do multiple exercises with semantic category CCC, so that the student understands the differences of comparisons" (#2).

Level 3. The results in Table 1 reveal that the frequency of responses that fall into this category shows different trends depending on the problem.

In Problem 1, most of the PSTs are linked to it, 84.6%, by the decision-making they provide for the use of materials. In the case of semantic structure, only a single PST (PST #53) reached this level for decision-making, where semantic structure was taken into account. The same is true for the

introduction of diagram management or pictorial representation. Relevant is the case of the PST#58, which reaches the highest level for diagrams, as it also reaches this level for the use of materials.

PST#53: Because of the above, *I would go back to the previous step and practice on State-Comparison-State exercises with the unknown in the first term*. When I was sure he/she knew how to do those, I would take those same exercises and *reformulate them to ask the question with the comparison*, instead of the initial state, *changing the position of the unknown and the sign of the operation*. [...]

PST#58: In this case, I think that we should give them a similar problem *with smaller data so that, first of all, they can solve it manipulatively (with cards).* Finally, solve it with the corresponding mathematical operations.

In the case of Problem 2, the degree of complexity of the semantic structure characterising the statement is perceived by 4 students who point out the need to present problem statements involving a progression in semantic structure SCS.

Conclusions

We can conclude that there are certain similarities in the level of reflection that PST develop in decision-making (Jacobs et al., 2010), despite the difference in the semantic structure (Vergnaud, 1982) of both problems, SCS and SSS, and, consequently, the different degree of difficulty (Carpenter & Moser, 1982). The most notable difference in decision-making between the two problems lies in the use of material. While in Problem 1 the decisions are precise, considering reducing the size of the numbers in order to use a tangible material, usually tokens; in the case of Problem 2, the decisions are more generic and involve little more than considering a scale to establish the comparison.

In relation to the link between the categories and development levels, it has been observed that for the semantic structure category, most of the PSTs are at Level 2, while the use of diagrams or drawings is more frequent for Level 1. However, not many PSTs reach Level 3. It is precisely the level that should be reached by all PSTs at the end of their training, both for their degree of reflection and for the variety in the categories addressed in decision-making. Thus, a difficulty in decision-making as a future teacher is identified, as pointed out in the review carried out by Stahnke et al. (2016), which needs to be addressed for adequate professional development from the initial teacher training.

As a future perspective of this research, it is intended to address the creation of teacher profiles based on the decisions considered and to identify factors preventing pre-service teachers from progressing beyond the lowest level despite instruction and design ways to support their competency development. Furthermore, the research can be expanded by analysing combined categories and characterising PSTs based on the levels achieved of the categories, as different levels may be reached depending on the category.

Unveiling number sense performance in preservice primary school teachers through hands-on activity

Linda Devi Fitriana[1], Zoltán Kovács[2,3] and Christiyanti Aprinastuti[1,3,4]

[1]University of Debrecen, Debrecen, Hungary; flindadevi@gmail.com

[2]Eszterházy Károly Catholic University, Eger, Hungary

[4]Sanata Dharma University, Yogyakarta, Indonesia

This study explores how hands-on activities, specifically paper folding, reveal the number sense performance of preservice primary school teachers. By engaging in tasks introducing and exploring number patterns, participants demonstrated their ability to transition from the real world of quantities to numerical expressions, recognise relationships among numbers, and intuitively identify sequence patterns. The result discloses varying ability levels to translate between number representations, understand the additive and multiplicative structures of numbers, and grasp the interaction between this translation process and the conceptual understanding of operations.

Keywords: Number sense, paper folding, preservice primary school teachers.

Introduction and theoretical background

Primary school teachers in Indonesia must develop a comprehensive mathematical foundation to effectively convey mathematical concepts to young learners, with number sense being a fundamental component, providing the critical foundation for further learning and cognitive development. While there is still no consensus on the definition of number sense (Pitta-Pantazi et al., 2014), the significance of fostering number sense among students has gained increased attention from mathematics educators globally. Studies by Yang et al. (2009) emphasise the critical role of number sense in children's mathematical growth and advocate for its inclusion in mathematics curricula across primary and secondary education. Therefore, assessing the number sense of preservice teachers is critical (Aktaş & Özdemir, 2017).

The study introduced a hands-on activity for preservice primary school teachers (PSTs) to introduce number sequence, allowing them to explore patterns, transition from tangible to abstract, and intuitively recognize sequences. This approach supports educational practices that link numerical patterns to physical or visual representations, which benefit both students and preservice teachers (Rivera & Becker, 2005; Whitin & Whitin, 2014). PSTs should thoroughly understand number sequence as it underpins essential arithmetic skills, pattern identification, and cognitive development (Griffin, 2009), all critical in early mathematics instruction.

The importance of number sense as a foundational idea in mathematics (NCTM, 2000) necessitates research on how preservice teachers demonstrate this skill. While much research has been conducted on number sense in students, there is relatively limited literature on the number sense of PSTs. This study aims to contribute to the literature by investigating how paper folding may reveal the number

sense of PSTs. Specifically, this study explores PSTs' abilities across selected dimensions of number sense, as defined by Sowder (1992), which are elaborated further in the following section.

There has yet to be a universal consensus on the exact definition of number sense (Pitta-Pantazi et al., 2014). Some studies indicate that the number sense has two dimensions (Berch, 2005; Jordan et al., 2006). The first involves basic skills like counting, number recognition, pattern understanding, and nonverbal calculations. The second pertains to arithmetic, including problem-solving and number combinations. Additionally, number sense is the ability to see numbers as meaningful, involving skills like using different representations, recognizing magnitudes, using benchmarks, composing and decomposing numbers, understanding operations, estimating, doing mental math, and assessing result accuracy (Pitta-Pantazi et al., 2014).

Building on the existing definitions and characteristics of number sense, Sowder (1992) has provided a comprehensive list of behaviours that demonstrate the presence of number sense. This list, while not without some overlap, is a valuable resource in understanding the complex and multifaceted nature of number sense.

> (1) Ability to compose and decompose numbers, to move flexibly among different representations, to recognize when one representation is more useful than another; (2) Ability to recognize the relative magnitude of numbers; (3) Ability to deal with the absolute magnitude of numbers; (4) Ability to use benchmarks; (5) Ability to link numeration, operation, and relation symbols in meaningful ways; (6) Understanding the effects of operations on numbers; (7) The ability to perform mental computation through "invented" strategies that take advantage of numerical and operational properties; (8) Being able to use numbers flexibly to estimate numerical answers to computations, and to recognize when an estimate is appropriate; and (9) A disposition toward making sense of numbers. (Sowder, 1992, pp. 4–6)

The central question guiding this study: how do PSTs perform number sense across Sowder's dimensions 1, 5, 6, and 9? We interpret having good number sense in the context of our study as the ability to precisely translate between different number representations, grasp the structure of addition and multiplication, comprehend how these conversion processes interact, and have a conceptual understanding of operations.

Methods

The study involved 90 PSTs enrolled in their third semester at a university in Yogyakarta, Indonesia. These participants had completed introductory mathematics courses on numbers, spatial reasoning, and symmetry. We conducted the study in the third month of the semester to ensure the participants had a thorough understanding of fundamental mathematics. In this research, participants were tasked with performing a folding activity, in which they received a piece of paper and were instructed to fold it in half multiple times (Mason et al., 2010) (see Figure 1 for clarification of the folding process). The questions were: (1) How many fold line segments are in the first, second, third, and seventh folds? (2) What is the general rule for the n^{th} fold? This paper focuses solely on the first question. The rationale for the seventh fold is the practical impossibility of folding paper seven times and more. The task prompts participants to explore what is happening in the paper folding, express the structure

of how a sequence is generated, and turn to objects to manipulate, make, and justify conjectures (Mason, 2010). Consequently, the task aligns with and supports participants in engaging with the four overlapping number sense dimensions outlined by Sowder (1992). In addition, as noted by Sjaastad (2023), tasks that encourage inquiry activities like exploration, conjecture, and reasoning can enhance number sense.

The lesson was implemented in 90 minutes and divided into three phases: independent work, paired discussions, and a whole-class discussion. This study is part of a broader research project and focuses specifically on individual work to assess the participants' original performance in number sense. Several precautions were implemented during the individual work phase to ensure the validity of the result. Participants were seated individually and reminded to complete their tasks without collaborating. The instructor actively observed the room while a designated observer documented participant behaviour to monitor this process. Data were collected through written responses and researcher notes. The participants' solutions were coded at two levels, namely, (i) the correctness of the final solution and (ii) the correctness of the starting point.

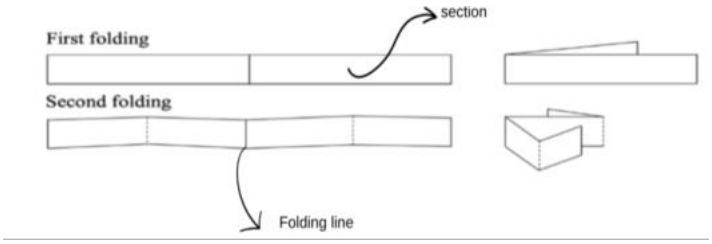

Figure 1: Illustration of the folding

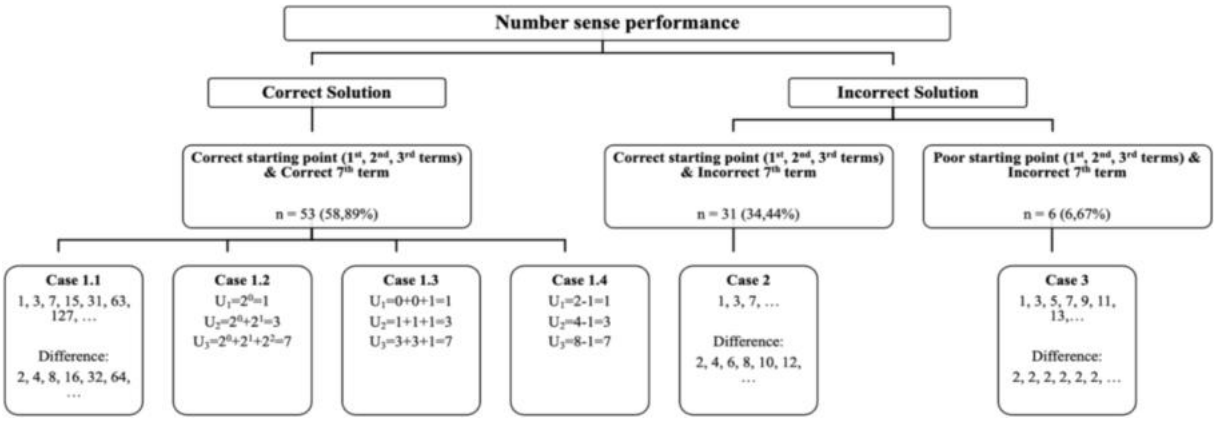

Figure 2: Distribution and details of performance

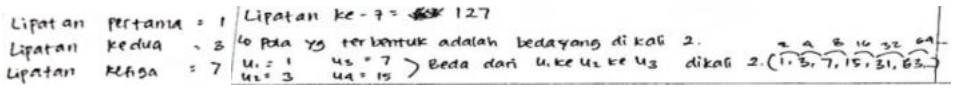
Results

The participants' performance was analysed by classifying the final results into correct and incorrect solutions, with Figure 2 highlighting the key steps leading to correct or incorrect outcomes. Based on the results, we selected the responses of several participants (HW, VH, AK, MA, NJ, and AB), which represent each case.

Correct solution: Correct starting point and correct 7th term

Case 1.1

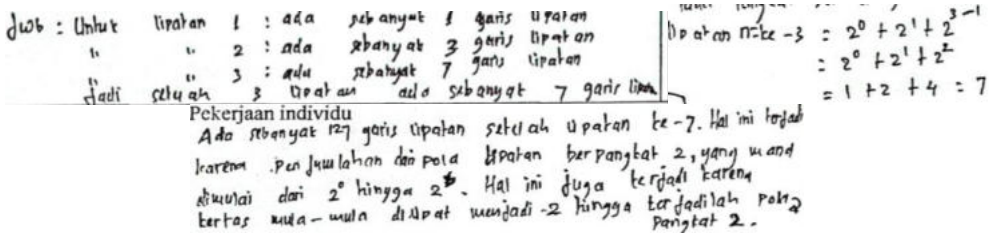


Translation: First fold = 1; second fold = 3; third fold = 7. Seventh fold = 127. The pattern formed is the difference multiplied by 2. $U_1 = 1;\ U_2 = 3;\ U_3 = 7, U_4 = 15$. The difference from U_1 to U_2 to U_3 is multiplied by 2.

Figure 3: Answer by HW

As evidenced by Figure 3, the PST correctly identified the sequence of fold line segments, suggesting she understands the basic idea of observing differences between successive terms, which increase in a structured way, i.e., kept getting multiplied by two. Each subsequent term can be determined by summing the previous term and the continuously doubled difference. Finding the seventh term using this rule remains a reliable method.

Case 1.2

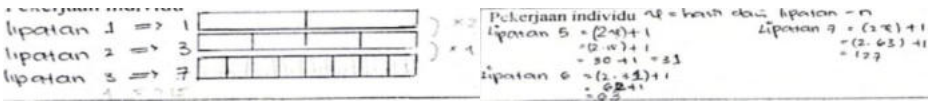


Translation: First fold, there is 1-fold line segment. Second fold, there are 3-fold line segments. Third fold, there are 7-fold line segments. Third fold $= 2^0 + 2^1 + 2^{3-1} = 2^0 + 2^1 + 2^2 = 1 + 2 + 4 = 7$. There are 127-fold line segments on the seventh fold. This is due to the sum of the fold patterns in powers of 2, starting from 2^0 to 2^6. This is also because the paper is initially folded in 2 until a power of 2 pattern occurs.

Figure 4: Answer by VH

Based on Figure 4, the PST accurately recognized that the number of fold line segments follows an exponential pattern with base 2. She employed the formula $2^0 + 2^1 + \cdots + 2^{n-1}$ to articulate how the fold line segments accumulate, performing an advanced and accurate mathematical representation. By identifying the recursive relationship inherent in this exponential sequence, she demonstrated an understanding of how each fold builds upon the previous ones. Her statement, "the paper is initially folded in 2 until a power of 2 pattern occurs," indicated that she made a connection between the physical act of folding and the mathematical pattern.

Case 1.3



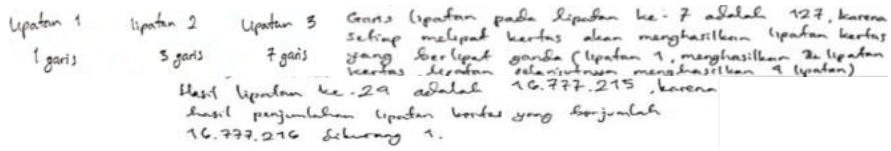
Translation: First fold: 1-line segment, second fold: 3-line segments, third fold: 7-line segments. x: result of the nth – fold. Fifth fold $= (2x) + 1 = (2 \times 15) + 1 = 30 + 1 = 31$. Sixth fold $= (2 \times 31) + 1 = 62 + 1 = 63$. Seventh fold $= (2x) + 1 = (2 \times 63) + 1 = 127$. (Note: The sketch indicates that the number of sections doubles in each fold)

Figure 5: Answer by AK

Referring to Figure 5, the PST attempted to formulate a general rule for each subsequent fold using the expression $2x + 1$ to describe the relationship between the current and the previous terms. The

appearance of this expression suggests that she fully captured the recursive nature of the sequence but struggled with fully articulating it, indicated by x being noted as a "result of the nth fold" rather than "the number of the fold line segments on the previous fold". Even though there is no verbal description regarding the number of sections or fold line segments, her sketch highlights that the number of sections doubles in each fold, which signals a connection to the folding activity.

Case 1.4



Translation: The number of the fold line segment at the 7th fold is 127, because each fold will produce doubled sections (the first fold produces 2 sections, the next fold produces 4 sections). The result of the 24th fold is 16.777.215 because the number of sections (16.777.216) is minus 1.

Figure 6: Answer by MA

As shown in Figure 6, the PST correctly identified that the number of sections doubles in each fold, reflecting an understanding of geometric progression. He grasped that the total number of fold line segments equals the number of sections minus one and correctly applied this reasoning to the 7th and 24th folds. His statement that "each fold will produce doubled sections" confirms a connection to the folding activity. This manifestation of the PST revisiting the folding activity indicates a deductive closure.

Incorrect solution: Correct starting point and incorrect 7th term

Case 2

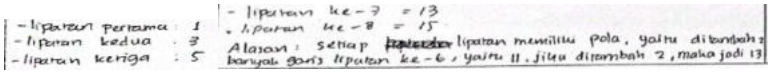
Translation: First fold = 1 line segment, second fold = 3 line segments, third fold = 7 line segments, seventh fold = 43 line segments.

Figure 7: Answer by NJ

As depicted in Figure 7, the identified sequence is $1, 3, 7, \ldots, \ldots, \ldots, 43$, where the difference between two terms might be $2, 4, 6, 8, 10, 12$. While the fourth fold could have been physically performed, the PST could not accurately identify the fourth term, indicating disconnection with the folding activity. The incorrect sequence follows a pattern of adding successively increasing even numbers, reflecting a simple arithmetic progression. This point suggests that the PST overgeneralized his understanding of basic arithmetic sequences, applying a linear pattern where a non-linear pattern was required.

Incorrect solution: Poor starting point and incorrect 7th term

Case 3



Translation: First fold: 1, second fold: 3, third fold: 5, seventh fold: 13, eighth fold: 15. Reason: Each fold has a pattern, which is plus 2. The number of lines on the sixth fold is 11, if it is plus 2 then it becomes 13.

Figure 8: Answer by AB

As presented in Figure 8, the identified sequence $1, 3, 5, 7, 9, 11, 13$ with a consistent difference of 2 between consecutive terms indicates that the PST incorrectly interpreted the pattern as a linear arithmetic progression. This reliance on a linear arithmetic pattern suggests an overgeneralization rooted in familiarity with basic sequences. The sequence that does not match the actual results reflects either a misunderstanding of the instruction or a disconnection with the folding activity. If not due to instructional misinterpretation, this case suggests a gap in his ability to translate concrete experiences into numbers as one of the mathematical representations.

Discussions

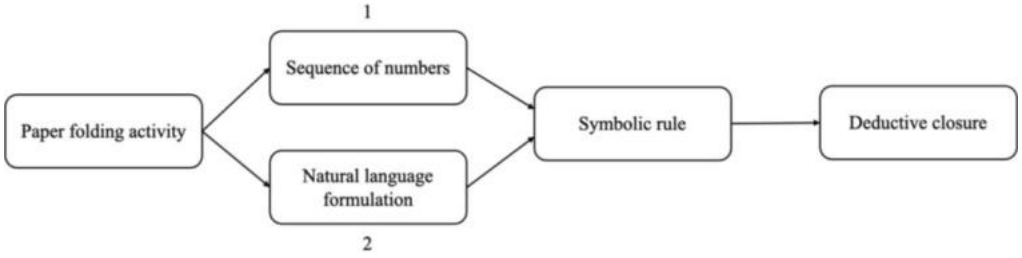


Figure 9: Translation process

Figure 9 depicts two possible approaches for translating the hands-on activity to reach the deductive closure as the optimal step. In this translation, certain visible features of the PSTs' responses are examined and connected to Sowder's (1992) dimensions of number sense. The folding activity could be translated into a mathematical object in two distinct ways:

First, if the fold line segments are simply enumerated, a sequence of numbers $(1, 3, 7, 15, ...)$ emerges without relational understanding from the translation process. This simplest manifestation of number sense aligns with dimension 1 (the ability to move flexibly among different representations), which is evident in how the manual activity produces a number at each step. If this counting is incorrect (Case 3), it could suggest a rudimentary number sense in this dimension or that the PST needed to recognize the need to count the fold line segments after each step. The error might stem from a tenuous grasp of numbers or misunderstanding the instruction. Meanwhile, Case 2 illustrates a specific circumstance where the PST accurately represented the number of line segments only for the first three folds, suggesting an inconsistency between representations.

Second, the translation process can also lead to formulating a rule based on natural numbers' additive and multiplicative structure. This rule could be established after the counting, either by abstracting the activity and identifying the pattern or directly linking the activity to a structured object. This process aligns with the manifestation of dimension 5 (the ability to link numeration, operation, and relation symbols in meaningful ways). Case 1.1 provides a concrete example of this dimension where the PST recognized the difference between consecutive terms. Case 1.3 gives another example, where the PST demonstrated a different approach to recursion, not by analysing the difference but by formulating a direct rule to describe the pattern.

In the latter approach, the relationship could be articulated in natural language: "In each fold, twice as many sections are formed as before, and the number of fold line segments is one less than the number of sections." This formulation necessitates an understanding of the operations' effects on

numbers, reflecting dimension 6. Case 1.2 further exemplifies the presence of this dimension as the PST recognized that consecutive multiplication by two could be expressed as the sum of exponential numbers with base 2, suggesting the formulation of a general rule. This work contrasts with Case 1.1, where the progress stalled in identifying the difference between consecutive terms, and no general term was formulated. Thus, the PST's understanding was confined to the arithmetic level.

Optimally, recognizing the pattern in the number sequence concludes with a deductive reasoning process, connecting back to the folding activity. This manifestation reflects a disposition toward making sense of numbers, which characterizes dimension 9. The emergence of this dimension is evident in Case 1.4, where the PST explained the connection between the folding activity and the rule, providing a clear justification and argumentation for why the sequence is correct. Moreover, the sketch in Case 1.3 serves a visual explanation for the stated rule, simultaneously exemplifying the manifestation of dimension 9.

In summary, some PSTs accurately determine the seventh term, demonstrating their comprehension of the instructions. This performance implies their ability to smoothly transition between representations (dimension 1) from physical to mathematical forms. When PSTs demonstrate procedural knowledge, they often reflect their understanding of how operations affect numbers (dimension 6), as they can execute procedures accurately and make connections between their actions and numerical outcomes. Some PSTs demonstrate a conceptual understanding of exponential growth, recursive patterns, and their connection to the folding paper activity by linking numeration, operations, and relational symbols. It means they understand how the number of folds relates to exponential increases and can articulate these connections meaningfully using mathematical symbols and operations. On the other hand, some of the PSTs needed help to express the rule clearly and tend to overgeneralize arithmetic sequences (dimension 5). Finally, when PSTs connect the folding paper activity to mathematical representation, it shows a disposition toward making sense of numbers (dimension 9). They actively engage with the numerical patterns and relationships, demonstrating an inclination to understand and explore mathematical ideas. Overall, some participants performed well, and some others faced challenges in performing dimensions 1, 5, 6, and 9. In line with this result, another study by Aktaş & Özdemir (2017) highlighted the preservice elementary school mathematics teachers who have lower than expected number sense performance.

Conclusions and pedagogical implications

This study revealed varied performance of number sense among PSTs, particularly in recognising numerical patterns, recursion, and linking concrete actions to mathematical abstractions. To improve these areas, teacher educators should: (1) explicitly encourage PSTs to justify identified patterns, fostering deeper conceptual understanding rather than superficial recognition; (2) use activities like paper folding to strengthen the connections between tangible experiences and abstract mathematical concepts, encouraging PSTs to verbally and visually articulate mathematical relationships.

Students' recognition of characteristics in addition and subtraction problems as a prerequisite for flexible mental calculation

Timo Flückiger[1] and Elisabeth Rathgeb-Schnierer[1]

[1]University of Kassel, Germany; flueckiger@uni-kassel.de

Flexibility in mental calculation is a central topic of elementary mathematics education. Our study focuses on capturing flexibility in mental calculation through the link between the cognitive elements that sustain the solution process and the solution tools. In this paper, we put emphasis on students' recognition of characteristics in addition and subtraction problems and investigate the repertoire of recognised problem characteristics. Furthermore, we focus on the role of the problem selection. In this context, we analyse in which problems the students recognise more or fewer problem characteristics. The results reveal that there is a broad range regarding students' recognition of problem characteristics. Furthermore, the number of recognised characteristics depends on the structure of a problem and varies between different problems.

Keywords: Flexibility in mental calculation, problem characteristics, number patterns, elementary arithmetic, addition and subtraction problems.

Introduction

Fostering flexibility in mental calculation is a central goal in elementary mathematics education. On the one hand, this is evident in several national curricula (for an overview see e.g., Torbeyns & Verschaffel, 2016). On the other hand, many researchers emphasise the importance of the development of flexibility in mental calculation (e.g., Green & Rathgeb-Schnierer, 2020; Hickendorff, 2022; Torbeyns & Verschaffel, 2016). Different research reports that elementary students often use the standard algorithm when solving multi-digit addition and subtraction problems (e.g., Hickendorff, 2022; Selter, 2001). However, various studies show that it is possible to promote students' flexibility in mental calculation with specific teaching approaches (for an overview of the approaches, look for example, at Heinze et al. (2020) and Hickendorff et al. (2022)). Some of these studies highlight the important role of students' skills to recognise problem characteristics, number patterns, and relationships (abbreviated in the following as 'problem characteristics'; e.g. Rechtsteiner & Rathgeb-Schnierer, 2017).

In general, studies show that students use various strategies while solving problems with different problem characteristics with some strategies being used more frequently than others (e.g., Hickendorff, 2022; Macintyre & Forrester, 2003; Peltenburg et al., 2012). Furthermore, some studies focus on the recognised problem characteristics by students, but not with regard to various problems and their specific characteristics (e.g. Rathgeb-Schnierer and Green, 2013). Peltenburg et al. (2012) report that the proportions of students' problem-solving strategies differ depending on the specific characteristics of a problem. Thus, for assessing flexibility in mental calculation, we need instruments with arithmetic problems that include various problem characteristics. In this context, it is crucial to consciously select problems according to their specific inherent characteristics (e.g., Peltenburg et al., 2012; Torbeyns et al., 2009). Research results suggest that problems which require crossing the ten boundary are more difficult to solve than problems that do not (e.g., Hickendorff, 2022;

Peltenburg et al., 2012). However, Rathgeb-Schnierer & Green (2015) point out that if students recognise further problem characteristics that make the problem easier to solve (such as the second number is close to the next full ten in problem 46 – 19), the ten boundary would not be a challenge anymore. These findings suggest that the problem characteristic of crossing, respectively not crossing the ten boundary, is crucial to distinguish problems and the (successful) use of strategies.

The wide range of research regarding flexibility in mental calculation is contrasted by inconsistent terms, definitions, and operationalisations (for an overview of the definitions and operationalisations look for example at Green & Rathgeb-Schnierer (2020) and Hickendorff et al. (2022)). Despite the different definitions, there is a consensus that flexibility in mental calculation can be understood "as an appropriate way of acting when faced with a problem based on a repertoire of available strategies, which is to say that flexible strategies are adapted dynamically to problem situations" (Green & Rathgeb-Schnierer, 2020, p. 3). Rechtsteiner and Rathgeb-Schnierer (2017) gave an overview of the different approaches to define and operationalise flexibility in mental calculation. We take a closer look at one of the approaches which puts emphasis on the *cognitive elements that sustain the solution process* (e.g., Rathgeb-Schnierer & Green, 2013) and considers the link between those cognitive elements and the exhibited solution tools. In this vein, Rathgeb-Schnierer and Green (2013) emphasise: "Only if the tools of solution are linked in a dynamic way to problem characteristics would we consider as evidence of flexibility in mental calculation" (p. 357). Our definition of flexibility in mental calculation is based on these authors. Specifically, we define flexibility in mental calculation as mental processes that involve the ability to recognise the characteristics of a problem and adapt solution methods accordingly. By problem characteristics, we mean specific number patterns and numerical relationships (for example, see Table 1).

In summary, current research on flexibility in mental calculation shows that students use various strategies with varying frequencies while solving problems with different problem characteristics (Macintyre & Forrester, 2003; Peltenburg et al., 2012). Moreover, there is a conscious that flexibility in mental calculation involves that "flexible strategies are adapted dynamically to problem situations" (Green & Rathgeb-Schnierer, 2020, p. 3). However, no study has yet investigated the role of problems with different characteristics in relation to students' recognition of those characteristics. We address this research gap with our study, which pursues two research questions based on our definition (RQ):

RQ1: How many different problem characteristics do students recognise in various problems with different inherent characteristics?

RQ2: In which problems do students recognise problem characteristics and what differences do occur?

Methods

Sample and procedure

155 third-grade students participated in the videotaped interview. Almost half of the sample consists of female students (n = 77) and half of male students (n = 78). Of all students, the mean age is 9.52 years (SD = 0.37 years), of the 77 girls it is 9.46 years (SD = 0.33 years), and of the 78 boys it is 9.58 years (SD = 0.40 years).

Interview

Data was collected by a semi-structured, guided interview which was detailly introduced at the last CERME (see Flückiger & Rathgeb-Schnierer, 2023). In this paper, we put emphasis on the first part of the interview which includes the sorting and reasoning of 12 addition and subtraction problems (see Figure 1).

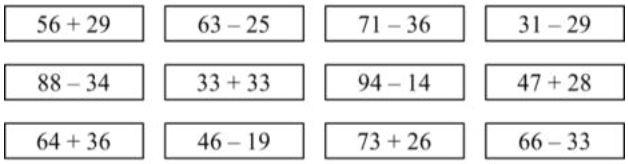

Figure 1: Overview of the problems

In the first part of the interview, we encourage the students to sort the problems into the categories "easy" and "hard", and to give reasons for their sorting. The students' reasoning is a central part of this interview since it provides the possibility of revealing whether students rely on procedures or problem characteristics because they can use both types of reasons (see Table 1 for examples of inherent problem characteristics of three problems). Consequently, that is an appropriate approach to capture students' individual cognitive elements that sustain the solution process (e.g., Rathgeb-Schnierer & Green, 2013). In the further course of the interview, we asked the students to solve the problems.

Table 1: Examples of inherent problem characteristics

Problem	Inherent problem characteristics
63 - 25	Crossing the ten
31 – 29	Both numbers are close together The second number is close to 30 The first number is close to 30 Crossing the ten
66 - 33	The second number is half of the first number The tens and ones of both numbers are the same Inverse problem to 33 + 33 Not crossing the ten

Data analysis

Based on the *Qualitative Content Analysis* by Mayring (2014), we developed a coding system for data analysis. The coding system includes main coding levels with various sub-categories that allow to assign the statements of the students. The main coding levels are: sorting of problems, correctness

of the solution, justifying the sorting, and used solution tools. Table 2 displays a part of the coding system for the main coding level, justifying the sorting with some examples for sub-codes (for more detail, see Flückiger & Rathgeb-Schnierer, 2023). The students' statements were coded at the second sub-code level.

Table 2: Excerpt from coding system

Sub-codes (1st level)	Sub-codes (2nd level)
Numbers at the ones place	The ones are equal One of the ones is twice the other one The sum is less than ten
Relationship of the numbers	Distance between the two numbers

All interviews were independently coded by two trained coders (the first author of this paper and a teacher-student). The coding level for justification of the sorting included 52 sub-codes. The intercoder-reliability for this coding level is $\kappa = 0.81$ (strong intercoder-reliability based on conscious thresholds, e.g., McHugh, 2012). The specific coding process made various analyses possible, such as the calculation of the percentage of problems that were reasoned by problem characteristics as well as the repertoire of mentioned problem characteristics. The repertoire describes the number of different problem characteristics the students have named. When analysing data, it is possible to focus on the entire problem set as well as individual problems separately.

Results

In our last CERME-paper, we provided descriptive results of the first 20 double-coded interviews (Flückiger & Rathgeb-Schnierer, 2023). In this article, we build on this and present the descriptive results of all 155 double-coded interviews. Table 3 reports descriptive results (mean and standard deviation) of three categories: reasoning by problem characteristics as well as the repertoire of those reasons, counting only one reason per problem and all reasons in total. The categories are based on the codes assigned at the second sub-code level.

Table 3: Descriptive results of all of the 155 interviews

Categories	Mean (*M*)	Standard deviation (*SD*)
Reasoning by problem characteristics	6.24	3.44
Repertoire of reasoning by problem characteristics (one per problem)	3.52	1.80
Repertoire of reasoning by problem characteristics (all reasons in total)	4.12	2.21

The values in the lines include correctly and incorrectly solved problems. The first line (reasoning by problem characteristics) exhibits the number of problems whose assignment to a category during the sorting process was justified by problem characteristics. On average, students justified the assignment

to a category with problem characteristics in 6.24 out of 12 problems (52.0%; *SD* = 3.44). The second and third lines refer to students' repertoire regarding reasoning by problem characteristics. Hereby, we identify repertoire by the number of different given reasons. In this context, two different approaches are possible: either to consider one named problem characteristic for each problem or to consider all. We decided to present both aspects, as the 12 problems are different in terms of the number of inherent problem characteristics (see Table 1). Therefore, when all problem characteristics are considered, some problems may have a larger share of the repertoire value. Regarding the repertoire which includes just one reason per problem, the students justified their sorting with an average of 3.52 different problem characteristics (*SD* = 1.80). When focus on the repertoire containing all reasons, the students justified their sorting with an average of 4.12 different problem characteristics (*SD* = 2.21).

Table 4: Descriptive results per problem

Problem	**Number of students who…**	
	reasoned by problem characteristics (percentage)	**referred exclusively to crossing the ten boundary (percentage)**
66 – 33	123 (79.4%)	0 (0.0%)
33 + 33	118 (76.1%)	2 (1.7%)
46 – 19	88 (56.8%)	82 (93.2%)
71 – 36	78 (50.3%)	68 (87.2%)
56 + 29	73 (47.1%)	51 (69.9%)
47 + 28	73 (47.1%)	70 (95.9%)
31 – 29	70 (45.2%)	33 (47.1%)
94 – 14	69 (44.5%)	3 (4.3%)
63 – 25	66 (42.6%)	65 (98.5%)
64 + 36	64 (41.3%)	4 (6.3%)
88 – 34	53 (34.2%)	34 (64.2%)
73 + 26	51 (32.9%)	32 (62.7%)

Table 4 displays descriptive results of all 155 interviews regarding recognised problem characteristics for each problem individually. The first column displays the number of students who recognised problem characteristics as well as the respective percentage of those reasons in comparison to all given reasons (sorted from high to low values). The second column considers only students whose

reasons refer to characteristics, and shows the number of students who only named the characteristic of crossing the ten boundary. The percentages in this column result from the proportion in relation to the number of all recognised problem characteristics in column one.

Regarding all problems, the mean of recognised problem characteristics is 77.17 (49.8%; *SD* = 22.57), and hereof the number of the characteristic crossing/not crossing the ten boundary is 37.58 (24.2%; *SD* = 29.99). The results reveal that whenever students' reason by problem characteristics, there is a large share of the justification by the problem characteristic crossing/not crossing the ten boundary. Regarding and comparing individual problems, it is obvious that the number and percentage of justifications by recognised problem characteristics vary greatly. The problems 66 – 33 (123; 79.4%) and 33 + 33 (118; 76.1%) show the highest proportion, and the problems 88 – 34 (53; 34.2%) and 73 + 26 (51; 32.9%) show the lowest proportion. It is noticeable that the proportion of reasoning by the characteristic crossing/not crossing the ten boundary is very high in some problems. For example, this proportion is over 90% for the problems 63 – 25 (98.5%), 47 + 28 (95.9%), and 46 – 19 (93.2%). At the same time, there are problems such as 66 – 33 (0.0%), 33 + 33 (1.7%), 94 – 14 (4.3%), and 64 + 36 (6.3%), where the percentages are very low. In addition, the percentages vary in problems in which the second number is very close to the next full ten (46 – 19, 56 + 29, 31 – 29). Regarding the problem 46 – 19, most students who reasoned by problem characteristics only mentioned the characteristic crossing the ten boundary. Just five students recognised that the subtrahend 19 is close to 20. In the addition problem with the same structure, 56 + 29 far more students (19) recognised that the second summand 29 is close to 30. Regarding the problem 31 – 29, six students mentioned that 19 is close to 20, and 30 students recognised that both numbers are close to each other.

Discussion and outlook

In this paper, we reported the descriptive statistics regarding students' reasoning for various addition and subtraction problems with specific emphasis on reasons that refer to problem characteristics, and the differences between the different problems. Our approach of sorting, reasoning, and solving problems in a semi-structured interview allows us to reveal the cognitive elements that sustain the solution process, such as recognised problem characteristics or procedures (Green & Rathgeb-Schnierer 2020). Thus, we can see whether students refer to problem characteristics and how many different problem characteristics they recognise (RQ1). In this context, it is interesting that the standard deviation of reasoning by problem characteristics is relatively high (*M* = 6.24; *SD* = 3.44). This means that there is a high scattering around the mean value in the way of justification (via problem characteristics or procedures).

Existing studies show that students use various strategies with varying frequencies while solving problems with different problem characteristics (e.g., Macintyre & Forrester, 2003; Peltenburg et al., 2012). Our method of analysing the data allows us to identify in which problems students recognise problem characteristics and in which they do not. Here, we can see that students also give different reasons with varying frequencies while reasoning about problems with different problem characteristics (RQ2). There is a wide range of the problems regarding the reasoning via problem characteristics. Another aspect of problems is the role of crossing/not crossing ten boundary (e.g., Hickendorff, 2022; Peltenburg et al., 2012). In our results, we can see that reasoning by crossing/not

crossing the ten boundary has a large share in the category reasoning by problem characteristics, and the percentage share also varies greatly between the different problems. However, if students recognise problem characteristics such as the second number is close to the full ten, the ten boundary is no longer a determining factor for the difficulty of the problem (Rathgeb-Schnierer & Green, 2015). In our results, we see that the frequency with which students recognise problem characteristics that do not relate to crossing/not crossing the ten boundary varies greatly between the problems. This result confirms that the problem selection is crucial (e.g., Peltenburg et al., 2012; Torbeyns et al., 2009).

The problem selection is also important for revealing the cognitive elements that sustain the solution process and enables the high scattering in the way of justification discussed above. The chosen method of collecting (interview) and analysing (category system) the data allows further analyses. In the further course of the interview, we asked the students to solve the problems. This conversation, which provides information about the solution process and the result, enables conclusions about utilised solution tools and accuracy. Thus, we will be able to analyse the connection between the cognitive elements that sustain the solution process and the used solution tools. With this approach, we capture flexibility in mental calculation by identifying whether students adapt their strategies dynamically to a problem situation or not (Green & Rathgeb-Schnierer 2020).

Teaching two-digit subtraction with a structural approach in the second grade

Éva Fülöp, Hoda Ashjari, Marie Fredriksson and Angelika Kullberg
University of Gothenburg, Faculty of Education, Gothenburg, Sweden; eva.fulop@gu.se

It has been shown that many students end up in difficulties when solving multi-digit subtraction tasks. This study report on findings from an intervention about teaching subtraction with two-digit numbers in second grade. During one semester four teachers collaborated with two researchers in designing six lessons emphasizing a structural approach, using part-whole relations for solving subtraction tasks. The aim of this paper is to identify what students learned from the intervention. Written pre- and post-tests from three intervention classes and seven comparison classes were analysed with particular focus on the task 204–12=? The results show that the intervention group to a higher extent than the comparison group solved the tasks by decomposing the subtrahend, using a sequential strategy. Two ways of using the sequential strategy in the intervention group was found, decomposing the subtrahend in tens and ones, and decomposing the subtrahend to bridge through ten.

Keywords: Two-digit subtraction, intervention, structural approach, variation theory, elementary.

Introduction

Solving multi-digit subtraction tasks is found to be a difficulty for students in early grades (Heinze et al., 2018; Van Der Auwera et al., 2023). For example, a study found that less than half of the students could solve the task 701–698=? in third grade (Selter, 2001). There is a substantial amount of research on students' ways of solving subtraction tasks (e.g., Selter et al., 2012; Van Der Auwera et al., 2023). However, there are few studies about how to overcome students' difficulties solving subtraction tasks with multi-digit numbers (e.g., Blöte et al., 2001; Heinze et al., 2018). It has been suggested that a structural approach emphasizing part-whole relations for solving addition and subtraction tasks may benefit student learning since it can also be used in higher number ranges (Ellemor-Collins & Wright, 2009). In this study we worked in collaboration with a team of second grade teachers during one semester, designing a series of lessons together. We used a structural approach in the intervention which means for example a focus on mathematical relationships found between elements, for instance part-whole relations of numbers and operations (Reuter, 2023; Venkat et al., 2019). The aim of this paper is to identify what students learned from the intervention. Our research question is: In what ways were students' learning affected by the intervention building on a structural approach?

Learning of multi-digit subtraction

Torbeyns et al. (2009) distinguish between three different types of strategies for calculating subtraction with multi-digit numbers such as 49–25=?. Decomposition is the strategy where tens and ones are divided separately (40–20=20, 9–5=4, 20+4=24), while *Sequential* means that the whole is preserved (49–20=29, 29–5=24). A third type involves strategies where the numbers in the task are changed to facilitate calculation (50–25=25, 25–1=24). The strategy decomposition works well when

solving the task 49–25=? but can create problems when students solve tasks that involve bridging through ten, for example 32–25=? Kullberg et al. (2024a) found that students that used the sequential strategy were more successful than students who decomposed both the minuend and the subtrahend. They argue that students' choice of strategies for solving tasks is influenced by how students perceive and use number relations. To develop powerful strategies for solving multi-digit tasks it has been argued that students need to be able to structure numbers into parts and wholes (Schmittau, 2003). Then they can use part-whole relations to solve a subtraction as an addition 25+5+2=32, or 'see the two and three in the five' in order to bridge through ten e.g., 32–25=, 32–2=30, 30–3=27, 27–20=7. Van Der Auwera et al. (2023) suggests interventions to improve children's understanding of the complement principle (a+b=c thus c–a=b), and to incorporate subtraction as 'determining the difference' in primary mathematics education to provide a more comprehensive understanding of subtraction. In this study the idea was for students to learn to approach subtraction problems considering the structure of part-whole relations using a sequential strategy.

Methods

In this section the method and the intervention and its theoretical foundation is described. Four teachers worked in collaboration with two researchers during one semester designing lessons with the aim to increase second grade students' ability to solve two-digit subtraction tasks using number relations. The teachers and researchers met eight times, whereof six times to plan and analyse the lessons in the intervention. The planning meetings took place at the teachers' school. The teachers had multiple years of teaching experience and had taught their classes from first grade. The intervention group comprised of students from three classes (eight-year-old students) at the same school in a municipality near a larger Swedish city (middle socioeconomic status). The comparison group comprised of seven classes from five schools in similar areas. The participating teachers and the legal guardians of the students in all classes had signed a written consent to participate in the study. In the study video-recorded lessons, student interviews, and written pre- and post-tests were collected as data. All participating students completed the same test as both a pre-test during the first two weeks of the semester and a post-test in the final month. The control group followed standard practices without any researcher-imposed modifications. In this paper we analyse one task (204–12=?) out of fourteen, from the pre- and post-test in more detail to study the learning outcome of the intervention. The task, involving a three- and a two-digit number, was chosen because the intervention focused only on two-digit number tasks. The task allows for multiple ways of using decomposition of numbers while requiring an understanding of place value and the concept of "zero."

The answers to the task were coded by two researchers who first developed a coding scheme, which was then discussed within the research team. Students' solutions were coded according to this scheme, with difficult cases being discussed by the team. The coding included frequencies of correct and incorrect answers, as well as strategies used in the solutions. "No answer" and "No explanation" were also included in the coding scheme. The students were told to calculate the tasks in the pre- and post-test without using the standard written algorithm. The following strategies were identified: single-unit counting, the standard written algorithm for subtraction, decomposition and sequential. If a student had decomposed the minuend and the subtrahend, this was coded *Decomposition* (decomposing both the minuend and subtrahend), and if a student decomposed only the subtrahend,

this was coded *Sequential* (decomposing the subtrahend). The goal of the intervention was to develop a deeper understanding and enable the students to structure numbers using part-whole relations using a Sequential strategy when solving multi-digit subtraction tasks. In this paper we only focus our analysis on two strategies, Decomposition and Sequential.

An intervention based on a structural approach and variation theory

The intervention was based on a structural approach and on the variation theory of learning (Marton, 2015). From a variation theory perspective, to master an object of learning (in this case being able to subtract two-digit numbers) there are critical aspects that students need to discern. Critical aspects can be identified from e.g., a student test, text, interview or during teaching. The critical aspects need be made noticeable for the learners by means of variation, for example by contrast (difference). Insights from previous intervention studies (Björklund et al., 2021; Kullberg et al., 2024b) on addition and subtraction in lower number ranges based on a structural approach and the same theoretical framework was used as a foundation for the intervention in this study, however additional critical aspects were also found during the intervention.

Six lessons were designed in collaboration with teachers in the intervention group and enacted in all participating classes during the same weeks. The first two lessons concerned seeing addition and subtraction tasks as part-whole relations. The triad model was introduced and used to visualize the number relations (whole and parts) when working on tasks creating number sentences. This involved using the same number relation for addition and subtraction while emphasizing the parts and the whole in number sentences. During the task the students were told to circle the whole to see that the placement of the whole shifted in addition and subtraction and in relation to the placement of the equal sign. Lesson 1 focused on single digit numbers (e.g., 7/5/2) whereas in lesson 2 two-digit numbers were used (e.g., 21/18/3). The same critical aspects, e.g., the whole consists of two parts and the whole does not always come after the equal sign, were made possible to experience. The first two lessons and the pre-test showed that the students had difficulties in understanding the meaning of multi-digit numbers, therefore lesson 3 was designed to show the meaning of the positioning system. The teacher discussed and illustrated place values in numbers which were similar and different in place value positions; 222, 202, 226, 27 and 207. However, this lesson was not specifically targeting the object of learning.

The last three lessons particularly targeted the object of learning, solving subtraction tasks with two-digit numbers using number relations. Lesson 4 and 5 focused on the *Sequential* strategy, only partitioning the subtrahend when solving tasks with two-digit numbers. Two ways of subtracting, starting with the ones or the tens, keeping the minuend unaltered (critical aspect), where simultaneously possible to experience. Also, *Decomposition*, decomposing both the minuend and subtrahend which often ended up with an incorrect answer were discussed (e.g., 32–25=?, 30–20=10, 2–5=3, 10+3=13) as a contrast. The different steps taken while solving the subtraction task were also shown simultaneously and on the number line (Figure 1). Special attention was paid to how the ones in the subtrahend can be partitioned to bridge through ten.

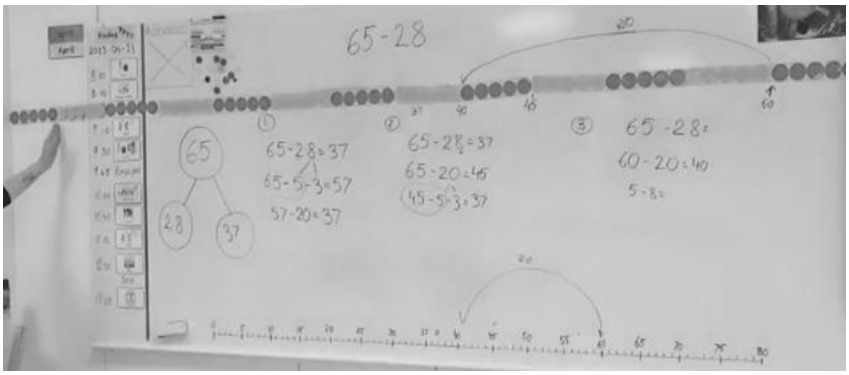

Figure 1: The task 65 –28=? was solved in three ways (1. sequential starting with the ones, 2. sequential starting with the tens, and 3. decomposition of tens and ones)

Thereafter the students worked in pairs with a task where students were to solve several subtraction tasks with two-digits numbers using the two *Sequential* strategies (starting with the ones or starting with the tens) on the same paper. This made it possible for the students to try both strategies for the same task hence to experience a variation in ways of solving. In this way a contrast between starting with the ones or tens were made possible for the students to experience. In lesson 5 and 6 *Subtraction as addition* was introduced as a contrast to the *Sequential* strategy. This was done by contrasting Jonna's and Linus's strategies to solve 35–27=? (Jonna: 35–20=15, 15–5=10, 10–2=8, answer: 8, Linus: 27+3=30, 30+5=35, answer: 8.) The goal was for students to experience the complement principle (a+b=c then c–a=b). Discussion of the different strategies provided an opportunity to experience a contrast between a subtraction task solved as a subtraction or as an addition. Thereafter, the students worked with solving the same subtraction tasks using both strategies. Lesson 6 focused foremost on using the strategy Subtraction as addition for solving subtraction tasks.

Results

First, we present the learning outcomes of the intervention and comparison group on the task 204–12=? on the pre- and post-test and the strategies students display. Following this, we give examples of various ways students applied the sequential strategy. The number of students not providing an answer decreased from the pre- to post-test in both the intervention and comparison group (see Table 1). While the percentage decreased from a higher starting point in the comparison group, from about 28% to 11%, it dropped from about 17% to 6% in the intervention group. It should be noted that there were more students in the comparison group who did not answer the task. In the intervention group the students to a lesser extent answered with no explanation. Although a comparable percentage of students gave no explanation in the pre-tests (intervention group about 17 % correct + about 21% incorrect and comparison group about 19% correct + about 26% incorrect) a more pronounced difference emerged in the post-test. Students in the intervention group providing no explanation while giving correct answers (about 8%) and incorrect answers (about 4%) decreased. In contrast, the comparison group shows a slight increase in correct answers (about 25%) and a decrease in incorrect answers (about 16%). Thus, fewer students in the intervention group responded without showing any form of calculation in the post-test.

Table 1: Student strategies used for solving 204–12=? in percentages (n in parentheses), correct answer in bold, and incorrect answer below correct answer. Note *Other strategies* is not included in the table, which explains the discrepancy in the total number

	Pre-test Intervention group N= 48	Post-test Intervention group N=48	Pre-test Comparison group N=89	Post-test Comparison group N= 89
No answer	16.7 (8)	6.3 (3)	28.1 (25)	11.2 (10)
No explanation	**16.7 (8)** 20.8 (10)	**8.3 (4)** 4.2 (2)	**19.1 (17)** 25.8 (23)	**24.7 (22)** 15.7 (14)
Decomposition- decompose the minuend and subtrahend	**2.1 (1)** 2.1 (1)	**0 (0)** 2.1 (1)	**0 (0)** 1.1 (1)	**2.2 (2)** 3.4 (3)
Sequential - decompose the subtrahend	**27.1 (13)** 2.1 (1)	**64.6 (31)** 8.3 (4)	**18.0 (16)** 1.1 (1)	**24.7 (22)** 5.6 (5)

When students showed their solution (as asked for in the task), we could distinguish that they either decomposed both the minuend and the subtrahend, thus applying decomposition, or kept the minuend preserved and only decomposed the subtrahend. In both groups, only a few students decomposed both the subtrahend and minuend when solving the task in both the pre- and post-test. Far more students solved the subtraction task sequentially. In the pre-tests about 27% of the intervention group did so correctly and about 2% incorrectly, while in the comparison group, 18% solved it correctly and about 1% incorrectly.

A greater portion of the intervention group already displayed a sequential strategy in the pre-test, and more importantly, this difference was amplified in the post-tests. The comparison group increased to about 25% (correct answer) and about 6% (incorrect answer), while the intervention group increased notably to about 65% (correct answer) and about 8% (incorrect answer). In total 73 % (34) of the students in the intervention group solved the task using the sequential strategy in the post-test. Almost half of these students (about 33% (15)) solved the task by decomposing the subtrahend into tens and ones (12 =10+2), while about 42% (19) by decomposing the subtrahend into 8 and 4 (12=8+4). Next, the identified variation within the two sequential strategies from the post-test is illustrated with examples from the intervention group.

Student examples of the sequential strategy - decompose the subtrahend

We identified two different ways of using the sequential strategy in the intervention group. The students who used the sequential strategy all preserved the minuend (204) but decomposed the subtrahend (12) in different ways. The first way was to decompose the subtrahend into tens and ones (Figure 2), either starting with the tens or the ones. This was done either as Student A (Figure 2) subtracting the ones (2) first, or as Student B and C beginning by subtracting the tens (10). Student A solves the task by first calculating 204–2=202 and keeps the minuend unaltered. Next the students calculated 202–10=192. Student B calculates 204–10=194, and thereafter 194–2=192. Student C starts as Student B with the tens and shows the decomposition of 12 with a triad (Figure 2) although

uses the equal sign incorrect in the calculation. During the intervention the students had the possibility to simultaneously experience subtraction starting with the ones or the tens and the critical aspect 'keeping the minuend unaltered'. We infer that this is also shown in their ways of solving.

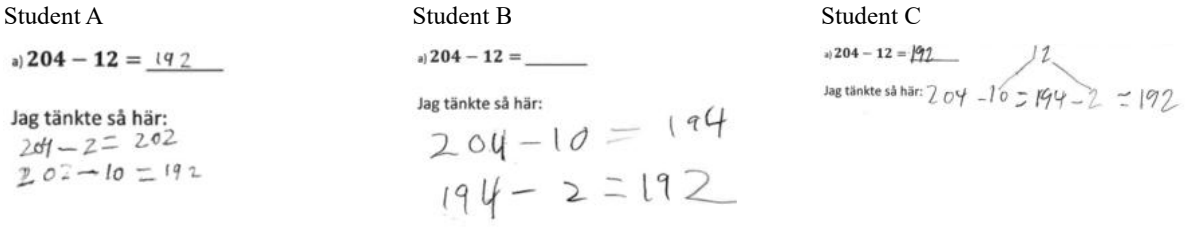

Figure 2: Sequential strategy, decomposing the subtrahend in tens and ones

In the second way of using the sequential strategy, the students decomposed the subtrahend (12) into 4 and 8, 'seeing the four and eight in the twelve', in order to bridge through ten (Figure 3). Hence, these students have likely discerned the critical aspects 'keeping the minuend unaltered', 'ten as a benchmark' and 'parts in the part (12)' brought up during the intervention. Student D calculates the subtraction in two steps, first subtracting 4 to bridge through ten (204–4=200), then subtracts the remaining part (200–8=192). Student E applies the same decomposition strategy, and in addition show the decomposition using a triad (Figure 3) but use the equal sign incorrectly. In contrast, Student F bridges through ten by decomposing 12 in three parts (2, 2, 8). Seemingly Student F decomposes 12 in 2 and 10, thereafter decompose 10 into 2 and 8, subtracting 4 to bridge through ten in the minuend (204–2–2=200).

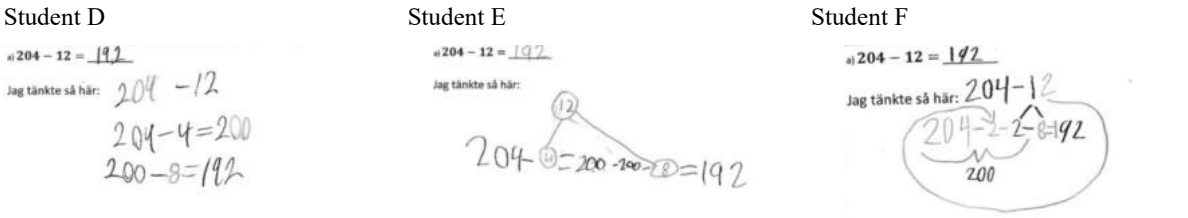

Figure 3: Sequential, decomposing the subtrahend bridging through ten

The post-test revealed that approximately 65% of the students in the intervention group successfully applied the sequential strategy to reach correct answers. However, despite utilizing the same strategy, around 8% (n=4) of the intervention group provided incorrect answers (see Figure 4). These students saw the four and eight in the twelve, indicating that they had discerned the critical aspects 'keeping the minuend unaltered', 'parts in the part (12)'and 'ten as a benchmark'. However, in this case different calculation errors led to incorrect answers.

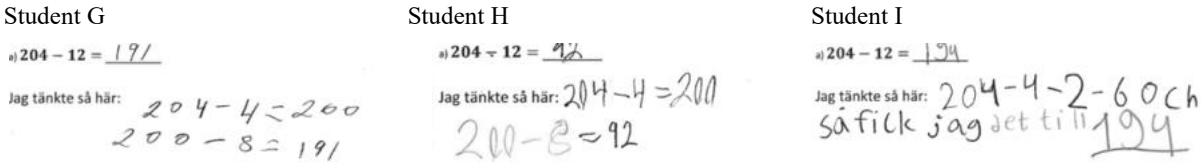

Figure 4: Sequential, seeing the four in the twelve – incorrect answer

Discussion

The results show that the intervention focusing on subtraction with two-digit numbers (65–28=?) had a notable impact on students' adoption of the *Sequential* strategy for solving 204–12=? This was evident in the post-test, where a greater proportion of students in the intervention group employed this strategy compared to the comparison group. Additionally, we found an increase in the frequency in which students provided explanations for their answers. In the post-test, about 88% of students in the intervention group offered explanations, compared to about 60% in the comparison group. This suggests that the intervention not only influenced students' subtraction strategies, but also encouraged greater awareness of their way of solving. By focusing on the structure of part-whole relations when solving two-digit subtraction and having the possibility to experience critical aspects of the object of learning, students in the intervention group most likely developed a deeper understanding for solving the subtraction task with two and three-digit numbers. Our study adds to previous findings (Heinze et al., 2018; Selter, 2001; Torbeyns et al., 2009) by showing how students were influenced differently by the same intervention, hence when solving the same task in another number range they applied sequential strategies in two different ways (Figure 2 and 3). Moreover, Kullberg et al. (2024a) found that how students decomposed numbers when solving 204–193=? reflected the number relations attended to by students in the solving process. Specifically, strategies like 'decomposing the difference' and 'decomposing the subtrahend' led to correct answers, while 'decomposing into digits' and 'decomposing both the minuend and subtrahend' often resulted in incorrect solutions. In our sample few students in both the intervention and comparison group decomposed both the minuend and subtrahend which is a different finding compared to Kullberg et al. (2024a), who found this strategy more common. Our findings suggest that student learning was influenced a great deal by a rather small intervention (only three lessons targeting the subtraction strategies with two-digit numbers). The analysis of 204–12=? contributed to identifying distinct differences between the control and intervention groups in their use of the sequential strategy, as well as revealing variations within the strategy itself. It seems important to continue to analyse several tasks in the pre- and post-tests to determine whether students consistently use the same strategy across different tasks or employ task-specific strategies. Further research is also needed to identify additional critical aspects and explore how these can be effectively implemented in teaching practices.

Improving primary students' understanding of division

Michael Gaidoschik[1], Myriam Burtscher[2] and Heidi Pechlaner[2]

Teaching division in primary school is a challenging task, not least because the distinction between quotative and partitive division is often poorly understood by students. This paper reports initial findings from an ongoing teaching experiment designed to improve students' understanding of both types of division. The approach integrates direct comparisons of quotative and partitive division to improve students' ability to explain and apply these concepts. The paper reports on how children who participated in the first cycle of the teaching experiment interpreted material representations of division. Qualitative interviews show that most children could interpret three groups of four cubes as a representation of a division in both ways, although some showed conceptual and linguistic difficulties that will be addressed in the next cycle for further refinement of the approach.

Keywords: Partitive division, quotative division, mental models, conceptual understanding

Theoretical Background and Empirical Framework

Concerning the teaching of division at primary and secondary school level, a distinction is made between two types of division and two related concepts, namely quotative division (so-called, e.g., by Fischbein et al., 1985; e.g., Neuman, 1999, uses "quotitive division", e.g., Carvalho & Ponte, 2019, "measurement division") on the one hand, and partitive division (or "sharing"; e.g., Fischbein et al., 1985) on the other. In this paper, we will use "quotative" and "partitive division". In a quotative division $a : b = c$, the divisor b stands for the size of one of the equal groups that the dividend a is divided into, and c for the number of equal groups of this given size. In a partitive division, conversely, b is the number of equal groups into which a is divided, and c gives the size of one group.

Neuman (1999, p. 101) notes that "one problem with teaching division to children is whether they experience this difference and, if not, whether one should draw attention to it". Regarding the latter, there are different and even contradictory recommendations in the mathematics education literature. For example, Downton (2013, p. 242) suggests that "students need to understand the concept of division and its inverse relationship to multiplication rather than whether a task involves partitive or quotitive division". In contrast, Wartha and Schulz (2021) advocate working with children towards a clear *conceptual* distinction, which should also include a clear *linguistic* distinction between the two types of division (Wartha & Schulz, 2021, p. 136).

How do children deal with the dual nature of division as either partitive or quotative? Research on what might be called "individual models" (Prediger, 2008, p. 7) of division and their evolution over the years is scarce. However, studies show considerable deficits in the conceptual understanding of division, both in primary school (e.g., Royar, 2013) and beyond (e.g., Ehlert et al., 2013). Research into whether children are more likely to acquire one or the other of the two basic ideas of division is inconclusive. Fischbein et al. (1985, p. 14) conclude from the difficulties of secondary school students

that the "partitive model" is the "intuitive primitive model for division problems" and that quotative division only later, if at all, becomes an available model for thought. Studies with primary school students do not support this assumption, and Neuman's (1999) study suggests that when children are first confronted with division problems, they tend to favour solutions that follow a quotative interpretation even for partitive problems. In Burtscher's (2022) longitudinal study of 12 Austrian children from the middle of the second to the end of the fourth grade, the children showed a clear preference over time for the quotative interpretation when trying to show and explain a given term using manipulatives. However, the same children were more successful in creating word problems when they had chosen a typical partitive situation as the starting point of their story. Overall, Burtscher (2022) observed several difficulties:

- *Difficulties in creating word problems*: Many children were unable to create any kind of appropriate story for a given division term (only 30% of attempts were successful).
- *Interference between partitive and quotative interpretations*: When inventing a word problem, children often switched between ideas of quotative and partitive division, which prevented them from arriving at an appropriate story.
- *Inconsistencies within explanations*: Inconsistencies occurred when children placed the manipulatives according to a quotative interpretation (divisor as the size of one part) but tried to explain what they were doing with a partitive story (divisor as the number of equal parts).
- *Reluctance to recognize both interpretations*: Children often did not accept the alternative interpretation (quotative vs. partitive) as also fitting after they had initially chosen the other one when asked to explain the meaning of a given division term using manipulatives.

The incidents of interference between partitive and quotative thinking reported above must be seen in the context of how division had been taught in the classroom. The teachers had introduced division in the second school year via quotative problems, and later treated partitive tasks as well, but at no time had they explicitly addressed the fact that there are divisions of two different types, nor had they compared them (Burtscher, 2022).

DiVA – a Teaching Experiment

Given the apparent difficulties that many children have with division, the authors aim to develop and evaluate a design for the initial teaching of division that effectively addresses these challenges. Building on the theoretical background and empirical framework summarized above, we propose that the lessons should not only pay equal attention to both types of division – quotative and partitive – but also explicitly highlight their similarities and differences. We hypothesize that this approach will improve students' ability to model real-world problems in general and, more specifically, prepare them for the conceptual shifts required when extending their understanding of division from natural numbers to rational numbers (cf. Fischbein et al., 1985; Prediger, 2008).

To achieve these goals, we launched the design research project DiVA ("**Di**vision als **V**erteilen und **A**ufteilen verstehen" in German, i.e., "understanding division as partitive and quotative" in English) in the spring of 2023. It involves the development and evaluation of a sequence of teaching activities over several weeks with the explicit aim of helping children to develop a solid understanding of division in both ways. The minimum aim was that by the end of the didactic sequence, the children

should be able to demonstrate and explain the meaning of a division term using manipulatives and to invent word problems that fit a given term, in at least one of the two types of division problems (quotative or partitive). The ultimate aim was for children to demonstrate and explain both types of division on their own initiative when asked to explain a given term using manipulatives, to create word problems of both types that fit a given term, and to explain the similarities and differences between divisions of both types in their own words. However, the aim was *not* for students to verbally categorize problems using *technical terms* commonly used in mathematics education literature, or to create problems on demand based on these terms. Table 1 provides an overview of the lesson design, which consists of five phases and spans approximately 20 lessons.

Table 1: Phases of the Teaching Experiment

Phase	Time	Content
Phase 1: Introduction (quotative division)	4 h	Introducing division as a new type of problem, different from the already familiar addition, subtraction, and multiplication, with problems such as "How many packets of six eggs are needed to pack 24 eggs?"
Phase 2: Consolidation and expansion of the basic concept 1	4 h	Division as creating equal portions of a given size in different contexts (forming groups, spending money, measuring in the strict sense, e.g. filling bottles and jugs of a given volume...); emphasize the common aspect: "We divide a given quantity or number, and we know the size of a part or portion or group."
Phase 3: Solving a division problem by skilful computation	2 h	Finding the multiplication problem that is the inverse as a clever solution method for any division problem (2 hours just to develop this idea; from then on, clever calculation was a matter of constant training)
Phase 4: „Fair sharing" (partitive division)	6 h	Introducing a new type of problem: Dividing when number of parts is given, size of a part not; working out similarities and differences with problems dealt with so far; developing a common way of talking about the two types: "dividing when you know how big a part is" vs. "dividing when you know how many parts you have".
Phase 5: Consolidation of both basic concepts	4 h	Solving word problems of both types; inventing word problems of the two different types that fit the same division term; representing and comparing the two types of division using manipulatives and illustrations.

Four classes participated in the first cycle of the project: three from South Tyrol, Italy, and one from Salzburg, Austria, involving a total of 58 children. With the overarching aims described above, a teaching sequence was designed, refined and implemented in five phases over a period of several weeks (Table 1). The teachers who volunteered to participate in the project decided when to work on each phase and covered other mathematical topics in between. Division was not to be introduced until the children had a solid understanding of multiplication. Also, mastery of at least the core multiplication facts (with factors 2, 5, 10) and the ability to derive other single digit multiplication tasks from these core tasks were considered prerequisites for successful work on division (cf.

Gaidoschik, 2014). For this reason, the teacher of two classes decided to elaborate division only in the third grade. Thus, phase 1 began in May 2023 for two classes at the end of their second year and in October 2023 for two other classes, at the start of their third year.

Teachers were provided with detailed plans for each lesson, including content, objectives, materials, and worksheets for tailored tasks, usually starting with a problem for the children to solve independently, alone or in groups. A key design principle was to include whole-class discussions to help children reflect on the problems and verbalize new insights. The planning included detailed instructions on how to conduct these discussions, including how to formulate prompts and how to deal with the heterogeneity of the class. The objectives and tasks were discussed and reflected upon with the teachers repeatedly, and minor changes to the plan were made based on this feedback over the course of the several weeks that the project was running. Students' worksheets were collected, and lesson preparations were documented. The teachers recorded their experiences and impressions in keywords for each lesson.

As a design research project, DiVA combines "instructional design [...] and educational research" (Gravemeijer & Prediger, 2019, p. 34) by implementing the theory-based initial lesson design in several cycles in different classes and testing its feasibility and effectiveness. The second cycle is currently being prepared. As an essential basis for this, qualitative individual interviews were conducted in all four classes after the completion of Phase 5 with all 58 students (all parents gave the necessary consent). Some selected findings from these interviews are reported below.

Research question and methods

From a wider range of research interests explored in the above-mentioned interviews, we report in this paper, due to limited space, exclusively on the following research question (omitting the parts of the interviews on word problems):

> How do children who have participated in phases 1 to 5 of DiVA perform when they are asked to explain the meaning of a division term with reference to a given representation using manipulatives?

We are particularly interested in whether and in what ways the children show awareness of the double nature of division as quotative and partitive, whether there are indications of preferences for one of the two variants, and whether the existence of two possible interpretations causes misunderstanding or problems of any kind.

To answer our research questions, we interviewed the children individually outside the classroom. All interviews followed semi-standardized guidelines and were videotaped, transcribed and subjected to qualitative content analysis. From the many ways of operationalizing "explaining the meaning of a division term using manipulatives", we chose the following: Children were presented with 12 wooden cubes in three separated groups of four and asked whether they could identify one or more *arithmetic* problems in them, and if so, which one(s). Once they had named a *division* term (e.g., 12:4 for a quotative or 12:3 for a partitive interpretation), they were asked to write it down and explain in more detail why and how this term fits the cubes. If they had not already considered both variants in their answer, they were asked after the explanation whether they could recognize another division in

the same representation. If they did not come up with the alternative term themselves, they were presented with it (written on a flash card) and asked whether it also matched the cubes on the table and why or why not.

The analysis criteria were partly deductive. First, we noted whether a child proposed a division term and whether this term matched the representation, then whether it corresponded to a partitive or a quotative interpretation, and whether the child had needed prompting. Inductive categories were created to capture the variety of behaviours, particularly to analyze how children commented on interpretations they had not initially suggested. We grouped children's responses into four categories: one for children who recognized both interpretations as equivalent and were able to justify this convincingly. Another category was used when a child acknowledged both interpretations as fitting, but there were ambiguities in the explanations. A third included trials where the child stated that the alternative interpretation was also correct but then rearranged the material (see below for a more detailed explanation). The fourth category included responses in which the child presented only one interpretation and considered the other to be inappropriate.

Results

As can be seen in Table 2, about 81% of the children were able to interpret the given picture showing equal groups of cubes as (the result of) a division in both aspects, quotative and partitive division. About 17 % of the children were classified as finally accepting only either the partitive or the quotative interpretation. There was only one child who, when interviewed, was unable to give at least one interpretation of the division represented by the cubes.

Table 2: Interpretations given to three groups of four by the participating students (n = 58)

Both partitive and quotative interpretation		Either partitive or quotative interpretation			Neither partitive nor quotative interpretation
47 (≈ 81 %)		10 (≈ 17 %)			1 (≈ 2 %)
Convincing	Ambiguous	Rearrange	Only partitive	Only quotative	
36 (≈ 62 %)	11 (≈ 19 %)	5 (≈ 9 %)	3 (≈ 5 %)	2 (≈ 3 %)	

Of the 47 children who interpreted the cube display as both 12:4, i.e., as a quotative, and 12:3, i.e., as a partitive division, 11 did so spontaneously, while the other 36 did so immediately after being asked whether a second division fits, having spontaneously named one of the two variants. For all 47 children in this group, the interview further explored whether they could explain clearly how the given representation corresponds to 12:4 and 12:3. 36 of the 47 children then provided a convincing explanation for both interpretations. This group of 36 included all eleven children who had previously suggested both division terms as appropriate spontaneously, and 25 others who had first only mentioned one division but added the second one at the interviewer's request, as to whether another term would also fit. An excerpt from the interview with Gabriela (pseudonym), translated from German into English, is included here as an anchor example for what we rated as a "convincing" two-

fold interpretation. Gabriela was one of the children who spontaneously wrote down both 12:4=3 and 12:3=4, when she saw the cube display. She was then asked to explain what she had written:

Gabriela	[referring to her first interpretation of the cube display as 12:4=3]: Well, you could see that the first package has four cubes [points to a group of four], and then how many packages there are, and there are three packages, and then three times four equals 12. [...]
Interviewer:	And what does the 3 tell us?
Gabriela:	The 3 tells us how many packages there are.
Interviewer:	And for this calculation [points at Gabriela's writing 12:3=4], can you briefly explain how you see the different numbers and what they tell you?
Gabriela:	Well, the 12 is again the total, the 3 means how many equal groups you make, and the 4 means how many cubes are in each group.

In 11 other cases, children who had first given one interpretation and on request also the other, gave justifications that were considered as ambiguous. An anchor example of this is provided by the interview with Damian, who first interpreted the cube representation as 12:4=3 on his own. The following conversation developed:

Damian:	You do this if there are 12 sweets and then three children come, let's say. And they always take the same number of sweets. And then you divide them up into equal numbers, I mean, packages. That's, just how big the group is.
Interviewer:	Okay, and where do you see the 12?
Damian:	When I put them all together.
Interviewer:	And the 4? What does the 4 say?
Damian:	It says how many groups there are, just, how big the group is.
Interviewer:	And what does the 3 say?
Damian:	How many groups there are.
Interviewer:	Do you see another division problem here?
Damian:	Yes, 12:3=4. There are 12 sweets again, then three children come, and they want the same number and then you divide everything fairly into the same number of groups.
Interviewer:	And what does the 3 tell us?
Damian:	How big?
Interviewer:	How big?
Damian:	No, how many.
Interviewer:	And the 4 there?
Damian:	The 4 tells you how big the group is.

Damian starts his explanation with 3 children sharing 12 sweets, which does not fit with his previously written 12:4=3. However, he goes on with "equal numbers" and "how big a group is," which corresponds to a quotative interpretation and therefore is consistent with 12:4=3. He then explains the 4 in 12:4 as "it says how many groups there are", which again points at a partitive interpretation. He immediately rephrases this as "how big a group is." Later, when he tries to explain 12:3=4 as a second appropriate interpretation of the cube display, he first suggests, in a questioning voice, "how big?" as the meaning of the 3 and then switches to "how many" when the interviewer repeats his answer. At this point, the interviewer is suggestive and does not ask enough follow-up questions, but Damian at least shows uncertainty throughout the interview about the assignment of "size of a portion" and "number of equally sized portions" to the numbers of a division term in both variants.

Ten children were assigned to the "either partitive or quotative interpretation" category. Notably, however, five of them initially said that both 12:3 and 12:4 fit the cube-display. However, when asked

to explain how the alternative term also fitted, these five students rearranged the cubes into four sets of three, which they then interpreted corresponding to the either partitive or quotative understanding they had initially demonstrated in explaining the three sets of four.

Discussion

Compared to the children who were given similar tasks by Burtscher (2022) without being specifically taught to differentiate and compare partitive and quotative division problems, the children interviewed for this study showed an overall high level of awareness of the two types of division. Thirty-six out of 58 (about 62%) not only accepted 12:3 and 12:4 as equally fitting interpretations of four groups of 12 cubes but also explained each interpretation in a clear way that demonstrated a sound conceptual understanding. The difficulty that other children had in verbally justifying how the two different terms fit equally with the same representation reflects the significant conceptual and linguistic challenge that DiVA deliberately presents to children. Distinguishing between "four groups" and "groups of four", between "portion size" and "number of portions" is also difficult for adults. Eleven of the 58 children indicated that they were aware of the two possible interpretations but showed uncertainty in explaining them. Ten other children recognized only one division term as fitting. However, at least five of them gave clear indications that they had learned in class that two interpretations were possible. For themselves, however, they seem to have understood this to mean that the same set must be rearranged in two different ways to fit either one or the other term.

This misunderstanding will be addressed directly in a second cycle. Overall, however, we are encouraged by the results. All children, with one exception, were able to make a connection between a division term and a material representation; the vast majority considered both the partitive and the quotative interpretation. This contrasts sharply with the widespread fundamental deficits in the conceptual understanding of division reported on in studies such as those by Royar (2013) or Ehlert et al. (2013).

We will use the second cycle to further refine the design (especially the weighting of individual elements and the provision of clearer guidance for teachers) and, at the research level, to address the methodological weaknesses of this study, especially in the conduct of interviews (standardize the handling of prompts, establish clear criteria for ending interviews to ensure comparability), to strengthen both qualitative and quantitative statements. However, we can already say that, contrary to what some authors suggest for this age group, the children were generally not overwhelmed by the task of recognizing and verbalizing the differences and similarities between the two types of division. The one child who was unable to interpret the cube representation as a division at all – either partitive or quotative – struggled with significant language barriers due to being a migrant child. We are aware that DiVA places high linguistic and cognitive demands on both the children and the teachers who implement the concept in the classroom, but it seems worth the effort. Of course, further research is needed in the form of longitudinal studies to determine whether the DiVA approach also works in the long term when children will be requested to understand and apply division with rational numbers. We assume that the conceptual change (Fischbein et al. 1985; Prediger, 2008) required for this is more likely to succeed if it can be based on sustainable concepts in the field of natural numbers.

Number sense towards real numbers

Virginia Garrido-Adame[1], Olimpia Figueras[1] and Minerva Martínez-Ortega[2]

[1]Centre of Research and Advanced Studies (Cinvestav), Mexico; virginia.garrido@cinvestav.mx

[2]Centre of Industrial and Services Technological Studies (CETIS), Mexico

Number sense in basic education has been studied for over three decades. The numbers involved in these investigations are predominantly natural, integer, and rational. However, students aged 15 to 18 use real numbers, and it is most beneficial to develop their number sense regarding these numbers. This paper presents an adaptation of the Broken Keys activity, which aims is to compose and decompose irrational numbers. Data analysis made it possible to identify which abilities related to number sense about real numbers high school students used to solve the proposed tasks.

Keywords: Number sense, Real numbers, Secondary education.

Introduction

Researchers such as Andrews & Sayers (2015), Anghileri (2007), and Yang & Huang (2004) have recognized the importance of developing elementary school students' number sense. At this educational level, the numbers most commonly used are natural, integer, and rational. However, simply calculating the n-th root of a natural number could make students jump to irrational numbers and thus enter the domain of real numbers. Students aged 15 to 18 face these leaps, some merely stand by as spectators because their previous reflections and analyses may have focused solely on rational numbers. Therefore, it is necessary to extend the development of number sense to include real numbers so that students strengthen their flexible thinking and can recognize the properties, similarities, and differences of these mathematical objects and used them properly.

Considering this background, a research project was conducted with the aim of strengthening and developing pre-university students' number sense related to real numbers. In this paper, results obtained to answer the question: What skills related to the number sense of real numbers do students use to solve the tasks proposed in the "Broken Keys" activity? are described. This activity, which is described later, is part of the aforementioned study.

Conceptual framework

Number sense has been the subject of study of several researchers (e. g. Greeno, 1991; Mcintosh et al., 1992; Löwenhielm et al., 2017), whose goal was to define it, characterize it, recognize its elements, or analyse tasks related to this construct. These studies involved natural, integer, and rational numbers. In the Broken Keys activity, in addition to the number systems mentioned above, irrational numbers are included, so it is more convenient to adopt the characterization of number sense related to real numbers described in Garrido-Adame et al. (2022), where it is considered that "number sense is the set of knowledge and abilities regarding real numbers that a person uses to make mathematical judgments and develop numerical strategies when solving problems involving these numbers" (p. 46).

Knowledge of real numbers is related to their properties, as well as the characteristics of the domains they contain: natural, integer, rational, and irrational numbers. These have been considered according to the characterizations made by mathematicians (e.g. Spivak, 1967).

The abilities are related to the use of real numbers and are in Figure 1. These can be used as indicators to observe the use of number sense by students. The first ten abilities are based on behaviours that demonstrate the presence of number sense, as suggested by Sowder (1992). Abilities 11, 12, 13, and 14 were proposed based on observations made during teaching practice. Ability 15 was proposed by Resnick (1989).

Number	Abilities
1	Ability to compose, decompose and recompose numbers
2	Ability to identify which representation of a number is more convenient than another
3	Ability to compare numbers
4	Ability to order numbers
5	Ability to deal with the order of magnitude of a number in concrete situations
6	Ability to use reference points
7	Ability to link symbols of operations and relationships in a meaningful way
8	Ability to recognize the effects of operations
9	Ability to do mental calculations using own strategies
10	Ability to make estimates
11	Ability to associate numbers with the context in which they appear
12	Ability to locate numbers on the number line
13	Ability to recognize given facts
14	Ability to distinguish differences and similarities between number systems
15	Ability to self-regulate

Figure 1: Abilities related to number sense about real numbers

Methods

The methodology used for this qualitative study is known as design research. The design of this research consists of two cycles (see Figure 2) with its three phases (design, experimentation and retrospective analysis). Based on the retrospective analysis of the first cycle new activities were proposed and others were redesigned. In this paper we expose results regarding students' performance in the Broken Keys activity of the second experimental cycle (in grey in Figure 2).

Design Phase. The Broken Keys activity is based on tasks related to number sense proposed to primary school students (Pacio-Quiterio & Juárez, 2024), where it is assumed that some keys on the calculator do not work, so the children must write the numbers of the indicated operations in another way. To answer the questions, the use of calculator was allowed because it is thought that this device can be used as a learning tool to develop number sense (Figueras et al., 2021). The main changes were the numbers proposed, and the type of calculator used. In the first cycle basic calculators were used, and in the second cycle ones that had keys for entering the square and cube roots of a number, as well as fractions and π were used. The operations proposed in the first cycle were with natural and integers numbers. The second cycle's questions can be seen in Figure 3.

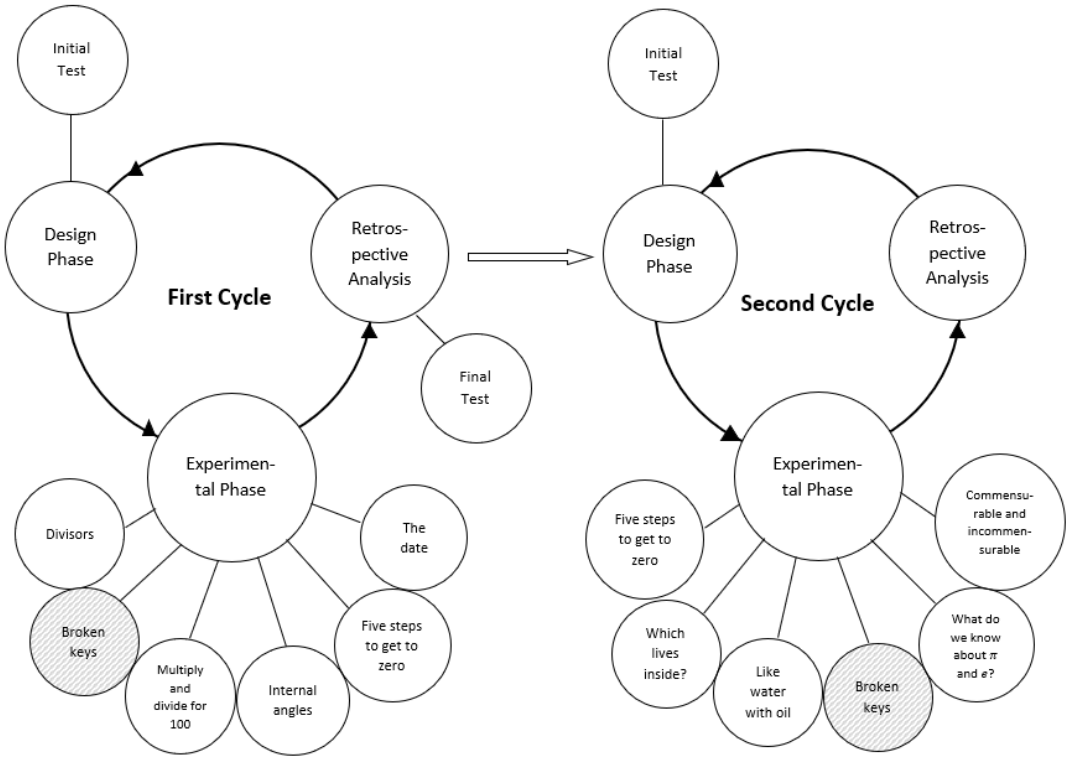

Figure 2: Design experiment cycles

The goal of the activity is to compose and decompose irrational numbers additively and multiplicatively. Students were asked not to use approximations in order to prioritize the use of mathematical symbols for irrational numbers. The activity focuses on irrational numbers, however, it is important to note that an efficient use of the natural numbers (included in the radicands) is required, as well as knowledge about integers in the case of Final Reflections (see the third column of Figure 3). The square root of a negative number is included, with the intention to discuss the existence of different numbers from real numbers.

Initial Reflections	Problem Statement	Final Reflections
How else can you write $\sqrt{20}$? What is the result of $\sqrt{24}+\sqrt{12}$? What is the result of $\sqrt{8}+\sqrt{32}$? What is equal to $\sqrt{50}+\sqrt{30}$? How else can you write $(\sqrt{12})(\sqrt{3})$?	$\sqrt{18}+\sqrt{28}$, broken key [8] $5\sqrt{39}-\sqrt{13}$, broken key [9] $\sqrt{7}+\sqrt{8}$, broken key [$\sqrt{\square}$] $\sqrt{10}-\sqrt{11}$, broken keys [$\sqrt{\square}$] , [$\frac{\square}{\square}$] and [.] $9\pi-\pi$, broken key [π]	How else can you write $\sqrt[3]{54}$? What is equal to $\sqrt{-25}+\sqrt{40}$?

Figure 3: Questions posed in the Broken Keys activity

Experimentation Phase. An initial selection of eight students aged 15 to 16 years was made, according to the results of an initial test on number sense they showed more structured performances regarding the use of numbers. Four additional students of the same age were also considered. Although their

performances did not have the same characteristics as those in the initial choice, they expressed interest in participating in the project, so they were included in the study's sample. This latter group of students was in no way considered a control group; their role was the same as that of the other eight. Therefore, data collection was carried out with a total of twelve students, divided into three teams of four: two from the initial selection, named A and B, and the group of the students who requested to participate, it was named C.

This phase took place during an inter-semester period. The activity was developed in three stages. First, all twelve students were gathered to establish rules such as: do not use approximations or erase their different attempts, record their discussions, and calculators can be used. In the second stage, each team moved to a space where they could discuss and record how to answer the questions in each section, as well as write their answers on a worksheet. In the third stage, they shared their answers with the other teams. Data were collected through answers in the worksheets and the video recordings of the discussions that arose among the team members while answering the worksheets. Additionally, there are videos of semi-structured interviews conducted with each team the day after the activity, aimed at clarifying or complementing any of the written responses.

1. Decompose the radicands (natural numbers)
   1.1. multiplicatively
   1.2. additively
2. Use properties of the square root operation with respect to:
   2.1. Multiplication
   2.2. Addition
   2.3. Addition and multiplication (distributive property)
3. Recognize the square root of perfect squares
4. Write at least one decomposition of an irrational number:
   4.1. Multiplicative
   4.2. Additive
   4.3. Combined
5. Decompositions of irrational numbers involve a natural number multiplied by an irrational number
6. Write an irreducible expression for the indicated irrational number

Figure 4. Code used to analyse the data in the Initial Reflections section

Retrospective Analysis Phase. First, the images of the responses to each question were grouped by section. There were 15 responses for Initial Reflections, 15 for Statement, and 6 for Final Reflections. A description for the strategy used by each team for each question was stated. When the writing on the worksheets was unclear or there was no trace of the procedure the students followed, the information was supplemented by reviewing videos of the peer discussions. Descriptions by the three researchers were triangulated. When the fifth part of these specifications was completed, it was possible to inductively construct a scheme of codes. Codes were interrelated to the abilities in Figure 1. For example, the codes shown in Figure 4 are associated with the ability to compose and decompose numbers. With the schemes of codes, it was possible to classify the students' responses into categories and thus select the images presented in the Findings section.

Findings

This section presents representative examples of the use of the abilities of Figure 1, since putting them into practice encourages their development.

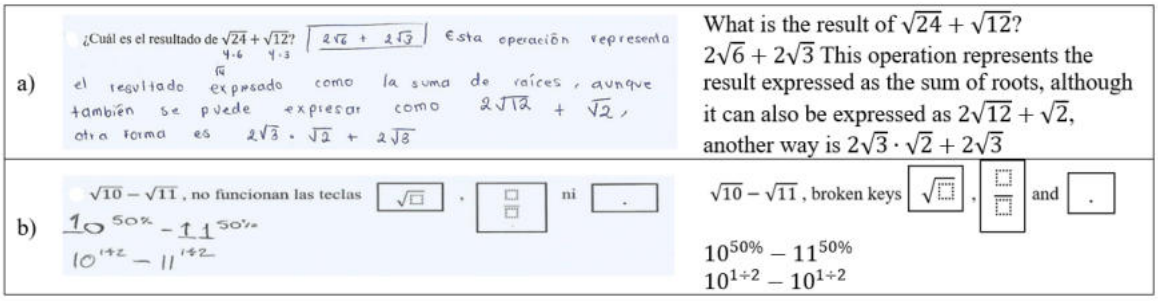

Figure 5: Evidence of the use of ability 1 and 2

Team B used the *Ability to compose, decompose, and recompose number,* with natural and irrational numbers; unfortunately, they were wrong about the decomposition $2\sqrt{12}+\sqrt{2}$. On the other hand, Team A related percentages to fractions (Figure 5b), which is not common, but since the calculator allowed them to perform that operation, they proposed it as their answer. Therefore, it can be stated that they used the *Ability to identify which representation of a number is more convenient than another*.

A behaviour related to the *Ability to recognize the effects of operations* can be observed in Team A's response, as they recognized that to write 5 inside the square root, it was necessary to enter it as 25. Additionally, they noticed that multiplying and dividing by π did not alter the given number. This fact is linked to the knowledge of the multiplicative identity, and even the $1=\frac{\pi}{\pi}$ proposed, also involves knowledge of the reciprocal of a number (see Figure 6). In the team discussion video, it was possible to hear that the students decided to include the number π because "they missed it", and they recalled that irrational numbers were not only square roots.

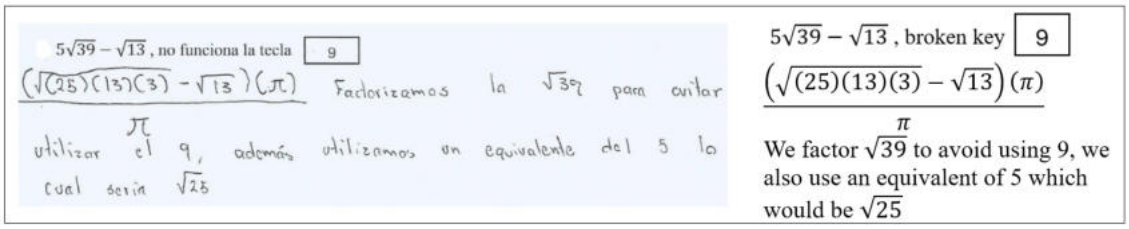

Figure 6: Use of ability 8

The *Ability to link symbols of operations and relationships in a meaningful way* was used by the students in Team B. They first answered that with no other key could they calculate the square root of a number (see Figure 6). However, in the same figure, it can also be seen that in another question, they proposed a way to link the symbols with the square root. Since the origin of this change could not be identified in the team discussion video, the students were asked about it in the interview the following day. They replied that they had made a query to Meta AI (Meta's AI-powered assistant, which can be used via the WhatsApp app in some Latin American countries) during an intermediate time before starting the second discussion. Their query was about the first question. Since in the operation $\sqrt{10}+\sqrt{11}$ there were more restrictions regarding the keys that were not working, the

participants made a combination between the answer provided by Meta AI and their own, verifying with their calculator that linking symbols of operations and relationships involved was correct.

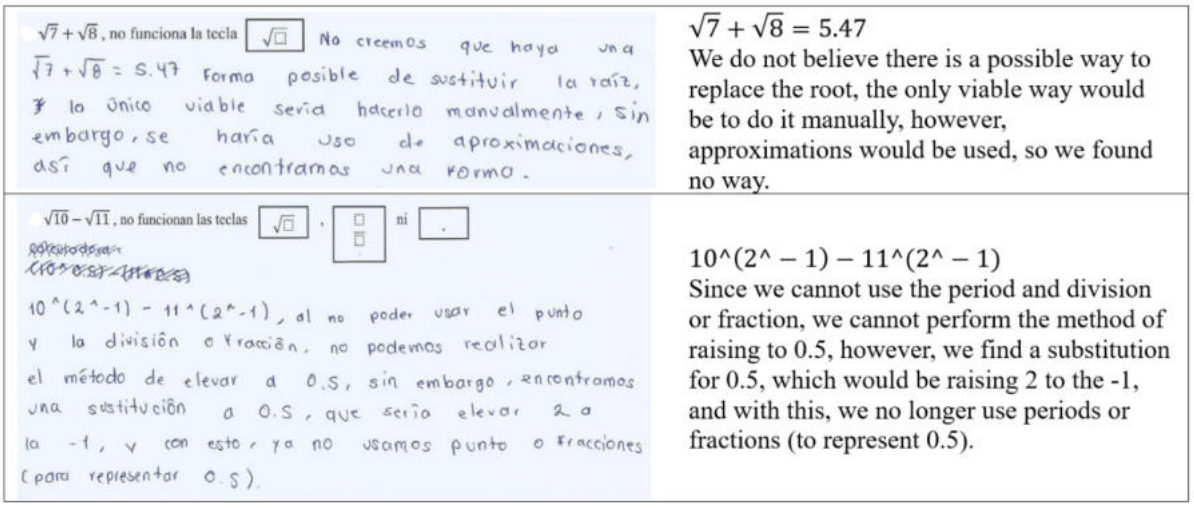

Figure 7: Use of ability 7 to interpret a response from Meta AI

A behaviour associated with the *Ability to use reference points* can be seen in Figure 8. Team C considered π as 3.1416, however, they forgot the instruction not to use approximations. The members of Team A used π as a reference point, understanding it as an irrational number, and they couldn't find a key that would substitute for this number. In the video of their discussion to answer the question, the students argue that π is a different number, that it does not involve any operation like the numbers in the previous questions, and that this is a reason they could not write it in another way. Although Team A knows that π is the ratio of the circumference's length to its diameter, they could not explain why they couldn't use another key on the calculator. In fact, they commented that they wouldn't know if the change would be correct, as they do not know all the decimal digits of π, recognizing that this number has an infinite number of non-repeating decimal digits. The statements that can be made based on these observations will be discussed in the next section of this paper.

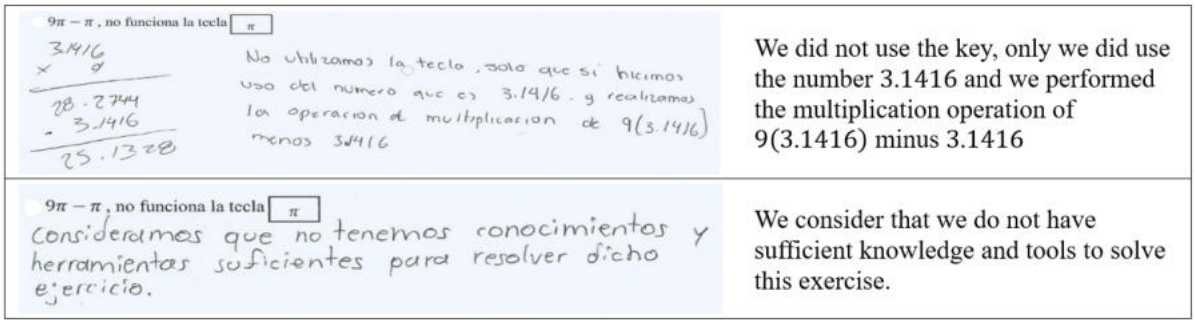

Figure 8: Use of reference points

Discussion and conclusions

In the Broken Keys activity, most of the real numbers used arose from calculating the square root of natural numbers. However, real numbers are very diverse; there are algebraic and transcendental numbers, facts that may go unnoticed if the development of number sense regarding these numbers

is not promoted. A clear example is how the students in Team C converted π into the rational number 3.1416, showing that their number sense remains within this domain.

Therefore, it is necessary to reflect on and analyse with students the properties of real numbers, their different representations, and operations, and not just teach the specific mathematical knowledge of the corresponding subject (for more arguments see Moutinho & Zazkis, 2019). Usually, teachers assume that students can use real numbers fluently, but the reality is that, in the best case, their developed number sense is based on natural, integer, or rational numbers.

Data analysis allowed to answer the posed question: What are the abilities related to number sense of real numbers that students use to solve the tasks proposed in the Broken Keys activity? Referring to the conceptual framework, visualized in Figure 1, those abilities are (1) ability to compose, decompose and recompose numbers, (2) ability to identify which representation of a number is more convenient than another, (6) ability to use reference points, (7) ability to link symbols of operations and relationships in a meaningful way, and finally, (8) ability to recognize the effects of operations. These five abilities revealed during data analysis, and therefore, were evident in the data. However, the use of other abilities, such as (14) ability to distinguish differences and similarities between number systems, should not be ruled out, as students were attentive to the type of numbers they were using in order to decide which operations could be performed and which could not.

There are studies that include activities to promote the development of number sense (Lyublinskaya, 2009; Reys, 1994; Scheiner & Thompson, 2000) which can be adapted or extended to real numbers. The design of the Broken Keys activity in the second experimentation cycle demonstrates that it is possible to adapt or design different activities to promote the development of abilities related to number sense about real numbers. Likewise, activities can be proposed with the intention of reflecting on knowledge associated with these numbers.

Calculators and artificial intelligence are potential tools for promoting the development of number sense, as seen in Figure 7, students made a query to Meta AI and from this they were able to answer three more questions using mainly the Ability to link symbols of operations and relationships in a meaningful way. The use of these resources could be explored in depth because students are already using artificial intelligence tools.

Mastering the basic facts of multiplication and division till the end of grade 3–selected results of a longitudinal study

Sandra Gleißberg[1], Klaus-Peter Eichler[1,2] and Moritz Seibold[1]

[1]University of Education Schwäbisch Gmünd, Germany; sandra.gleissberg@ph-gmuend.de

[2]NORD University, Faculty of Education and Arts, Bodø, Norway

We present the results of a longitudinal study regarding mastery of the basic multiplication and division tasks in Baden-Wuerttemberg, Germany. We used the same speed test at the end of grade 2, at the beginning of grade 3, and at the end of grade 3 in 39 classes in 18 Schools. A total of 535 students who were present at all three measurement points were included in the evaluation. We present and discuss the development of mastery of the basic tasks. It must be emphasised that, despite the many positive developments at the end of grade 3, only 223 out of 535 students met the requirements for mastery of the basic tasks, while 145 students were at the lowest level. Possible reasons and possible directions for further development are discussed.

Keywords: Elementary school mathematics, multiplication, division, basic multiplication facts.

Context of the study and research questions

Multiplication and division are part of the core content of mathematics in the primary school curricula worldwide. The learning objectives for these operations include, firstly, that students have a conceptual understanding of multiplication and division; secondly, that they should be able to determine the value of any product and quotient using various strategies; and finally, that they should know from memory all basic facts of multiplication and derive the basic facts of division[1] at skill level (e.g., Kling & Bay-Williams, 2015; CCSSO & NGA, 2017; KMK, 2022).

Retrieving basic facts from memory is a tool for solving more complex tasks like 27 × 6, shortening fractions, or computing simple percentages mentally. Wong and Evans (2007, p. 91) state, "Many tasks across all domains of mathematics and across many subject areas call upon the recall of basic multiplication facts as a lower-order component of the overall task." Also, memorised facts are essential prerequisites for developing advanced mathematical skills such as problem-solving (Burns et al., 2016). Recalling facts reduces cognitive load (Sweller, 2016) and allows students to concentrate on solving complex tasks. Those who cannot retrieve the basic equations are significantly disadvantaged compared to more practised classmates. If the basic equations are not acquired in primary school, it is unlikely that these deficits will be compensated in secondary school (Steel & Funnell, 2001). Consequently, the Common Core State Standards for Mathematics (CCSSO & NGA, 2017, p. 23) demand: "By the end of Grade 3, know from memory all products of two one-digit numbers". Nevertheless, the meaning of the equations must be understood as Gaidoschik et al. (2017,

[1] Basic fact (also called "basic equation") of multiplication means in this paper an equation of multiplication in which both factors are less than ten or equal to 10. Basic fact (also called basic equation) of division means an equation of division in $\mathbb{N}$ in which the divisor and the quotient are both less than 10 or equal to 10.

p. 2) emphasise: “There seems to be an international consensus nowadays that students should both acquire a sound conceptual understanding of multiplication and eventually solve all basic tasks accurately and effortlessly.”

The crucial starting point for discussing the conceptual understanding of operations is that terms like 3×4 or $12 : 4$ are non-verbal, symbolic representations of concepts, and concepts are mental reflections that describe classes of situations that occur in reality. Conceptual understanding enables students, e.g., to solve word problems. It also allows students to solve every multiplication task, especially those with factors larger than 10, using manipulatives, skip counting, or deriving answers using reasoning strategies based on known facts (Baroody, 2006; Kling & Bay-Williams, 2015).

The work on multiplication and division begins in Germany, usually in the second half of grade 2. Students learn to describe real-life contexts with products and quotients and determine the values of any products and quotients. In doing so, they discover that new tasks can be solved using previously learned ones as an essential method in mathematics. In grade 2, but especially in grade 3, the focus is on memorising the basic multiplication equations. Ideally, students should be able to retrieve the basic multiplication facts from memory in the middle of grade 3. Also, students should be able to solve basic division tasks at a skill level by applying basic multiplication facts.

However, three problems occur again and again up to the secondary school level: *First*, there are deficits in the mastery of basic facts, i.e., in their retrieval from memory. These can be seen, for example, when they cannot reduce fractions like $\frac{48}{56}$ in secondary school, because they cannot identify common factors. *Second*, while students can often reproduce the basic equations from memory, they cannot solve multiplication tasks with a factor greater than 10. *Third*, we repeatedly observe difficulties with the conceptual understanding of multiplication and division: Students know that $6 \times 3 = 18$ but struggle to justify this because they lack the term’s meaning. Often, they argue that 6×3 is a short notation for $3 + 3 + 3 + 3 + 3 + 3$. Similarly, students see division equations often as nothing more than multiplication equations written in reverse: They can only explain the value of quotients such as $24 : 6$ by referring to the inverse equation $4 \times 6 = 24$, but not to real-life contexts.

Considering these facts, we concentrate in this paper on how far students from the end of grade 2 until the end of grade 3 can retrieve the basic multiplication facts from memory and solve the basic division tasks at a skill level. Consequently, we discuss the following research questions:

RQ1: To what extent have students memorised the basic multiplication equations at the end of grade 3, and to what extent can they apply this knowledge at a skill level to solve basic division tasks?

RQ2: How does the level of memorised basic equations and the level of solving division tasks change over one year from the end of grade 2 to the end of grade 3?

Method

To answer these questions, we conducted speed tests with the same basic multiplication and division tasks at three crucial measurement points (MP) in 18 schools with 39 classes in a larger region of Baden-Württemberg. The selected schools included both rural and urban settings with diverse sociocultural backgrounds. The mathematics curricula of the federal states of Germany are

comparable in terms of work on multiplication and division, particularly after the establishment of the educational standards by the KMK in 2004. The same applies to the textbooks used in class, although these are published by different publishers (Gleißberg & Eichler, 2019). It can, therefore, be assumed that our findings, according to the schools and classes, are representative of a larger scale.

A total of 535 students participated in all three measurement points. We assume that excluding students randomly absent due to illness or change of residence did not affect the sample's representativeness. We assessed how far students can retrieve the basic facts from memory at these three MPs. As MP1, we chose the end of the second school year. Following the educational plans for mathematics lessons in the federal states of Germany, we can expect that students understand the concepts "product" and "quotient", can determine the values of products and quotients, and have memorised many basic equations. As MP2, we chose the first weeks of the third school year. We determined the extent to which the students remembered the basic facts learned in grade 2 after the summer vacation. Completing the test in all 18 schools in one week was impossible. Therefore, in some classes, content from grade 2, particularly the basic tasks, may have been repeated in the days before the test. At the end of grade 3, designated as MP3, we assessed how well students mastered the basic facts after one and a half years of dealing with multiplication and division.

In the speed test, the students had to solve 15 multiplication and 15 division tasks in 3 minutes, given as terms on a worksheet (see Figure 1). So, the average time for solving a single task was 6 seconds. We used only 30 tasks in the test to minimise the effect of decreasing concentration. The limited time is crucial because, in just 3 minutes, it is impossible to compute many results. Students can solve only one or two tasks by computing in this short time. The results of the speed tests show to what extent students can retrieve basic multiplication facts from memory and apply at skill level relationships between multiplication and division, as well as properties of multiplication like the commutativity.

We included multiplication tasks with factors 0 or 1, division tasks with dividend 0, and division tasks with divisor 1. These tasks are often solved incorrectly because it is not trivial to build mental images and an understanding of the meaning of terms such as 3×0, 0×6, $0 : 9$, and $5 : 1$ (Van de Walle et al., 2019; Levenson et al., 2004).

About the matter: Mastering multiplication and division basic facts

Mastering the basic facts of multiplication must be distinguished from fluent computing: Fluently computing means determining a term's value by using strategies and properties of the operation and computing at skill-level (Kling & Bay-Williams, 2015). Mastering the basic tasks of multiplication means the ability to retrieve from memory their values. Mastering the basic tasks of division means

that the result is derived directly and without calculating from the corresponding basic multiplication equation. This means that the relevant number triple is available as a semantic network and can be flexibly retrieved as an equation for multiplication or an equation for division.

Mastering is indispensable by the middle of grade 3 at the latest because this knowledge is needed to solve other tasks. In line with Bülow (1985), we use 4 Acquisition Levels (AL) determined according to the number of correct solutions in the test. These levels apply to the present work:

Acquisition Level I (AL I) means the student solves at least 27 of the 30 tasks correctly (90% or more). The basic multiplication tasks are mainly solved by reproduction, and the basic division tasks are solved by reproduction or applying a basic multiplication equation at the skill level.

Acquisition Level II (AL II) means the student correctly solves at least 24 of the 30 tasks (80% or more). At acquisition level II, most tasks can be solved by reproducing or applying basic multiplication equations at the skill level. Only a few tasks are solved by computing.

Acquisition Level III (AL III) means the student correctly solves at least 18 of the 30 tasks (60% or more). At acquisition level III, there are many incorrect solutions. There is also an increased time requirement because the student calculates and cannot perform these calculations at the skill level.

Acquisition Level IV (AL IV) means the student solves fewer than 18 of the 30 tasks correctly (less than 60%). Many incorrect solutions or unfinished tasks characterise acquisition level IV. The solution procedures cannot be used confidently by the student, or are not available as solution procedures. This results in a high time consumption.

Findings

Figure 2 shows the results of a few of the 39 classes. The significant differences from class to class and from school to school are remarkable. In addition, there are substantial variations in the results in the classes, even at the end of grade 3.

School	Class	n	MP1			MP2			MP3		
			Mean	SD	Mdn	Mean	SD	Mdn	Mean	SD	Mdn
4	1	8	25.62	4.98	27.0	24.25	6.39	26.0	28.75	3.15	30.0
7	1	20	14.70	6.89	14.0	14.40	8.62	11.0	16.25	7.43	15.5
7	2	15	17.13	9.79	16.0	19.80	6.90	21.0	23.47	5.99	22.0
7	3	16	16.88	6.23	15.0	20.56	6.47	20.5	17.12	6.25	15.5
7	4	21	18.67	6.05	20.0	13.71	6.31	12.0	20.90	7.22	23.0
9	1	13	16.54	7.59	13.0	20.31	5.99	20.0	18.38	6.81	16.0
9	2	9	20.33	9.95	25.0	19.33	8.65	16.0	23.00	7.42	26.0
17	2	17	21.82	8.46	24.0	20.18	7.61	20.0	26.00	6.78	29.0
17	3	13	25.31	5.96	26.0	17.85	8.77	17.0	24.15	7.55	27.0
18	1	14	23.57	6.78	27.0	19.71	5.97	18.0	26.64	4.65	28.5
18	2	15	14.67	5.22	15.0	14.53	6.31	14.0	19.53	5.28	18.0

Figure 2: Performance of a few of the 39 classes across the three MPs: Mean, SD, and Mdn

AL I (27 or more correctly solved tasks) represents the learning objective at the end of grade 3. However, based on the mean, only one of the 39 classes achieved this goal. Even if considering the median, which is more stable and robust against outliers, only four classes, e.g., 41, 172, and 181, achieved AL I. At the same time, both the mean values and the medians of classes 71, 73, and 91 are at AL IV. In these classes, most students are far from achieving the learning objective. The differences between schools and different classes within the same school are remarkable, for example, the classes 73 and 74, or the classes 181 and 182.

Figure 3 displays the Average Score (AS) trajectory as the mean of the points achieved by all 535 students. Over the three measurement points (MP), the AS of all students in the test follows an expected path. Before the summer vacation (MP1), the AS was slightly higher (M=18.5, SD=7.57) than at the beginning of the third school year (M=18.3, SD=7.43). At the end of the third year (MP3), the AS was (M=22.4, SD=7.01), which reflects the positive effect of continued learning during the school year. However, it should be noted that the goal, according to the standards, is the red line.

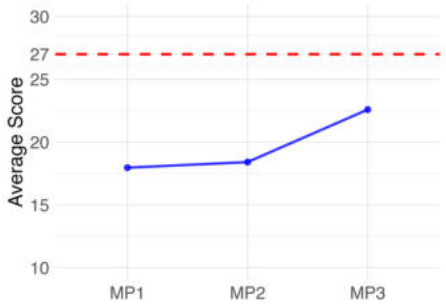

Figure 3: Mean performance of all students across the three MPs

The Sankey diagram (Figure 4) illustrates the flow of students between the four different acquisition levels across the three measurement points.

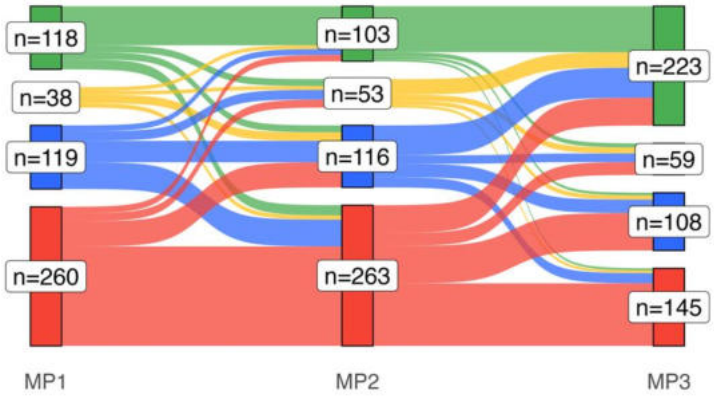

Figure 4: The flow of students across the three measurement points

The coloured bands represent summarising groups of students with the same performance development and their transitions. The width of the bands reflects the number of students in the same category transitioning together from one level to another. The different colours correspond to the

different acquisition levels at the beginning of each of the two intervals: Green represents AL I, yellow is for AL II, blue is for AL III, and red is for AL IV.

The Sankey diagram shows that at the end of grade 3, only 223 students (41,7 %) meet the curriculum requirement. Among these, 69 students (12,9%) are at AL I across all three MP. In addition, there are 145 students (27,1%) who, even after one and a half years of working with multiplication and division, only achieve the lowest acquisition level, AL IV. 103 of the 535 students (19,3%) are at the lowest level across all three measurement points.

Figure 5 shows the performance trajectories of all classes across the three MPs to reveal class-specific dynamics. We found three categories of trajectories of the average scores (AS):

- *Category A*: AS(MP1) < AS(MP2) < AS(MP3) Performance has steadily improved over time
- *Category B*: AS(MP1) > AS(MP2) ∧ AS(MP2) < AS(MP3) Performance dropped after summer vacation (MP2) and improved during grade 3 (MP3)
- *Category C*: AS(MP1) < AS(MP2) ∧ AS(MP2) > AS(MP3) Improvement of the performance after the summer vacation (MP2), followed by a decline during the school year.

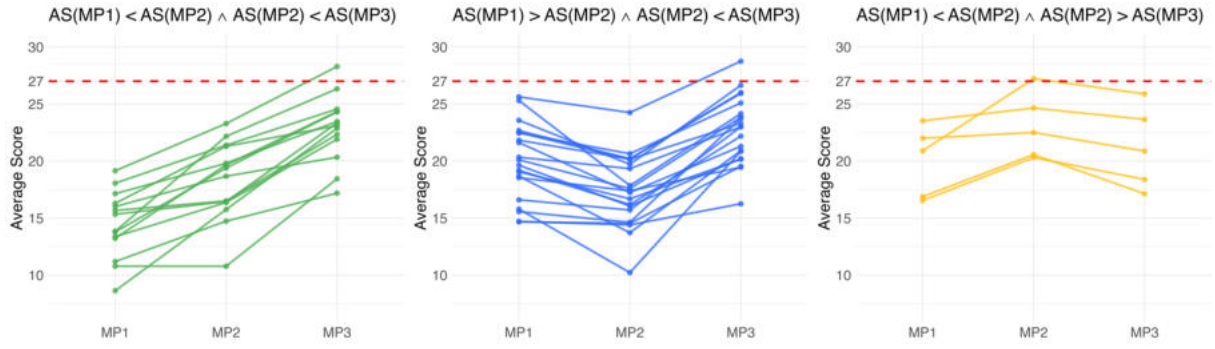

Figure 5: Average score performance by class across MPs

Of the 39 classes assessed, most fell into Category B, with 20 classes showing a recovery in performance following an initial drop in performance after the summer vacations, and 14 classes in Category A followed a continuous path of improvement. In comparison, five classes in Category C declined over the school year.

Discussion

Figures 2 and 4 show that a remarkable number of students moved from lower (AL IV and AL III) to higher levels (AL II and AL I). This indicates an overall positive trend over the year. As good as this trend may be, it was to be expected given one school year of math lessons. Much less was to be expected that, contrary to the positive trend, 312 out of 535 Students (58,3%) could not reach AL I (27 points or more), the learning objective. Figure 5 provides insight into significant differences in performance between classes. At the end of grade 3, only two of 39 classes reached an average score above 27 points (the red line) and met the learning objective.

Because of the similar teaching conditions, our findings are representative and transferable far beyond the classes and schools investigated.

The present study's findings result from the teaching and how students work with tasks. They can be explained by how the teaching is designed and can only be improved by changing this teaching design. Since teaching materials, such as textbooks and workbooks, are the primary medium for teaching, their tasks have a significant impact on teaching and its outcomes. The insufficient quality and quantity of the tasks offered in the grades 2 and 3 teaching materials must be considered as one reason for the reported unsatisfactory findings. Gleißberg & Eichler (2019) showed that tasks to develop a conceptual understanding of multiplication are underrepresented in these teaching materials. Gleißberg & Eichler (2019) also found that the number of tasks in grade 3 is significantly lower than in grade 2, resulting in fewer opportunities in grade 3 to consolidate basic equations. We suspect that the inadequate performance of the students identified in our study may also stem from several reasons that require further analysis.

It is important to memorise basic equations for the long term and be able to reconstruct them in case they are forgotten. Applying the distributive law of multiplication over addition is an important tool for reconstructing forgotten equations. In textbooks, the sequences of multiples of a number are typically presented only up to ten times that number. To develop the ability to solve problems by applying the distributive law, many problems, such as 13×7 or 24×3, where one factor is greater than 10, must be addressed. Such tasks occur rarely or not at all in second-grade textbooks.

Semantic networks help reconstruct basic equations. In almost all textbooks, related tasks such as 5×8 and 6×8 or 3×7 and 6×7 are presented together with the best intentions. It is necessary to examine whether students work on these tasks in the intended way, connecting equations, or whether they solve these tasks in isolation without understanding and utilising relationships. In our opinion, it would be more productive to assign only one task, such as 6×8, and ask students to find other tasks, such as 3×8 or 5×8, that are usable to solve the given task.

Considering these results, the current practice of working through the multiplication table "sequence by sequence" seems questionable. Kaufmann (2019) observed a strong emphasis on addition when students explain multiplication. It is worth investigating whether a stronger orientation towards semantic networks, which students actively construct and use, could help to overcome this one-sided focus on repeated addition. Furthermore, hard, motivated and continuous work on memorising all basic multiplication facts should play a much greater role than it currently does. As Wong and Evans (2007) and Burns et al. (2016) emphasise, memorised facts are a prerequisite for developing advanced mathematical skills and acquiring process-related competencies.

What is a high-quality solution to an arithmetic task?

Robert Gunnarsson[1] and Ioannis Papadopoulos[2]

[1]School of Education and Communication, Jönköping University, Sweden;
robert.gunnarsson@ju.se

[2]School of Primary Education, Aristotle University of Thessaloniki, Greece

"Show all the work", we sometimes tell students when they solve tasks. But what does this mean? Is a solution better if the students have shown or not shown the component calculations? In this short report, we describe a central part of an ongoing study of conventions about what is required of a student's solution to an arithmetic task to be good, or even of high quality. We made a pilot study where we asked 21 persons, upper secondary school teachers as well as researchers in mathematics education, about what aspects of a solution are important for the quality and what constitutes a high-quality solution. We show that the data can be analysed qualitatively by thematic analysis. The tentative result shows three main themes of arguments for what constitutes a high-quality solution.

Keywords: Mathematics education, arithmetic, structure sense.

Introduction

What triggered the present study is what we have seen in previous research data (Gunnarsson & Papadopoulos, 2019) presented at CERME11. That data was collected amongst Greek and Swedish students at the age of 11-12, who solved different arithmetic expressions. In many cases, we could see the same procedures and calculations in both the Greek and the Swedish data. However, in some specific instances, we could see differences between the two groups regarding the number of correct answers. We could not make any conclusions about the two school systems or curricula, but differences were more likely due to that we collected the data in different classrooms.

The difference we focus on here considers students' evaluation of one single expression, $2 \times 3 \times 5 - 4 \times 2 + 6$. The reason for choosing this example is that it showed a significant difference between the two countries. For this particular expression, the correct answer was given by 46% of the students (51 out of 112) in the Greek classrooms, and the correct answer was given by 22% of the students (27 out of 123) in the Swedish classrooms. That is, we find twice as high a "solution rate" in some classrooms compared to others. With a closer look at how the students solved the task (or rather how the students described their solutions), we see differences in how the solutions are presented. Hence, this is something we wanted to continue exploring. Could it be due to that the teachers considered different types of solutions being better or of high quality?

Theoretical framework

In literature, a considerable number of studies have been devoted to students' ideas about how to solve arithmetic tasks (see, e.g., Blando et al., 1989; Glidden, 2008; Headlam, 2013; Tabak, 2019). The studies show that many students tend to use a left-to-right principle and ignore the rules for the order of operations. These studies indicate that the arithmetic errors made by students are due to

miscalculations, or due to misuse, or ignorance of mathematical rules and conventions, like the rules for the order of operations. In contrast, some studies point out that this kind of errors could be related to a poor "feeling", or perhaps we should call it intuition, about how to calculate (e.g., Banerjee & Subramaniam, 2005; Linchevski & Livneh, 1999; Pittalis, 2023). A concept to capture this feeling is 'structure sense', a term coined by Linchevski and Livneh (1999). Structure sense has mainly been used to discuss the relation between algebraic expressions and arithmetic expressions and has sometimes been used as a predictor of algebraic proficiency based on arithmetic performance (Lüken, 2012) or a precursor to more advanced mathematics (Vincent et al., 2017). Hoch (2003) suggests that a student "who chooses an efficient and elegant method to solve a problem is displaying good structure sense" (p. 2), which could be applied to both arithmetic and algebraic expressions. However, we also know that structure sense and manipulation skills do not always go hand in hand (Hoch & Dreyfus, 2006). Moreover, Banerjee and Subramaniam (2005) have shown that developing a structural understanding of expressions requires a consistent use of the procedures and rules or arithmetic.

Regarding what could be criteria for the quality of students' solutions, a recent review study by Teledahl et al. (2024) has explored what quality can be for students' solutions to mathematical problems. They propose that what is considered to be "good" mathematical writing should cater for semantic issues (whether the answer is coherent and with relevant calculations) and syntax issues (whether the answer is written with correct language and symbols).

Aim of the study

These studies above shed light on the way students solve arithmetic tasks and what can be considered high-quality mathematical writing. But the studies leave aside how the solutions are perceived by mathematics teachers in terms of the aspects considered important for the solution as well as what constitutes a high-quality solution. Therefore, this study aims to explore what is required of a student's solution to be good, or even of high-quality. The research questions are: (RQ1) Is there a qualitative difference between the different types of solutions? In addition, (RQ2) what aspects are important for a high-quality solution?

Background data from the previous study

As input to the present study, we take data from the previous study by Gunnarsson and Papadopoulos (2019) and particularly from the answers to the task $2 \times 3 \times 5 - 4 \times 2 + 6$. Five different types of student solutions could be identified. The different types of solutions are shown in Figure 1. All solutions are mathematically correct (the correct answer is 28, according to the rules for the order of operations). None of the solutions in Figure 1 misuses the equality sign (however, we could see such solutions in the data too). The main difference between the solutions is the way the partial calculations are performed and described. In other words, the main difference is how much of the work is shown by the students. Solution A presents a solution with successive calculations in one line. Solution E is vertical with each step below each other. Solution B accounts for each of the binary operations separately. Solution C accounts for calculation of each term (two and one operation, respectively) and solution D is a short version of solution C but account only for the result of the intermediate

calculations. None of the answers given by the students were just "28", hence all student solutions showed some partial calculations.

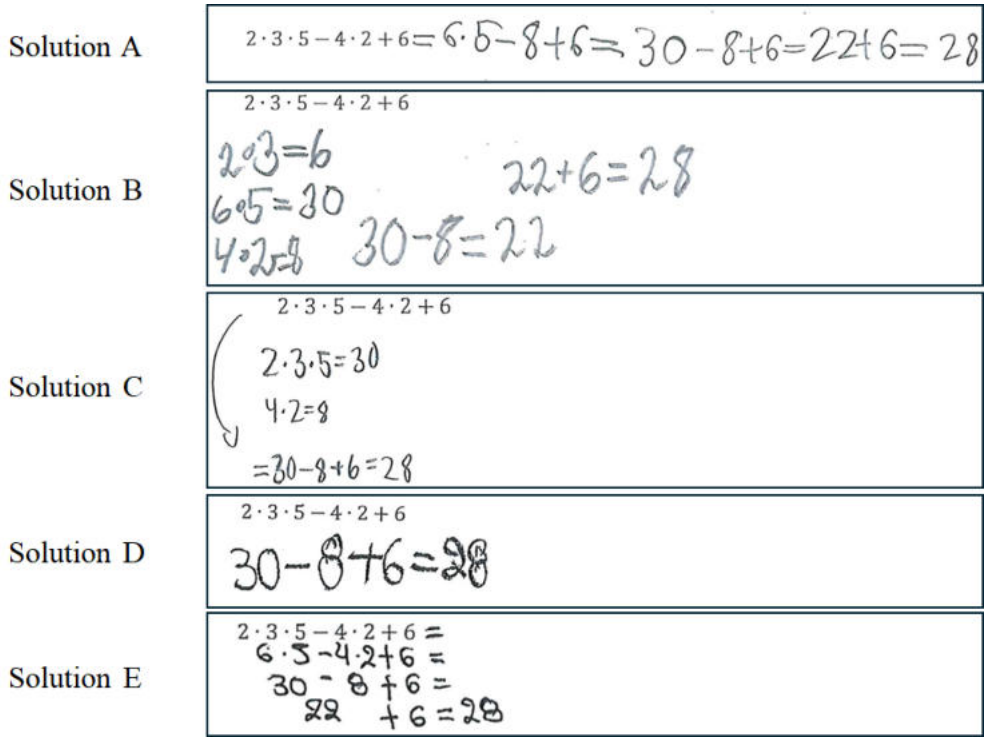

Figure 1: The five different types of students' solutions

Going back to the data and examining how these solutions are distributed among Greek and Swedish students, we found that there is a difference between their solutions. Figure 2 shows the distribution of the different types of solutions (A-E) amongst the correct answers to the task $2 \times 3 \times 5 - 4 \times 2 + 6$ (those who gave 28 as the final result). In both groups, we found answers that we could not easily categorize ("uncat" category in Figure 2), mainly because of a misuse of the equal sign. An example of an uncategorized solution could be $2 \times 3 = 6 \times 5 = 30 - 4 \times 2 = 22 + 6 = 28$, which is a solution that has led to the correct answer and used a procedure similar to type A, but with a misuse of the equal sign.

From Figure 2 we find that a large part of the 27 correct answers from Swedish students belonged to type B (12 students). The 51 correct answers from the Greek students were almost evenly distributed across the solution types A (12 students), D (11 students), and E (19 students). Interestingly, we did not find any solution of type E in the Swedish data set to the task, nor did we find any solution of type B or C in the Greek data set.

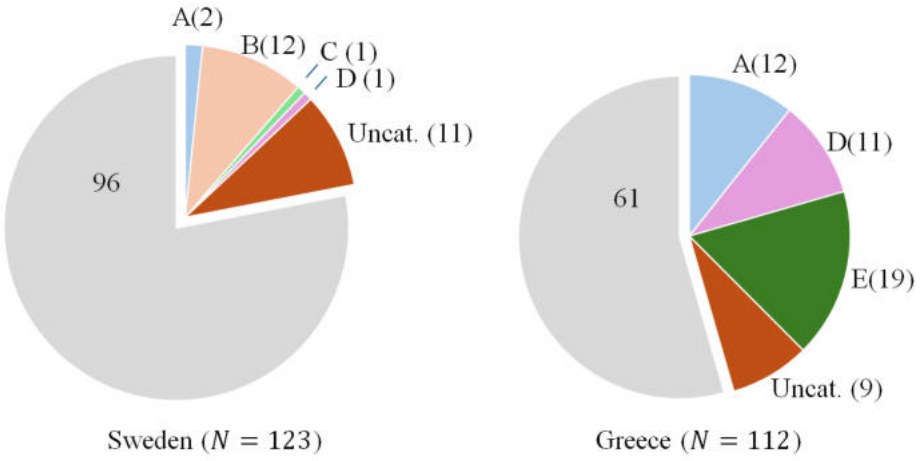

Figure 2: The distribution of the different types of solutions in the data set

This distribution of the correct answers across the five types of solutions became the starting point of the present study. Could it be that the different types of solutions lead students to different arithmetic manipulation skills or different structure sense? Or more fundamentally, are the different types of solutions of different quality, and if so, in what way? Hence, our aim is to explore what a high-quality arithmetic solution is, answering the questions if there is a qualitative difference between the different types of solutions (A-E, Figure 1), and what aspects are considered important for a high-quality solution.

Methods

Design of study. For this pilot study, a written survey was considered to provide adequate data for answering the research questions. We consider it sufficient to validate the qualitative differences between the solutions and start searching for qualitative differences that need to be handled in the bigger study. A written survey was designed, and two groups were identified for data collection.

Survey. The survey was composed of the five different student solutions shown in Figure 1. These are all genuine student solutions to one of the tasks in Gunnarsson and Papadopoulos's (2019) study: $2 \times 3 \times 5 - 4 \times 2 + 6$. The solutions were chosen to represent qualitatively different ways of solving the task. The following questions based on these solutions were posed to the participants: (*i*) Are the solutions equal in quality? (*ii*) If 'yes', why? (*iii*) if 'no', which solution has the highest quality? and which has the lowest quality? (why?) and (*iv*) What aspects do you find important for a high-quality solution? The questions did not specify what aspects of quality were to be considered but left this open for the participants to decide. The questions were designed to be sufficiently opened to allow for a certain "thickness" of the description of themes (see "analysis" below), while still maintaining the survey tool sufficiently compact and handy.

Participants. For the study, participants were chosen by convenience from two groups. *Group 1 (8 participants):* Mathematics education researchers. The data from this group comprise answers from participants at an international mathematics education research conference with a special focus on educational research on arithmetic, numbers, and mathematical operations. *Group 2 (13*

participants): Mathematics teachers. Data from this group comprise answers from upper secondary school mathematics teachers (school years 10-12) in Sweden. Both groups were chosen because of their solid mathematical knowledge and knowledge of the relation between students and the subject matter, from different perspectives and with different academic levels. In total, both groups consisted of 21 participants. The non-randomness of participators is not considered a problem since the aim is not to make a quantitative analysis of the pilot data. The analysis is in progress, therefore at the moment we present the unified data, but in the future, the ambition is to compare opinions between the two groups

Analysis. The collected open answers were analysed by a simplified form of thematic analysis (Braun & Clarke, 2006). The six phases of Braun and Clarke's thematic analysis are followed to get a (thick) description of themes. The "thickness" of the descriptions is limited by the length (the compactness) of the survey. Through the thematic analysis, the themes are inductively found in the data of the open questions in the survey. The themes were extracted from the data, and not predefined. Although the analysis is not yet completed, we allow ourselves to provide a presentation of some tentative results. However, the complete analysis is yet "in progress".

Tentative results

Many participants (14 out of 21) responded that there are qualitative differences between different solutions. Almost all participants also indicate the solutions with the highest and lowest quality and justify their decision. Only two of the participants did not mark any qualitative differences between the solutions and answered "yes" to the question "Are the solutions equal in quality?"

Figure 3 shows the highest and lowest ratings for each participant (1 to 21). Some participants rate more than one solution as the highest or lowest in quality. According to Figure 3, it seems that most of the participants (12 participants) think that the solution E is the one with the highest quality. Then follow solutions A (9 participants) and D (7 participants). The solution with the lowest quality is almost unanimously solution B (chosen by 16 participants). This is strengthened by the fact that in Figure 3(a) none of the participants considered this solution as one with high quality.

Although all phases of the thematic analysis are not yet carried out completely, the qualitative analysis allows some preliminary findings. Given that the participants found qualitatively different solutions, our effort was to identify aspects that contribute to the quality of the solutions. It seems that there are different themes in relation to what aspects are important for a high-quality solution. Until now three themes emerged from the analysis of the data: the correctness of the solution, the strategy efficiency, and whether the solution is communicative or not.

The first theme is the *correctness of the solution*. A high-quality solution is a solution that leads to a mathematically correct answer respecting the mathematical properties (for example, the correct use of the equal sign) and conventions (for example, the rules for the order of operations). Indeed, we were able to collect several answers in this spirit. Some of them were: "the solutions are presented correctly", "the student considers the order of operations", "the student uses the equality signs correctly" and "[the solution] is the best from the point of view of math".

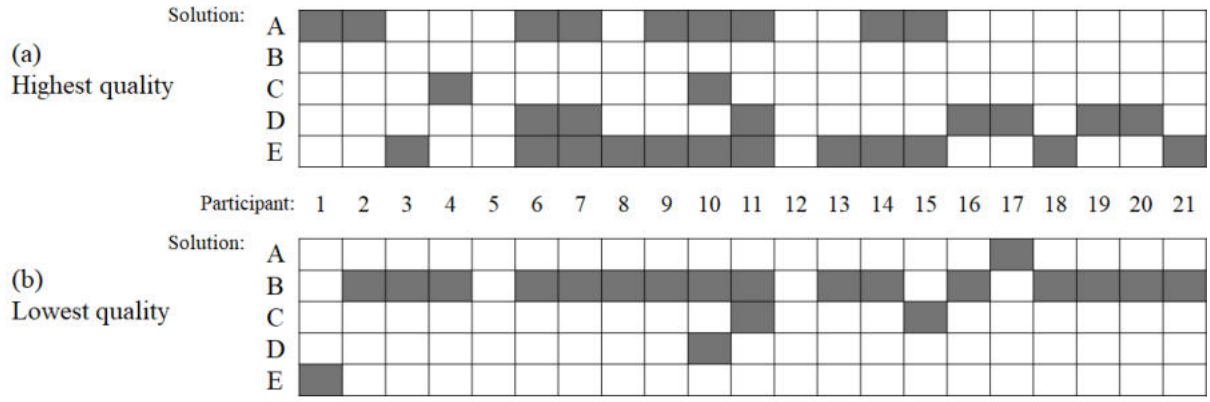

Figure 3: Schematic of what solutions (A-E) were marked as having (a) highest quality and (b) lowest quality, respectively, for each participant (1-21)

The second theme that emerged from the analysis was that the solution should describe an *efficient strategy* or a strategy that is sustainable for the student and can be used in other tasks. Examples of answers within this theme include "the design of the solution is a support for solving the task by not allowing for sign-errors", and "[about low-quality solution strategy] is much harder to apply in future [tasks]".

The third theme is that the solution should be *communicative*. In parts of the data, the communicative role of the solution is manifested as the solution is well structured or easy to follow. In fact, here there are two different objects for this communication. In some answers, the solution should be communicative for the students themselves. But in most cases, a high-quality solution is a solution that is communicative for someone else, for instance, a teacher. Typical answers in this theme contained words like "clearer", "more easy to follow", and solution B that it is "messier".

Discussion

In conclusion, we note that the different types of solutions are considered to have qualitative differences between them (RQ1). This is, as an example, also shown in Figure 3. Moreover, we note that a "criterium" for a high-quality solution (RQ2) can be composed of different aspects, and we found three such aspects in our data; [A high-quality solution should have] (mathematical) correctness, be efficient, and be transparently communicated.

The main aim of this study was to identify what a high-quality arithmetic solution is for mathematics teachers and mathematics education researchers. Is it that the solution leads to correct answers (first theme)? Regarding the qualitative data, mathematical correctness is fundamental for all solutions. Naturally, the data selected for this survey are the ones that have not fallen into the misuse of the order of operations as described by Blando et al. (1989) or Headlam (2013). The participants (teachers/researchers) of this study are quite well synchronized with the data from Sweden and Greece. Solutions A, D, and E are considered as having high-quality, whereas solution B is considered to have low quality (see Figure 3). This is in agreement with the lower solution rate observed in the Swedish data set compared to the Greek data set. Therefore, we could hypothesize that bringing the five different solution types to teachers or students in Sweden along with a discussion on what

constitutes a high-quality solution, could result in the requested goal – to create awareness of what is required of a functioning solution.

Is it important the efficiency of the strategy (second theme)? Of course, we still examine only the correct solutions. For the Swedish data, we have correct solutions achieved by using low-quality solution strategies. In other words, it needs further examination of the fact that the students are finding the correct solutions *despite* using a low-quality solution strategy. This raises the need to examine whether a higher awareness of what constitutes a high-quality solution can improve (increase) the solution rate. This is our aim for the next step which we think would be highly interesting.

Finally, is the communicative character of the solution its most important characteristic (third theme)? The participants argued that the solution could be well-structured. Hence, comparing to the concept of structure sense (as coined by Linchevski & Livneh, 1999) we find that the participants refer to high-quality solutions as "well-structured" or more "efficient". One can say that this structural aspect refers mainly to the syntax of the written expression of the solution and its compatibility with the necessary mathematical conventions. Actually, with the definition of Hoch (2003) that structure sense is related to the ability to choose "an efficient and elegant method to solve a problem", we find a close relation to this communication theme.

This is also in line with the quality criteria by Teledahl et al. (2024), where coherent and relevant calculations and correct language (i.e., communication quality) are considered "good" mathematical writing. However, their study was based on what was considered to be quality criteria for text solutions to mathematical problems. Our study has, when completed, the potential to add research-based information on what high-quality of numerical solutions could be considered to be. Based on the tentative analysis of this pilot study, we make no claims about what high quality is concerning arithmetic solutions or that the list of criteria above is complete. And possibly, hopefully students' awareness of what a high-quality solution could be, can improve the solution frequency of arithmetic tasks.

Primary school students' ability in fractions as operators

Diana Herreros-Torres[1], Maria T. Sanz[1], Carlos Gómez-Ferragud[1], Hélia Oliveira[2] and Renata Carvalho[2]

[1]Facultad de Magisterio, Universidad de Valencia, España; diana.herreros@uv.es

[2]Instituto de Educação, Universidade de Lisboa, Portugal

The learning of fractions improves when they are explored in various ways and their representations and contexts are interconnected. This exploratory study aims to identify the errors and difficulties faced by 213 fourth-year primary school students in developing their ability with fractions as operators. A problem-solving test and a mathematical exercises test are used across two contexts (continuous and discrete) and through two approaches (arithmetic and graphical). The results indicate that the fraction as an operator remains a significant challenge for students, as evidenced by the students' overall low performance, the lack of interconnection between tasks, and their limited ability to approach the tasks from different perspectives.

Keywords: Fraction as an operator, problem solving, primary school students, errors, difficulties.

Introduction

The learning of fractions is a crucial component in primary education, as it lays the foundation for understanding more advanced mathematical concepts and ensures academic success in later stages (Braithwaite & Siegler, 2021). However, teaching and learning fractions, particularly their use as operators, present numerous challenges for both students and teachers (López Arias, 2012).

The fraction as an operator, which involves applying a fraction to modify another quantity, often confuses due to the level of abstraction required and the multiplicity of representations it can take. According to Kieren (2020), mastering fractions requires not only conceptual understanding but also the ability to apply this knowledge in various contexts and through different methods of representation. This study, therefore, aims to identify the errors and difficulties faced by fourth-year primary students when developing their ability with fractions as operators in mathematical problems and exercises, considering different contexts (continuous and discrete) and various problem-solving approaches (arithmetic and graphical). Identifying the specific problematic areas for students in this concept, which is introduced in the fourth year of primary education in Spain according to the guidelines and minimum requirements established in a Royal Decree (Gobierno de España, 2022), may provide insights that could guide its teaching.

Theoretical background

One of the main challenges in teaching fractions lies in the difference between natural and rational numbers, which leads students to perceive a fraction as a whole, without distinguishing between the numerator and denominator (Butto Zarzar, 2013). This difficulty is further intensified when fractions are treated as multiplicative operators, requiring a transformation between their terms and the initial and final quantities (Behr et al., 1983).

In Spain, the teaching of fractions primarily focuses on the part-whole concept, prioritising the partitioning of units, counting, and the mechanisation of rules, which limits their connection to real-world situations (Gómez & Pérez, 2016). As a result, fractions and their arithmetic operations are among the most difficult topics for students to comprehend (Fazio & Siegler, 2011). As noted by Rico (1997), errors are an inherent part of the mathematical learning process and are reflected in the various tasks students perform. In this regard, arithmetic word problems (AWP) provide a key tool for exploring student ability across different contexts and tasks (Rodríguez- Nieto et al., 2023).

Recent studies confirm that the greatest difficulties with fractions arise in multiplication and in operations combining fractions with whole numbers (Sartono & Karso, 2020). Furthermore, when solving problems, the lack of understanding of fraction components hinders students' ability to obtain adequate spatial information, leading to errors in graphical representation. This reveals difficulties in operating correctly and exposes weaknesses in students' skills in analysis, reasoning, and interpretation when reading contextual problems (Herreros-Torres et al., 2022; Padilla-Escorcia et al., 2022). Therefore, errors should be viewed as a starting point for improving learning.

Methods

This exploratory study follows a predominantly qualitative methodology and forms part of a broader project that analyses the teaching and learning process of the fraction as an operator in Primary Education. The methods section includes: sample, instruments and variables, and analysis.

Sample

The study involved 213 fourth-year Primary Education students (aged 9-10) from six public schools and one semi-private school in the Valencian Community, Spain, mostly coming from lower-middle socioeconomic backgrounds.

Instruments and Research Variables

After teachers explained the concept of fraction as an operator, the students completed two paper-and-pencil tests. Firstly, Test 1 was administered, containing these two arithmetic-word problems:

> *Problem 1: A well containing 10 litres of water has three-fifths ($\frac{3}{5}$) of its water emptied to water the plants. How many litres were emptied?*
>
> *Problem 2: I have 10 apples in a basket, and I drop three-fifths ($\frac{3}{5}$) of them. How many apples did I drop?*

Subsequently, Test 2 was provided, featuring two mathematical exercises on the same content but without the context of a word problem:

> *Mathematical Exercise 1: Calculate: $\frac{3}{5}$ of 10 =*
>
> *Mathematical Exercise 2: Colour $\frac{3}{5}$ of the circles. How many circles have you colored? (There were 10 circles drawn).*

In both cases, the fractions operated on a natural number, and students were required to solve the tasks (the different questions included in the tests) using both arithmetic and graphical methods. To

make sure of this, the response section included two separate boxes, one for the arithmetic solution and one for the graphical one.

According to Schoenfeld's (1985) definition, a mathematical problem is any task for which the solver does not possess an immediate, well-rehearsed method, thus requiring exploration and reasoning strategies. In contrast, a mathematical exercise involves the direct application of a known technique or algorithm, without the need for prior investigation. The main difference between the problems lies in the context: Problem 1 is continuous (litres), whereas Problem 2 is discrete (apples). The main difference between the mathematical exercises lies in the method of resolution: Exercise 1 arithmetically, and Exercise 2 graphically.

Six variables were analysed according to the type of task, context, and mode of resolution:1) CPA: Continuous problem, arithmetic resolution; 2) CPG: Continuous Problem, Graphical resolution; 3) DPA: Discrete Problem, Arithmetic resolution; 4) DPG: Discrete Problem, Graphical resolution; 5) AE: Arithmetic Exercise; 6) DEG: Discrete Exercise, Graphical resolution.

Each variable was evaluated considering two subvariables:

1) Type of Success: Whether the answer was correct (1), incorrect (0), or left blank (null).
2) Mode of Resolution: Numerically coded after a classification and categorization guided by the mathematical criteria of a group of experts based on works such as Fazio and Siegler (2011) and León-Robles (2011).

Data Analysis

The data were analysed through: 1) a content analysis, coding and categorising the responses according to success and mode of resolution through consensus among the researchers, achieving an agreement index above 0.8 after three rounds of revision, and 2) a descriptive quantitative analysis, calculating success frequencies and percentages. Additionally, contingency tables were used to explore the relationship between success and modes of resolution, identifying trends and difficulties. Data processing was carried out using Excel, and version 2.3.16 of The JAMOVI Project, 2024.

Results

The results are organised around the subvariables Type of Success and Mode of Resolution, along with a section on Errors and Difficulties in Student Performance.

Type of Success

Table 1 presents the frequencies of student responses according to the success in each variable. The analysis of responses from the 213 students reveals notable variations in their performance, depending on the type of task (problem or exercise), the context (continuous or discrete), and the method of resolution (arithmetic or graphical). Generally, students encountered greater difficulties with graphical resolution compared to arithmetic, regardless of the context or type of task. This is reflected in a higher percentage of incorrect and blank responses in graphical tasks, particularly in mathematical problems versus exercises without verbal context. In Problem 1 (continuous context, litres), graphical resolution (CPG) presented more significant difficulties than arithmetic resolution, with a notable difference in the percentage of correct responses (30.5% in CPA versus 6.1% in CPG).

Table 1: Frequency of values for each variable according to success in responses

	Subvariable: Type of Success		
Variable	Success 0	Success 1	Null
CPA	110	65	38
CPG	188	13	12
DPA	107	61	45
DPG	144	43	26
AE	85	95	33
DEG	140	61	12

In Problem 2 (discrete context, apples), the differences between arithmetic and graphical approaches were less pronounced, although graphical resolution (DPG) still showed a lower success rate (20.2% in DPG vs 28.6% in DPA). Mathematical exercises without verbal context also demonstrated students' better performance in arithmetic resolution (44.6% in AE) than graphical (28.6% in DEG).

In summary, students faced greater challenges in developing the fraction as an operator when solving a mathematical problem rather than an exercise, and arithmetic resolution proved to be more accessible than graphical across all types of tasks, especially in the continuous context problem (Problem 1), where graphical difficulties were more evident.

Mode of Resolution

Table 2 displays the frequency of the most common modes of resolution used by the students, distinguishing between correct responses (success 1) and incorrect responses (success 0) according to whether the method was arithmetic or graphical.In the correct responses (success 1), the method "operator" ($10 \div 5 \times 3$) predominates, applied both in arithmetic resolution (38 to 50 times) and graphical resolution (9 to 61 times). Many students, particularly in arithmetic resolution, provided direct answers without showing their process (10 to 40 times), while a smaller group used the "multiplication" method (10×3 followed by $30 \div 5$). It is also noteworthy that three students employed a non-conventional method, "Subtract and Then Multiply" ($5 - 3$, then 2×3), which indicates that these students do not consider the fraction as a singular mathematical entity but rather treat the numerator and denominator as two independent numbers to operate with. In graphical resolution, 16 students replicated the results obtained arithmetically without applying a proper graphical method, reflecting a tendency towards the arithmetic approach even in graphical tasks.

In summary, Table 2 shows that less than ¼ of the students who participated in the study adequately understand the fraction as an operator. In addition, it should be added that there is a lack of consistency between the solving methods and the types of tasks. Despite dealing with the same mathematical content, more than 20 students change their method of solving arithmetic problems 1 and 2, and more than 10 change their method of graphically solving problem 2 and exercise 2, despite the tasks being similar.

Table 2: Categorisation and frequency of different modes of resolution of tasks according to success

	Arithmetic Resolution				Graphical Resolution			
	Mode of resolution	CPA	DPA	AE	Mode of resolution	CPG	DPG	DEG
Success 1	Operator	46	38	50	Operator	9	28	61
	Direct response	11	15	37				
	Subtract and then Multiply	2	1	0	Copy from arithmetic	2	14	0
	Multiplication	6	5	8				
	Addition	0	2	0	Colour 6 out of 10 without calculating	2	1	0
	Mode of resolution	CPA	DPA	AE	Mode of resolution	CPG	DPG	DEG
Success 0	Direct response	10	6	55	Drawing without correct graphic representation	76	18	0
	Use a data point from the statement	15	15	0	Inadequate consideration of quantities	12	29	0
	Indicate process but do not calculate	11	13	0	Consider only $\frac{3}{5}$	62	38	5
	Subtract fractions	7	7	0	Arithmetic-Based interpretation	12	11	0
	Subtraction with natural quantities	44	39	0	Apply only the numerator	6	21	62
	Incorrect operator	0	0	8	Colour 3 and 5	0	4	19
	Others	18	27	22	Colour 5 out of 10	11	7	26
					Others	9	16	28

Errors and Difficulties in Student Performance

This section analyses the errors and difficulties encountered by students based on the modes of resolution that led to an incorrect result (success 0) as detailed in Table 2. Only the most frequent methods are detailed.

In the arithmetic resolution of mathematical problems, four recurring modes were identified:

1. Direct response without process: Students provided an answer without showing the procedure. For example, answering 2 for $\frac{3}{5}$of 10 without demonstrating the calculation process.
2. Use a data point from the statement: Some students used a given data point from the problem statement as their response. For instance, simply providing $\frac{3}{5}$as the answer.

3. Indicate the process, but do not calculate: Students indicated they needed to calculate $\frac{3}{5}$of 10 but did not perform the calculation.
4. Subtracting with natural quantities: involved subtracting the quantities given in the statement from each other. They used different methods, for example: $5-3$ and/or $10-3$.

In Mathematical Exercise 1, direct responses were predominant (55 cases), alongside the incorrect use of the fraction as an operator. Specific errors were also observed in Problems 1 and 2. The most common errors are illustrated in Figure 1.

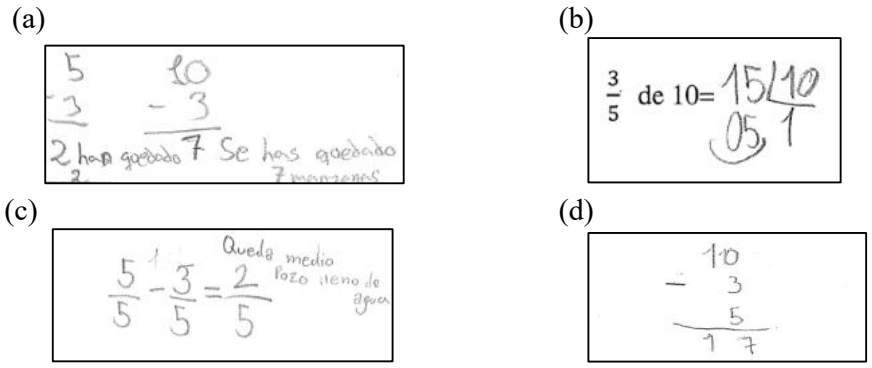

Figure 1: Four example of errors: (a) subtraction with natural quantities, (b) incorrect operator, (c) subtracting fractions, (d) considering natural numbers

In graphical resolution of the mathematical problems, the most common errors were:

1. Drawing without correct graphical representation: Many students drew a depiction of a well instead of a correct graphical representation of the quantities involved in the problem.
2. Inadequate consideration of quantities: Some students applied quantities that were not given in the problem statement.
3. Arithmetic-Based interpretation: Students coloured 6 out of 10 litres or apples by directly using the arithmetic result without an appropriate graphical representation.
4. Consider only $\frac{3}{5}$: Students did not consider the total number of apples or litres to which $\frac{3}{5}$should be applied.

Additionally, across the two problems and Mathematical Exercise 2, recurring incorrect methods included: a) applying only the numerator, b) colouring the values corresponding to the numerator and denominator (3 and 5), and c) colouring 5 out of 10. Finally, notable errors also appeared in Mathematical Exercise 2, where the pupils divided each circle into fifths and shaded three, interpreting the context as continuous rather than discrete (Figure 2).

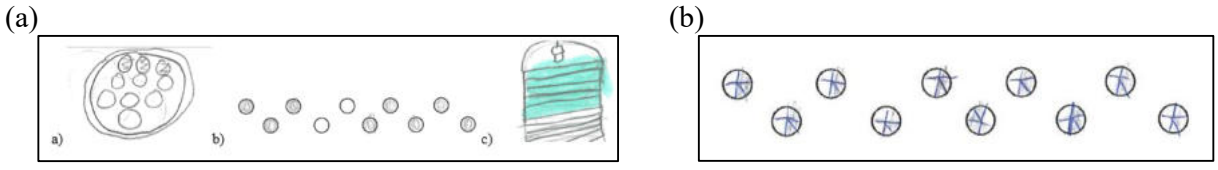

Figure 2: (a) Different graphical resolution modes, (b) dividing each circle into five parts and coloring three

Discussion and conclusion

In this study, two main factors underlie the difficulties in using fractions as operators: 1) the type of task (problem vs. exercise) and 2) the solution method (arithmetical vs. graphical). While the context in which the fraction operates, whether continuous or discrete, also presents challenges, these are less significant and mainly affect graphical solutions. Regarding the type of task, students performed better in exercises than in problems. This aligns with Gómez and Pérez (2016), who note that widely used textbooks often prioritize discrete counting and mechanized rules without real-life contexts, and with Padilla-Escorcia et al., (2022), who observe that primary students struggle to connect everyday language with mathematical language when reading contextual problems. As for the method of solution, the graphical approach proved more complex than the arithmetic one, consistent with the findings of Herreros-Torres et al. (2022), who reported similar findings in Year 6 tasks involving fractions acting on both whole and fractional numbers. This difficulty may stem from Spanish curricular materials (Real Decreto, 2022), which emphasize graphic representations mainly in the early years of primary school (up to 8-9 years old) and not later, before focusing on arithmetic, or to the representational development of students (Bruner, 1964), where many have not yet mastered the iconic stage to obtain precise visual representations.

Table 2 shows that the ability to use fractions as operators is low in the studied group, with fewer than a quarter of the students adequately developing this concept. Moreover, there is an inconsistency between the methods of solution and the types of tasks within the same individual (more than 20 students change their method each time). The alternative approaches to task solutions, along with the recorded errors and difficulties, continue to highlight two significant points: 1) operations that combine fractions with whole numbers still present errors and difficulties (Sartono & Karso, 2020) and 2) the distinction between natural and rational number systems remains a major challenge in learning fractions (Butto Zarzar, 2013).

In conclusion, this study emphasizes the need to focus on reviewing the errors and difficulties in developing fractions as operators across different contexts and representations, to promote a more effective teaching methodology that limits their persistence and enables the deep understanding defined by Kieren (2020): mastering not only conceptual understanding but also the ability to apply this knowledge in various contexts and through different methods of representation.

Advancing the use of retrieval-based strategies with a new manipulative: The case of Nanuka

Sarah Hopkins[1], James Russo[1], Jane Hubbard[1], Anne Roche[1], and Janette Bobis[2]

[1]Monash University, Faculty of Education, Victoria, Australia; s.hopkins@monash.edu

[2]The University of Sydney, Australia

In this paper, we describe findings from an intervention study involving a female student (aged 10 years) who appeared to be stuck using counting strategies for simple addition. The intervention involved using a new manipulative called the Keyboard - a tool depicting a linear representation of number position, which makes use of students' subitising skills. Using a microgenetic approach we present findings highlighting the efficacy of the Keyboard intervention in terms of promoting retrieval-based strategies and illustrate how it led to the variable use of derived-fact strategies.

Keywords: Counting, addition, subitising, microgenetic, variability

Introduction

It is imperative that students come to use retrieval-based strategies to solve single-digit addition problems rather than counting strategies (Geary, 2011). Retrieval-based strategies encompass direct retrieval (or recall), where an answer is retrieved from a store of facts held in long-term memory; as well as derived-fact strategies, where answers are derived using a retrieved (known) fact. There are two main types of derived-fact strategies: decomposition strategies and varying strategies (Torbeyns et al., 2009). Decomposition strategies involve partitioning one or more operands to make use of a known fact and include the near-doubles strategy, [e.g., 6 + 7 = 6 + 6 (known) + 1], and the bridging-10 strategy [e.g., 6 + 7 = 6 + 4 (known) + 3]. Varying strategies involve changing an operand to make use of a known fact and making up for this change. These include the overshoot strategy [e.g., 5 + 9 = 5 + 10 (known) - 1] and the balance strategy [e.g., 9 + 7 = 10 + 6 (known)]. Retrieval-based strategies are advantageous as they place fewer demands on working memory than counting strategies and allow for higher-ordered learning to take place (Canobi, 2009; Geary, 2011).

There is growing concern that many students in primary/elementary schools around the globe persist with using counting strategies for simple addition at a time when they are expected to be using retrieval-based strategies. Traditionally in the literature, persistent counting was considered to be uniquely characteristic of learners with mathematical learning disabilities/difficulties (MLD) or learners who exhibited persistent low achievement. The development of retrieval-based strategies was thought to be hindered for students with MLD as, compared to peers without MLD, they made more counting errors due to the use of inefficient counting strategies, and made more retrieval errors due to difficulty inhibiting irrelevant information during the retrieval process (e.g., Geary et al., 2012). Recent research, however, has highlighted persistent counting to be widespread among students in many countries (e.g., Graven & Venkat, 2021), not just among the lowest achieving students. Furthermore, persistent counters often use the most efficient counting strategy (starting at the larger addend and counting on the smaller addend) and make few errors (Hopkins et al., 2022). Hence, there is a burgeoning need for contemporary research to be focused on explaining persistent

counting and on enhancing the teaching of early arithmetic to promote the use of retrieval-based strategies at an appropriate stage of schooling. We are undertaking such a research project using a series of intervention studies designed to help students think about numbers in terms of position.

In this paper, we describe case study findings from one intervention involving a female student in Year 4 (aged 10 years and 3 months) called Nanuka (pseudonym). The intervention involved using a new tool to represent the linear positioning of numbers, called the Keyboard. Microgenetic methods were adopted to address the research question: How does using the Keyboard intervention facilitate the use of retrieval-based strategies for students who appear to be stuck using counting strategies?

Methods

Microgenetic methods require that participants are tested individually and involve an intensive (trial-by-trial) analysis of data collected on multiple occasions to document change as it happens (Siegler & Crowley, 1991). These methods are less common in educational research but have been popular among developmental psychologists to study change as it happens, including the factors that precede change.

The current study builds on the early work of Siegler (Siegler & Jenkins, 1989) who applied microgenetic methods to study how preschool children (4 and 5 years old) developed new strategies for solving addition problems as a result of practice. This seminal work led to the construction of an influential theory of strategy development called the overlapping waves theory (Siegler, 1995). This theory highlights an intermediate stage of strategy variability where children discover and use different strategies to solve the same problem on different occasions, and models how children choose among multiple strategies to eventually exhibit *strategy flexibility* and *strategy adaptivity*. Strategy flexibility involves choosing an efficient procedure depending on the characteristics of the problem (Blöte et al., 2000) and strategy adaptivity involves choosing an effective procedure depending on what works best for an individual (Siegler & Lemaire, 1997). Importantly with Siegler's model, strategy choice is modelled as being an implicit process that is influenced by experience solving specific problems and general problems similar in type, rather than a metacognitive process involving consciousness or deliberateness. The project extends Siegler's early work in two important ways: (i) the participants are older and were expected to use derived-fact strategies and not just counting strategies or retrieval, and (ii) change is studied as a result of teaching interventions (as well as practice).

Participant selection and procedure

Three participants in Year 4 were selected from a suburban primary school in Australia, where curriculum expectations state that by Year 2, students are able to recall and demonstrate proficiency with addition and subtraction facts within 20. These participants were among a cohort of 81 students from the same school who completed an individual assessment (interview) to ascertain the strategies they used for single-digit addition. They were selected for the intervention because they most frequently used counting strategies. Each participant was individually withdrawn from class to work with the research assistant (RA) for the duration of the study that spanned a month. Findings for one

participant (Nanuka) are reported in this paper - the participant who benefited most from the Keyboard intervention.

Nanuka was required to solve a set of 49 single-digit problems on (i) five consecutive school days in the pre-intervention phase (days 1-5), (ii) seven consecutive school days in the post-intervention phase (days 13-19), and (i) one final day, one week after day 19 (day 20). Each session took around 15 minutes to complete and included all single-digit addition problems (49 problems altogether) written in the form 'x + y' where x, y > 2, which were randomly displayed on a computer screen. The intervention phase encompassed learning activities taking around 20 minutes each day for seven consecutive school days (days 6 -12). All phases of the study were video-recorded.

Consistent with a microgenetic approach, a combined method of self-report and observation was used to identify the strategies Nanuka used on a problem-by-problem basis. This approach involved the student answering problems whilst being observed by a researcher (fourth author) and immediately after giving the answer, explaining to the researcher how they had solved the problem. The researcher used computer keys to control the presentation of each problem and record the participant's answer, and the digital program recorded the time taken to provide the answer (reaction time, RT). The strategies reported by the student were coded by the researcher on paper, in situ. The validity of the self-reports was established first by observation, second by RT analysis, and third by video analysis where two additional researchers (authors one and three) viewed the videos (attaining 94.2% agreement with initial coding). The scheme used to code strategies is detailed in Table 1.

Table 1: Scheme used to code strategy use with examples

Strategy Type		Strategy	Example problem and self-report
Counting		Min-counting	3 + 4, started at 4 and counted 5, 6, 7
		Count-from-first	3 + 4, started at 3 and counted 4, 5, 6, 7
Derived-fact	Decomposition	Bridging-ten	7 + 5 = 7 + 3 (known) + 2
		Near doubles	6 + 7 = 6 + 6 (known) + 1
		Fives*	5 + 8 = 5 + 5 (known) + 3
	Varying	Overshoot	8 + 9 = 9 + 9 (known) - 1
		Balance	6 + 9 = 5 + 10 (known)
Retrieval			Just knew it
Other		Not sure	
		Not elsewhere coded	

*The fives strategy was coded separately since the fact 5 + 5 = 10 could be considered either a doubles fact or an add-to-ten fact.

The Keyboard Intervention

The Keyboard comprises a handle and board with 20 "keys" that represent the numbers 1–20. It has no moving parts and no numbers written on it. To use the Keyboard, students use their left hand to hold (or press down on) the handle and their index finger on their right hand to point to the keys. Students move their finger forward (away from the handle) to add numbers and backwards (towards the handle) to subtract numbers. Each fifth key is coloured black (representing 5, 10, 15 and 20) to support students' use of subitising skills when locating and identifying specific keys, and when adding or subtracting numbers. Two or more Keyboards can be joined to represent longer number sequences.

Figure 1: The Keyboard

The intervention involved 7 x 20-minute sessions delivered on consecutive school days. Participants were introduced to the Keyboard in the first four intervention sessions (days 6–9 for Nanuka) using games and activities. The game called "Guess my Number" required the student to guess a number on the Keyboard given a clue, such as, "it is two more than a black key" or "one less than a black key". The activity, Keyboard Race, involved taking turns with the RA to throw a dice and move forward on the Keyboard the number shown on the dice, with the winner reaching the end first. Other activities included using the Keyboard to skip-count forward by 2, 3, and 4 starting from zero, skip-counting backwards, and using different combinations of two or three jumps to land on a given number (e.g., 10 + 5 = 15 or 8 + 2 + 8 = 18).

The last three intervention sessions involved solving the problem set each time using the Keyboard. Minimal explicit instruction was given on how participants could use the Keyboard since we were interested to investigate how students intuitively used the tool. We predicted they would be likely to start at the larger operand given their propensity to min-count. If they did this, the RA showed them how the Keyboard could be used by starting at the first addend (e.g., 4 + 7 = 4 + 6 + 1) for three specified (but different) problems in each session. No self-report data were collected during these three sessions but each session was video-recorded. During the post-intervention phase (days 13–17), Nanuka was provided with a Keyboard and could choose any strategy she wanted to use, including the Keyboard. Trials where Nanuka used the Keyboard were coded simply as having used a Keyboard strategy. (Note, a trial refers to an occasion where a problem was solved by the participant.) Mostly, she touched the Keyboard but occasionally she just looked at the Keyboard. During trials where she looked, she was asked how the Keyboard had helped her. Video of Keyboard trials was later viewed to examine how she had used the Keyboard. On days 18, 19, and 20, the Keyboard was not made available (day 20 was one week after day 19).

Results

In the pre-intervention phase, Nanuka predominantly used a min-counting strategy to solve the problem set (133 trials). On nine trials she used a count-from-first strategy, starting at the first addend and counting on the second addend. Her propensity to min-count meant that she used few retrieval-based strategies during this phase of the study (as shown in Figure 2). She did however consistently and correctly retrieve most doubles (3 + 3, 4 + 4, 5 + 5, 6 + 6, 7 + 7, and 8 + 8, but not 9 + 9) and six problems with smaller sums (3 + 4, 3 + 5, 4 + 5 and their turnarounds 4 + 3, 5 + 3, and 5 + 4). She used a derived-fact strategy on 21 trials. On eight trials, Nanuka made use of an answer she had calculated on a previous trial. For example, to solve 8 + 6 she remembered 8 + 5 was 13 from the previous trial where she had used a min-counting strategy, and added one more. This strategy was coded as a previous-problem strategy (under the Other strategy type), rather than a derived-fact strategy.

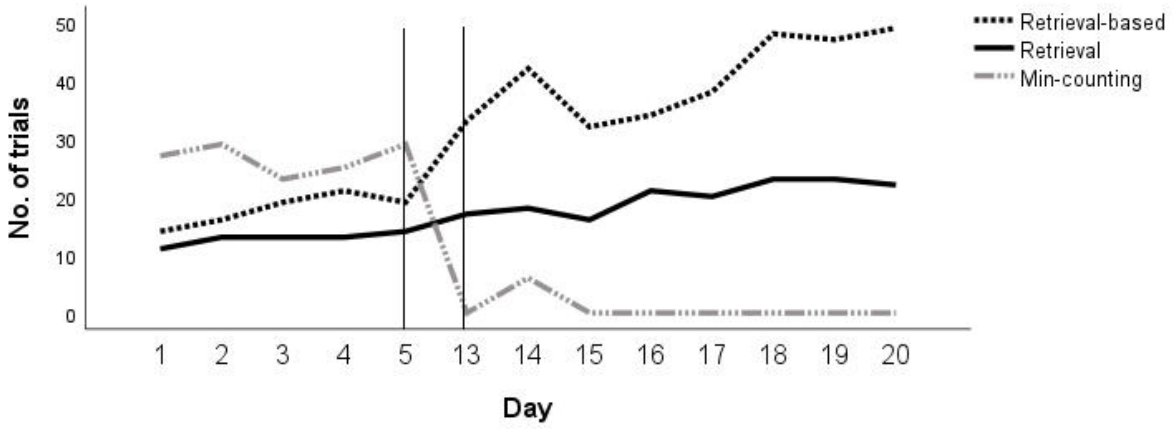

Figure 2: Strategy use for pre-intervention phase (days 1-5) and post-intervention phase (days 13-20)

Nanuka made only four errors during the pre-intervention phase (4/245 trials representing 1.6% inaccuracy): one using a count-from-first strategy, two using a previous-problem strategy, and one where she was "not sure" how she had arrived at the answer. In the post-intervention phase, she recorded 10 errors (10/392 representing 2.6% inaccuracy).

During the post-intervention phase (days 13-20), Nanuka used a min-counting strategy on only six trials (all on day 14). During the post-intervention phase (days 18-20), Nanuka correctly and consistently retrieved answers to six problems in addition to those she retrieved in the pre-intervention phase: 3 + 7, 7 + 3, 6 + 4, 4 + 6, 6 + 5 and 6 + 3. She also increased her use of derived-fact strategies to solve between 14 and 20 problems each day (making only one error that was quickly self-corrected). Most notably in this phase, Nanuka solved problems with an addend of nine using a bridging-ten strategy [e.g., 9 + 4 = 9 + 1 (known) + 5] or an overshoot strategy [e.g., 9 + 7 = 9 + 9 (known) - 2], and problems with an addend of five using a fives strategy [e.g., 8 + 5 = 5 + 5 (known) + 3].

Comparing Nanuka's performance in the pre-intervention phase to that in the post-intervention phase (see Figure 2), her use of retrieval appears to have increased at a similar rate as a result of practice

during both phases. However, her use of retrieval-based strategies jumped from 19 trials in day 5 to 33 trials in day 13, reflecting a notable increase in the use of derived-fact strategies (note, retrieval-based strategies encompass retrieval and derived-fact strategies), and a corresponding decrease in use of min-counting. Furthermore, her use of retrieval-based strategies increased at a higher rate during the post-intervention phase than the pre-intervention phase. It is important to keep in mind here that use of a derived-fact strategy was only recorded for trials where the Keyboard was not used.

When examining video data of trials involving the use of the Keyboard, we found evidence suggesting the Keyboard facilitated the transition from min-counting to retrieval for some problems, from min-counting to derived-fact strategies for some problems, and from min-counting to derived-fact strategies to retrieval on other problems. We illustrate these findings in Table 2 by summarising trials for four problems, including the strategy used (M = min-counting, R = retrieval, D = derived-fact, K = Keyboard, O = Other), the reaction time (RT) recorded, and if an error was made (incorrect trials are shaded grey).

Table 2: Strategy and reaction time (secs) recorded each day for four problems

	Pre-intervention phase					Post-intervention phase							
	1	2	3	4	5	13	14	15	16	17	18	19	20
3 + 7	M	M	M	M	M	K	D	K	R	R	R	R	R
	4.5	2.3	5.3	2.8	2.5	4.6	2.6	7.2	1.7	2.0	1.4	1.8	2.6
8 + 5	M	M	M	M	M	D	M	K	K	K	D	D	D
	5.1	3.3	3.4	2.9	2.8	6.5	7.9	5.9	7.7	12.1	5.1	8.9	3.0
5 + 7	M	M	M	M	M	K	O	K	K	K	D	D	D
	4.0	3.4	6.3	3.0	3.0	6.6	10.6	4.7	4.4	8.4	6.5	9.8	3.0
9 + 7	M	M	M	M	M	K	D	K	K	K	R	D	D
	4.7	3.5	4.4	4.0	3.5	9.4	6.1	6.5	6.6	5.6	2.0	7.8	7.0

Note. M = min-counting, R = retrieval, D = derived-fact, K = Keyboard, O = other. Incorrect trials are shaded grey.

To solve all four problems shown in Table 2, Nanuka consistently and accurately used the min-counting strategy throughout the pre-intervention phase. Differences in RTs for these trials appeared to reflect her efforts to first determine if she knew the answer.

In the post-intervention phase, Nanuka chose to solve 3 + 7 on days 13 and 15 using the Keyboard. On these trials she placed her finger on seven and moved it forward in one movement to point to 10 while at the same time stating that “7 plus 3 is 10”. From day 16 onwards, she confidently retrieved the answer 10. Use of the Keyboard supported her here to make the transition from min-counting to retrieval.

When solving problems 8 + 5 and 5 + 7, the Keyboard supported Nanuka to transition from using min-counting to derived-fact strategies; however, the transition encompassed remarkable variability in strategy choice. To solve 8 + 5 in the post-intervention phase, she used the Keyboard on four occasions (days 13, 15, 16, and 17) by pointing at eight, moving her finger forward five in one movement to 13, and reporting "I imagined two and then three" or "I saw two and then three". On days 18 to 20, she used a derived fact-strategy, but on each of these days, the strategy was different [9 + 5 (known) - 1, 8 + 2 (known) + 3, and 5 + 5 (known) + 3)]. To solve 5 + 7 in the post-intervention phase, Nanuka used the Keyboard four times (days 13, 15, 16, 17) by either pointing or looking at seven, then moving forward five keys, stating that she broke the five up into three and two. She used a derived-fact strategy on the last three days (day 18–20) but it was different to the strategy she had modelled using the Keyboard: on these trials she used a fives strategy [5 + 7 = 5 + 5 (known) + 2].

After the intervention phase, Nanuka solved the problem 9 + 7 using the Keyboard on three occasions by pointing at nine and moving forward seven in one movement (jump), reporting "there's three, two and another two" (day 13), "I counted two, three and another two" (day 15) and "I saw two, and three, and then another two (day 16). On day 17, she pointed to nine, then ten and looked at 15 on the Keyboard reporting "nine plus six is 15 so I plussed one". On day 18 (when the keyboard was not available) she retrieved the correct answer, and on the two final days she used a derived-fact strategy [9 + 1 (known) + 6 on day 19; 9 + 9 (known) - 2 on day 20]. These trials indicate that the Keyboard facilitated the transition from min-counting to derived-fact strategies and retrieval. The time Nanuka took to solve the four problems shown in Table 2 using a derived-fact strategy is noteworthy when compared to the time taken to solve them using a min-counting strategy (discussed below).

Discussion

There is a growing realisation that many students are using counting strategies for simple addition at a time when it is no longer advantageous for them to do so (Graven & Venkat, 2021; Hopkins et al., 2022). Nanuka is an example of such a child. Curriculum expectations suggest that by around Year 2, Nanuka would have replaced counting strategies with efficient retrieval-based strategies for simple addition, but she was still counting on two years on in Year 4. The Keyboard intervention was highly successful in enabling her to replace min-counting with retrieval-based strategies.

From a theoretical perspective, this is an important case study. Nanuka frequently used the most efficient counting strategy (min-counting) to solve simple addition problems and almost never made a mistake when using it. This is intriguing and at first glance appears to challenge Siegler's theory that retrieval will come to dominate performance if students use an efficient and accurate backup strategy. However, the matter is not straightforward when one considers the transitional role derived-fact strategies play in leading to retrieval (Gaidoschik, 2012). Importantly for this student, derived-fact strategies were not particularly efficient in terms of speed. Nanuka could calculate answers more quickly and just as accurately using a min-counting strategy compared to a derived-fact strategy: thus, it could be argued that her propensity to min-count before the intervention reflects the adaptive use of strategies. In relation to the research question, the Keyboard allowed Nanuka to experiment with solution procedures other than counting, which propelled her towards using derived-fact strategies even though these required more time for her to execute. She used these with remarkable variation.

Consistent with Siegler's theory, her choice of strategy appeared to be influenced not only by previous experience solving the same problem, but also by previous experience solving similar problems (i.e., problem types). With practice, Nanuka is likely to become faster at using derived-fact strategies.

Pupils' understanding of numerical pattern: an analysis of pupils' solutions to similar problems in grades 2 and 3 of primary school

Darina Jirotková[1] and Jana Slezáková[1]

[1]Charles University, Faculty of Education, Prague, Czech Republic; darina.jirotkova@pedf.cuni.cz

This paper presents the results of analyses of pupils' solutions to a problem focused on numerical patterns for pupils of the 2nd and 3rd grade of primary school. The theoretical part offers justification of the importance of this topic. We used data from a three-year research project in which one group of pupils (N = 669) was followed for two years. We focused the analysis to detect different categories of the pupils' solutions. We identified 7 categories according to the correctness of the results in the different fragments of the patterns of a given task. Based on this we formulated three levels of pupil´s perception and understanding of linear increasing number patterns. For pupils identified in the project as being at risk of school failure (N = 43), we assessed their success in solving this task.

Keywords: Number series, understanding pattern, relationship, algebraic thinking.

Introduction and theoretical background

The paper deals with the perception of the number series by pupils of the 2nd and 3rd grade and the use of its pattern and possibly the relationship between two series to solve the problem. The task was given to grade 2 pupils and a year later a similar task to the same pupils in grade 3 as part of the project *Teachers' Understanding of the Causes of School Failure and the Effectiveness of Pedagogical Interventions*. The entire didactic test in mathematics, together with 11 other test items (in Czech language, psychology, questionnaire survey of pupils' conditions for learning, their performance at school, etc.) was aimed at identifying pupils at risk of school failure. We are aware that a pupil's possible deficit in understanding the pattern threatens the pupil's development of the ability to generalize, the development of algebraic and functional thinking. "Generalization is an essential component of computational thinking[1] that involves identifying patterns, rules, and relationships that are generally applicable in various mathematical contexts." (Purwasih, et al., 2024, p. 404).

The importance of the concept of pattern for the development of pupils' mathematical thinking is evidenced, for example, by its key place in curriculum documents defining important mathematics-related knowledge and skills learners should develop in the area of algebra (e.g. recognize, describe,

[1] Computational thinking and mathematical thinking differ in their focus, approaches, and goals, although they overlap and complement each other. Computational thinking is based on the principles of computer science and focuses on solving problems that can be formulated and solved using algorithms or computers.

extend, and generate patterns) not only in the Czech Republic[2], but also worldwide – Global Proficiency Framework for Mathematics, Grades 1 to 9 (2020)[3].

The key role of the discovery of patterns in the cognitive process in mathematics is mentioned e.g. by Z. Dienes in his formulation of the six stages of the mechanism of the cognitive process in mathematics (Dienes, 1960). The recognition and creation of patterns creates in the mind of the pupil the basis for the gradual understanding of more complex mathematical concepts and later the transition to abstract thinking. Also, in Grover and Pea (2021) the authors state that pattern recognition along with algorithmic thinking, abstraction, and decomposition are part of computational thinking.

Orton and Orton (1999) explore how to use patterns as an effective tool for teaching algebra as a key and challenging component of mathematics, and they emphasize that working with both numerical and geometric patterns help pupils better understand basic algebraic concepts such as variables, equations, and functions. An extensive investigation of primary school pupils' thinking when working with geometric patterns has been conducted by E. Swoboda (2006) and her team of collaborators (Rozek, 2005). In their research they demonstrate the importance of the concept of patterns for mathematical thinking. They consider them as a key tool for developing pupils' ability to discover patterns and structures. Patterns contribute to the development of geometric reasoning and logical thinking, especially in younger children as they learn to recognize repeating elements or symmetries.

In Blanton and Kaput (2005), the authors emphasize that a good foundation of algebraic thinking in the early stages of education requires the creation of a learning environment that encourages exploration and generalization of patterns. Thus, in addition to learning to solve specific problems, pupils learn to predict other members of a pattern, and they learn to see mathematical relationships and structures that are the essence of deeper mathematical reasoning. Thus, working with patterns allows pupils to move from concrete arithmetic reasoning to abstract algebraic thinking (Cobb, 1998; Lee et al., 2011; Mason, et al., 2010; Mason, 2018; Sophian, 1997). The idea that early cognitive abilities and pattern skills predict future success in mathematics is also introduced in Lee et al. (2012).

Methods

It was noted above that the task we focus on in this paper was part of a large-scale testing of Grade 2 and Grade 3 pupils. In total, 669 pupils took part in the testing. However, not all pupils participated in all items of testing due to reasons such as illness or transfer to another school. The pupils were from 29 classes, so we worked with 29 teachers. The classes were from 22 mainstream primary

[2] A major review of curriculum documents is currently in progress in the Czech Republic in collaboration between recognized experts and the wider teaching community. As far as mathematics at primary schools is concerned, these documents have added one whole area called Algebra with an emphasis on working with patterns.

[3] This document was developed by the UNESCO Institute of Statistics (UIS); the U.S. Agency for International Development (USAID); the World Bank Group; the Foreign, Commonwealth and Development Office (FCDO); the Australian Council for Educational Research (ACER); the Bill and Melinda Gates Foundation; and representatives of many other development partner organizations, including several university professors.

schools, from different areas of the country. The condition for selecting a teacher and thus a class was that the teacher had a good reputation in the way of conducting their lesson at the school and at least three years of experience. The research team of the whole project consisted of 25 experts from the fields of psychology, pedagogy, special education, Czech language, mathematics and statistics. A team of mathematics educators was responsible for creating the didactic test and interpreting the data, but everything was discussed by the entire team. The test in Grade 2 was administered in spring 2021 (N = 632) and the test in Grade 3 was administered in spring 2022 (N = 612).

Task creation

The task for the mathematics didactic test was created based on an analysis of several textbook series of mathematics for 1st and 2nd grades most used in the Czech Republic in terms of expected pre concepts. We found that pupils should have experience with repeating patterns given by namely color, shapes, or symbols, both linear (e.g. a-a-b-a-b-) and cyclical. Pupils continue the patterns or complete them forwards and backwards. Next, they complete the missing elements of a pattern. They also experience a pattern with repeating patterns given by two parameters, e.g. color and shape. Pupils also have experience of completing number series, e.g. completing missing numbers or even marks on the number line and completing two parameter tables in which they add numbers in a relationship. This includes experience of multiplication series as a repeated addition. We have assumed these experiences of the pupils, and our expectations have evolved from this.

Tasks and their apriori analysis

The text of the task describes a story from the pupil's experience, how the missing numbers were created. The pupil's task is to fill in the missing numbers on the fragments. The picture of the three fragments in Figure 1 has a distorted number structure in two linear increasing series.

Text of the problem: *Peter wrote two rows of numbers on a piece of paper. His brother blacked out some numbers and tore the paper. In the picture you can see what was left. Can you find out which numbers are blacked out? Fill them in.*

Figure 1: Assignment for 2nd a 3rd grade

For Grade 2, this is an increasing series of small natural numbers in the 1st row and an increasing series of odd numbers in the 2nd row. For Grade 3, the 1st row is an increasing series of even numbers (multiples of two), and the 2nd row is an increasing series of multiples of three. The pupils' task is to continue the series forwards and backwards from the given number, and in the third fragment in 2nd row it is necessary either to reveal the link with the 1st row, (in Grade 2 task, under the number n in 1st row is the number $2n$-1 in the 2nd row, in the Grade 3 task, under the even number n in the 1st

row is the number $3n/2$ in the 2nd row) or it is possible to find missing numbers between the second and the third fragment. The problem diagnoses the pupil's orientation in two number patterns, the pupil's ability to detect the connection between the number series in the 1st and 2nd row.

Tasks of this type are crucial for the development of generalization skills, which are an important part of mathematical literacy (Dienes, 1960). They can also be considered as propaedeutic for the development of algebraic reasoning, which is the focus of the second stage of primary school (Orton & Orton, 1999).

Data analysis

We considered all the pupils' "mistakes" (any results that differed from the expected one) and we looked for their causes. However, we got the answers only when we watched the whole solution to the problem. We recognized that describing the causes of individual mistakes was not the way to go due to the high variability of the solutions (see Table 2). We decided to divide the solutions into categories according to the results in each fragment of two patterns in the task. We arrived at the following 7 categories:

A pupil

0. does not recognize even one number pattern (incorrectly filled in fields a, f and g),

1.A recognizes only one number pattern (i.e., the entire first fragment in the 1st or 2nd row),

1.B recognizes both number patterns (i.e., the entire first fragment is correct),

2.A recognizes the number pattern and continues it in the second fragment only in the 1st row (a) without, (b) with gap filling,

2.B recognizes the number pattern, continues it and applies the pattern rule in the third fragment in the 1st row (a) without, (b) with gap filling, or in the second fragment in the 2nd row,

2.C recognizes the rule of pattern and continues it in the third fragment in the 1st row and in the second fragment in the 2nd row (a) without, (b) with gap filling,

3. recognizes the rule of pattern in each pattern, completes the missing element and applies the rule of pattern to create the pattern of the 2nd row of the third fragment (a) without, (b) with gap filling.

Findings

According to these categories, we determined three pupil's levels of perception and understanding of the linear increasing number patterns. We consider the pupils whose solutions we classified into categories 0, 1A and 1B on level I. At level II we consider pupils whose solutions fall into categories 2A, 2B, 2C and at level III we consider pupils whose solutions fall into category 3.

Of the group of 43 grade 3 pupils who were identified as at risk in the project based on all 11 test items, 22 pupils were at level I and 21 pupils were at level II, no pupil reached level III.

In the test for Grade 2, the task was among the least successful, in the test for Grade 3 it was the opposite. The average success rate between the grades increased significantly (from 59% in Grade 2 to 78% in Grade 3).

In Figure 2 we show fields coding in the task, which is the same for both Grade 2 and Grade 3.

Figure 2: Coding of fields

Table 1 gives an overview of the success rates in each field.

Table 1: Percentage success rate in each field

	a	*b*	*c*	*d*	*e*	*f*	*g*	*h*	*i*	*j*	*k*	*l*
G 2	92,09	70,25	72,31	66,14	68,83	44,46	54,27	22,94	23,42	5,70	5,85	6,01
G 3	92,65	70,75	73,37	64,54	64,87	91,01	88,89	56,70	56,37	10,78	11,44	10,13

Let us note some interesting phenomena from Table 1. P1. Improvement between fields f and g (the first fragment) in Grade 2 and a slight deterioration in Grade 3; P2. rapid improvement in the field f between Grade 2 and Grade 3; P3. rapid improvement between Grade 2 and Grade 3 in the field h (or in field i); P4. rapid deterioration when moving from the first to the second fragment, i.e. from field g to h in both grades; P5. slight deterioration between Grade 2 and Grade 3 in the fields d and e; P6. significantly poor results in the fields j, k, l in both grades.

To illustrate the variability of the pupils' solutions we offer Table 2 in which we add the information about the most frequent pupils´ mistakes and their frequency to the percentage success rate. The first and the third columns show the expected results in certain fields. E.g. 13 [33] in the second row, second column means that mistake 13 occurred in the field d 3times.

Table 2: Percentage success rate and mistakes in the fields

Grade 2		Grade 3	
d = 15	66,14%; 13 [33], 14 [18], 11 [12]	**d = 30**	64,54%; 32 [46], 26 [27], 28 [20]
e = 16	68,83%; 15 [38], 14 [17], 18 [11]	**e = 32**	64,87%; 33 [47], 28 [19], 30 [15]
f = 7	44,46%; 6 [102], 8 [55], 4 [29]	**f = 12**	91,01%; 1 [9], 7 [4], 11 [4], 14 [4]
g = 11	54,27%; 10 [162], 12 [23], 8 [18]	**g = 18**	88,89%; 17 [12], 14 [6]
h = 19	22,94%; 21 [215], 13 [42], 17 [39], 15 [24]	**h = 30**	56,70%; 28 [38], 24 [37], 21 [29], 34 [22], 32 [21]
j = 29	5,70%; 18 [143], 25 [79], 24 [49], 31 [35]	**j = 45**	10,78%; 39 [130], 40 [67], 42 [44]
k = 31	5,85%; 19 [150], 27 [61], 25 [50], 33 [32]	**k = 48**	11,44%; 42 [138], 43 [50], 45 [35], 36[26], 38 [26]
l = 33	6,01%; 20 [143], 29 [55], 26 [47], 35 [32]	**l = 51**	10,13%; 45 [128], 46 [58], 48 [46]

Discussion and conclusion

First, we will discuss and interpret the 6 phenomena mentioned above.

P1. Better results in field g than in field f in Grade 2 indicate that continuing the number series is easier than filling in the missing number. The slight deterioration in Grade 3 is explained by the fact that numerical mistakes were more frequent: e.g. 15 + 3 = 17.

P2 and P3. The rapid improvement is explained by the fact that in Grade 2 it is a series of odd numbers, which is not worked with as often, and in Grade 3 it is a series of multiples of 3, which is part of the core Grade 3 curriculum.

P4. The deterioration from moving from the first to the second fragment (from g to h field), (in both grades by about 30%) indicates a higher cognitive demand for the application of the rule of pattern.

P5. The slight deterioration in fields d and e (the fields of the third fragment) in Grade 3 is since the difficulty of the rule in pattern in the 1st row and, therefore, the application of this rule has increased.

P6. For all correct solutions in fields j, k, l of the third fragment, the strategy of continuing the row on the same line and filling in the missing numbers in the breakaway part in the gaps between the fragments was applied in Grade 2. In Grade 3, there were already 4% of pupils who did not write any auxiliary numbers in the gap, so we conclude that these pupils were already working with the relationship between 1st and 2nd row.

Now we will provide some illustrations for levels I and II. Figures 3, 4 and 5 illustrate Level I. In Figure 3 we can see an example where all fields are filled incorrectly. The 3rd grader does not recognize even simple number pattern in the first fragment (incorrectly filled in fields a, f and g).

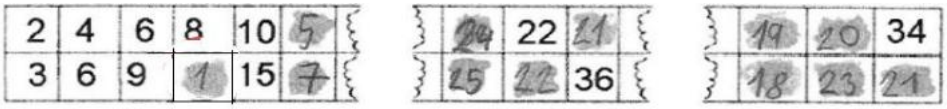

Figure 3: Category 0

In Figure 4 the pupil recognizes only one number pattern (the whole first fragment in 1st or 2nd rows). Although the pupil recognizes the pattern in the first fragment, he/she cannot apply the pattern rule and does not recognize that the series is increasing.

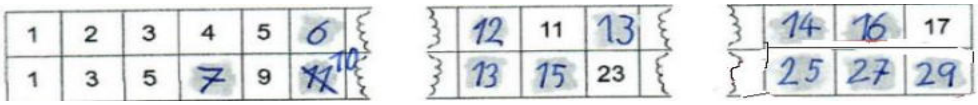

Figure 4: Category 1.A

In Figure 5 the pupil recognizes the pattern in both rows in the first fragment and can continue it but does not apply the rule of pattern in the next fragment. On the positive side, however, he/she is making his/her own pattern within each successive one; in the second fragment the number series grows by 3, in the third by 2. The pupil recognizes both number patterns (i.e. the entire first fragment is correct).

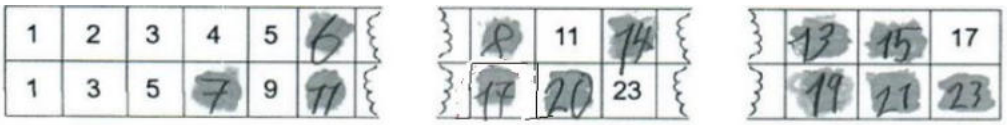

Figure 5: Category 1.B

Figures 6, 7 and 8 illustrate solutions on Level II. In Figure 6 the pupil uses the strategy of filling in the gaps between the fragments. The pupil recognizes the number pattern and continues it in the second fragment only in the 1st row.

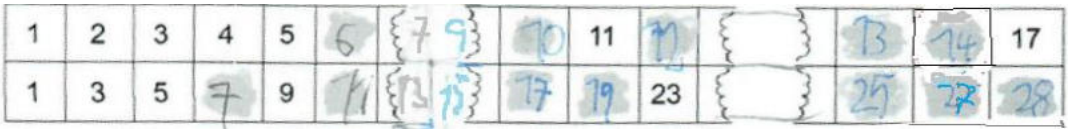

Figure 6: Category 2.A

In Figure 7 the pupil uses the strategy without filling in the gaps between the fragments. In the third fragment there is a number pattern, but it does not follow the second fragment. The pupil recognizes the number pattern, continues it and applies the rule of pattern in the third fragment in the 1st row.

Figure 7: Category 2.B

In Figure 8 the pupil recognizes the rules of both patterns, and can even apply them to the next fragments, but in the third fragment in the 2nd row it does not follow.

Figure 8: Category 2.C

The levels we determined for this task largely correspond to Dienes' (1960) categories of the cognitive process. The pupils in our research showed a great variety of solutions to one task, and in fact, covered the whole range of the cognitive process within one grade. Let us add that if a pupil is at level I in Grade 3, this is a condition that threatens the pupil's further cognitive development (Lee et al., 2012). The 22 pupils out of 43 identified as at risk also confirm by solving the task itself that they belong to this group, as they have only reached level I. With these pupils it is necessary to work more intensively with patterns and to return to simpler patterns (with repetition) given by shape, colour or rhythm presented kinesthetically and acoustically. Only then it is possible to move on to numerical patterns.

To take into account, the wide range of cognitive levels of the pupils when working with patterns, the teacher should be familiar with the content and goals of the pattern tasks and interpret the content in an exaggerated "hundred times different" way based on an understanding of the pupils and their learning processes.

Word problems as a possible means of raising awareness of arithmetical structures

Eszter Kónya[1,2]

[1]University of Debrecen, Hungary; eszter.konya@science.unideb.hu

[2]MTA-DE Early Science Learning Research Group, Hungary

In the transition from arithmetic to algebra, it is crucial to move from a focus on numerical solutions to the methods and procedures that led to those solutions. Our research focuses on identifying the arithmetic structures of word problems and using them to the solution. We surveyed 145 upper primary students and analysed their solutions for appropriately constructed word problems. Investigating the solution strategies, we conclude that the tasks presented are suitable as a starting point for working with arithmetic structures. However, a classroom discussion following the task solutions seems to be necessary.

Keywords: Word problem, quantitative reasoning, arithmetic structure.

Introduction

In the transition from arithmetic to algebra, it is crucial to move from a focus on numerical solutions to the methods and procedures that led to those solutions (Warren, 2003). Therefore, many studies (Herscovics & Linchevski, 1994; Kieran, 2018b; Linchevski & Livneh, 1999; Pitta-Pantazi et al., 2022; Warren, 2003) highlight the need for awareness of arithmetic structures and their impact on early algebra learning. Arithmetic operations are interpreted through word problems (WPs) in various contexts, and these tasks also provide practice in performing operations. Researchers generally agree that building a mathematical model for a situation formulated in a WP is more complex than determining the result of operations on numbers. However, some research also argues that a well-formulated and carefully chosen WP can help even lower-ability learners find the correct answer to a sequence of operations (Verschaffel et al., 2020). In this case, the text's connection with everyday life may help them make sense of the operations. Our research focuses on identifying the arithmetic structures of WPs and using them during the solution. The two problems presented in the paper can be solved by simply performing arithmetic operations and reasoning based on the arithmetic structure of the problem. We wonder whether these WPs contribute to identifying the problem situation's arithmetical structure and, thus, indirectly developing early algebraic thinking. Therefore, we formulate two research questions: (1) Can students in grades 3-4 correctly answer WPs whose arithmetic background implies the possibility of identifying the properties of operations and their relations? (2) What problem-solving strategies do they use?

Theoretical framework

Linchevski and Herscovics (1996) suggest that appropriate preparation, i.e., developing the operation sense in upper primary school, would assist students in overcoming many obstacles they face when learning algebra. Mason et al. (2009) emphasise that mastering procedures is essential to exploiting mathematically meaningful opportunities, but recognising mathematical structure makes a significant difference in understanding. They use the term ‘structure’ to refer to the generalised properties of and

relationships between mathematical objects. The arithmetic structure of an expression is, therefore, determined by the properties of the operations it contains and the relationships between them. Maffia and Mariotti (2017) describe the awareness of the structure sense in arithmetic as a set of competencies. Two of the six competencies are particularly relevant to our study. The first is identifying an arithmetical expression as an entity, for instance, comparing two expressions without calculating partial results. The last is recognising which manipulations are possible and which are useful. According to the aim of transformations (comparing or calculating), some manipulations can be more helpful or more effective.

Warren's study (2003) points out that most students leave primary school with limited awareness of arithmetic operations as general processes. From the instances they are experiencing in arithmetic, they have failed to abstract the relationships and principles needed for algebra. Consequently, Warren highlights that preparation should occur in the early years. Pitta-Pantazi et al. (2022) surveyed 6th grader students, where the tasks in the arithmetic test could be solved based on calculation procedures or identifying general properties. It was found that low achievers used strategies based on calculations more often. In contrast, high achievers did not perform calculations immediately, but they analysed and used the embedded structure. The results also showed that students who could manipulate structure within arithmetic expressions could also manipulate the syntactical structure of algebraic expressions where calculations are impossible.

In primary mathematics, WPs play a crucial role in building a situational model of an everyday life context and transforming it into a mathematical model (more precisely, into an arithmetic model). They can be described as "verbal descriptions of problem situations wherein one or more questions are raised that the answer to which can be obtained by the application of mathematical operations to numerical data available in the problem statement" (Verschaffel et al., 2000, p. ix). Traditionally, it was assumed that WPs are solved by identifying and applying the mathematical concept, operation, or rule formulated verbally. Therefore, WPs can only be solved by learners who have already acquired the necessary mathematical knowledge. Consequently, they are more complex than their corresponding symbolic representation. However, an essential result of cognitive analyses of elementary arithmetic WP solving was the discovery and systematic analysis of the various informal ways children successfully solve these problems well before being taught the corresponding mathematical knowledge and skills in school (Verschaffel et al., 2020).

Whereas young children try to process the problem sensibly, older students often apply ready-made strategies. This type of schematic knowledge is only found in proficient WP solvers because schemata are constructed through practice and abstracted from numerous encounters with the same exemplar of a problem category. However, sometimes, a more efficient strategy to solve the problem would be desirable. This strategy supposes that the solver managed to inhibit the activation of typical problem schemata to construct an alternative mental representation of the problem situation. "In other words, individuals seem to be able to weigh the costs and benefits of either blindly applying straightforward schemata or engaging in a cognitively more demanding activity to construct an alternative mental representation" (Thevenot, 2017, p. 16). We should first refer to Vergnaud's work, which distinguished numerical and relational calculus to understand this phenomenon. Numerical calculus involves operations on numbers to find the result, while relational calculus describes transformations

of relationships given in situations (Vergnaud, 1979). The two kinds of calculations are relatively independent and are probably carried out separately. However, they are linked because our decisions about what type of calculation to perform often depend on our understanding of the relation between the quantities involved in the problem (Nunes et al., 2016). Thompson (1993) emphasised the difference between numerical and relational calculation, introducing the term 'quantitative reasoning': "A prominent characteristic of reasoning quantitatively is that numbers and numeric relationships are of secondary importance and do not enter into the primary analysis of a situation. What is important is relationships among quantities" (p. 165). In our view, reason quantitatively helps to construct the situation model of a problem and abstract from the numerical aspects of a particular situation. This way, the focus is transferred from the specific numbers to the generalised features.

We assume that an appropriately chosen arithmetic WP can contribute to recognising the underlying arithmetic structure because its context can draw attention to the relationships between quantities. Based on the research findings above, it also seems possible that these tasks can be solved by students with lower skills or less knowledge of the respective mathematical concepts and procedures, relying on quantitative reasoning.

Methods

The survey involved 76 third- and 69 fourth-grade students (aged 10-11) from a primary school in a large city in Hungary, three classes per grade. The school has above-average academic performance and was in the top 20% of the National Mathematics Competency Assessment in 2022. Students are referred to as S1, S2, ..., S145 in this paper.

The survey took place in May 2023. An exercise sheet with 12 WPs had to be solved individually, each WP based on a particular operation property or a relationship between two operations. No time limit has been set for the written work. A common feature of the problems was that they allowed students to use various solution strategies: arithmetic calculation, quantitative reasoning, or reasoning based on an identified arithmetic structure. The three-digit numbers in the texts were chosen so mental calculations could be easily performed, and using written algorithms was unnecessary. According to the national curriculum, by the end of the second school year, students have mastered the mathematical background of the tasks and have gained practice in solving WPs. In the present study, two comparison problems are discussed.

WP1. Marci and Boti bought a pack of football cards for 350 HUF each. Marci had 850 HUF left after the purchase and Boti 690 HUF. Which of the boys initially had more money? By how much? Justify your answer.

This task is an additive comparison WP. It contains linguistic inconsistency because the keyword 'left' suggests subtraction, but the required arithmetic operation is addition. We must compare the boys' original money (using subtraction) to answer the difference.

– The expected arithmetic answer (AR): Originally, Marci had 850+350=1200 HUF, while Boti had 690+350=1040 HUF. Since 1200 is more than 1040 by 160 HUF (1100–1040=160), Marci had more money by 160 HUF.

– The answer based on quantitative reasoning (QR): Both boys spent the same amount, so whoever had more money initially had more left over. Marci had (850–690=) 160 HUF more money left, so he had that much more originally.
– The answer based on arithmetic structure (AS): If you subtract the same number from a larger number, the difference will be larger by the difference between the two initial numbers. Now, we know that the larger difference belongs to Marci, so Marci initially had more money, by (850-690) = 160 HUF.

WP 2. Luca had 600 HUF, and Sári had a third of that. Their grandmother gave Luca 200 HUF for her birthday while, at the same time, she tripled Sári's money. Which girl now has more money? Justify your answer.

WP2 is semantically complex because it needs to perform two multiplicative and one additive operations. The language is consistent; the keyword 'third' requires division, 'tripled' multiplication, and 'gave' addition.
– The expected arithmetic answer (AR): Originally, Sári had 600÷3=200 HUF. After the grandmother's present, Luca had 600+200=800 HUF, while Sári had 200×3=600 HUF, so Luca had more money.
– The answer based on quantitative reasoning (QR): Grandma supplemented Sári's money to match Luca's original money. Luca, in turn, received extra money from her, so she ended up with more.
– The answer based on arithmetic structure (AS): If you triple a third of a number, you return the same number. If you add a positive number to a number, you get larger than the original one.

To analyse the solutions, we set up a code system. In addition to the correctness of the answer, the chosen solution strategy was also examined. Pre-defined codes were used considering the research aim and the need to code all student answers.
– AR: Correct answer. The arithmetic calculations were done either mentally or using written algorithms. The sub-results were indicated. (Minor calculation errors are ignored.)
– QR: Correct answer. Verbal explanation based on the context of the WP. No calculations appear.
– AS: Correct answer. Verbal explanation based on the structure of the arithmetic model. No calculations appear.
– NE (No Explanation): Correct one-word answer without any explanation.
– MI (Misinterpretation): Incorrect answer. The answer is based on an incorrect arithmetic model without accurately understanding the situation.
– NA (No Answer): Missing answer or wrong one-word answer.

Two coders worked independently and then decided together on the few mismatches. No Answer and Wrong One-word Answer codes were merged after coding because they have similar meanings from the research perspectives.

Result and discussion

The correctness of the problem solution is summarised in Table 1. Proportionally, more correct answers were received for WP1, while more misinterpretations occurred for WP2. Due to the semantic structure of the tasks, their complexity (number of operations to be performed), and the type of operations required (additive, multiplicative), WP1 proved to be easier than WP2 in both grades.

At the same time, it also stands out that both tasks were solved more successfully by the 4th graders. These findings are consistent with our preliminary expectations based on the literature (Daroczy et al., 2015) and our educational experience.

Table 1: Correctness of the answers

		Correct answer (AR, QR, AS, NE)	Misinterpretation (MI)	No Answer (NA)	Total
Grade 3	WP1	84,2% (64 st.)	14,5% (11 st.)	1,3% (1 st.)	76 st.
	WP2	50% (38 st.)	38,2% (29 st.)	11,8% (9 st.)	76 st.
Grade 4	WP1	92,8% (64 st.)	4,3% (3 st.)	2,9% (2 st.)	69 st.
	WP2	75,4% (52 st.)	21,7% (15 st.)	2,9% (2 st.)	69 st.

Although the semantic structures of the WPs are quite complex, the difficulty level of the problems was not an insurmountable obstacle for the survey participants. The high success rate (even in grade 3, half of the students solved the more difficult WP2) confirms the assignment of these tasks; a significant proportion of students interpreted both WPs correctly. Therefore, a deeper analysis of the correct answers seems reasonable. Answers with MI and NA codes are excluded from further investigations.

Table 2 summarises the strategies identified in the solutions where the answer was correct. (We have created a mixed code to characterise solutions with AR and QR features.)

Table 2: Solution strategies

		AS	AR	AR+QR	QR	NE	Total
Grade 3	WP1	0 st.	52 st.	0 st.	8 st.	4 st.	64
	WP2	0 st.	33 st.	5 st.	0 st.	0 st.	38
Grade 4	WP1	2 st.	33 st.	10 st.	11 st.	8 st.	64
	WP2	2 st.	26 st.	13 st.	4 st.	7 st.	52

For both WPs at both grades, there is a strong dominance of expected arithmetic answers, but answers referring to quantitative reasoning also appear. However, QR-answers are expressed verbally at different levels. In WP1, for example, there are 6 of the 8 third-grader students whose quantitative reasoning is indicated only by the subtraction of remainders (850–690). Grade 4 students answered more precisely, e.g., “If you have more money after the shopping, you had more before” (S103). In WP2, the following types of answers (10 students) were also classified as QR: “Luca has more money because she originally had more money”. This reasoning is incorrect, but it may condense the idea that after the grandmother’s gift, both girls’ money increased, and Sári’s just reached Luca’s original amount. In addition, some students provided much more well-articulated answers, for example, AS.

Recognition of the arithmetic structure was indicated clearly by only 2 fourth-grade answers (belonging to 3 students in total) for both tasks. One student, S116, gave this type of answer for both tasks (Figure 1). In the solutions, the role of numbers (350 and 3) was identified, but no operations were performed.

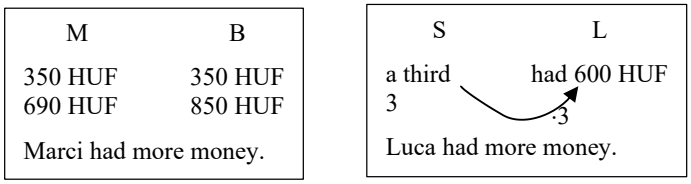

Figure 1: S116 answer based on arithmetic structure (WP1 left, WP2 right)

For both WPs, it was observed that although many students wrote down the proper arithmetic expression, they did not notice the structure this expression exemplifies; they just performed the operations. This may suggest that learners lack practice in deciding whether it is necessary to perform the operations or whether there are other ways of providing the answer. Table 3 shows this phenomenon in more detail regarding the AR-type answers for WP2.

Table 3: Summary of the arithmetic answers for WP2

	600÷3=200, 200×3=600	600÷3x3 600÷3=200, 200×3=600	600÷3=300, 300×3=900	600÷3×3 600÷3=300, 300×3=900
Grade 3	29 st.	3 st.	5 st.	1 st.
Grade 4	23 st.	14 st.	1 st.	1 st.
Total	52 st.	17 st.	6 st.	2 st.

Sixty-nine students calculated 600÷3=200 and 200×3=600 in two consecutive steps without at least noticing the identity of the first and last numbers (Columns 1-2). Although the expression 600÷3×3 or (600÷3)×3 was found in the work of 17 students, none of them determined the final result without calculation (Column 2). The work of S113 illustrates the lack of identifying the relationship between division and multiplication (Figure 2). The missing looking back phase of the problem-solving process (Polya, 1945) is seen exceptionally well by the work of those 8 students who made a mistake in their calculation (600÷3=300) and then accepted 900 as the answer for Sári's money (Column 3-4).

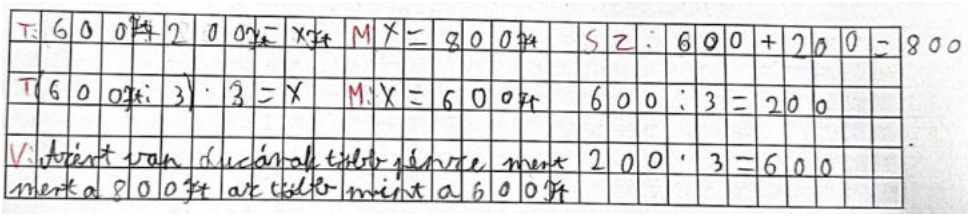

Figure 2: A grade 4 student's (S113) arithmetic answer

Figure 2 also shows traces of schematic thinking: S113 marks the learnt steps – T (Plan), Sz (Calculation), M (Answer), V (verbal answer) – in red. The verbal answer (Luca has more money because 800 HUF is more than 600 HUF.) only confirms the result and contains no new information. We found that all students in S113's class indicated the solution steps in this manner. This suggests that such 'compulsory elements' were practised in the classroom and used as scaffolding. The scaffolding reinforces the need for giving an arithmetic answer and does not encourage students to look for other, sometimes more effective, problem-solving strategies. Therefore, it can be stated that the exclusive use of the "T-Sz-M-V" scaffolding may hinder the recognition of operation properties or relations between operations when solving WPs.

Conclusion

Answering the first research question, we can establish that more than half of the students answered both WPs correctly. Furthermore, a higher proportion of older students (4th graders) answered both tasks correctly. It was also found that the additive task was more successful than the multiplicative one. About the second research question, we found that the strategy most often used, resulting in the correct answer, was to perform arithmetic operations. The students referred to the property between operations (WP1) or the relationship between operations (WP2) only in a few cases. On the one hand, many students do not recognise the structure manifested in the arithmetic model of the task despite having correctly described the model itself (i.e., the arithmetic expression). On the other hand, after 3-4 years of learning experience in school, students typically approach the problem based on a well-established arithmetic solution scaffolding and do not look for an alternative strategy if the previous one is easy to perform. The number of answers that relied on quantitative reasoning was also low.

The participants in previously presented studies were older students (6th graders). Limited awareness of arithmetic operations as general processes was assessed by solving arithmetic sentences, and the need to start this development in earlier grades was expressed. Our study examined younger students, and the arithmetic structure was embedded in the context of WPs. Our results are similar in that we also detected many arithmetic answers. Nevertheless, many other solution strategies appeared, especially among 4th graders. Overall, we conclude that the WPs presented are suitable as a starting point for working with arithmetic structures; however, a class discussion following the task solution seems to be necessary. This is also supported by the findings that the verbalisation of mathematical ideas during quantitative reasoning was often vague; consequently, formulating students' mathematical ideas needs to be improved. In all these activities, the role of the teacher is crucial, but this is a topic for future research.

Pupils' solving strategies of the word problems Fidgets type

Karolína Mottlová[1]

[1]Charles University, Faculty of Education, Prague, Czech Republic;
karolina.mottlova.ruzickova@gmail.com

This paper explores fifth-grade pupils' strategies for solving atypical word problems named as Fidgets, which lack explicit questions and require inserting provided data (numbers, words, etc.) into marked gaps in a problem text. Over six sessions in three weeks, pupil pairs engaged with these problems. Findings show that the most common heuristic strategy is Guess-Check-Revise (GCR), applied through mathematical, contextual, and linguistic senses. Pupils used direct matching or elimination to insert data and checked their solutions via calculative, semantic, and linguistic tests, though not always consistently. Revisions were done either systematically or randomly, with some strategies remaining unobservable. The study highlights the complexity and variability in pupils' reasoning processes.

Keywords: Word problems, problems solving, primary school, solving strategies, heuristic strategies.

Introduction

Word problems (WPs) repeatedly cause difficulties for pupils. Some pupils have insufficient literacy skills (Daroczy et al., 2015). They often do not draw on their real-life experiences to create a situational model of the WP (Palm, 2008) or do not perform a semantic test after solving the WP (Vondrová et al., 2019). The project *Support of the integration of mathematical, reading and language literacy in primary school pupils* aimed to help overcome these difficulties. As an outcome, the project produced an open-access methodology designed for Czech teachers, didacticians, and researchers, which includes four types of WPs along with methodological recommendations for addressing pupils' difficulties. One type is WPs of the type Fidgets. This type of WP is characterised by a larger number of correct solutions. The large number of correct solutions opens space to work with the text of the WP, e.g., to assess which solution is realistic, which one is improbable, and to discuss among pupils the meaning of the numbers used.

Theoretical framework

Among the many definitions and delineations of a WP (e.g., Verschaffel et al., 2014), we use the delineation of Semadeni (1995), i.e., that a WP consists of three components: the mathematical structure, the context, and the format. Mathematical structure refers to the relationships between data (most often numerical) whose precise arrangement in the problem forms the mathematical model of the problem (Goldin & McClintock, 1979). One piece of data can then be omitted from the model, which must be found to solve the problem. Mathematical structure can be divided, for example, according to the types and counts of operations to be performed in the calculation. The context is set of information about the situation in which the problem is embedded (Hembree, 1992). The format of a WP can be seen as a way of wording it. The format is most often a coherent text.

In relation to the solver, we focus on the process of solving WPs and how the three components intertwine the different phases of the solution. We follow the Model of Reusser (1990): 1.

Understanding the text; 2. Understanding the situation and context (creating a situational model); 3. Translating the situation into the language of mathematics; mathematization (creating a mathematical model); 4. Calculation; 5. Creating the answer. Those phases do not go fixed step by step, but the solver continuously returns to specific phases and freely transitions between them.

The solution process is the overarching framework for selecting and applying strategies. When solving WPs, the solver goes through phases and, in each phase, selects and uses different strategies in order to successfully complete the current phase. "When solving problems, the solver first integrates the textual information into an appropriate situation model or a mental representation of the situation being described in the problem, which then forms the basis for a solution strategy" (Daroczy et al., 2015, p. 4). This suggests that the choice of WP-solving strategy starts at the boundary between the second and third phases. The solution can then be approached in three ways: trial without feedback, straight-forward way as a learned solution algorithm, and heuristic strategy. "Heuristics are cognitive strategies that help to solve a task for which one does not have a clear answer or ready-made solution method. Specifically, heuristics are search strategies for problem analysis and transformation that do not guarantee, but significantly increase the probability of, finding a correct solution because they induce an active and systematic approach to the task" (Verschaffel et al., 2020, p. 5). We agree with the research (e.g., Depaepe et al., 2010; Eisenmann et al., 2015) that developing heuristic strategies is a necessary and valuable tool for coping with problems in general. At the same time, we believe that offering WPs that target using heuristic strategies will reduce the likelihood of formal uses of direct paths as surface strategies (Vondrová et al., 2019). Fidgets-type WP supports using these strategies when appropriately implemented by the teacher in the classroom.

Word problem of the type Fidgets

This type of WP comes from the Singapore methodology (Kaur & Har, 2009). WPs of the Fidgets type have three parts: the instruction, the gallery of offered data, and the text of the problem situation with missing data instead of gaps. The pupil's task is to fill in the numbers so that the problem situation makes sense. Each problem situation text must make sense mathematically, contextually, and linguistically. In addition, the specifics of each language govern the words' forms and the numbers that determine the count associated with those words. The following is an example of the WP called "The party" (problem 1).

> *Fill in numbers 32, 2, 80 and 5 in the gap in such a way that the text makes sense.*
>
> There were __ children at a party. Ms Sally bought __ packet of the sweets. There were __ sweets in each packet. During the party, she gave __ sweets to each child and had none left.[1]

Problem 1 has eight possible solutions by filling numbers in the gaps. The difficulty is mainly due to the mathematical structure. The solver may have difficulty finding the relationships between the data in the first (g_1) and fourth (g_4) gaps and between the second (g_2) and third (g_3) gaps. The mathematical model is then, for example, $g_2 \times g_3 \div g_1 = g_4$. Limiting the number of solutions can be achieved either by reasoning based on the context of the problem (e.g., "Only 2 children will not

[1]Adapted from: Shaping Maths (Activity book 3A Part 2, Q4, p. 22) by Pearly Tan (Kaur & Har, 2009)

go to the party.") or, in the case of Slavic languages, the location of numbers is influenced by the ending of the word. In Czech, the word "was" has different endings: for the number 1 [by**l**]; for the number 2–4 [by**ly**]; for the number 5 and more [by**lo**]. This WPs' translation uses "was" to use the numbers five and more before the third gap.

Other WP Fidgets type used were "Jonas is shopping" (problem 2) and "The tram" (problem 3).

> Jonas puts __ cucumbers per __ crowns and cabbage for __ crowns in his shopping basket. He paid __ crowns. (*numbers to fill in: 4, 8, 12, 44*)
>
> When the tram arrived at the stop, there were __ passengers in it. __ got off and __ got on. At the next stop __ people got off and __ people got on. There was then a total of __ passengers on the tram. (*numbers to fill in: 3, 4, 6, 8, 17, 20*)

For those three problems, the solver must use all the numbers offered. There are WPs where fewer numbers are offered, and the solver must determine the remaining numbers himself. Other times, more numbers are offered, and the solver chooses the appropriate ones.

Methods

In this research, we worked with five homogeneous pairs of pupils from two 5th-grade classes (10-12 years old). To create homogeneous pairs, pupils were selected according to their communication ability and their mathematical and reading skills, which were identified based on classroom listening and interviews with the teachers. The 10 pupils were presented with a six series of 2–3 WPs of the Fidgets type they had never encountered before. The solution itself was not preceded by any form of preparation or training. During the six sessions (20 minutes each), pupils solved the problems using the think-aloud method. The 27 video recordings and 140 pupils' written solutions were used to create a research database which was qualitatively analysed using grounded theory techniques (Strauss & Corbin, 1990). The transcripts of each part of the research were divided into thought steps and provided with didactic commentary. Subsequently, using ATLAS ti software, the thought-steps were coded and categorized into phenomena corresponding to the research question: Which strategies do pupils use to solve atypical WPs Fidgets type?

Results

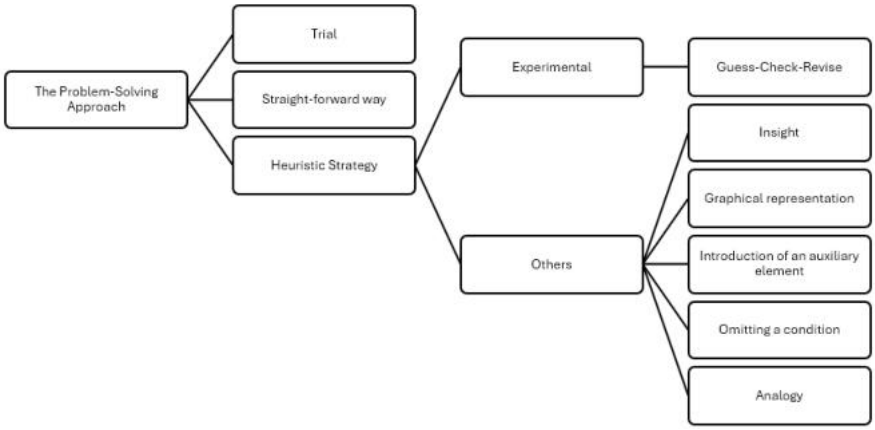

Figure 1. Pupils' problem-solving approach

Figure 1 presents the possible approaches used by the pupils in solving the Fidgets WP. The trial was used only occasionally, as demonstrated in the following example.

5A: I'm going to write Michal's solution because I want to copy it.

Since the pupils had never encountered this type of problem before, they did not have a ready-made solution and could not rely on a straightforward method. Instead, they mostly applied heuristic strategies, which we grouped into two categories: experimental and others. The main approach used by the pupils was experimental heuristics, particularly GCR and its variations, such as systematic experimentation and working backwards. Given that GCR was the most used heuristic, we now explore it in greater detail.

Guess

Guessing can be done systematically or unsystematically, directly or indirectly, i.e., by the exclusion method. The guess is always based on one of three aspects of the WP: linguistic (e.g., declension of words), context (real–life experience of the solver), and mathematics (relationships between data).

4B: ...I wrote 44 very first because of the fact that it's actually the biggest one and it's actually the sum of them all there. (problem 2)

Pupil 4B (she) perceived that focusing on the mathematical structure of the problem is important for maintaining meaningfulness. She deduced from the story and keywords where the largest number needs to be inserted (she placed it directly) and explicitly demonstrated a focus on the mathematical aspect of the problem with the word "sum". Her strategy can also be called the working backwards strategy because she realized the end state.

1A: Because...it's like, I don't know if she'd go to a party with like 2 kids, and I don't know if she'd go to a party with 32 or 80. (problem 1)

Pupil 1A (he) commented on the location of the number based on his experience of the number of children at the party. He eliminated unlikely possibilities and selected an option that made sense within the given context.

2A: Well, I just like looked it up, that the 4 cucumbers in there was probably clear because 12 cucumbers and 8 cucumbers, 44 cucumbers probably wouldn't go in there. (problem 2)

Pupil 2A (he) described his solving process by putting the number 4 directly in front of the word "cucumbers", whose form in Czech corresponds only to the use of numbers 2–4. He performed this action in the first phase of the solving process – comprehension of the text – before reading the whole problem text and creating a situational and mathematical model. He eliminated the remaining numbers, which he proved by using numbers with incorrect word forms[2].

[2]For non–Czech–speaking readers, we can illustrate by the example that we cannot connect the plural to the word "dog". The solver would say: "Here, only the number 1 can be used, because neither 2 dog or 5 dog can be said."

Check

After filling all or most data into the gaps, the pupil proceeded to the check step. Due to the research design, which involved working in pairs, this checking was done either independently or through interaction with the peer or the researcher. The check could be done right or wrong, which could then cause an incorrect answer. The solver made three types of check: a linguistic test (re-reads the text to see if it conforms to the rules of the language), a semantic test (verifies that the information matches the real situation), and a calculation test (whether the data can be put into an equation that fits the mathematical model of the problem situation).

2A: I'm thinking if the calculation works for me. But I'm guessing, again, 32 kids were at the party. She bought 80 packages and there were 5 candies in each package. So that's 400 candies total. And if it's 32, she gave them each 2. That means... 32 times 2 equals 62, so that doesn't work for me. I'll cross that out. (problem 1)

Pupil 2A (he) described the entire calculation process using the think-aloud method after fitting the numerical data into the constructed mathematical model of the problem. He concluded that his attempts were unsuccessful.

3B: Would it make sense if I wrote that the number of children at the party was 80? [laughing]

3A: Like... It seems like a lot, already, ... It wouldn't even fit in an apartment. [laughing]. (problem 1)

The dialogue illustrates the interaction between pupil 3A (she) and pupil 3B (she). Pupil 3B asked a question. Pupil 3A evaluated the completion of the number concerning the context and thus made a semantic test. Although it was unclear from pupil 3B's question whether she is uncertain about the completion of the number specifically concerning the context, pupil 3A, who answered, perceived context as the main aspect determining the use of the number.

R: Do you think you could read the whole text to me again with the numbers just added, thank you.

…

4A: Well, so we're just, we're just stopping there. Now, that it doesn't make sense to read.

After discussing the correct location of the numbers in the mathematical view, the researcher (R) invited pupils to read the whole text with the added data. Pupil 4A (she) then only stated that the solution was incorrect based on the linguistic test, although the completed numbers were correctly located based on another aspect.

Revise

After checking and in case of detecting the incorrect location of numbers in the text, the pupil proceeded to a new guess. This attempt was done either systematically or unsystematically, i.e., randomly. A systematic revise began with an initial guess, followed by a series of deliberate revisions. In the following case, we focus on an example of a systematic revise.

3B writes: first guess [20,17,8,4,_,_]; first revise [20,8,_,_,_]; second revise [20,6,8,_,_,_]; third revise – first completed solution [17,6,8,3,4,20]; second guess [8,6,17,4,_,]; fist revise of second guess – second completed solution [8,6,17,3,4,20]. (problem 3)

Pupil 3B (she) carried out a systematic revision. She filled in the number 20 in the first gap and gradually changed the number by size in the second gap. After three revisions, she placed the second largest number, 17, in the first gap and immediately arrived at a solution that matched the mathematical model of the problem. She then attempted to find a new solution by filling in the number 8 in the first gap—one she had not tried before. By chance, this led to an incorrect solution, but she realized that by changing the numbers in the fourth and fifth gaps, she could reach the correct one.

> 3B: I was thinking, like...32 kids. And, uh... 32, and if she gave each kid the 5 candies, 32 divided by, uh, 5, wait, that's not possible. That's with the remainder. ... It doesn't work. [Laughing] Because 32 divided by 5 equals 30 and the remainder is 2. ... Well. So, theoretically it could be like 80 divided by 5. Oh, I will calculate here. (problem 1)

In another problem, pupil 3B (she) performed an unsystematic revision. She made an error by incorrectly identifying the operation as division instead of multiplication. Despite constructing an incorrect mathematical model of the problem, she made a correction based on mathematical reasoning. Pupil 3B noticed the multiplicative relationship between the numbers and attempted to apply an operation that would result in an integer.

Other heuristic strategies

Other heuristic strategies included insight (created by a sudden understanding of a problem), graphical representation, introduction of an auxiliary element, omitting a condition, and analogy. Each of those strategies was used significantly less than the experimental one. As an example, Figure 2 illustrates the use of the graphical representation strategy in solving a WP[3].

Figure 2: graphical representation of WP "The pheasants" by pupil 3B (she)

According to Reusser (1990), the final phase in problem-solving is providing the answer. In the case of the Fidgets WPs, this phase involves justifying the correctness of inserting specific numbers into the text of the problem situation. The reasoning used to justify the answer is usually grounded in the nature of the test or verification process the pupils carried out.

Discussion

The results show that pupils use various strategies, as also identified in previous research by Eisenmann et al. (2015). The most common heuristic strategy is the experimental strategy, specifically GCR. Students approach the guess from three aspects of the WP: mathematical, contextual, and linguistic. They fill in the data in the text directly, i.e., identifying which data belongs

[3]Children brought pheasants to a rescue station. They brought __ pheasants. They bought grain in __ packages. There were __ kg of grains in each of the packages. That means that if divided fairly among them, each pheasant would get __ kg of grain. (*numbers to fill in: 2, 4, 5, 10*)

to which gap or by the elimination method (elimination of possibilities). Some pupils use a combination of both. They then check according to the three aspects: calculative, semantic, and linguistic tests. However, they do not always perform all three tests simultaneously. They then perform revisions systematically (e.g., starting from the largest number) or unsystematically according to random common attributes. However, it is impossible to say unequivocally for all revisions, whether systematic or not. For example, the pupil revises the change in the first gap according to its quantity, but the other gaps are filled randomly. In some cases, pupils mentally discard certain partial revisions before writing them down, for example, by considering number parity. In addition, some pupils appear to follow internal strategies that are not easily identifiable by researchers.

Conclusion

The paper briefly introduces the Fidgets WPs and the process by which pupils solve them. By analysing pupils' statements and written solutions to the problems, the types of strategies were identified. Notably, the heuristic strategy known as GCR emerged as the most frequently used. The previous findings (e.g., Mottlová & Kilienė, 2023; Mottlová & Slezáková, 2022) show that pupils' approaches to atypical WPs differ significantly from those seen in typical WP solving, suggesting that such problems have strong potential to foster the development of diverse problem-solving strategies. The format of the problems supports cross-curricular relationships between mathematics and language and offers flexibility in difficulty levels. We plan to continue investigating these aspects and to explore how pupils' experiences with Fidgets WPs can support their problem-solving in other mathematical contexts.

Problem posing by preservice teachers: The case of open problems

Ioannis Papadopoulos

Aristotle University of Thessaloniki, School of Primary Education, Greece; ypapadop@eled.auth.gr

In this study two groups of preservice teachers (PTs) (with and without experience in problem solving) are asked to pose open problems based on a simple given closed problem. The aim was to examine the characteristics of the posed problems and the role of the posers' experience in problem solving. The findings give evidence that the dominant conceptualization of the participating PTs is that open problems are the ones with multiple solutions. To create these problems, they mainly kept both the given problem and the task environment, either unaltered or slightly modified. The experience in problem solving was not a significant factor for the problem posing per se since there were not differences between the groups. However, the participants with experience in problem solving demonstrated a better understanding of the distinction between open-closed problems which was not so clear for the other group.

Keywords: Problem posing, open problems, preservice teachers.

Introduction

Problem posing is recognised as a significant activity in school mathematics which can increase students' access to sensemaking and learning in mathematics (Cai, 2022). This makes evident the need to examine teachers' ability to pose mathematical problems for their students. In the book "Mathematical problem posing: From research to effective practice" (Singer et al., 2015) one can find several studies concerning the kinds of problems teachers pose, i.e., whether the posed problems are solvable, their mathematical complexity, their similarity to the textbook problems, whether they include a variety of mathematical topics, whether they are multi-step problems, etc. Problem posing is also strongly linked to open problems since to a great extend this is what mathematicians do. They not only solve open problems but also formulate their own problems according to their experience and interests (Silver, 1995). Thus, if the aim of the teaching is to provide students with such authentic experiences (working like mathematicians), open problems and problem posing are significant elements. At the same time, problem posing is interwoven with problem solving and can be seen as a special type of problem solving (Cai & Rott, 2024). Indeed, in problem posing the necessary information is given and the 'problem' (goal) of the poser is to form a new problem. In this setting this study aims to combine these three components (problem posing, open problems, problem solving) to examine PTs' ability to pose open mathematical problems. More specifically, the characteristics of the posed problems such as their kind of openness and the way the posers intervene to the task environment when posing open problems will be examined in order to answer the twofold research question: (i) What are the characteristics of the open problems generated by PTs? (ii) How do these characteristics vary according to whether the posers have experience on problem solving?

Theoretical framework and literature review

The theoretical framework of this study builds on the notions of problem posing and open problems. Several definitions of problem posing can be found in the research literature. Papadopoulos et al. (2022) organized them in five categories. This paper is aligned with one of them, "problem posing as both generating new and/or reformulating given problems" which reflects mainly the way problem posing is perceived by Silver (1994). Then it is the notion of open problems. Pehkonen (1997) uses the term "open problems" in a broad sense including problems according to the openness of their starting situation (open-start problems) and/or the goal situation (open-ended problems) defined by the task. Silver (1995) attributes to the term "open problem" three meanings: the problem is susceptible to different interpretations and/or answers, (ii) it invites different methods for its solution, and (iii) it suggests other problems or generalizations. Especially for the second meaning it is worth mentioning that even simple routine tasks afford multiple solution methods, and this multiplicity is not always due to the task itself but also to the poser's mathematical knowledge, abilities, etc. Leikin (2018) elaborated more the meaning of the term by organizing and talking about different types of openness including among others multiple answers tasks, nonroutine problems, insight-based problems, multiple solution tasks, sorting tasks, etc. In this paper we follow the approach of Mamona-Downs and Papadopoulos (2017) which is rather aligned with Silver (1995) (see also Samková, 2019) and according to which a problem might be open in relation to: (i) the interpretations of the task situation, (ii) the variety of methods for its solution, and (iii) its different solutions. Mamona-Downs and Papadopoulos (2017) claim that these three meanings are convenient for encouraging problem posing and describe four different paths the process of posing a new problem takes place: (i) The initial problem and the task environment remain unaltered (the poser's task is to ask new questions that fit to the given data), (ii) the task environment is kept but the problem is changed (It refers to changing some or all the numerical data of the problem, or to interchange the given and the goal of the given problem, thus making the known unknown and vice versa), (iii) the task environment is modified (new properties are added to the given problem objects which are necessary to the solution), and (iv) a new task environment is used (this means that the poser is able to grasp the mathematical idea hidden in the problem and transfers the same idea in another environment).

Silver and Mamona (1990) claim that problem posing can start with transforming closed problems to open. Several studies examine teacher's ability to pose problems without specific emphasis to open problems. Crespo (2003) examining problem-posing strategies of preservice mathematics teachers found that after certain training they were able to shift from posing traditional single steps and computational problems to posing problems having multiple solutions and approaches. Later, Crespo and Sinclair (2008) found that teachers often pose trivial, non-mathematical or poor problems attributing this to the lack of opportunity to engage in a problem situation and explore it before posing. Cai and Hwang (2020) presenting the state-of-the-art in problem posing say that the existing studies "have generally supported the claim that both preservice and in-service teachers are capable of posing interesting and important mathematical problems" (p. 4), although in many cases the problems posed by the participating teachers are routine problems similar to those in mathematical textbooks, or one-step problems.

The link between problem posing and open problems lies, according to Silver (1995), in the nature of problem posing since the process of posing problems can be seen as a problem-solving process where the solution (i.e., the problem to be posed) is ill-defined and consequently several problems can be posed. This makes problem posing, however, an open problem. Given also their link with the way mathematicians work, open problems are seen as having a legitimate place in mathematics classroom. Silver (1995) mentions the "What-if-not" approach as an example of a form of mathematical instruction related to this. In this case open problems and problem posing are combined into the teaching of mathematics by focusing on the creation of new problems through negating one or more elements of the given problem. He also emphasizes the potential of problem posing and open problems for both teaching and assessment purposes. Although important, this link is not specifically examined in the research literature. There is, however, one study (Nicol & Bragg, 2009) where the participating teachers were asked to pose open-ended problems. The researchers identified the teachers' unfamiliarity with this kind of problems which made challenging the problem-posing process itself. This is a difficulty originating from the participants' exposure to (closed) problems having only one solution or requiring a specific known solution process.

Finally, both notions, open problems and problem posing, are closely linked to problem solving. Silver (1995) explains the first based on the idea that open problems are associated with multiple solutions and therefore such problems not only encourage students to solve -when possible- a problem using different solution methods but also to accept the existence of different solutions for the same problem. For the second, he claims that this link stems from the work of Polya who suggests to "think of a related problem", or to think about generating related problems during the "Looking back phase".

In this setting, this paper examines PTs' problem posing on the basis of the three elements of the problems' openness and the four ways of carrying out the process of posing, in relation to whether the participant have or have not experience on problem solving.

Methods

Two groups (A and B) of PTs participated in this study. They were all university students in the same School of Primary Education. They had the same mathematical background coming from their regular mathematics classrooms in secondary education. Both groups (A and B) had a very short introduction on this issue during one teaching session in the context of a compulsory course on mathematics education. During this introduction both groups were presented with the three kinds of openness and the four modes of posing problems. However, Group B had later an extra optional course that lasted a whole semester, dedicated exclusively to problem solving including topics such as heuristics, mental argumentation, experimentation, modeling, control, proof, with a considerable amount of time spent on posing. This gave them the opportunity to deal in depth with problem solving, problem posing and the notion of open problems. Thus, it can be said that Group A 53 PTs did not have any substantial experience in problem solving, unlike the 11 members of Group B. The problem given to all the participants was a very simple closed problem: *I have six 20-cent coins and twelve 50-cent coins. How much money do I have?* The participants were asked to pose three different open problems based on the given problem. The task environment here is that there is a collection of coins and their kind as well as their total number determines the total amount of money. The specific problem,

although simple, can be transformed into a new open problem belonging to any of the three different kinds and these open problems can be generated by intervening with all the four different modes on the given problem. For example, keeping both the problem and the task environment unaltered, an open problem might be: *I have six 20-cent coins and twelve 50-cent coins. How much is 1/3 of all the money?* There is only one solution, but it can be found either by calculating the total amount of money and then dividing it by three, or by calculating 1/3 of each partial amount of money (20-cent coins and 50-cent coins) and then add these two results. This makes the problem open in relation to the solution methods. Another example might be: *I have small cubes with edge length 5cm and 10cm. How many of them do I need to effectively fill a cubical box with an edge length 30cm?* This is an open problem in relation to its interpretation. What does it mean 'effectively fill'? At the same time the task environment is new. Instead of coins we have now edges of cubes but the arithmetical relationship 1:2 between them is kept, namely 5cm and 10cm. The participants had been given as much time as they wanted, but the average time they needed to complete their effort was around 20 minutes. The collected problems posed by the participants constituted the data of this study which were qualitatively analyzed following thematic analysis in the spirit of a priori coding (Mayring, 2014) in two levels: (i) their kind of openness (interpretation, different solutions, different solution methods) and the kind of intervention to the problem and its task environment (keep both unaltered, keep the environment but change the task, modify the environment, new environment).

Results and Discussion

The analysis of the results can be summarized using a double entrance table which combines both the kind of problems' openness and the kind of the posing intervention (Table 1).

Table 1: Summarized results for both groups

Openness / Intervention	Interpretation		Solutions		Solution methods		Closed problems	
	Group A	Group B	Group A	Group B	Group A	Group B	Group A	Group B
Keep environ. keep problem			17 15.32%	2 6.67%				
Keep environ. change problem			32 28.83%	16 53.33%	3 2.7%	1 3.33%	20 18.02%	
Modify environment		2 6.67%	38 34.23%	7 23.33%	1 0.9%	2 6.67%		
New environment								

The numbers in Table 1 refer to the posed problems and not to the participants. As it can be derived from Table 1, 111 problems were posed by the 53 participants of Group A (no experience on problem solving). This means that the average number of posed problems per participant was 111÷53,

approximately 2 problems per participant. The total number of posed problems for the 11 participants of Group B was 30 (approximately 3 problems per participant). Although the size of the samples is small to justify the use of percentages, they are used to facilitate any comparison between the two groups. The first finding as it can be seen in Table 1 is that not all the possible combinations between kinds of openness and interventions were identified in the PTs' posed problems. The collected problems fit to six (out of twelve) such combinations as it will be presented.

Combination–1: Keep unaltered both, the given problem and the task environment, to pose an open problem with multiple solutions: The participants continued working in the context of coins and money, keeping the problem as it was. They only tried to find another question that could be answered using the same data: "I have six 20-cent coins and twelve 50-cent coins. **What other combinations of these kinds of coins are possible to get the same total amount of money?**"

The problem lies in the context of coins and their value (same task environment). It keeps the same data (six 20-cent coins and twelve 50-cent coins) as well as the same total amount of money. But the question now is to use as many as possible different combinations of 20-cent and 50-cent coins to get the specific amount. This is an open problem with multiple solutions. Two of them might be fourteen 50-cent and one 20-cent coins, or ten 50-cent and eleven 20-cent coins.

Combination–2: Keep the task environment but change the given problem to pose an open problem with multiple solutions. In this case the task environment remains the same (collection of coins of certain kind) but some elements (i.e., the numbers) from the initial problem are changed: "**I have some** 20-cent coins **and twice as many** 50-cent coins. How much money do I have?" The ratio between the number of coins has been kept (1:2) and the question of the problem remains the same (total amount of money). But the answer is not uniquely determined since the total number of moneys depends on the number of the 20-cent coins. Each decision for the first component leads to a different solution.

Combination–3: Keep the task environment but change the given problem to pose an open problem that affords multiple methods for its solution. The difference now is that the open problem can be solved in various ways (multiple solution approaches): "I have six 20-cent coins and twelve 50-cent coins. I want to share the total amount equally between 2 kids. How can I do this?". The solution to this problem can be achieved by (i) calculating the total amount of money and then divide by two, or (ii) by calculating separately the amount of money that corresponds to the 20-cent and 50-cent coins, divide each partial amount by two and then add the two results, or (iii) divide each set of coins by two and give each subset to the kids without calculating the amount of money.

Combination–4: Modify the task environment to pose an open problem with multiple solutions. The posers continue working in the environment of the given problem but now they modify it by either adding new components that have an impact on the solution or modifying the given ones. An example was: "I have six 20-cent coins and twelve 50-cent coins. **I need a third kind of coin to get in total 10€. How many new coins do I need**?". In this case, according to the kind of coin we choose the answer will be different. The initial collection makes 7.20€. So, we need 2.80€ more. This might mean fourteen coins if we choose 20-cent coins. The answer will be different if we choose 1-cent coins.

Another example was: “I have **five 2-euro** coins, **five 1-euro** coins and **one 5-euro note. I want to spend all my money to buy oranges (2€ per kilo) and strawberries (4€ per kilo). What are the different combinations of oranges and strawberries amounts**?” The poser is working within the environment of money, but the kind of coins has been modified (coins of 1 and 2 euros), a new kind has been added (notes of 5 euros) and transactions have been also added asking for different combinations to get in total 20€.

Combination–5: Modify the task environment to pose an open problem that affords multiple methods for its solution. Again, the difference here is that the posed problem can be solved in various ways, but all of them lead to the same answer: “I have **ten 2-euro** coins, **five 1-euro** coins and **five 10-euro notes**. What is the 1/5 of my total amount?”

Although the problem seems like the previous one (changing the two kinds of coins and adding a new kind, a note) the difference is that now the answer can be calculated in more than one way. It can be done by either calculating the total amount and then divide it by 5, or by calculating the 1/5 of each sub-collection and then adding these partial results.

Combination-6: Modify the task environment to pose a problem open in relation to its interpretation. In this case the answer is dependent on the way some of the elements of the problem are interpreted. A different interpretation leads to a different solution: “A book necessary for my classroom costs 4€. How much money do I need to buy **enough** copies for **the needs of my classroom**?” The word ‘enough’ must be interpreted by the solver to get an answer. If the interpretation is to get one book per child, then I must multiply the number of students by four. But the problem can be interpreted differently according to what it means “needs of my classroom”. If the intention is to have a book per pair of students or per a group of three or four students, then the solution becomes different.

Finally, and only for Group A, twenty of the posed problems were closed, thus not aligned with the given instructions. An example is: “Student A has six 20-cent coins, and student B has twelve 50-cent coins. Who has more money?”. The solution to the problem is unique and can be achieved in a straightforward manner. The solver can calculate the total amount of each kid and then it is easy to decide who owns more.

It seems that for the openness aspect most of the posed problems (almost 80% for both groups) are problems with multiple solutions. This might reflect the participants’ dominant concept of ‘open problems’ and this is aligned with Chapman (2012) who found that for teachers, openness in problems meant ‘more than one answer’. Moreover, almost 1/5 of the problems posed by the participants of Group A (no experience in problem solving) were closed, which shows also a difficulty in the conceptualization of the notion of open problems. Although there are instances of examples representing other aspects of openness (solution methods and interpretation), their frequency is very small, and they are met mostly in Group B having experience in problem solving. Finally, it seems that the most demanding aspect of openness is to pose open problems in relation to their interpretation. Participants in Group A did not pose any problem in this category, whereas for Group B only two problems were generated through the modification of the task environment. This brings us to the second aspect, the way the posers intervened to the problem and its environment to pose their problems. The most difficult part (zero instances) was to use a new environment. Since this

presupposes for the poser to realize the mathematical idea negotiated within the given problem, a possible explanation might be the not so strong mathematical background of the participating PTs. The participants mainly preferred to (i) keep the problem as it is and pose questions that could fit to the given data, (ii) remain in the same environment but changing the given problem, and (iii) modifying the environment by either adding extra components similar to the given ones or adding new components that should be taken into account for the solution of the new problem. The second research question was focused on the role of experience in problem solving. According to Table 1 the choices the two groups made were more or less similar. What was different was the frequency for each combination. So, Group B exhibited a preference for working in the same environment but changing the problem (changing numbers, reversing given and unknown, etc.) to pose multiple solution problems. Their conceptualization of open problems although limited (no interpretation, very few problems with various solution methods) was in the correct direction (zero closed problems). The picture for Group A is not so much different. The PTs preferred also to intervene in a similar manner with Group B (with different percentages). However, they did not produce open problems in relation to their interpretation and their understanding of open problems is partial (20% of the posed problems were closed).

Conclusions

In this paper the problems posed by PTs were examined in relation to their openness and the intervention approach used. Some of these aspects are rather demanding (open problems in relation to their interpretation or use a new environment to pose a problem). Our two populations had small differences in their problem-posing processes, and it seems that the experience in problem solving contributed more to the PTs' clear understanding of the notion of openness rather on the use of more demanding aspects of openness or more demanding ways of intervention. Perhaps this relates to the posers' mathematical background instead of their experience in problem solving, which is the case that will be examined in the next step of this study. The aim of this step is to work with mathematicians who have a more solid mathematical background compared to preservice primary school teachers. This will help us to examine whether the solid background has an impact on the quality and complexity of the posed problems.

Toward a conceptualization of %: Some preliminary advances

Jérôme Proulx

Laboratoire Épistémologie et Activité Mathématique; Université du Québec à Montréal, Canada; proulx.jerome@uqam.ca

This paper aims to contribute to advancing on conceptualizations of the notion of %, as a way of understanding it better as well as making use of it in analyzing data on students' reasoning processes. The first part presents some preliminary developments on a conceptual frame about %. The second part mobilizes that frame to give meaning to preliminary data gathered from individual interviews.

Keywords: Percentage, conceptualization, absolute value, relative value

Introduction

This paper is part of a wider project aimed at investigating students' understanding of %. As a starting point, we aimed at clarifying and conceptualizing what % is, for then engaging with empirical studies on how students understand it. The 1st part of the paper explores and lays out some of the conceptions of % regularly found in articles, textbooks, lexicons, and so forth, as an attempt to offer a robust conceptualization of %. The 2nd part presents preliminary analyses of data gathered from individual interviews, which are aimed to be fed back into the conceptualization developed on % to enrich it.

Part 1: Theoretical reflections on conceptualizing %

The literature solely dedicated to conceptualizing % is scarce, where % has more than often been subsumed or integrated into work on rational numbers (e.g. Behr et al., 1983; Moss, 2000), or tucked in an isolated part in works on general statistics (e.g. Gauvrit, 2014; Huff, 1954; Spiegelhalter, 2019). Although seemingly conceived as an elementary notion, the work conducted on % presents and defines it along numerous and different meanings: as a ratio, as a fraction, as a decimal number, as an operator, as an index, and so on. In front of this literature, one might feel at lost mathematically and in need of gathering this scattered collage of meanings into a coherent frame that succeeds in coordinating and taking advantage of % many facets. This 1st part aims to contribute to this issue.

% as ratio

The ratio conception is probably the most natural one, even considered its purest form in line with % historical origins in taxes and interest (see Parker & Leinhardt, 1995). Interpreted in a literal way, an assertion like 22% is to be read "22-per-cent", pointing directly, as Baruk (1995) mentions, to a comparison between two quantities (here, 22 and 100 or cent). Some dictionaries align with this view:

- Per cent – Literally from the Latin 'in every hundred' (Earl & Nicholson, 2021)
- Percentage – A proportion, ratio or rate expressed with a denominator of 100. (Borowski & Borwein, 2002)

Considered this way, a % is presented as a "specific sort of rate" (Champlain et al., 1996) or a "special ratio involving parts per hundred" (Glatzer, 1984, p. 25), where % is read as "for 100" and "for every 100": 22% is 22-for-each-100. Van den Heuvel-Panhuizen (1994) phrase % as a ratio of so-many-out-of-so-many, hence "so-many-out-of-hundred", leading, as Baruk (1996) explains, to "bring back" or transform a situation in relation to 100. If there are 5 kids in a group of 20 persons, transforming

this in % requires asking "what if it were for 100 persons?", leading to 25 and thus 25% of the group being kids. Here, establishing a % in a situation implies finding equivalent ratios through working with proportions, where e.g. 5 is to 20 as 25 is to 100, represented symbolically by $\frac{5}{20} = \frac{25}{100}$. As well, finding B% of P in a ratio conception is also to be conceived as solving a proportion. Finding 27% of 81 amounts to asking "27 is to 100 as X is to 81" to find X or "if there is 27 for each 100, how much is there for each 81?", represented by $\frac{27}{100} = \frac{?}{81}$. That it be seen as a ratio with 100, a special rate to 100, or any other comparison with 100, the ratio conception of % places an emphasis on the relation that exists between two quantities (one being 100). In other words, in the ratio conception, the key element is the relation between quantities, where the % is an indicator of this relation to 100.

% as fraction

If the ratio conception of % is seen as its more natural one, the fraction conception is assuredly the most encountered one. This conception is generally found in the familiar usage of vocabularies and symbolisms linked to fractions for expressing a % (fraction on, fraction of, numerator, denominator, a/100, etc.). Along this line, a % becomes a fraction out of 100:

- Percent – A percent is a fraction in which the denominator is assumed to be 100. (Downing, 2009).

Transformations from any fraction to one with 100 at the denominator is thus grounded in equivalent fractions. In his lexicon for elementary schools, Grignon (1970) asserts: "The fraction ¼ can be expressed with 100 at the denominator; one says then that it is expressed in percentage. ¼ can be written as 25/100 (twenty-five hundredths) or 25% (twenty-five percent)". This entry on fractions on 100 also enables to consider % as a decimal fraction, linked to hundredths: the % implies a decimal fraction $a/10^n$, where n=2. Thus, 75% becomes 75 hundredths and is written in decimal form as $75/10^2$ or 75/100. Another meaning is to see % as fractions part-of-a-whole, where a whole is partitioned in 100 pieces and the numerator represents the number of pieces taken: 28% means that 28 pieces were taken from a whole cut into 100 pieces, hence 28/100. Here again, converting fractions to % is rooted in equivalent fractions: e.g. with ¾, a whole is cut in 4 pieces and 3 of those are taken; to convert in %, the same whole is now cut into pieces 25 times smaller, giving 100 pieces, and maintaining equivalence requires to take 25 times more of these, that is 75 pieces: ¾ = 75/100 = 75%. In both cases, finding 27% of 81 means that one wants 27/100 of 81, obtained by direct multiplication as in 81 × 27/100. As Deledicq (2004, p. 232) asserts: "Generally, taking *p*% of a number A is multiplying this number by *p*/100". Or, if fraction part-of-a-whole, 27% of 81 means wanting 27 hundredth of a whole of 81: this 81 is split in 100 pieces for which 27 of these are taken (e.g. 81 divided in 100, then multiplied by 27). Whereas the ratio conception focused on the relation between two quantities, with fractions the emphasis is placed on (different) partitioning. Beyond the mechanical conversions between % and fractions, the fraction conception points to % as a partitioning, a part of something.

% as decimal number

The conception of % as a decimal fraction leads to one where % is conceived as a decimal number. If 35% is read as "35 hundredths", it can also be written as 0.35. This conversion in decimal form enables manipulations of the %, obtained by numerically dividing by 100. Converting 35% in decimal form gives 35÷100=0.35, leading to the equality 35%=35/100=0.35. This represents one of the most frequent conversions for operating with %, where e.g. the value of a 35% discount is obtained through

multiplying the initial price by "0.35". As a decimal number, the % can be written as a power of 10, with 10^n and n=⁻2: 25% becomes 25×10^{-2}. When transformed this way, a % can somehow be treated as a number, e.g. by placing it directly on the number line: 35% as 0.35 is between 0.3 and 0.4.

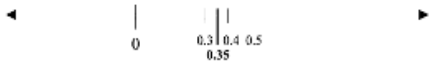

Figure 1: 35% as 0.35 on the number line

Finding 27% of 81 leads to a multiplication by a decimal number, and amounts to 81 × 0.27. As Deledicq (2004, p. 232) asserts: "Taking 12% of a number is like multiplying this number by 0.12". This conception mostly focuses on the numerical representation of %, its number dimension, and the possibilities it offers for operating with it (e.g. comparing, ordering, calculating).

% as operator

Following directly from conversions of % in fraction or decimal form, the operator conception is focused on "reading" the % sign as a request for operating. As Szymanski (1998, p. 101) states: "The words "per cent" mean "per 100", or divided by 100." This operation can also be of "× 1/100" or of "× 0.01". As such, 27% is read as "27 × 1/100", "27 ÷ 100" or "27 × 0,01". This leads the % to be transformed into an operation, where the % is not kept in its original state but instead calls for action; the same when the square root symbol is read as a demand to "take the root": √8 becomes 2.8284… (other conceptions could keep √8 as is, e.g. as a number). Seeing the % symbol in 27% leads to multiply the 27 by 1/100 or 0.01, or to divide it by 100: 27% becomes 27% = 27 × 1/100, 27% = 27 × 0.01 or 27% = 27 ÷ 100. Finding 27% of 81 is multiplicatively obtained by the transformation (27 × 1/100) x 81, (27 × 0,01) × 81 or (27 ÷ 100) × 81. This conception of % as operator is thus mostly focused on calculations, on how to do them and on its result.

% as index

Another "number" conception is one where a % is conceived as an index, always and explicitly linked to another number, that is, its referent number (Berry, 1999). The % is here seen as an indication of what is to by taken from this referent number, insisting less on the conversion of the % than on its connexion to that referent number. As index, a % does not have a predetermined value without that referent number, and it is not possible to operate (compare, order, calculate) without it: e.g. 4% is not a number *per se* e.g. on the number line, not necessarily equivalent to 4/100 or 0.04, where 4% can be worth 12 (4% of 300), ⁻26 (4% of ⁻650), 3217 (4% of 80425), and so forth. As such, this 4% can be smaller or bigger than 12% depending on their respective referent number; 4% cannot be added to 12%, again without knowledge of their respective referent number. Finding 27% of 81 in this conception somehow makes explicit the referent of 81 to which the 27% refers to, and the precise value of 27% of 81 is to be determined through various conversions, be them with ratios, fractions, decimal numbers, etc., as seen above. Seen as index-number, the focus is here on considering % as a relative object, through its connection with a referent number.

Complementarity and flexibility between various conceptions of %

Although presented separately, these conceptions of % are constantly entwined and complement one another. This complementarity is found, as mentioned, in lexicons, textbooks and articles addressing %, where definitions move from one conception to another seamlessly. For example, De Champlain

et al. (1996) define % as a ratio by saying "Rate with a second value of 100". They then offer an operator and a fraction conception with "The symbol for percentage is '%' which means 'divided by hundred' or 'over hundred' and is read 'per cent'". Côté (2002) also aligns sentences interweaving the fraction and operator conceptions: "A percentage is a fraction for which the denominator is 100. The symbol % is read 'per cent' and means '× 1/100'". As well, one can find tons of equalities of the sort "20% = 20/100 = 1/5 = 0.2", joined with mentions of the necessary link of these % with their referent number. Beyond numerical conversions, these all point toward the complementarity existing between different conceptions of %. Here are examples:

- The fraction conception of %, as a decimal fraction, can be linked to decimal numbers through numerical conversions (e.g. 75% = 75/100 = 0.75). This conception can also be related to the index-number one, when considered as fraction part-of-a-whole (e.g. 75/100 of? 75% of?). It can be associated to the operator conception, representing the necessary number to operate on (e.g. 75% becomes 75 × 1/100, or 75% of P becomes P × 75/100).
- The decimal number conception of % can be linked to the operator one, representing as well the needed number to conduct the operation (e.g. 75% becomes 75 × 0,01 or 75% of P becomes 0.75 × P). This conception can point toward an index-number one, when the decimal number is linked to a specific whole, for example when "75% of" becomes "0.75 of". It can be linked to a ratio conception, where 75%=0.75 is meant to be a rate of 0.75 for 1.
- The ratio conception of % is connected to a number conception when related to a rational number a/b with b=100 (e.g. 75% is 75 for 100 symbolized as 75/100). It can be aligned to a referent whole, in which the repartition is linked to a relation to maintain, as in its origin in taxes and interests (e.g. out of 3200, for each 100 there is 75 of these that needs to be handed out), pointing to the index-number and fraction part-of-a-whole conceptions of %.
- The operator conception of % is connected to the fraction and decimal number conception through the operation "× 1/100" or "× 0.01". What is then obtained is a numerical value linked to the %. This conception is linkable to the index-number one, representing the operation for determining the value of the % in relation to its referent number.
- The index-number conception, as mentioned, is linked to the operator one: 75% is 75% of a referent number, and the operation "× 1/100" or "× 0.01" enables calculating its value. Linked to fraction and decimal number conceptions when interpreted along their referent (e.g. 75/100 of, 0.75 of), it can also align with the ratio one (e.g. 75 for each 100 of a referent number).

These associations allow addressing % in a flexible way. In other words, each conception is not sealed and is opened to a transition toward the others. What comes out of these links is their complementarity, a connectedness enabling the passage from a number, operator, fraction, index conception, etc., depending on what is at stake. Along with Janvier's (1983) metaphor, the different conceptions of % can be envisaged as each representing the point of an immersed star (see Figure 2). When one conception is put forward, it is made salient, but it is not isolated: the other conceptions are still there, present and connected to it, waiting and wanting to be made salient themselves. In other words, the other conceptions of % are always connected, but are immersed and represent potentialities that can be exploited and made explicit if need be. To these can be added Parker and Leinhardt's (1995) distinction between a % as a *statistic*, for describing a situation (e.g. 75% of kids wear glasses

vs. 56% of adults), and a % as a *function*, for operating and creating another number (e.g. 75% of 520 kids wear glasses, that is 390). Each of these uses can be mobilized for interpreting or operating on %. This versatility of the nature of the % as a "statistic" or as a "function", lying at the center of the % star, illustrates that the emerged conception can take profit of it in the situation. This star illustrates an array of possibilities for %, through the complementarity between conceptions, and the necessary fluidity between these when working and interpreting %.

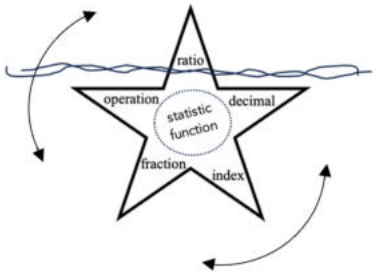

Figure 2: The %-star with its various complementary and interconnected conceptions

Part 2: Preliminary case studies on %

Our research team aims to investigate students' understanding of %. The first phase of our experiments focuses on individual interviews with (voluntary and available) students and teachers, as pilot-testing to prepare the second phase of classroom-wide experiments. This paper reports on aspects of this first pilot-testing phase. Audio-recorded interviews were planned, which consisted of presenting a task and giving students and teachers about 15 seconds to solve it mentally, and then for them to explain their answers (orally, using sheets of paper to leave traces). A series of tasks on arithmetic operations frequently found in textbooks were used: e.g. "50% + 3", "25%/75%; 5% × 12%; 25% + 50%; compare 3%/4 *vs*. 3/4%. These tasks were chosen because they possibly required conversions between the different conceptions of %, and at the same time might raise issues related to an index-number conception since no explicit referent for the % was given in these tasks. Each interview usually lasted between 10 to 20 minutes, depending on the participant's availability. The research data consisted of the audio explanations of the solutions, as well as occasional notes left on paper. The analysis of this preliminary data involved using the %-star conceptions to precisely code the different parts of solutions to the task, as a way for understanding which (and how) the conceptions of % were mobilized in those (and complemented one another). Being preliminary, only excerpts from solutions obtained for the "50% + 3" question are reported (for two participants, namely Marco and Julie, pseudonyms). At this stage, the analysis of Marco and Julie's solutions (1) contribute additional reflections on the nature of %, and (2) enrich understandings about the above complementarity between % conceptions (all interactions are translated from French to English).

Marco's answers

Marco is a 14-year-old boy that just completed Grade-8, and frequently worked on % during his school year. When asked what "50% + 3" gave, his first explanation was as follows:

Marco:	3 and 50. Because 50% is equivalent to ½ and ½ is equivalent to 0.5. And, 0.5 + 3 = 3.5. […] But if you do "of something", it will not render the same thing. Let's say 50% of 10, plus 3, so it is 5+3=8.
Int.:	So is the answer 8 or 3.5?
Marco:	No, this is just an example!

Int.: 3.50 is not an example?
Marco: No, it is the question. This one [8] it is if it would be 50% of something.
Int.: And that's not the same thing.
Marco: No, it's 50% that's all. It is not "of" or "about" something. […] This [50%+3=3.5], is the question, but then *I* decided to act as if it was 50% of something.
Int.: And is there an example that would give 3.50?
Marco: Yes, 50% of 1.

Julie's answers

Julie is an experienced teacher (Grade-7 to 11), who also has been head of her mathematics department (in school districts and at the national level). When asked "50% + 3", she responded:

Julie: If I take it in a purely numerical mode, 50% + 3 could be 350%. […] If one takes 50% in its decimal form, it would give 50 hundredths, and with 3 it gives 3 and 50 hundredths, so 350 hundredths thus 350%.

After being asked if there was other possible answers, she replied:

Julie: If one reasons on the % in relation to a whole, the 3 can also be related to it and it can influence the answer. I would need to have what the 50% refers to. If I have a whole of 6, the 3 is then 50%: 50%+50% would be 100%, or 6. Since 3 is 50% and 50% is 3, hence 6. […] If the whole is 18, 50% of 18 is 9. And, 9+3 gives 12. Twelve is the answer or 12 eighteenths. Or, my 3 in relation to 18 is 1/6 or 3/18, and finding what 1/6 is in %...it's 16.6% so it's 66.6%.

Dialectical relation between absolute and relative dimensions of %

In their answers, both Marco and Julie make use of %, fractions and decimal forms interchangeably, converting from one to the other with ease: one can thus see the %-star used "in action". Both their second answers, that is, Marco's 'examples' and Julie's referral to a 'whole', point to how % can be tied to a referent number and become indexes to be able to grasp its value; hence fluidly transiting toward an index-number conception. Both select examples (8, 1, 6, 18), and use those to illustrate their point. They thus raise two different ways of interpreting the question – although Marco insists that 3.50 is the legitimate answer because of the way the question is posed – from a direct numerical conversion to one variable in relation to a referent number for the %. This is particularly salient in the difference made by Marco between his "3.50", one being *the* answer and the other being simply one example among many. In both Marco and Julie's first answers, the 50% is considered in the absolute as 0.5, a value to operate on or place on the number line. In their second answers, the 50% becomes relative, linked to a referent for obtaining its value. As such, beyond fluidly going from one conception of % to the next, as offered in the %-star, there appears to be a dialectical relation at play that emerges in both Marco and Julie's understanding between work on numerical conversions (from % to fractions and decimal numbers) and the place of the referent of the %. This dialectical relation raises a rich interplay between "absolute" and "relative" dimensions of %, that is, % with or without a referent. Through navigating between conceptions of %, Marco and Julie's work appear to tap directly into that dialectic, transitioning from one to the next with some ease. Their answers show their capacity to go from numerical conversions to referent numbers, to discuss and compare them, showing the difference between each while accepting both as "possible" ways of interpreting the task.

Reflecting on a midway perspective

This absolute-relative dialectic about % that emerges from the initial analyses of Marco and Julie's work can give rise to a subsequent perspective on %; one that in fact appears to have strong ties to

how % is treated in school textbooks. This perspective appears situated midway between an absolute and a relative view of %: it considers the referent of the % by fixating it to "one thing", to one unit, used as a referent, e.g. to a geometrical square cut in 100 smaller squares, to a collection of objects, to a specific number or even to 1. In this midway, the referent is made explicit as one unit, for then undertaking operations (e.g. comparing, ordering, calculating). By stabilizing the referent to one unit, the value of the % is not seen as absolute, like in numerical conversions, but it is not completely relative or variable either. (As such, contrary to Marco who sees one of his "3.50" merely as an example, Julie will assert at one point that 50% is 0.5 as if it was 50% of the number 1, somehow referring to this midway perspective.) This reference to one unit can enable one to compare two %, for example, since both can be linked to the same one unit (25% < 50% of the same referent, which is not necessarily true with different referents; 10% + 5% = 15% of the same referent, which is not necessarily true either, etc.). Lodged within the dialectic, this midway perspective might be seen to emerge in the back-and-forth between relative and absolute, maintaining the link of the % to a referent (by fixating it temporarily to one unit) and taking advantage of the conversions to obtain, temporarily, a numerical value for that %. This offers an additional layer to the (ongoing) conceptualization of %.

Table 1: Three perspectives for working on and considering %

Absolute perspective on %	**Midway perspective**	**Relative perspective on %**
Implicit referent (or not mentioned)	Referent fixated temporarily (for the task at hand)	Variable referent (determined by and through the task)
% as number, its value is obtained by converting it (for operating)	Value of % linked to a fixed unit	% as index-number, its value is relative to a referent (to be known)
50% = 50/100 = 0.5 50% > 25% 50% + 25% = 75%	50% of is 50% of is 50% of is 50% > 25% and 50% + 25% = 75%	The added dotted-square in is both an addition of 50% or $33.\overline{3}$% of the new whole. John spent 50% of his money. Mary spent 25%. Who spent more?

Concluding remarks

The conceptualization of % offered in the first part outlines that conceptual and calculational dimensions are at the heart of interpreting and working with %: interpreting % by making sense of their referent number necessarily implies calculational abilities, and in turn the calculations and numerical conversions with % imply giving meaning to %. Both go hand-in-hand, and this is where the aforementioned dialectical relation illustrated in Julie and Marco's work between %-absolute and %-relative can be seen to situate itself. From this dialectical relation emerges the midway "step" of fixating the referent whole to one unit for the time being while handling the % for the problem at stake. Transiting between these three perspectives (numerical conversions, fixating the referent to one-unit, variable referent) might play a key role in interpreting and working with %. This conceptualization also points to the inherent connectedness and complementarity between various conceptions of %, through the metaphor of the immersed star, allowing flexible navigation from one conception to another (which appears crucial for developing ease with interpreting and working with

%). This (necessary) flexibility might explain the found presence of different but simultaneous conceptions of % in lexicons, dictionaries, textbooks and articles addressing issues of %.

The data presented here is obviously preliminary and this conceptualization is evolving (and Marco and Julie are only two examples, used here to deepen our understanding of %, and in no way are proposed as representative or illustrative of all students or teachers we worked with). More is to be done to better bridge the %-star of conceptions with the dialectic between relative and absolute values of %. It is hoped that our next research phase on classroom experimentations can lead to deepened understandings of % inner workings and in turn bolster this continuously growing conceptualization.

Effects of spoken number words on place value understanding: A comparative study with German and Danish second graders

Mia Lene Ransiek[1] and Thomas Rottmann[1]

[1]Bielefeld University, Faculty of Mathematics, Bielefeld, Germany;

thomas.rottmann@uni-bielefeld.de

One characteristic of a sound understanding of place value is the ability to switch between different number representations. There are clear differences in the formation of number words in different languages. Both German and Danish use an inverse number word formation, starting with saying ones before tens. This exploratory study compares the abilities and difficulties of second graders from two schools each in Germany (N=96) and Denmark (N=84) in tasks involving translation processes between number representations. Our results show differences between the two groups in terms of both the frequency and type of errors. The German students make fewer errors overall, but in contrast to the Danish students, they show inversion errors particularly frequently. This indicates that it is not only the inverse number word formation that influences the occurrence of errors, but that there are other influencing factors. This also makes the results interesting for studies on other languages.

Keywords: Number concepts, place value, number word inversion.

Introduction

A sound understanding of place value is seen as an important basis for the development of further numeracy skills like written arithmetic procedures. On the other hand, an insufficiently developed understanding is a barrier to successful arithmetic learning and is recognised as one of the main signs of particularly severe and long-lasting difficulties in arithmetic learning (Fromme, 2017). Accordingly, studies show that place value understanding serves as a predictor for later arithmetical performance (Habermann et al., 2020; Moeller et al., 2011).

The development of place value understanding places several demands on children. In order to understand place value, students need to develop knowledge of the fundamental principles of our decimal number system, namely the regrouping principle and the place value principle.

> The *regrouping principle* describes that the same number of units is bundled continuously […]; the *place value principle* states that each digit gives two pieces of information by its position, which indicates the bundling unit it stands for, and its face value, which tells the number of the represented bundling units. (Jensen et al., 2024, p. 3)

In addition, the ability to relate different representations of multi-digit numbers (as a symbolic representation with digits, as a spoken number word and as a quantity; Figure 1) and to switch between these representations is considered essential for understanding place value (Ejersbo & Misfeldt, 2015; Fromme, 2017; van de Walle et al., 2023). Apart from using only digits for symbolic representation (e.g. 32), other notations can be chosen, e.g., with indication of the place values (e.g., 3 tens 2 ones). Quantities can be represented using a variety of materials; one commonly used material is the base ten blocks, which show the place values in a very clear way (Figure 1).

Tasks that require switching between these representations can also be used to assess students' understanding of place value. The mastery of translation processes is an indication of a developed place value understanding. However, the use of different representations places different demands on students. For writing and reading a symbolic representation of a number, it is essential to understand the place value principle, particularly that the position of a digit determines its value in terms of powers of ten (Fromme, 2017; Jensen et al., 2024). For transcoding spoken number words, it is important to have a strong knowledge of the principles and rules underlying the construction of number words.

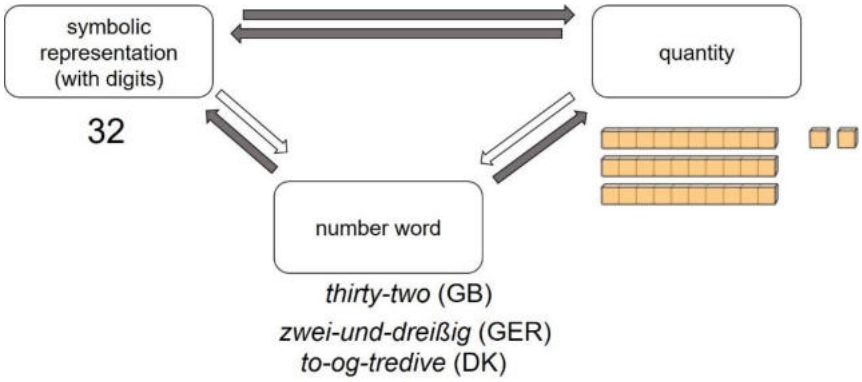

Figure 1: Representations of (multidigit) numbers and translations between the representations

Both the representations by digits and by quantities are independent of the child's language and are (more or less) the same internationally. When it comes to the formation of number words, however, different languages are very different from each other. While Asian languages in particular have a very regular structure, most European languages show some clear irregularities. This can include differences in the number words for ones and tens, but also differences in the order in which place values are given.

In Japanese, as in most Asian languages, the spoken number words have a highly regular structure and directly name the place value (32 is 'three ten two'). In contrast, most European languages show some irregularity in the number words and use specific names for the tens (Fromme, 2017). In English, some of the names for the tens differ from the names for the ones (e.g. 'thirty' instead of 'threety'). Some European languages construct (some) number words for the tens based on remnants of a base 20 system; for example, the French number word for 80 is 'quatre-vingts', meaning 'four (quatre) times twenty (vingt)'. The Danish number words for tens in particular have a high degree of irregularity. For example, the number word for 4 ('fire') differs significantly from the number word for 40 ('fyrre'), while there are clear similarities with the number word for 80 ('firs'). 'Firs' is a hidden remnant of a base 20 system ('four times twenty'), with the additional difficulty that 'twenty' does not appear as part of the number word at all (unlike in French). The same applies to the number word for 70 ('halvfjerds'). In this number, the prefix 'halv' (meaning 'half') encodes 'half times twenty'. Therefore, 'halvfjerds' means 'half four times 20'. "'Half four' is a half taken to four (of three), so it means 'three and a half' (as in German time counting, where 'half four' means 'half past three')" (Sun et al., 2018, p. 108). These construction principles, with many irregularities, are not comprehensible

to students learning Danish number words and therefore have to be memorised (Ejersbo & Misfeldt, 2015).

In addition, some languages show another peculiarity by inverting the position of the tens and ones in the (spoken) number words. This applies to German and Danish, for example. Both languages use a number word inversion by starting with the ones before saying the tens. 32 is 'two and thirty' ('zwei-und-dreißig' in German or 'to-og-tredive' in Danish). The syllable 'und' resp. 'og' means 'and' and is used to connect the number words for ones and tens.

Several studies have already investigated the influence of (verbal) number word formation on the learning of place value understanding and number processing. In general, studies show advantages of regular number word formation, as it is used especially in Asian languages. Most research in this area deals with English and/ or Asian languages (Habermann et al., 2020; Hewitt & Alajmi, 2023). However, some studies also consider languages with a number word inversion, mainly German (Clayton et al., 2020; Moeller et al., 2011; Steiner et al., 2021). As a result of their literature review, Larkin et al. (2024) highlight that "the alignment between the order of writing the digits and the order of naming the numbers, contributes to opportunities or difficulties in learning place value" (p.107). Languages with inverse number word formation have clear disadvantages compared to other languages. In their comparison of English- and German-speaking first graders, Clayton et al. (2020) found significantly more inversion errors (e.g., 35 instead of 53) in the German-speaking students, which also had an impact on mathematical competences in general.

However, it has not yet been investigated in detail whether number word inversion alone is responsible for these differences or whether there are other influencing factors. Previous studies tend to compare languages that differ in the number word inversion. Studies investigating languages that all use number word inversion are still lacking.

In our study, we compare German and Danish second graders' abilities in relating different representations of two-digit numbers. This is particularly interesting because both languages use a number word inversion, but the number words for tens are constructed in a fundamentally different way. In particular, we are interested in students' difficulties and errors when switching between number words, symbolic representations with digits and quantities, with a special interest in inversion errors and errors with the number words for tens. The main research questions are:

RQ1: Which difficulties and types of errors are visible in the translation processes?

RQ2: What are the differences between German (GER) and Danish (DK) students in this study?

Methods

Our study has an exploratory nature to get some initial indications as to whether there are differences between the two languages and whether further research might be worthwhile. We selected one school in an urban setting and one in a rural setting per country to reflect some diversity. However, the groups do not meet the requirement of being representative of the two countries. In total, 96 German and 84 Danish second graders participated in the data collection in autumn 2023. The tasks were given in a paper-pencil test and focused on translation processes between three different representations of numbers: as a symbolic representation with digits (e.g. '32'), as a (spoken) number

word (e.g. 'thirty-two') and as a quantity. For the quantity representation, we chose base ten blocks, presented as an iconic representation (with lines for the tens and dots for the ones), to allow students to make their own representations of the material in the paper-pencil test.

After the introduction of the tasks and the representations used (esp. the iconic representation of the quantity), the students worked on a total of 25 items with the four types of translation (dark arrows in Figure 1): (1) from (spoken) number word to symbolic representation (10 items), (2) from (spoken) number word to quantity (5 items), (3) from quantity to symbolic representation (5 items) and (4) from symbolic representation to quantity (5 items). The number words were given orally by the teacher in German or Danish, respectively, and the students were asked to write down the numbers or to draw them on a pre-structured sheet of paper. The two types of transitions to a (spoken) numerical word were excluded because they could not be implemented in a written test.

Results

Overall, the test (with a max. score of 25) is quite simple, resulting in ceiling effects. The children succeed in the vast majority of translations. The German (GER) students (N=96; M=23.35; SD=2.82) scored higher than the Danish (DK) students (N=84; M=22.32; SD=3.53). To compare the groups, the non-parametric Mann-Whitney U test was used, as there was no normal distribution in either group (Kolmogorov Smirnov $p<.001$). The results show statistically significant differences between the two groups (GER: Mdn=24.00, range=16; DK: Mdn=24.00, range=14), U=3260.0, Z=-2.303, p=.021, r=.17.

However, it is interesting to analyse the errors that occur in more detail. With regard to the required translation processes, both groups make the fewest errors in the translations from (spoken) number words to symbolic representations (errors in 5.1% of the respective translation processes in GER resp. 6.1% in DK) and the most errors in the translations from (spoken) number words to quantity (errors: 10.8% in GER resp. 13.8% in DK; Table 1). Low familiarity with the (iconic) representation of the base ten blocks may potentially contribute to the higher error rate.

Table 1: Percentage of errors in the respective translation processes

	GER	DK
number word → symbolic representation	5,1%	6,1%
number word → quantity	10,8%	13,8%
quantity → symbolic representation	5,6%	13,3%
symbolic representation → quantity	7,3%	12,6%

Even though this was not considered an error, the comparatively frequent use of mirrored digits by Danish students is particularly striking. While this notation was not used at all by the German students, the Danish students used mirrored digits in 8% of the transitions to a symbolic representation (8.5% for transitions from number words and 6.9% for transitions from quantities; Figure 2).

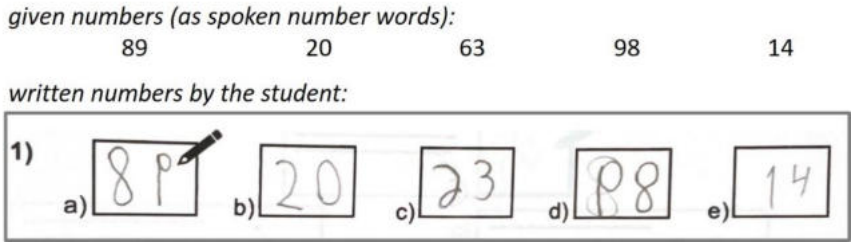

Figure 2: Examples for mirrored digits

In addition to the general errors, we take a closer look at two types of errors, namely *inversion errors* and *errors with incorrect tens*. Several studies show that inversion errors (e.g. 35 instead of 53) are frequent and very typical errors made by German students. The main reason for this is considered to be the inversion of number words (starting by saying the ones before the tens; Clayton et al., 2020).

In our study, *inversion errors* occur more often in German students (number of inversion errors in the 25 tasks: M=0,93; SD=2.31) than in Danish students (M=0,23; SD=0.64), but the difference is not significant (GER: Mdn=.00, range=13; DK: Mdn=.00, range=3), U=3645.0, Z=-1.734, p=.083. Nevertheless, inversion errors are the most frequent type of error made by German students (in 3.7% of tasks, corresponding to 54.4% of errors in total; Table 2). This error is particularly relevant in translations starting from the spoken number word. Danish students, on the other hand, make such errors extremely rarely (in 0.9% of the tasks, corresponding to 8.7% of the errors in total), despite the fact that inversion of number words is also used in Danish language.

Table 2: Percentage of inversion errors in total and in respective translation processes

	GER	DK
inversion errors in total	3,7%	0,9%
number word → symbolic representation	4,9%	1,1%
number word → quantity	6,3%	0,7%
quantity → symbolic representation	0,6%	1,0%
symbolic representation → quantity	1,9%	0,7%

It is also interesting to look at the distribution of this error among individual children. Most students in both countries (80.2% in GER and 88.1% in DK; Table 3) do not make this error in any of the tasks. However, in contrast to the Danish students, there is a relatively high proportion of students in Germany (9.4% in GER resp. 1.2% in DK) who make this error very often (in more than 10% of the tasks).

Table 3: Frequency of number inversion errors among individual students

	GER (n=96)	DK (n=84)
0%	80,2%	88,1%
> 0% - 10%	10,4%	10,7%
> 10%	9,4%	1,2%

Because of the high level of irregularity within the Danish number words for tens, we also focus on *'incorrect tens'* as the result of a task. This category is for answers with the correct number of ones but an incorrect number of tens. Overall, there are only a few errors in this category, and almost exclusively among the Danish students (errors in 1.1% of tasks in DK and 0.1% in GER, respectively). Some of the errors indicate incorrect counting of tens in the iconic representation, as the result differs by 1 from the correct result. However, most errors in this category occur in transitions from spoken Danish number words. This may be due to the specific irregularities of this language.

Figure 3 shows two examples for errors with a close connection to peculiarities of the Danish number words for the tens. In the given spoken number word 'tre-og-**tres**' (63; translated: 'three and three times twenty') in the first example, the Danish number word 'tres' for 60 shows a strong correspondence to the number word 'tre' for three. This similarity could be the reason why the student uses the digit 3 for both the ones and the tens and thus writes down 33 (originally 'tre-og-tredive' in Danish).

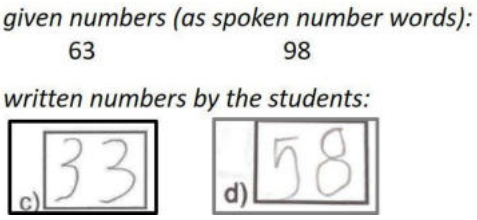

Figure 3: Examples for 'incorrect tens'

The second example shows a similar error. The given spoken number word is 'otte-og-halv**fems**' (98; translated: 'eight and half five times twenty') and is incorrectly written by the student as 58 (originally 'otte-og-halvtreds' in Danish). 'Fem' is the Danish number word for five and is also a component of the number word 'fems'. This probably leads to writing the digit 5 for the tens.

Discussion

The aim of our study was to compare German and Danish second graders' abilities and difficulties in relating different representations of two-digit numbers and to analyse the errors that occurred. The exploratory design of the study limits the generalisability of the results. Nevertheless, the results can be seen as a first indicator of language-related differences between the two countries. Although students in both countries get a high percentage of tasks correct, there are statistical significant differences between the two groups in the success rate. The Danish students make on average more errors compared to the German students. A more detailed analysis of the errors made also shows differences between the two groups. The errors made by the German students show a clear pattern.

By far the most common errors made by the German students are inversion errors (54.4% of all errors). Our data is consistent with the findings of Clayton et al. (2020), who found this error to be particularly relevant for German first graders.

Inversion errors do not play a comparable role for the Danish students in our study (with a proportion of 8.7% of all errors), although number word inversion is also made in Danish. This is particularly interesting because the reason for inversion errors in German is mainly seen in this specific characteristic of number word formation (Clayton et al., 2020; Steiner et al., 2021). However, our study shows that other aspects of number word formation also seem to have a relevant influence on this type of error. This also makes our results interesting for studies on other languages. It seems necessary to take a detailed look at the respective characteristics of number word formation and their differences in different languages (Larkin et al., 2024). One possible explanation for the fact that inversion errors occur less frequently among Danish pupils could be the peculiarities of the number names for tens. Whereas in German, for example, there are clear sound similarities between 'fünf-und-dreißig' (for 35) and 'drei-und-fünfzig' (for 53), this is not the case in Danish ('fem-og-tredive' for 35 and 'tre-og-halvtreds' for 53). The unambiguous distinction between the Danish number names for tens and ones may be a significant factor contributing to the rarity of confusion. However, it is important to note that the difference between the mean numbers of inversion errors in the two groups is not statistically significant. This is probably due to the large number of students in both groups who did not make any inversion errors at all. Nevertheless, it is noticeable that a relatively large proportion of the German students (9.4%) made inversion errors in more than 10% of the tasks, whereas this was the case for only one Danish student.

Unlike the German students, the Danish students do not show any clear patterns of error. Yet it turns out that the formation of number words for tens is a particular challenge for Danish students (Ejersbo & Misfeldt, 2015). Similarities between number words (e.g. 'fire' for 4, 'fyrre' for 40 and 'firs' for 80) seem to encourage confusion between these numbers.

For our further research, we intend to conduct an interview study to provide a more comprehensive and nuanced qualitative analysis of the errors in the two countries. Including students with a different first language could be particularly interesting. It also seems sensible to extend the tasks by including translations into spoken number words and further aspects of place value understanding, particularly the regrouping principle and the place value principle (Jensen et al., 2024). This may assist in the identification of the underlying causes of the discrepancies in the errors of German and Danish students, thereby potentially facilitating the development of intervention strategies. In this context, intervention studies also appear to be valuable. An interesting approach could be to introduce regular number words in addition to the standard number words, as proposed in the design based research project by Ejersbo and Misfeldt (2015), and thus encourage students to reflect on the formation of number words.

General explanations–conditions and role in the learning process of a child with special difficulties in learning mathematics

Charlotte Rechtsteiner[1] and Michaela Scheffknecht[2]

[1]PH Ludwigsburg, University of Education, Ludwigsburg, Germany;

rechtsteiner@ph-ludwigsburg.de

[2]PH St.Gallen, Switzerland

Children with particular difficulties in learning mathematics need to develop conceptual and lexical understanding to achieve in arithmetic. General Why-explanations play a central role in this understanding. This article presents a study in which a third-grader with difficulties in learning mathematics received weekly lessons to support mathematics learning over a period of 15 weeks in addition to regular lessons. The study focuses on the link between the task format used and the language actions encouraged by the teacher to stimulate general Why-explanations. The results show that the teacher's stimuli are of central importance. And they indicate that these explanations can be regarded as a prerequisite for transferring the recognized relationships to the next remedial session as well as to higher number ranges and to tasks with varying characteristics.

Keywords: Going beyond counting, reasoning skills, conceptual understanding, low-achieving students in mathematics.

Introduction

Learning mathematics goes far beyond producing correct results, also for children with particular difficulties in learning mathematics (e.g., Gaidoschik et al., 2021). However, for children to develop a deeper mathematical understanding beyond performing individual tasks, the learning process must increasingly focus on general observations and explanations that are independent of tasks. On the one hand, this involves considering the link between the child's content-related (conceptual) and lexical learning trajectories (macro-scaffolding) in conjunction with stimuli provided by the teacher (micro-scaffolding). On the other hand, it is of interest to consider the role general explanations play in the learning process of a child with particular difficulties in learning mathematics.

Theoretical framework

In first grade, going beyond counting is seen as the central goal of mathematics lessons (e.g., Gaidoschik et al., 2021). To this end, children must overcome both content-related and relationship-oriented challenges. Content-related challenges include developing a comprehensive understanding of numbers and a basic understanding of arithmetic operations (operational understanding and strategic means[1]). Relationship-oriented challenges include developing an understanding of the relationships between numbers, terms, and tasks (Rechtsteiner & Rathgeb-Schnierer, 2017). Ellemor-Collins and Wright (2009) conclude that number structuring represents a bridge between counting

[1] Strategic means are distinct devices used to modify problems to make them easier. They can be flexibly combined in a solution process and include, for instance, composing and decomposing, modifying a problem, deriving the solution from a known fact and using analogies (e.g., Rathgeb-Schnierer & Green, 2013).

and non-counting solution strategies, fostering the process of going beyond counting. Hence, the discovery of mathematical relationships is regarded as one of the most important prerequisites for the ability to flexibly solve unknown tasks (Purpura et al., 2016). Studies on early mathematical education also point to links between the development of numerical skills and children's understanding of patterns (e.g., Wijns et al., 2021). In particular, children with difficulties in learning mathematics partially perceive task characteristics, but then resort to counting strategies to solve tasks (Rechtsteiner & Scheffknecht, 2023). Against this background, it is crucial to focus on teaching children to understand the relationships between numbers and tasks as well as their characteristics in connection with the challenges posed by mathematics-related content in and outside the classroom.

"Zahlenblick" and its development – structure sense

The concept of developing "Zahlenblick" focuses on both content-related and relationship-oriented challenges. "Zahlenblick", as the learning outcome, is the competence to recognize problem characteristics, number patterns, and numerical relationships immediately, and to use them for solving a problem (Schütte, 2004). In some aspects, it can be equated with the terms number sense and structure sense. These concepts are defined in two distinct ways: (1) either as a result of experience-based development (e.g., Linchevski & Livneh, 1999) or (2) as an inherent skill (e.g., Dehaene, 1999). A comparison of number sense, structure sense, and "Zahlenblick" reveals that the meaning of number and structure sense, as an acquired skill, is quite similar to the notion of "Zahlenblick", which can be developed through specific activities. To facilitate understanding, we use the notion of structure sense in this text, as it highlights the focus on structures.

To develop this kind of structure sense, the activities are designed in a way that the pupil's impulse to immediately start calculating is delayed so that he/she recognizes the characteristics, patterns, and numerical relationships of a problem before starting to solve it (Schütte, 2004). Students are also deliberately encouraged to recognize number patterns, problem characteristics, and relations between numbers and problems, as well as to sort and arrange problems by using structural relations. In addition to a specific emphasis on content, all activities include cognitively challenging questions to provoke students' thinking and reflection (Rechtsteiner & Rathgeb-Schnierer, 2017).

Various studies have shown that activities that highlight number and task problems as well as their relationships foster the development of flexible arithmetic competences in all children in a class (e.g., Heinze et al., 2015; Körner, 2024). A study on the development of arithmetic skills in first-grade children with difficulties in learning arithmetic (Rechtsteiner & Rathgeb-Schnierer, 2017) showed that structure sense helped children to both go beyond counting and perceive numbers and task characteristics. Furthermore, children taught with such activities predominantly developed flexible arithmetic competencies.

The activity of "sorting": This study focuses on sorting activities. Sorting activities can be divided into four phases (Rechtsteiner & Scheffknecht, 2023): (1) justifying sorting, (2) developing a solution path, (3) finding further tasks, developing a general description and a Why-explanation, as well as (4) inventing further tasks.

Phase 1: Justifying sorting: In the first phase, children are encouraged to assign term cards with addition tasks, without solving them, to subjective or objective categories. This is followed by a discussion justifying why they sorted the tasks in a specific way.

Phase 2: Developing a solution path: First, the solutions to the tasks that have already been memorized are named by the student, and any strategic means that have already been mastered are discussed. Based on this, the student develops a new solution path and examines whether a task he/she has already memorized can help him/her to solve a task for which the student still needs to do the counting.

Phase 3: Finding further tasks: After a new strategic means has been developed, the child is encouraged to identify any further tasks with the task characteristic of the task just solved in the "I count" category. The aim is that he/she recognizes the same relationships previously perceived in a single task in the other tasks at hand. Then, the general characteristics of this type of task can be formulated to allow grouping on an algebraic level.

Phase 4: Inventing tasks: The child invents and notes down other tasks with the same characteristic. In this way, the more reception-oriented grouping phase (3) moves to the active discovery phase.

In all phases, the mathematical aid (e.g., the Abaco) can be used to clarify and produce Why-explanations (Klein, 2009) regarding the implementation of the relationships under discussion. In this way, links between the levels of representation can be made visible and emerge.

Linking conceptual learning trajectories and lexical learning trajectories

The development of conceptual understanding always takes place based on so-called "hypothetical learning trajectories" (Pöhler & Prediger, 2015, p. 1697). These trajectories describe "hypothetically sequenced learning development" (Götze, 2019, p. 101). Pöhler and Prediger (2015) differentiate between a "conceptual learning trajectory" (p. 1698) and a "lexical learning trajectory" (p. 1698), focusing on the link between these two trajectories. The conceptual learning trajectory can be described throughout the phases of the above “sorting” activity, in which the development of strategic means increasingly involves producing a Why-explanation (Klein, 2009). In terms of the lexical learning trajectory, a distinction can be made between language acts and language tools. Language acts focus on descriptions that are fundamental for developing understanding, ranging from example-based and general descriptions to justifications (Götze, 2019). In contrast, linguistic devices are concrete formulations for technical words and parts of sentences. By linking the perspectives of these two trajectories, the development of theoretical mathematical competency can be described and analysed. Various empirical studies have reconstructed "individual pathways" (Pöhler & Prediger, 2015, p. 1698), showing that children do not follow the theoretically formulated learning trajectories encouraged by teachers all the way to the level of general explanation (Götze, 2019). For this reason, they need support in the form of discursive dialogue. Häsel-Weide (2016) also conclude that targeted stimuli are of considerable importance for learners to see and interpret relationships and thus explain the Why. While theoretical sequential descriptions are classified as macro-scaffolding, support in the form of discussions is referred to as micro-scaffolding.

Methods

The present study considers the last step of the conceptual and lexical learning trajectory, explaining the Why (the connection between task characteristics and strategic means) and generating a related general description in the context of a "sorting" activity. The focus is on the research question: Which situational conditions at the level of the conceptual and lexical learning trajectory, together with support in the form of discursive dialogue, facilitate or hinder a child's description of task-independent characteristics, and what role do they play in the learning process?

The data set consists of ten videotaped remedial sessions with Emi, a third-grader with particular difficulties in mathematics (in the development of number concepts and the competence of calculating going beyond counting) diagnosed with a psychosomatic condition before the study.

The lessons to support mathematics learning (remedial sessions) provided by one of the authors were based on the content- and relationship-oriented challenges and consisted of activities to develop structure sense. At the beginning, the focus was on developing the concept of numbers; this was followed by work on understanding arithmetic operations. The part presented here focused on developing strategic means in conjunction with recognizing and using characteristics and relationships. Only the activities of sorting are considered to allow comparability. The ten videotaped remedial sessions were transcribed, sequenced, and divided into meaningful segments. As a rule, the sequences (S) contain similar content in terms of mathematics didactics (within an activity).

An interpretative research approach was used to interpret the reconstruction of the child's statements (Krummheuer, 2004). For this purpose, we carried out a two-step analysis combining an interactionist and epistemological approach (Steinbring, 2000). The two perspectives complemented each other in the data analysis, making conclusions and interrelationships possible (Korten, 2020). As part of the interaction analysis, alternative interpretations of the individual utterances and turn-by-turn analyses were carried out to analyse (1) the learning processes (Rechtsteiner & Scheffknecht, 2023) and (2) the scenes (Sc) where the child gave general explanations. We compared the different scenes to identify similarities and differences and to reconstruct interpretations to provide explanations (Krummheuer, 2004). These analytical steps were combined with an epistemological analysis to classify the conceptualization (Rechtsteiner & Scheffknecht, 2023). The interpretation was carried out against the background of learning trajectory theory, focusing on the research question. Next, we compared scenes from various remedial sessions in which general explanations were provided or not provided. Drawing on the epistemological triangle, we reconstructed the child's conceptual developments on both levels—regarding the strategic means and the relationship-oriented challenges—in the reference context (Häsel-Weide, 2016).

An analysis of Sc IV, S3, Remedial Session 9 (RS) is presented below as an example. It is described initially as part of the overall remedial process and then as part of RS9. Following an individual diagnosis of Emi's learning needs, the concept of numbers was taught first. From RS5 onwards, she carried out sorting activities. Up to RS9, strategic means were introduced, and she was assigned tasks requiring her to make connections, exchanges, and analogies. Tasks involving a summand of nine did not play a role before RS9. Here, Emi initially sorted tasks in the number range 20 according to subjective categories (Phase 1). She spontaneously tackled related tasks involving doubling and

decompositions of ten, such as 7+6 and 6+6/ 7+7 or 7+4 and 6+4. In S3, the focus turned to tasks with nine. The teacher prompted: "I was wondering if you know what ‘ten plus seven’ is by heart?" (Phase 2). Emi then explained that the task would help her to solve the task “7+9” from the "I have to count" category. Whilst the teacher wanted her to solve the task based on connections with Tasks 10 and 7, Emi solved it by making changes in the opposite direction ("Um, from the nine to ten it's one, then you subtract one from the seven, then you add ten, and then it's sixteen."). Later, after using the visual aid, Emi called this solution a "hopping trick". Next, she was asked to select further tasks that could be solved in the same way from the category "I have to count" (Phase 3). The following excerpt from the transcript starts at the end of this phase:

66	Teacher	Super! And is there another one where that works?
67	Emi	Hm. Yes, nine plus four.
68	Teacher	Hm (affirmative), and then how is it with that one?
69	Emi	Then you take one away from four (.) then you have three, add it to the nine, then you have ten. And then you add the three to the ten and then you have thirteen.
70	Teacher:	What does a task have to be like for that to work?
71	Emi	(...) Um, it always has to be before ten, so nine.

Sc IV began with Emi being asked whether any other tasks could be calculated using the strategic means. After reflecting briefly, she named the task nine plus four, which was confirmed by the teacher, who said "hm" and asked how the solution to the task worked. This can be interpreted as a request for Emi to check, who then explained her solution path. She subtracted one from four and increased the nine to ten accordingly, resulting in thirteen. In Turn 70, she was asked to name the characteristics that a task must fulfil to be solved in this way. Emi stated the characteristic of proximity to ten ("before ten") and specified this by naming nine. From an epistemological point of view, Emi explains the general structure of tasks as their proximity to ten (Figure 1). Her explanation is no longer based on examples, but refers to a task-independent characteristic. However, she lacks the linguistic means to describe this characteristic accurately, as she does not use the term summand, but instead chooses the pronoun "it".

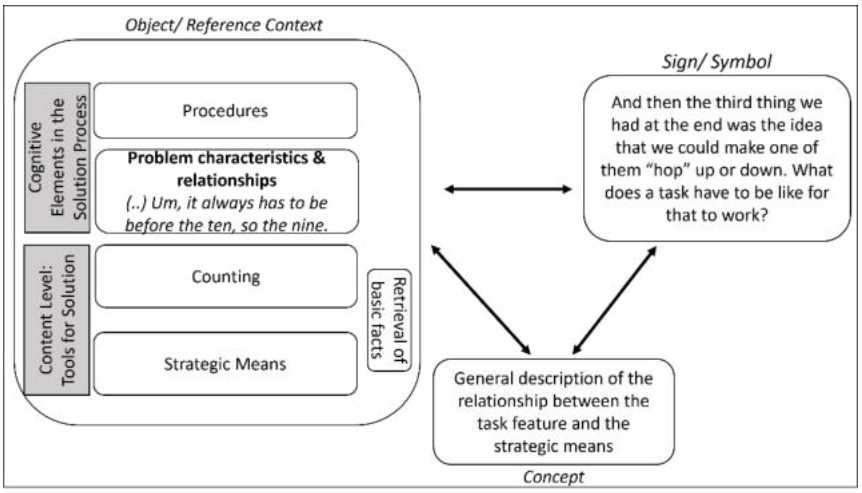

Figure 1: Epistemological triangle, Scene IV, Turns 70-71

Based on analyses of RS6 (Rechtsteiner & Scheffknecht, 2023[2]) and the present scene RS9, we compared the comparisons, interpretations, and reconstructions with a focus on the general Why-explanations relating task-independent characteristics and strategic means within the sequence and with sequences from other RS. All compared sequences were interpreted and reconstructed in the same way as for Sc IV, S3 in RS 9 (see above).

Results

Like in the scene above, the development of a general explanation after completing Phases 1-3 of the sorting activity was also evident in S6, RS6. In both sequences, after the development of the strategic means, Emi was asked to identify further tasks with similar characteristics to the completed tasks. This required different teacher prompts in each case (e.g., "So, among the tasks that you have to count, can you see another one that goes with the 'hopping trick'?" (RS9/S3)). She did not seem to have sufficient conceptual understanding to answer such questions at first. However, after overcoming the initial hurdle, she managed to find other tasks with the same characteristics and to justify their relationship on a lexical level by describing the comparable solution path. Hence, she succeeded in understanding the connection between the task characteristics and the developed strategic means on an algebraic level. However, Emi required teacher prompts to identify and describe the tasks with similar characteristics, reach an algebraic understanding, and formulate a general explanation on her own (e.g., Turns 66 and 70). Furthermore, in analogous scenes, the child did not give general explanations after identifying tasks with the same characteristics without explicitly being asked to do so (e.g., RS9. S1 and S2). Various sequences (RS7, RS11, RS12) indicate that after the child had explicitly formulated a general Why-explanation, she was able to spontaneously recognize the task characteristics and activate the strategic means independently in the next RS. In contrast, in some sessions, she did not recognize the task characteristics, and the strategic means had to be clarified again. This was the case when she had not acquired a sufficiently deep understanding of them to identify further tasks, clarify the general context, and thus provide general explanations (e.g., RS5 to RS6). However, when the child formulated Why-explanations, she was able to transfer the relationship between the generally described task characteristics and the strategic means to the higher number range when prompted by the teacher (RS11). She was also able to perceive slightly varied task characteristics and to adapt the strategic means to them independently (RS11; spontaneous answer to the question as to whether the solution was also possible for the task 65+28: "So from twenty-eight to thirty, there are two, then I subtract two from sixty-five, that's sixty-three, yes, and then you can calculate that.").

Discussion

The interplay between conceptual knowledge and the child's language actions makes it clear how closely they are connected (Pöhler & Prediger, 2015). As described above and in detail by Rechtsteiner and Scheffknecht (2023), scenes in which general explanations are given occur systematically throughout the phases of the sorting activity, which represent the conceptual learning

[2] The analysis in this article focuses on the potential of activities that highlight structures for a student with difficulties in learning mathematics.

path. However, Why-explanations have to be elicited by the teacher (Götze, 2019). These structure-oriented Why-explanations of the relationship between a strategic means and task characteristics appear to be central to the further learning process. Furthermore, the findings indicate that the formulation of general Why-explanations is essential for learning (flexible) calculation competences, and that the prior identification of further tasks with the same characteristics is an important precursor to developing task-independent Why-explanations. At the same time, the child's linguistic resources increase throughout the learning process, albeit not sufficiently to allow the formulation of such explanations. Even if knowledge of the appropriate language does not contribute to achieving a conceptual understanding of content (Götze, 2019), it can allow a more precise description of mathematical relationships.

Acknowledgment

We would like to thank Emi for the exciting experiences during the remedial sessions and her parents for their willingness to allow us to use the recordings.

This exploratory (pilot) study aimed to analyse the use of tree graphs to develop problem-solving skills in word problems involving ratios and percentages and evaluate students' performance using software implementing this method. Thirteen students from a public university in Mexico participated. The intervention included three sessions using pencil and paper, applying the analytical readings method by representing relationships between quantities through tree graphs. In a fourth session, students solved similar problems using specialised software designed to implement the method and track their problem-solving processes. Results showed that using tree graphs facilitated students' understanding and improved their performance, particularly in problems involving ratios, highlighting the method's potential for teaching mathematical concepts in diverse educational contexts.

Keywords: Rational numbers, word problem solving, tree graph, graphical representation.

Introduction

Problem-solving is a relevant topic in the educational field, as one of the main goals of all educational systems is to help students improve their ability to solve the problems they and their societies will face. So much so that international guidelines, set by the National Council of Teachers of Mathematics (NCTM, 2000), indicate that problem-solving involves mathematical tasks with the potential to provide intellectual challenges that enhance students' understanding, logical-mathematical development, and have applications in other curriculum areas.

Problem comprehension and resolution take on special significance as they arise naturally when reading the financial section of a newspaper, after election coverage, or while navigating social media (Roy & Roth, 2015).

From the early school years, graphical representation is used to aid in understanding problems (Brenner et al., 1997; Peng & Lin, 2019), and research on this topic is of interest from both educational and research perspectives (NCTM, 2006).

This study underscores the need for tools that assess students' graphical problem-solving processes and reading comprehension through mathematical tasks. To address this, it focuses on two key objectives. First, it aims to evaluate the use of tree graphs as a representation for developing problem-solving skills, particularly in word problems involving ratios and percentages. Second, it seeks to assess students' performance when solving problems using AWPSolver (UV-SW-202475R).

Theoretical background

The theoretical foundation of this work combines word problem-solving, the analytical readings method as a proposed approach for solving problems (López-Iñesta et al., 2021), and rational numbers as the underlying content of the problems. A word problem is a verbal description of a situation in which a question is posed, and its answer can be found by applying mathematical procedures to the numerical data provided (Verschaffel et al., 2020). The process of solving word problems is understood as the student's mental activity from encountering the problem to completing the task. Based on Polya's (1957) ideas, Puig and Cerdán (1988) proposed six phases in the problem-solving process: reading, understanding, translation, calculation, solution, and verification.

One variable associated with the word problem-solving process is the content, which relates to the mathematical meaning of the problem. In this study, the content variable is connected to rational numbers, focusing on their interpretation as percentages and ratios.

Based on the analysis-synthesis and Cartesian methods (Puig & Cerdán, 2014), the analytical readings method is proposed for solving both algebraic and arithmetic word problems. It involves five steps: reading the problem, forming a dictionary of quantities, constructing a tree graph, performing calculations, and verifying the solution. Since word problems often involve multiple steps and relationships, there is no single analytical reading or unique solution process.

In the first step, an initial reading of the complete problem is conducted. Then, the problem is read sentence by sentence, identifying the given data and the verbs associated with them. It is also important to identify the main unknown, i.e., what needs to be calculated. To form the dictionary of quantities, known and unknown variables in the word problem are identified. This information is organized into a table with three columns, corresponding to the second step of the method. For example, for this problem

Problem 1. Normally, a liter of alkyd enamel is sold at the hardware store for 310 pesos, but this month they have a 10% discount on all their products. Additionally, a further 20% discount is applied to all purchases for regular customers. If Ana is a regular customer and needs to buy 10 liters of alkyd enamel this month, how much will Ana pay? Solution: Ana will pay 2,232 pesos.

Table 1 present a dictionary of quantities. Note that, this table depend on the used analytical reading and can be different. The third step is to construct the tree graph by following the analysis-synthesis rules, so that all the numerical data from the problem and the main unknown are obtained. A tree graph has unique decomposition properties that allow for a visual representation of the strategy followed in the problem-solving process (Roy & Roth, 2015). We emphasise that the tree graph serves as a problem-solving tool rather than a pre-established solution. Much like how textbooks guide learners with intermediate questions, the tree graph helps break down the problem into manageable steps. Students are encouraged to formulate their own sub-questions as they build the diagram, ensuring the process remains exploratory rather than purely procedural.

A tree is a data structure consisting of nodes connected by edges, with the unique property of containing no cycles. For the analytical readings method, we specifically use a rooted binary tree,

where there is an upper node, commonly known as the tree's root, and each node is linked to either zero or two successive nodes (see Figure 1).

It should be specified that the upper node represents the main unknown of the problem, and the construction of the tree graph starts from this main unknown. If the problem is arithmetic, only quantities will appear at the base; if it is algebraic, unknowns will be present at the base. The problem will be solved from the base up to the upper node.

Table 1: Dictionary of Quantities for Problem 1

Information	Value	Description
Data	310	Original cost in pesos per liter of alkyd enamel.
Data	10%	Discount applied on all the products.
Unknown	U	First discount in pesos.
Unknown	Z	Cost in pesos per liter of alkyd enamel after the first discount.
Data	20%	Additional second discount applied to the already reduced price.
Unknown	V	Additional second discount applied to the already reduced price in pesos.
Unknown	Y	Cost in pesos per liter of alkyd enamel after the second discount.
Data	10	Liters of alkyd enamel to be purchased.
Unknown	X	Pesos that Ana will pay.

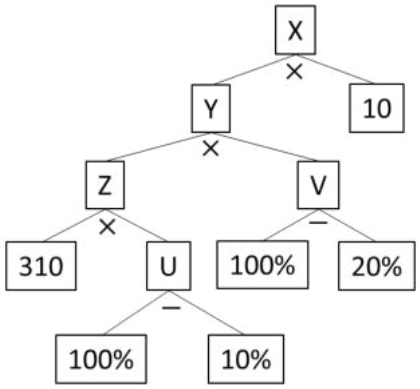

Figure 1: Tree graph of the Problem 1

Methods

This research is framed as an exploratory (pilot) study, intended to identify preliminary trends. It follows a qualitative methodology and forms part of a broader project that analyses the process of learning fractions through educational software, AWPSolver; that incorporates a problem-solving methodology using tree graphs. The software enables tracking the user's solution path, providing detailed performance analysis.

Sample

The study involved 13 students from the mathematics undergraduate program at a public university in Mexico. This group consists of students enrolled in various semesters of the program, all of whom share a common interest in teaching.

Intervention

In the first session, prior to explaining the analytical readings method, students solved isomorph problems to last session to assess their initial performance in this type of task. The session continued with a printed document simulating a student's solution to a word problem, which served as a discussion prompt. Students were divided into teams of 3 or 4 members to discuss the method, followed by a group discussion moderated by the instructor. The instructor explained the phases of the word problem-solving process proposed by Puig and Cerdán (1988) and outlined the steps of the analytical readings method. Students shared observations and questions. To reinforce learning, two additional problems were assigned; one student solved each on the board with feedback from classmates and instructor guidance.

In the second session, students reviewed the analytical readings method by solving a problem in teams and comparing results through group discussion. The instructor introduced different representations of rational numbers, followed by team-based problem-solving using the method. Students worked on four word problems involving fractions, ratios, percentages, and decimals. Each team's dictionary of quantities, tree graph, and final solution were compared and discussed.

In the third session, the relationship between the analytical readings method and the word problem-solving process was discussed in a debate moderated by the professor. Lastly, an anonymous survey was conducted to gather students' opinions on the use of the method.

The fourth session focused on using AWPSolver, where students solved three word problems using the analytical readings method. This report analyses their performance on two problems (percentage and ratio).

Instruments

The two problems analysed in this study both involve the use of rational numbers. The first problem specifically uses percentages (Problem 1 detailed in the theoretical framework). However, Problem 2 explicitly involves ratios, as shown below:

> *Problem 2. Concrete needs to be mixed for a construction project. First, sand and gravel are mixed at a ratio of 2:5. Then, cement is added to this mixture at a ratio of 1:7. If one ton of concrete is required, how many kilograms of sand are needed? Solution: 250 kilograms of sand are needed.*

It should be noted that, according to initial student feedback, Problem 1 is a familiar type of problem, whereas Problem 2 is not commonly encountered, previously, but it is done in the three first session.

The AWPSolver used allows for the implementation of tree graphs, as well as data collection regarding the time the user spends reading, operating, or constructing the graph. As shown in Figure 2a, the problem is presented with its statement shaded, which must be clicked by the student in order

to read it. As seen in Figure 2a, students must insert nodes by clicking "Node" and dragging them into the solution window. The user must fill in all the necessary information: the literal part (e.g., "Children in the park" or "Children going home"), whether the value is unknown (?), or known (value), and if unknown, the operation required to calculate it, as well as the connection between the quantities that allows the unknown value to be determined. Finally, note that the tool does not allow students to submit the solution (Submit) if there is something incomplete and will notify them if this is the case.

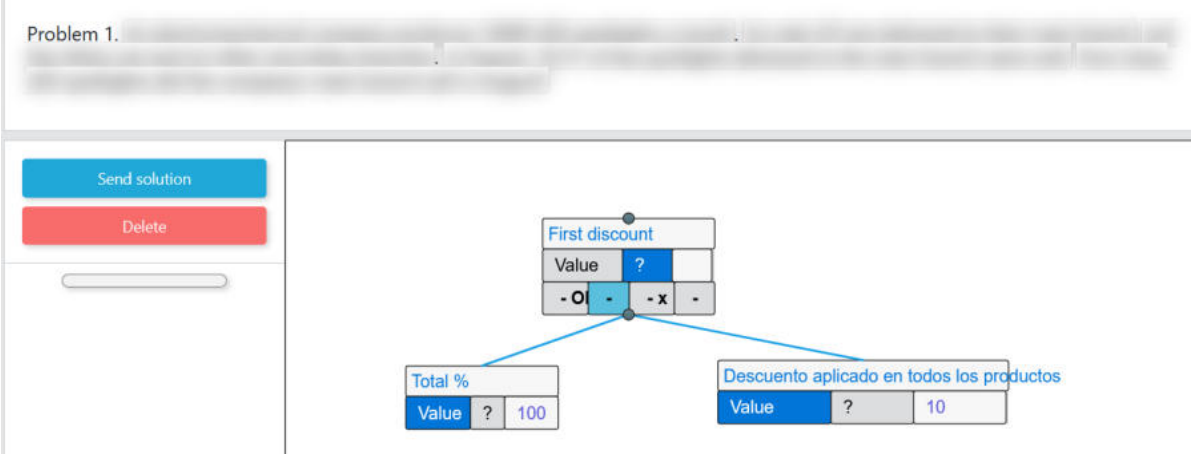

Figure 2: Task Implementation in AWPSolver. Tree graph construction process

In addition to serving as a data-collection tool for researchers, AWPSolver offers educational benefits to students: 1) allow rapid restructuring of branches, letting users easily move or edit nodes; 2) log the user's step-by-step decisions, enabling reflection and deeper insights into the problem-solving process; 3) save time otherwise spent erasing and redrawing, which can enhance motivation and reduce frustration; and 4) integrate modern ICT competencies by encouraging students to work in a digital environment—highly relevant to contemporary educational settings.

Research Variables

Thus, four research variables are extracted to address the study's goals. To answer Goal 1, which is to evaluate the use of tree graphs as a method for developing skills and acquiring knowledge, particularly in problems where rational numbers as ratios are involved, the following variables are used: a) success probability, indicating whether the solution is correct; b) reading time per word (tw_P1, tw_P2) and graph construction time (tg_P1, tg_P2), showing if the challenge lies in reading or building the graph; and c) graph construction moment (mg_P1, mg_P2), indicating if continuous reference to the problem statement is needed.

Times are relativized by dividing specific times by each student's total time. This accounts for differences in time spent reading or constructing graphs. The graph construction moment is calculated as the geometric mean of interventions on the graph: values near 0 indicate construction before detailed reading, around 0.5 indicate simultaneous reading and construction, and near 1 suggest construction after reading.

To address Goal 2, assessing students' performance using AWPSolver, an analysis of their different analytical readings will be conducted. Researchers will identify all possible readings and associated tree graphs to determine where students encounter the greatest difficulties.

Time is critical because constructing a tree graph step by step requires learners to reflect on each decision they make. In our study, we measured both reading and graph construction times to determine whether difficulties arose from interpreting the text (requiring repeated reading) or from structuring the solution (requiring frequent modifications to the tree). By analysing these times, we gain deeper insight into students' cognitive processes and their approach to problem-solving.

Results

The results are organized by goals, dividing this section into Goal 1 and Goal 2.

Goal 1

Prior to using AWPSolver, the researcher evaluated these isomorphic problems, with success rates of 84.6% for percentages and 8.3% for ratios. After intervention, for Problem 1, there is a success rate of 92.3%. The graph construction and reading are done jointly (Figure 3b), although it appears that the graph is somewhat anticipated before the reading (0.44±0.10). This is also observed alongside Figure 3a), which shows that little time is needed per word to read the text (0.39±0.22).

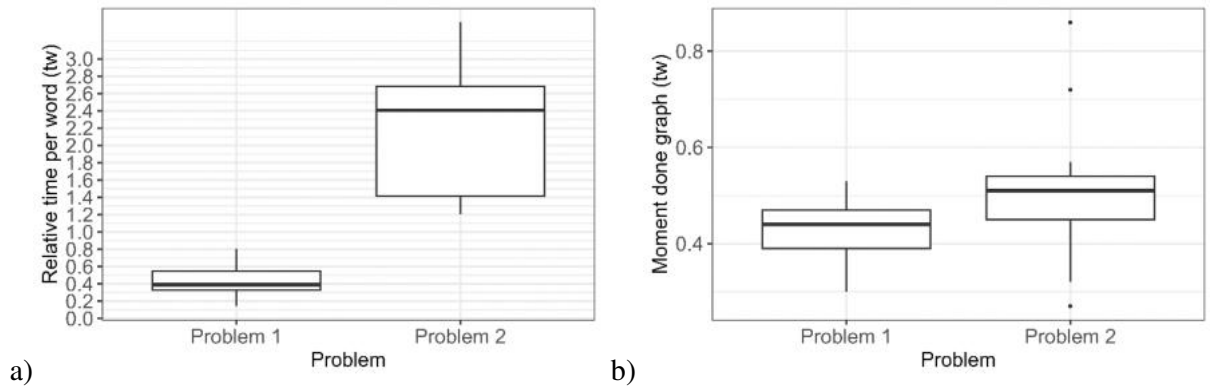

Figure 3: a) time per word; b) moment done graph

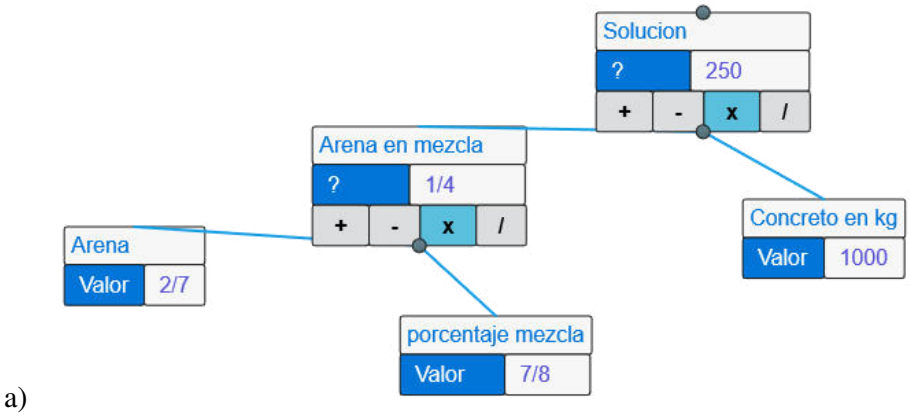
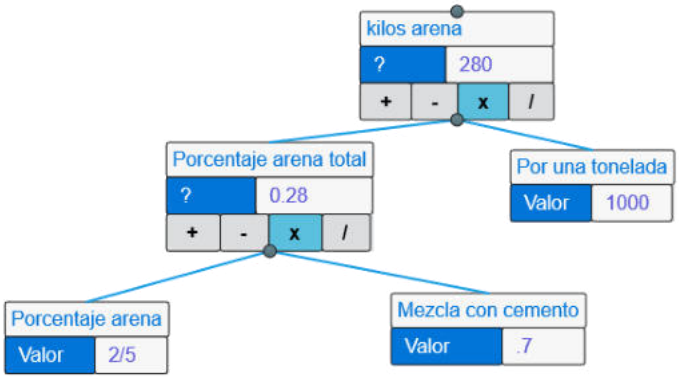
Goal 2

Due to space constraints, we focus the study on the graphs created by the students for Problem 2, as it is unfamiliar to them. The use of one graph predominates (Figure 4a), although it should be noted that five possible graphs were identified.



a)



b)

Figure 4: Tree graphs identified in the students' solutions

Among the students who provide incorrect solutions (6/13), three indicate that they do not know how to do it. Another three try to apply the graph shown in Figure 4a), but their difficulties come from not correctly identifying the fractions (for example, Figure 4b).

Discussion and conclusion

This study shows that the analytical readings method, which relies on tree graph representations, allows for the development of skills to implement this new methodology and improve the resolution of a particular kind of problems with the rational as a ratio.

Through an experiment evaluating a tree-graph representation methodology and involving two evaluation phases—the first using pencil and paper and the second using AWPSolver, an educational software—two types of problems were assessed: one involving percentages and the other involving ratios. The former is common in classrooms, while the latter is less familiar to students. High success rates were achieved with AWPSolver, suggesting that the method facilitated the assimilation of the concept of ratio, previously unfamiliar to students. Consistent with the studies by Brenner et al. (1997) and Peng and Lin (2019), the representation enhances students' performance in problem-solving.

The results indicate that for the problem familiar to students (percentages), they perform a quick reading of the statement and construct the graph simultaneously with reading, often anticipating the graph construction process. Nevertheless, for the problem involving unfamiliar concept (ratio), the

reading of the statement was slower, which aligns with research such as Rouet and Passerault (1999), who emphasize that more reading time is needed for tasks involving more complex mental processes, with graph construction lagging behind the reading.

Pupils with severe difficulties in learning arithmetic: An educational challenge for secondary schools

Volker Ulm[1], Annalisa Steinecke[1] and Moritz Zehnder[1]

[1]University of Bayreuth, Germany; volker.ulm@uni-bayreuth.de

The paper addresses the issue of how many pupils in the transition from primary to secondary level have such severe difficulties in learning arithmetic that specific support in secondary school appears to be indispensable. A study is presented in which the scores of fifth-graders in an arithmetic test have been interpreted by experienced teachers. The findings show that the need for support is considerable, but also strongly dependent on the type of secondary school. The results highlight the challenge for the school system to establish structures to identify these pupils, diagnose their difficulties in a differentiated manner, and support the pupils appropriately.

Keywords: Difficulties in learning arithmetic, dyscalculia, numeracy, secondary school.

Introduction

Over the past 25 years, international assessment studies such as TIMSS and PISA have repeatedly revealed that a significant proportion of secondary school pupils in Germany have insufficiently developed mathematical competences. In PISA 2022, for example, 30% of fifteen-year-olds in Germany did not reach competence level 2 (out of 6 levels) in mathematics; these pupils are considered to be particularly at risk of experiencing difficulties in education, employment, and social participation (Diedrich et al., 2023). To find possible approaches to improving this situation, in this paper we focus on secondary school pupils who have not succeeded in developing a sound understanding of natural numbers, the place value system, and arithmetic operations in their first three years of primary school. Without such a basic understanding of arithmetic, these pupils are significantly hindered in achieving the various learning objectives of secondary school mathematics. This paper is, in particular, a statement in favour of becoming more sensitive to pupils at secondary level with severe difficulties in the field of arithmetic. The school system is challenged to diagnose their difficulties in differentiated ways and to set up offers for individual support.

Theoretical Background

There are a variety of terms and concepts to describe particular difficulties in the field of arithmetic, such as developmental dyscalculia, severe numerical learning problems or numeracy disorder (e.g., Santos & Ribeiro, 2024; Kucian & Cohen Kadosh, 2022). In the following, we draw on a conceptualisation of the Society for Didactics of Mathematics from the German-speaking countries (GDM), which describes the special difficulties of pupils in learning mathematics from a didactic point of view (Gaidoschik et al., 2021). We speak of pupils with *severe difficulties in learning arithmetic* when they have serious deficiencies in

- the understanding of natural numbers,
- the understanding of the place value system or
- the understanding of arithmetic operations.

Here, “severe” means that the deficiencies cannot be overcome through undifferentiated further learning in regular lessons. The deficiencies can be in one, two, or all three of the areas mentioned.

From a mathematics didactics perspective, the term “understanding” can be differentiated and concretised in all three areas mentioned above (Steinecke & Ulm, 2025). A key aspect here is that pupils develop the concept of cardinal numbers—in addition to the concept of ordinal numbers. Only with the cardinal number concept can they understand the principles of the place value system and develop sound basic mental models (vom Hofe & Blum, 2016) of arithmetic operations. The above conceptualisation of severe difficulties in learning arithmetic is of high relevance for the school system: On the one hand, pupils’ understanding of natural numbers, the place value system and arithmetic operations can be analysed in differentiated ways. On the other hand, on this basis, pupils can be given individual and appropriate support (Gaidoschik, 2025). We will deepen this in the following sections.

Another way to define and diagnose severe problems in learning arithmetic is based on the International Classification of Diseases ICD-11 and uses the double discrepancy criterion. “The individual’s performance in mathematics or arithmetic is markedly below what would be expected for chronological or developmental age and level of intellectual functioning and results in significant impairment in the individual’s academic or occupational functioning” (World Health Organization, n.d., ICD-11, Code 6A03.2). On this basis, it is common practice in psychological and medical diagnostics, particularly in Germany, to carry out both an arithmetic test and an IQ test. A developmental learning disorder with impairment in mathematics is diagnosed if two criteria are met: Firstly, the individual score of the arithmetic test must be significantly below the average arithmetic test score achieved in the respective age or grade level. Secondly, the score of the arithmetic test must be significantly lower than the score of the intelligence test of the respective person.

However, there is considerable arbitrariness in setting the minimum discrepancy required to speak of this learning disorder (Murphy et al., 2007). A difference of 1 to 1.5 standard deviations is often demanded (e.g., Haberstroh & Schulte-Körne, 2019), some conceptualisations of dyscalculia also require further criteria (van Luit, 2019). Consequently, prevalence data vary greatly. For example, Wyschkon et al. (2009) found a proportion of between 0.1% and 8.1% of children with dyscalculia in a sample of 1970 pupils, depending on the definition chosen. Based on a literature review, Spiegel and Selter (2021) noted that data on the percentage of primary school pupils with severe problems in learning arithmetic ranged from 2% to 20%.

The use of the double discrepancy criterion has been criticised by mathematics didactics for decades. A pedagogical argument: If a pupil performs poorly in both the arithmetic test and the IQ test, the required difference is not achieved. If this pupil therefore does not receive mathematical support, this seems unfair and pedagogically unwise. A more theoretical argument: Intelligence is a multi-faceted construct that also includes mathematical components. Depending on the choice of the tests, the correlation between the intelligence test and the arithmetic test varies (Ehlert et al., 2012). Therefore, the discrepancy between the two test results depends on the quite arbitrary selection of the intelligence test and the arithmetic test. If an intelligence test that does not correlate with any mathematical abilities was used, however, the construct of intelligence would only be partially measured.

Research Questions

As mentioned above, diagnostic procedures based on the double discrepancy criterion do not fully meet the requirements of educational practice in schools. However, the school system needs information on how many and which pupils need specific support at secondary schools because of a lack of basic arithmetic competences from primary level. In the following, we look at pupils in grade 5, as this is usually the first grade of secondary school in the German school system. We study the following research questions:

1. How high is the proportion of pupils in grade 5 who need specific support in arithmetic?
2. How high is this percentage at the different types of secondary school?

Methods

We report on a quantitative study conducted with 2328 pupils in grade 5 in Bavaria, Germany. As background, a glance at the Bavarian school system is useful. Primary school comprises four school years. At the beginning of grade 5, pupils (who are about 10 years old) attend one of the following three secondary school types: basic secondary school, intermediate secondary school or grammar school. The study was conducted at 40 schools of these types (20 basic secondary, 10 intermediate secondary and 10 grammar schools). All fifth-graders at these schools took part in an arithmetic test. This was done at 20 schools at the beginning of the school year 2022/23 and at the other 20 schools at the beginning of the school year 2023/24. The sample can be regarded as largely representative of pupils in grade 5 in Bavaria since the 40 schools are spread across all seven administrative districts and are located in large, medium-sized, and small towns as well as in rural communities. Even though the data come from only one federal state of Germany, the results can provide impulses across Europe and beyond to recognise the difficulties of secondary school pupils in the field of arithmetic more sensitively and to react accordingly.

To assess the pupils' arithmetic competences the "Bayreuth Arithmetic Test" (in German: "Bayreuther Rechentest", BRT) was used. There were several reasons for this choice: This test is based on the above-mentioned conceptualisation of severe difficulties in learning arithmetic according to Gaidoschik et al. (2021). It assesses abilities in the three areas of understanding natural numbers, the place value system and arithmetic operations. Both the test and materials for analysing results are freely available (in German and English).[1] An important aspect of practical use in schools is that the test can be carried out by teachers. It is a standardised paper-pencil test with 24 tasks to be done in 40 minutes. This allows all pupils in a class to take the test during a lesson.

85 teachers from the 40 schools were involved in the study. They took part in a three-year teacher education programme to become experts at their schools in the diagnosis and support of pupils with severe difficulties in learning arithmetic. These teachers corrected the arithmetic tests at their school with standardised instructions. In addition, they then carried out structured diagnostic interviews in one-to-one settings with pupils who had achieved particularly low test-results. The aim of these interviews was to verify the results of the test and to gain deeper insights into the children's individual

[1] https://rechenschwaeche.uni-bayreuth.de/?Materialien_zur_Diagnostik

ways of thinking when dealing with numbers. These diagnostic results served as a basis for specific support lessons for the pupils given by these teachers at the respective school.

The teachers' professional expertise, their experience in diagnostics and their insights into the specific difficulties of pupils at their school were used to tackle the research questions. At a joint meeting, the teachers discussed the question: Up to which test result should pupils receive specific support in arithmetic and how could this be organised?

Results

A maximum of 60 points can be achieved in the arithmetic test. In the following analysis, the percentage of the maximum possible points achieved by pupils in the test is considered; this percentage is referred to as the *test score*.

Distribution of test scores differentiated by school type

Figure 1 shows a classified distribution of the test scores achieved, broken down by school type. The height of the bars indicates the percentage of pupils from each type of school who achieved a test score in the specified interval.

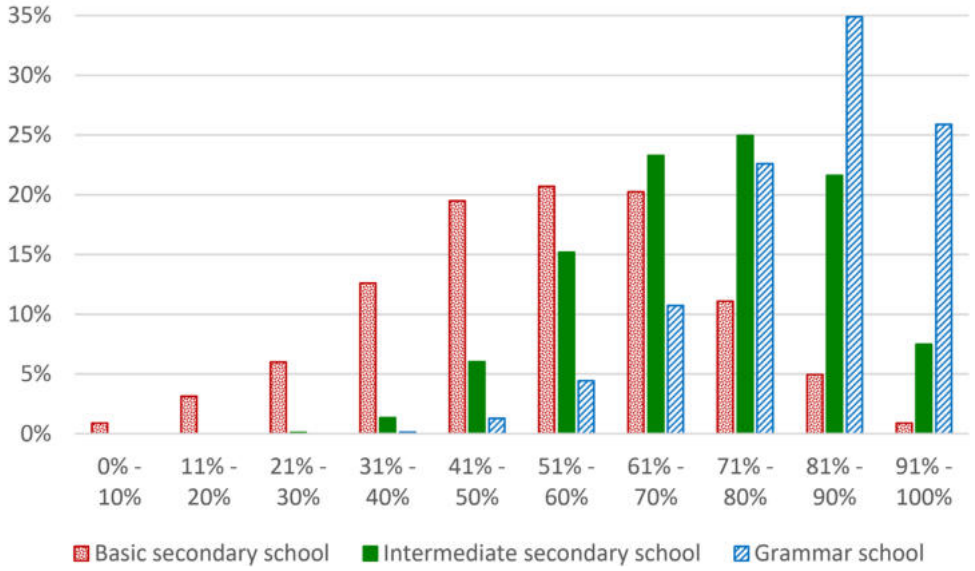

Figure 1: Distribution of test scores differentiated by school type

Comparing the three distributions, on the one hand, it is noticeable that the distributions are—as expected—shifted against each other. The results are better at grammar schools than at intermediate secondary schools and there again better than at basic secondary schools. The medians of the three distributions are 55%, 72% and 83% respectively. On the other hand, there are also considerable overlaps of the three distributions. For example, there are children at all three types of school who only achieve half of the points or less, but also children who achieve more than 90% of the points. Results in the range of 61% to 80% of the points are achieved by 31% of pupils at basic secondary schools, 48% of pupils at intermediate secondary schools and 33% of pupils at grammar schools. These overlaps of the distributions are not surprising, as the decision of which type of school a child attends in grade 5 does not only depend on his or her performance in arithmetic.

Distribution of test scores across school types

To obtain an overview of how test scores are distributed in the overall population of fifth-graders at basic secondary schools, intermediate secondary schools and grammar schools, the three school-specific distributions from Figure 1 are combined to an overall distribution. It is taken into account that the three types of school are attended by different numbers of pupils in grade 5 in Bavaria.[2] Therefore, the three school-specific distributions are weighted accordingly and then added up. As a result, Figure 2 shows the classified distribution of test scores in the population of pupils in grade 5 at basic secondary schools, intermediate secondary schools and grammar schools. The height of the bars indicates the percentage of pupils achieving a test score in the specified interval.

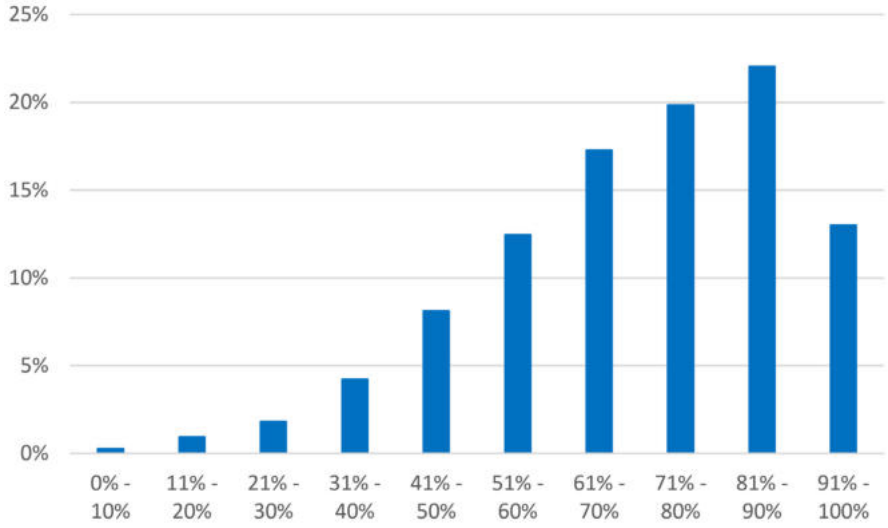

Figure 2: Distribution of test scores across school types

It becomes apparent that the arithmetic test differentiates mainly in the lower performance range. Half of the pupils achieved at least three quarters of all achievable points. The distribution in Figure 2 is particularly useful for relating the test results of individual pupils to the overall population of fifth-graders.

Cut-off values for severe difficulties in learning arithmetic

As described above, in a teacher education event for the 85 teachers at the 40 schools, it was discussed which pupils needed special support to overcome their difficulties in arithmetic. In a joint meeting, the group of teachers was asked orally up to which test score pupils should be given specific support. This question was particularly important for the teachers, as they had the task of setting up appropriate support programmes at their schools. Based on their experience in correcting the arithmetic tests of the 2328 pupils, their insights from the diagnostic interviews and their professional expertise, the teachers' joint discussion resulted in a differentiated recommendation:

[2] In 2023, 29% of pupils in grade 5 attended a basic secondary school, 28% an intermediate secondary school and 38% a grammar school. The further 5% attended schools for special needs or private schools with specific philosophical focus.

- Pupils who achieved less than 55% of the points in the arithmetic test should receive specific support. This can be done through differentiation in regular mathematics lessons or in additional support lessons.
- If only 35% or less of the points were achieved, support in extra lessons in addition to the regular mathematics lessons is urgently required.

Thus, regarding the organisation of support measures, the teachers differentiated between levels of severity of the difficulties.

Proportion of pupils with severe difficulties in learning arithmetic

With these teacher recommendations, the distributions of test scores (see Figures 1 and 2) can be used to directly determine the proportion of pupils with particular needs for support in arithmetic in grade 5 at the three school types and across the school types. This gives the data in Table 1 and thus the answers to the two research questions.

Table 1: Proportion of pupils with particular needs for support in arithmetic among all pupils in grade 5 of the respective school type and across the three school types

	Basic secondary school	Intermediate secondary school	Grammar school	Across school types
Proportion of pupils who need specific support (test score below 55%)	50%	12%	2.4%	20%
Proportion of pupils who need additional lessons (test score of at most 35%)	16%	0.3%	0%	5%

Across all three types of school, teachers judge that 20% of pupils in grade 5 need specific support to overcome their learning deficits in arithmetic; for 5% of pupils, this should take the form of additional lessons. At grammar schools, such additional lessons are not absolutely necessary. Here, 2.4% of pupils require specific support, which can usually be provided through differentiation in class. The situation is different in basic secondary schools, where half of all pupils require specific support in arithmetic. For 16% of pupils in this type of school, it is considered necessary for the support to take place in separate lessons in addition to the regular classes.

Discussion

The results presented show how many pupils at the beginning of secondary school have considerable deficits in their understanding of primary level arithmetic (see Table 1). However, the curricula and mathematics lessons at secondary level presuppose this understanding. They build on this, e.g., in the context of negative numbers, fractions, variables, terms and functions. If these pupils with severe learning deficits in arithmetic do not receive specific support, it is very likely that they will retain these deficits throughout their secondary school years. Furthermore, they will also be substantially hindered in achieving the various objectives of secondary mathematics education. It is therefore highly probable that, at the end of their schooling, they will be among the young people labelled as low achievers by PISA (Diedrich et al., 2023). They are at risk of experiencing barriers in their further

professional development and social participation, as arithmetic competences are required in many areas of professional and private life.

Thus, the results in Table 1 show a substantial challenge for the secondary school system. According to the judgements of secondary school teachers, 20% of pupils in grade 5 require specific support in arithmetic. In some cases, this could be achieved through differentiation in the classroom, but in other cases additional support lessons are necessary (see Table 1). Supporting these pupils requires systemic activities on several levels:

- Firstly, it is a challenge for teacher education. In Germany, prospective secondary school teachers usually acquire professional competences for teaching secondary level content, but not primary level content. They are not made acquainted with diagnosing and developing pupils' basic understanding of natural numbers, the place value system and arithmetic operations at primary school level. To really help secondary school pupils with severe difficulties in learning arithmetic, developments are therefore required in the area of teacher (further) education.
- Secondly, there are challenges at school organisational level. New support offers need to be set up for pupils with severe difficulties in learning arithmetic. For specific support during regular lessons, appropriate differentiation formats are necessary. Support lessons in addition to regular classroom lessons require appropriate organisational planning as well as additional staff capacity and therefore financial resources.
- Thirdly, teachers need concepts and materials for the diagnosis of difficulties and for the support of pupils with these difficulties. Textbooks and workbooks for secondary school mathematics lessons are usually not designed for this purpose.

For tackling these challenges, there are already a variety of successfully tried and tested concepts (e.g., Dowker & Sigley, 2010; Dowrick, 2015; Kucian & Cohen Kadosh, 2022; Prediger et al., 2019). A major task, however, is to put these into practice on a broad basis in teacher education and everyday school life. The data in Table 1 emphasise the need for such developments.

Assessing students' conceptual place value understanding at the end of primary school

Gerald Wittmann[1] and Katja Lenz[2]

[1]University of Education Freiburg, Freiburg i. Br., Germany, gerald.wittmann@ph-freiburg.de

[2]University of Education Schwäbisch Gmünd, Schwäbisch Gmünd, Germany

Place value understanding is a prerequisite for learning mathematics in secondary school. Therefore, students' place value understanding for numbers up to one million at the end of grade 4 is highly relevant. To assess conceptual place value understanding for numbers larger than a thousand, we developed a test instrument consisting of 13 items comprising three task types. All of the items require the transformation of a number's pictorial or symbolic representation to a numeral, whereby non-standard representations are crucial. The statistical reliability and validity of the instrument are demonstrated by confirmatory factor analysis and reliability measures.

Keywords: Place value understanding, conceptual place value understanding, representations of numbers, empirical study, confirmatory factor analysis.

Theoretical Background

Understanding multi-digit numbers in the decimal place value system is a prerequisite not only for everyday life but also for calculating and learning decimals (Fuson et al., 1997; Mix et al., 2023; Verschaffel et al., 2007). For example, crossing a tens boundary in written addition and subtraction is based on an understanding of place values, especially of bundling and unbundling. Likewise, addition and subtraction following both methods of split or jump require an understanding of numbers as a composition of ones, tens, hundreds, thousands, and so on.

Despite its importance, place value understanding remains a vague concept that many authors do not explicitly define. A shared but quite general explication considers place value understanding as the understanding of the meaning of a numeral represented in the decimal place value system, including its principles (especially bundling and unbundling). Following Herzog et al. (2019) and Van de Walle et al. (2023), the distinction between procedural understanding and conceptual understanding is helpful to clarify what place value understanding means.

Briefly summarized, *procedural place value understanding* comprises the reading and writing of numbers ("transcoding", Herzog et al., 2022). More precisely, this means both transfers between number words and the numerals. It consists mainly of semiotic and linguistic insights into the structure of number words and reading skills regarding numerals. Many studies focus on reading and writing multi-digit numbers (cf. Herzog et al., 2022; Nuerk et al., 2014). An essential aspect here is that in German and a few more European languages, the number words are built in the order hundreds-ones-tens, which is different from the order of the digits. As the inversion of tens and ones can cause problems for learners, procedural place value understanding is an important aspect, yet it represents only one aspect of place value understanding.

The core of *conceptual place value understanding* is the understanding of the relation between the decimal units, based on the processes of bundling and unbundling. As stated by Bruner et al. (1967), there are three modes of representation for mathematical knowledge in general and numbers in particular: concrete (e.g., using Dienes blocks), pictorial (e.g., by dots, lines, and squares, as an abstraction of the Dienes blocks, like in Figure 1), and symbolic (e.g., in a place value chart, as a numeral or as a number word). Following on from this, conceptual place value understanding means the ability to perform various transformations between symbolic representations on the one hand and concrete or pictorial representations on the other hand. Such transformations are considered crucial for acquiring a place value understanding (e.g., Resnick, 1989; Treffers, 2001; Van de Walle et al., 2023) and are an approach for assessing place value understanding, too.

According to the principles of the base-ten place value system, a maximum of nine units of each bundle size is permitted to note. Though, in the context of mathematics education, not only representations like "3 hundreds, 4 tens, and 6 ones" following mathematical conventions but also representations like "2 hundreds, 14 tens, and 6 ones" or analogue pictorial representations (cf. Figure 1) can appear. The latter are called non-standard representations (Van de Walle et al., 2023) or non-canonical representations (Herzog et al., 2019), and they are considered highly relevant in the learning process (Ross, 1989; Van de Walle et al., 2023) as well as for diagnostic purposes.

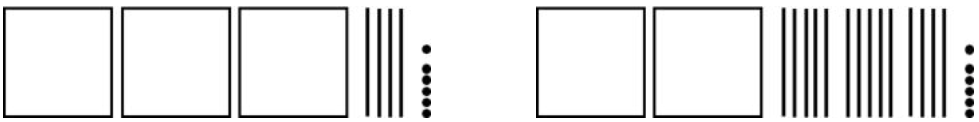

Figure 1: Pictorial representation of 346 (on the right, a non-standard representation)

A relevant empirical approach to place value understanding is the search for developmental models. As their focus is on the early development of place value understanding, most of these empirical studies deal with numbers smaller than a thousand. There are earlier attempts, e.g., Fuson et al. (1997), Resnick (1989), and Ross (1989), who describe some phases from counting to identifying ones and tens to an integration of ordinal and cardinal concepts. Following this tradition, in a more recent study Herzog et al. (2019) set up an empirically validated developmental model for place value understanding that consists of five hierarchical stages from a pre-decadic level to a general decimal-bundling-unit-relation. In keeping with the interest in a developmental model, the sample includes children from grade 2 to grade 5, and the hierarchical model reflects, to some extent, the curriculum.

There are also studies investigating the structure of place value understanding. For example, Jensen et al. (2024) asked third graders who had been systematically taught numbers up to a thousand to transform a representation like 7H 3O 19T into numerals. Analyzing students' errors qualitatively, two aspects of place value understanding could be separated: place value (when the order of the units is not the regular one) and regrouping (bundling in the case of a non-standard representation).

All of the studies show that a substantial part of the students up to lower secondary has severe difficulties in place value understanding, particularly in conceptual place value understanding (Herzog et al., 2019; Humbach, 2008; Jensen et al., 2024; Moser Opitz, 2013; Resnick, 1989; Ross, 1989).

Although there are some studies on conceptual place value understanding, they mostly do not address the understanding of numbers over a thousand. However, only in the higher number range, multiple bundling (basically 10 ones to 1 ten, but furthermore 10 tens to 1 hundred, 10 hundreds to 1 thousand, …) plays a role, which makes it interesting to focus on students' conceptual place value understanding and typical errors in that number range. Besides, most of the published test instruments capture conceptual place value understanding with only a few items.

Therefore, it is necessary to develop a comprehensive test instrument covering the higher number range and different transformations in order to gain deeper insights into the place value understanding of learners who have been systematically taught numbers up to one million.

The present study

The aim of our study is to develop a reliable and valid test instrument to assess students' conceptual understanding of place value for three- and four-digit numbers. In particular, the empirical evaluation of the construct validity and the reliability of the developed test instrument is highly relevant. Accordingly, we examine in this report whether a one-dimensional model representing conceptual place value understanding shows an appropriate fit to the empirical data, and whether a reliable scale can be formed using different transformation tasks.

Methods

Sample

The participants were $N = 630$ students who were spread over 34 classes of grade 4 in German primary school. The age of the participants was on average 10.3 years ($SD = 0.6$). Nearly half of the students were male (46.7%), and just over half were female (53.3%). The test took place at the end of the school year. In Germany, primary school generally lasts 4 years, and all students attend the same type of school. In this respect, it can be assumed that the sample is very heterogeneous. According to the curriculum, the children had been taught numbers up to one million and calculate with them.

Data collection

Data collection was run by specially trained research assistants with a Bachelor's degree during a 45-minute lesson in a whole-class setting. It was approved by the school authorities; students and their parents gave their informed consent.

The test instrument was a paper-pencil test. The students had as much time as they needed to work on it. As mentioned above, our test was designed to capture place value understanding by transforming pictorial and symbolic representations into numerals. We constructed three task types with space for free-text answers (Table 1).

The first task type comprises items where pictorial representations of numbers smaller than a thousand should be transformed into a numeral. This kind of pictorial representation is very common in German textbooks: 15 of the 16 textbooks licensed by the school authorities use it. In the second task type, a number given in a place value chart must be transformed into a numeral. The third task type focuses on the transformation of a base ten-number word into a numeral, each up to one million. In 11 of the 13 items, a non-standard representation was used. When constructing the items, two

aspects were systematically varied: (1) unfilled positions and (2) positions with a noted bundle size larger than nine.

There were two versions, A and B, of the test: Regarding task type 1, the items were the same in both versions but in a different order. Regarding task types 2 and 3, the items were structurally identical but with slightly different numbers.

Table 1: Task types, each with an example item

	Task type	Example item
1	Transformation pictorial representation → numeral (4 items)	Some children represent the number 423 like this: Which number is given here? Write it as a numeral.
2	Transformation place value chart → numeral (4 items)	Write as a numeral: **Th** | **H** | **T** | **O** 2 | 6 | 13 | 4
3	Transformation base-ten number word → numeral (5 items)	Write as a multi-digit number numeral: 3 thousands, 25 hundreds, 1 ten, 7 ones

Data analysis

The data analysis was conducted using the Statistical Package for the Social Sciences (SPSS 28, IBM Corp., 2021) and R (R Core Team, 2021), with particular emphasis on confirmatory factor analysis (CFA), using the lavaan (Rosseel, 2012) and semTools (Jorgensen et al., 2022) packages for structural equation modelling (SEM) and reliability assessment. First, the item difficulty (average response accuracy) was analyzed. Second, the factor structure of the measurement model was investigated. CFA was used to evaluate the model's fit to the observed data. To assess the construct validity of our measurement model, we conducted the CFA using the DWLS (diagonally weighted least squares) estimator, as the items were dichotomously coded (1: correct; 0: wrong or missing). The hypothesized model posited the latent factor 'place value understanding' indicated by three task types: (1) transformation pictorial representation → numeral, (2) transformation place value chart → numeral, (3) transformation base-ten number word → numeral (see Figure 2). Correlations among error terms within the same task type were allowed in the model to account for potential shared variance.

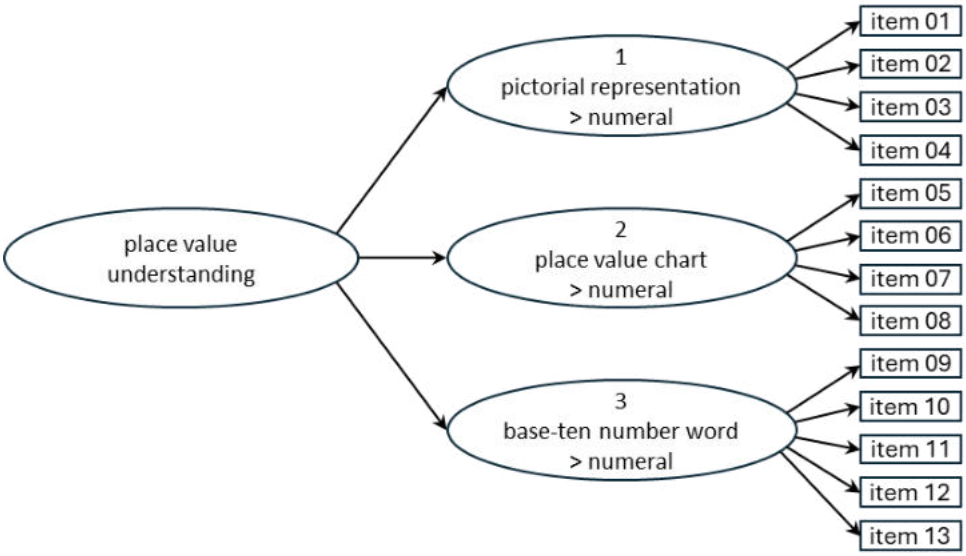

Figure 2: Structure of the model

Results

The item analysis revealed that one item exhibited a difficulty level of 0.87 that fell outside the acceptable range of 0.2 to 0.8. Consequently, this item was excluded from further analysis. Within task type 3, two items were excluded due to their low factor loadings < 0.4 (Kline, 2015). Descriptive statistics, including the mean values for the indicator variables in the structural equation model, are presented in Table 2.

Table 2: Descriptive statistics indicator variables (*N* = 630)

Indicator variable	Theoretical range	*M*	*SD*
1 Transformation pictorial representation → numeral	0–1	0.69	0.34
2 Transformation place value chart → numeral	0–1	0.56	0.41
3 Transformation base-ten number word → numeral	0–1	0.66	0.43

The results of the CFA, which will be detailed below, are based on the empirical covariance matrix. This covariance matrix was derived from the correlation matrix presented in Table 3, which displays the bivariate correlations among the measurement model variables.

Table 3: Correlation matrix of the indicator variables (*N* = 630)

Indicator variable	1	2	3
1 Transform. pictorial representation → numeral	1.00		
2 Transform. place value chart → numeral	0.45***	1.00	
3 Transform. base-ten number word → numeral	0.44***	0.82***	1.00

Note: *** $p < 0.001$

The CFA results show that the overall fit of the measurement model was adequate. The goodness of fit indices are presented in Table 4.

Table 4: Measures of global fit

Fit Index	Value	Recommended Threshold
CFI (scaled)	0.98	≥ 0.95
TLI (scaled)	0.98	≥ 0.95
RMSEA (robust)	0.03	≤ 0.06
SRMR (robust)	0.03	≤ 0.08
Chi-Square ($df = 56$)	51.23 ($p = 0.66$)	$p > 0.05$

The CFI and TLI values are both above the recommended threshold of 0.95, indicating an excellent fit of the model to the data (Hu & Bentler, 1999). The robust RMSEA value of 0.03 is well within the acceptable range of less than or equal to 0.06, further supporting the good fit of the model. In addition, the SRMR value of 0.03 is below the threshold of 0.08, indicating a good fit. The chi-square statistic with $\chi^2 = 51.228$ ($df = 56$) gives a p-value of 0.656. This suggests that the model fits the data reasonably well regarding the standard chi-square test.

All factor loadings for the observed variables were statistically significant ($p < 0.001$), with standardized loadings ranging from 0.41 to 0.95. The factor loadings of the indicator variables on the latent construct factor 'place value understanding' ranged from 0.53 to 0.96, indicating that the latent construct is well represented by its indicators.

The overall reliability of the latent construct was evaluated using McDonald's Omega (McDonald, 1999), which yielded a value of 0.91. An omega value above 0.70 indicates high reliability, suggesting that the latent construct is measured consistently across the included indicators (Raykov, 1997). The average variance extracted (AVE) for the latent construct was 0.57. AVE assesses the proportion of the variance in the indicators captured by the latent construct, as opposed to measurement error. An AVE value above the threshold of 0.50 indicates that the latent construct explains a substantial proportion of the variance in its indicators, thereby confirming the convergent validity of the construct (Fornell & Larcker, 1981).

Discussion

The goal of our study was to develop a reliable and valid test instrument for assessing students' conceptual place value understanding at the end of primary school. Our test instrument is designed to evaluate conceptual place value understanding by operationalizing it through bundling and transforming pictorial or symbolic representations into numerals. Focusing on this, non-standard representations play an important role. While our study addressed bundling and transformation extensively, it did not include unbundling processes—an equally significant aspect of place value understanding (e.g., considering written subtraction). Nevertheless, our test instrument goes beyond previous research, allowing for a more comprehensive assessment of conceptual place value

understanding by systematically varying positions of units more than nine and by focusing on the number range larger than a thousand. In addition, the results demonstrate satisfactory validity and reliability, which is crucial for drawing well-founded interpretations about learners' conceptual place value understanding. The final test instrument comprises 13 items, which can be assigned to three distinct task types, each targeting a specific transformation. As it is brief, it offers a highly time-efficient assessment for research and diagnostic purposes in school.

For future research, there is significant potential to extend the scope of analysis using the developed test instrument. One area of interest is the identification of typical error patterns to gain deeper insights into common misconceptions and difficulties encountered by students. Additionally, investigating the relationship between conceptual place value understanding and other mathematical skills, such as arithmetic fluency, could provide valuable perspectives on how place value knowledge contributes to broader mathematical competence.

Exploring the strategies utilised by primary pupils to solve equal group multiplication problems using the 'Stick and Split' app

Waqas Bin Sarfraz[1], Dave Hewitt[1] and Ian Jones[1]

Loughborough University, Department of Mathematics Education, Loughborough, United Kingdom; w.b.sarfraz@lboro.ac.uk

Keywords: Game-based learning, multiplication, problem-solving.

Introduction

Children often use intuitive strategies to solve multiplication problems before receiving formal education, which evolve into more advanced strategies with age (Downton, 2008). Literature suggests that primary pupils mostly rely on modelling, counting, grouping, repeated addition and multiplication facts to solve multiplication problems (Mulligan & Mitchelmore, 1997). Pupils select these strategies depending on their experiences, problem specificity, and cognitive development at the time (Lemaire & Siegler, 1995). In the last decade, education has embraced technology; as a result, many digital tools (i.e., apps and games) are now available to primary school pupils to help them grasp fundamental arithmetic concepts. Stick and Split is an interactive educational app designed to practise multiplication problems and learn arithmetic facts. A brief introduction to this app can be seen in a YouTube video: https://www.youtube.com/watch?v=lvISZHKWclc.

Stick and Split is developed to help pupils practise equal-group multiplication problems. It has 300 levels, in which pupils either join (stick) different rods of equal sizes into one bigger rod or break down (split) one big rod into several rods of equal sizes. The task at every level is to convert all the available rods into a number (i.e., target number), which is given at the top of the screen by utilising stick and split operations provided at the bottom. This study aims to explore the engagement of primary school pupils with the Stick and Split app to see the following: 1) What strategies do they utilise to solve multiplication problems posed by different levels of the Stick and Split app? 2) How similar are these strategies in relation to the strategies reported by the literature?

Methods

This exploratory qualitative study analyses a 30-minute recorded session of two Year 2 pupils interacting with the Stick and Split app at a primary school in England. In the first five minutes of the session, the pair were introduced to the Stick and Split app on an iPad screen. Following that, this pair interacted with the app for 25 minutes; during this time, they were asked to discuss their strategies while completing the following levels of the app: 78, 79, 106, 160, 161, and 108. These levels were shortlisted from the 300 available levels in the Stick and Split app according to the ready-to-access arithmetic skills criteria of Year 2 pupils outlined in the guidelines of the Department of Education (DfE, 2019, p.52). Thematic analysis was used to analyse the recorded session.

Results

The played levels were categorised into three groups based on their difficulty level, which indicated whether splitting is required and whether the available rods are factors of the target number. Those levels where the available rods were factors of the target number were classed as easy, those that

involved splitting were classed as intermediate, and those where splitting was required and none of the available rods were factors of the target number were classed as difficult (see Table 1).

Table 1: S&S level number, Target number, and the Given rods of the six played levels

Difficulty level	Intermediate		Easy		Difficult	
Level number	78	79	106	160	161	108
Target number	24	24	32	48	48	24
Available rods	8,16	12,18	4, 8	4, 12	20, 44	16, 24

The coding process revealed that pupils utilised four strategies to solve multiplication problems across the six Stick and Split levels: known or derived multiplication facts, a two-step multiplication model (combining one known and one derived fact), skip counting, and trial-and-error grouping. In easier levels, pupils first employed trial-and-error grouping, then known or derived facts, and finally two-step multiplication models when only rods of length 2 or 3 were present. They started with known or derived facts in intermediate levels before switching to trial-and-error grouping. With rods of length 2 or 3 left, they used skip counting in level 78 and the two-step model in level 79. In difficult levels, pupils completed level 161 solely with trial-and-error grouping, while in level 108, they transitioned from trial-and-error to the two-step multiplication model.

Discussion

The literature suggests that pupils' development tends to transition from modelling to counting and eventually to multiplication facts as a problem-solving strategy (Mulligan & Michelmore, 1997; Downton, 2008). Year 2 pupils' experience with multiplication problem solving likely contributed to their use of advanced strategy over basic modelling or counting. The two-step multiplication model emerged as an extension of known multiplication fact strategies. Pupils used these facts when available rods matched target number factors; otherwise, they relied on trial-and-error grouping. Notably, the Stick and Split app supported flexible strategy use, allowing ample practice and opportunities for pupils to deepen conceptual understanding of equal-group multiplication.

TWG 03: Algebraic Thinking

An introduction to TWG3 Algebraic Thinking

Maria Chimoni[1], Luis Radford[2] , Jorunn Reinhardtsen[3] and Stefan Korntreff[4]

[1]University of Cyprus, Cyprus; chimoni.maria@ucy.ac.cy

[2]Laurentian University, Canada

[3]University of Agder, Norway

[4]TU Dortmund University, Germany

Overview

In Thematic Working Group 3 on "Algebraic Thinking," 18 papers and 2 posters were presented, with a total of 27 participants from Europe and other continents. The contributions were presented and discussed in working sessions organized around four themes: (1) Functional Thinking, (2) Variables and Expressions, (3) Equivalence and Equations, and (4) Algebraic Thinking from Different Perspectives. Given the interconnected nature of these themes, the assignment of papers was guided by a "best fit" approach. Notably, the contributions collectively reflect progress in the research field of algebraic thinking on both theoretical and practical fronts. Central to this progress are key issues such as the nature and scope of algebraic thinking, the transition from concrete representations to abstract reasoning—and whether this shift constitutes a natural development or a rupture in students' understanding—as well as the pivotal role of teachers in supporting students' algebraic development across grade levels. Below, we discuss the papers presented under each theme. The report concludes with key issues and challenges identified in the discussions during the sessions.

Functional Thinking

This theme was prevalent among the papers presented in TWG3, reflecting a clear interest in function graph tasks as a means of developing algebraic thinking from the elementary grades onward. These papers reveal both students' learning routes and persistent challenges, as well as the crucial role of teacher knowledge and instructional practices. Radford demonstrated that Grade 6 students initially perceived function graphs as static images or maps, neglecting the concept of co-variation. However, through teacher-guided interactions, they gradually developed more sophisticated, culturally situated understandings of the dynamic relationships between co-varying quantities. Liao et al. showed that even Grade 2 students could reason with function graphs when supported by instructional sequences that organized functional relationships into a hierarchy of difficulty—for example, beginning with $y=x$ and progressing to $y=2x$. This finding highlights that an understanding of functional relationships can emerge earlier than traditionally expected. Also addressing early algebraic thinking, Tomaszewski and Nührenbörger illustrated that Grade 4 students were capable of reasoning meaningfully with four types of functional relationships—linear, quadratic, exponential, and inverse—suggesting untapped potential in primary mathematics education, where such topics are often addressed only implicitly. In the high school context, however, Šabaková and Semanišinová found that, despite prior instruction, students struggled to connect tabular data to the graph of a quadratic function. This points to deep-rooted challenges in coordinating different representations of functional relationships. At the instructional level, Belin et al. explored how the depth of teachers'

reasoning about co-variation influenced whether they employed correspondence or co-variation approaches in their teaching, potentially shaping how students encounter and understand quadratic functions. Complementing these findings, Pittalis and Gridos analyzed how Grade 8 teachers introduced the concept of slope. The study revealed that teachers primarily focused on the geometric ratio and the algebraic formula, without allocating time to explore the multiple conceptualizations of slope—thus limiting students' opportunities to develop deeper conceptual understanding. Reinforcing the sociocultural dimension, Reinhardtsen and Carlsen highlighted how the process of "togethering"—the committed engagement in joint activity with a shared ideal or material object between teacher and students—could either facilitate or hinder students' transition from arithmetical to algebraic thinking in the context of pattern tasks. This paper underscores that such transitions are not only cognitive but also deeply entangled with emotions and the joint construction of meaning within the classroom. Finally, Goñi-Cervera et al. contributed to this conversation through a poster focused on young students with Autism Spectrum Disorder (ASD). This work extended the discussion of early algebraic thinking into inclusive education contexts. The study showed that these students experienced similar difficulties to those reported in the literature for typically developing peers in grasping the "unit of repeat". Together, these studies underscore that the development of functional thinking is both cognitively and socially situated. They highlight the need for: (a) well-designed instructional sequences; (b) intentional instructional support; (c) attention to representational connections; (d) sensitivity to the emotional and dialogic processes that shape learning.

Variables and Expressions

The studies under this theme collectively emphasize the persistent challenges students face in algebra—particularly in interpreting variables and expressions—while also highlighting instructional strategies that support conceptual development. Christou et al. investigated how Grade 9 students frequently misinterpreted algebraic expressions with a negative sign, such as assuming that $-2x$ must always represent negative numbers, leading to errors in solving equations and inequalities. Although an instructional intervention using incorrect examples proved slightly more effective than using correct examples, neither approach resulted in long-term conceptual change, underlining the resilience of such misconceptions. Complementing this, Korntreff and Prediger explored how interactive instructional videos supported Grade 8 students in refining their understanding of variables. The interactive features of the videos helped students confront and revise deviant or partial solutions, promoted distinctions between variables as placeholders versus generalizers, and provided language resources to support this conceptual distinction. Similarly addressing students' misconceptions about algebraic letters, Klingbeil and Moons showed that instructional practices explicitly focused on the meaning of variables within algebraic expressions helped Grade 7 and Grade 8 students overcome the widespread "letter-as-object" misconception. Acknowledging the importance of conceptually understanding variables and expressions at the tertiary level, Wladis et al. demonstrated that students' scores on a validated algebra test significantly predicted both mathematics and STEM outcomes at a large, diverse urban university. These scores accounted for disparities in outcomes across race/ethnicity and gender beyond what course grades could explain. Taken together, these studies highlight critical insights: (a) misconceptions about variables—particularly regarding their sign, role, and meaning—are longstanding and persist across grade levels;

(b) distinguishing between different uses of symbols (e.g., variable as placeholder vs. generalizer) is central to conceptual growth in algebra; (c) instructional strategies that explicitly address these distinctions, such as interactive media or conceptually focused tasks, are essential.

Equivalence and Equations

This theme brings into focus the structural thinking dimension of algebraic thinking, particularly in relation to linear and proportional equations. Two studies addressed the challenges students face in solving linear equations, offering complementary perspectives on students' attention to structure. Holmlund and Pejlare's study with 16-year-old vocational students revealed that when tasked with sorting linear equations, they attended to a diverse range of features—both superficial and structural—highlighting the potential of such tasks for assessing students' sensitivity to structure. Weber et al. adopting a semiotic-pragmatic lens and using eye-tracking technology, further illuminated how pre-service teachers interact with the structural components of equations during problem solving. The study found that "adaptive experts" moved rapidly between sub-expressions, operations, brackets, and the equals sign, applying hierarchical structuring which led to more efficient problem-solving. In contrast, "routine experts" relied on more linear, left-to-right strategies, with particular emphasis on areas that support the standard solution approach. These strategies were associated with higher cognitive load and increased error rates. The studies by Tunc-Pekkan et al. and Tuncer et al. shift the focus from linear to proportional equations, further emphasizing structural thinking in a different algebraic context. Tunc-Pekkan et al's study examined how in-service teachers approached problems involving fractions and two varying quantities. The analysis revealed that they had difficulty making meaningful connections between visual models—which are designed to illustrate the underlying structure—with the corresponding algebraic equations. Tuncer et al. examined how gifted 7th-grade students performed on various proportional reasoning tasks and found that they did not experience the common difficulties reported in the literature. Their strong metacognitive skills—such as focusing on relevant information—appeared to support their ability to recognize and articulate structural relationships between quantities. This suggests that their emerging algebraic thinking may have played a key role in strengthening their proportional reasoning performance. Adding a higher education perspective, a poster by Cancec Murillo et al on limit tasks also highlighted the need for reinforcing structural sense in calculus contexts. Together, these studies suggest several key implications for supporting students' understanding of equivalence and equations across contexts: (a) students' ability to attend to the structure of equations—whether linear or proportional—is highly variable and often underdeveloped; instructional tasks that foreground structural features, such as equation sorting, may help build algebraic structure sense; (b) promoting flexible strategies can reduce cognitive load and improve accuracy in solving equations; and (c) the use of representations—particularly in proportional reasoning—requires careful scaffolding.

Algebraic Thinking from different perspectives

The final theme delves into the epistemological, cognitive, and developmental perspectives of algebraic thinking, offering deeper insights into its disciplinary foundations and the challenges it presents in educational practice. Hällback and Viirman, drawing on the Anthropological Theory of the Didactic, developed a Reference Epistemological Model (REM) to map the organization and

content of upper secondary algebra in Sweden. This model systematically described institutionalized algebraic practices and types of tasks valued in the curriculum, serving as a powerful tool for analyzing how algebra is structured and taught at a national level. Extending the theoretical discourse, Akinwunmi emphasized the need to clarify foundational constructs in algebraic thinking by distinguishing between "pattern" and "structure." She argued that while patterns are regularities in visible phenomena, structures refer to underlying mathematical properties and relations. Promoting algebraic thinking requires using representations and prompts that move beyond patterns to help students grasp these deeper structures. Pitta-Pantazi et al. explored algebraic thinking during the transition from primary to secondary education. The study revealed that Grade 6 students performed more successfully on tasks requiring inductive reasoning (e.g., recognizing and extending patterns) than on those demanding deductive reasoning (e.g., justifying general rules based on mathematical properties). This gap between inductive and deductive performance underscores the persistent challenge students face when moving from pattern-based reasoning to formal argumentation and abstraction—thus reinforcing Akinwunmi's call to foreground structural understanding and the role of reasoning in algebra learning. Together, these studies underscore: (a) the value of epistemological tools in analyzing curricular content and (b) the critical need to support students' development of structural awareness and deductive reasoning through purposefully designed instructional strategies.

Concluding Remarks

The studies presented in TWG3 reflect significant progress in algebraic thinking research, both theoretically and practically, while also highlighting critical challenges that call for further investigation. A key theoretical challenge is clarifying the nature and scope of algebraic thinking. There is growing recognition that early algebra cannot be seen simply as "generalized arithmetic." Rather, algebra involves a distinct, analytical form of reasoning, particularly in handling indeterminate quantities—a key difference from arithmetic. This raises questions about how students' generalizations evolve as they move from concrete arithmetic to abstract algebraic expressions, and how their understanding of variables, constants, equations, and graphs develops. For example, the variable-constant distinction signals a deeper conceptual shift in perceiving quantities within dynamic systems. Clearer frameworks are needed to understand these transformations and to inform teaching. Practically, a persistent challenge is translating theory into effective classroom strategies, especially in diverse settings including special education. The role of manipulatives and digital tools remains debated, as their effectiveness in bridging concrete and abstract understanding is complex and context-dependent. Future research should investigate under what conditions these means genuinely foster deeper algebraic thinking and when they might fall short. TWG3 discussions also stressed the importance of starting algebraic thinking development early. Equally important is the role of the teacher in navigating both the cognitive and emotional dimensions of learning. Teachers are not only responsible for facilitating conceptual understanding, but also for creating supportive environments that help students manage the uncertainty and discomfort often associated with abstract reasoning. Their ability to recognize and respond to students' emotional reactions to algebraic tasks—such as frustration, confusion, or disengagement—can significantly influence learning outcomes. By addressing these issues, future research can foster more robust, nuanced, and inclusive understandings of algebra as a foundational part of mathematics education from the earliest grades.

Understanding mathematical structures: A contribution to the discourse about the nature of algebraic thinking

Kathrin Akinwunmi[1]

[1]University of Münster, Germany; akinwunmi@uni-muenster.de

To constantly sharpen the character of algebraic thinking is a research desideratum, that has intensified in TWG03 in the last years (Hewitt et al., 2022; Chimoni et al., 2023). This paper aims to contribute to the discourse about the nature of algebraic thinking, considering possible perspectives on algebra and algebraic thinking and including a reference to algebra as a mathematical discipline. The paper highlights the important distinction between the terms pattern and structure and emphasises the critical role of representations in generalising. Consequences are derived for the discussion of the relationship between algebraic and arithmetic thinking.

Keywords: Algebraic thinking, patterns and structures, generalisations, representation-based proofs, properties and relations.

Introduction and objectives of the paper

It is an aim that has emerged in the last years, noted in the TWG03 proceedings (Hewitt et al., 2022; Chimoni et al., 2023), to constantly sharpen the nature of algebraic thinking. Following CERME13, Chimoni et al. (2023) emphasise the importance of working out the relation between arithmetic and algebra: "We feel that future work needs to address the differences more explicitly between arithmetic and algebraic thinking, as well as their evolving complementarities" (Chimoni et al., 2023, p. 511).

This paper is intended to continue the discussion at CERME12, where Akinwunmi and Steinweg (2022) presented an empirical study on children's generalisations with focus on patterns and focus on structures. In an exploratory study with fourth graders, we investigated how the theoretical distinction between patterns and structures is reflected in the children's generalisations (against the background the epistemological perspective of Steinbring (2005)) and what consequences this has for the development of algebraic thinking.

The current paper aims to elaborate on the theoretical background more detailed and consider it in the light of the exploration of possible perspectives on algebra and algebraic thinking. In the first section, the meaning of the term structure and its significance for algebraic thinking are derived from the development of algebra as a mathematical discipline. In the second section, based on the respective literature on algebraic thinking, I propose a theoretical distinction between the terms *pattern* and *structure*, which are sometimes used together or even synonymously. I argue, that it is important to differentiate between the two terms for a precise analysis and subsequent promotion of children's algebraic thinking. Section three offers an exemplary insight into previous studies (Akinwunmi & Steinweg, 2022; 2024) to illustrate how the understanding of structures can be promoted and highlights the role of representations in surpassing the focus on patterns. Finally, consequences for a perspective on the relationship between algebraic and arithmetic thinking are drawn from this theoretical framework and the study results.

The nature of algebraic thinking with reference to the discipline of algebra

A theoretically well-founded discussion of the definition of algebraic thinking must be in line with algebra as a mathematical discipline. Radford (2022), for example, expresses his understanding of algebraic thinking by listing elements that are necessarily characterising algebraic thinking. He focuses on semiotic systems and traces the origin of algebraic thinking not to the use of letter variables, but to a specific *deductive way of thinking*, as can already be found in the work of Al-Khwarizmi, the eponym of algebra from the 9th century. When analysing this way of thinking, he can also identify it empirically in primary school children's strategies when solving equations (Radford, 2022). Al-Khwarizmi (translation by Rosen, 1831), who described the solution strategies of different types of equations in continuous text with the help of word variables, is a good indication that symbolism is not necessary for algebraic thinking - even if it simplifies the operational scope enormously from our current point of view. This understanding of algebra is the basis for empirical studies like Steinweg et al. (2018), but also former works of Radford (e.g. Radford, 2010), that show the role of natural language, gestures etc., which take on the role of variables.

A reference to Al-Khwarizmi's algebra is a helpful and important perspective on the nature of algebra. At the same time, algebra as a mathematical discipline has developed continuously since then and has experienced various turning points in history. One such turning point is Galois' theory in the 19th century (Edwards, 1984). Instead of focusing on finding concrete solution strategies for increasingly difficult equations, Galois developed an abstract meta-perspective on the properties of mathematical objects that can be used to determine whether an equation is solvable. On the one hand, it may seem contradictory at first glance to base algebraic thinking at an elementary level on this more advanced and therefore even more abstract *structural algebra*. On the other hand, some of the properties investigated in Galois' theory already appear in the very first encounters of children with mathematics, albeit in an implicit way. For example, when children realize in the first year of school that addition problems can always be solved within natural numbers, but not subtraction problems, they inductively recognize the property of Closure. The power of Galois' theory lies precisely in looking at specific properties and relations across mathematical disciplines at a general level. Commutativity, for example, can be explored in arithmetic, e.g. for multiplication, but also in geometry in symmetry mappings for combining two rotations of a figure, in modular arithmetic for the addition of congruence classes, etc. Therefore, a reference to structural algebra explains why algebraic thinking permeates other mathematical fields as a specific way of thinking.

In this perspective, algebraic thinking involves both deductive and also inductive ways of thinking. Radford argues that “algebraic thinking […] calculates/operates with indeterminate magnitudes *as if they were known*” (Radford, 2022, p. 588). Steinbring (2005) claims that relational thinking means detaching arguments from the concrete numbers and seeing something general in them. Mason and Pimm (1984) call this *seeing the general in the particular*. For primary school, it can therefore be said that children also have to deal with concrete numbers *as if they were general*. Especially when children do not yet know any variables, children can communicate their general ideas through concrete examples and numbers. Steinbring (2005) calls this a necessary balance between *concrete, situated* and *general, relational knowledge*. This creates an approach to algebra in the early grades in which algebraic thinking is considered to be the understanding of structures.

The nature of algebraic thinking with reference to patterns and structures

In literature, algebraic thinking is closely associated with the concepts of patterns and structures. In Germany, the term algebra is not even mentioned in the primary school curriculum, but all processes concerning algebraic thinking appear in the strand “pattern, structures and functional relations” (Steinweg et al., 2018). This section will elaborate on the difference between the terms but also on their important relations. In CERME12, Akinwunmi & Steinweg (2022) showed that this distinction can also be found empirically in children's responses to pattern tasks. For the framework of the study and a more detailed description of the results, see Akinwunmi & Steinweg (2022).

Various studies worldwide describe the core of algebraic thinking as dealing with patterns and generalisations (e.g. Blanton et al., 2019). At the same time, however, patterns are also seen as the heart of all mathematics (Devlin, 1997) and the concept of pattern is intentionally broad. “Mathematics is the classification and study of all possible patterns. […] It is to be understood in a very wide sense, to cover almost any kind of regularity that can be recognized by the mind” (Sawyer, 1955, p. 12).

The sole reference to the recognition and generalisation of patterns can lead to a definition of algebraic thinking that is quite unspecific. In Akinwunmi & Steinweg (2024), we asked fourth-graders to work on tasks with patterns of e.g. the constancy of difference, i.e. subtraction tasks in which the minuend and subtrahend change in the same direction and the difference therefore remains the same. All fourth-graders were able to describe and even generalize the phenomenon. Contrarily, the students could not explain why the results remain the same. They referred to the constancy of difference as a kind of law or rule (“because that’s what we have learned”). Understanding mathematics as a collection of arbitrary patterns must not be the aim of mathematics lessons and lacks algebraic thinking.

This is where the term structure becomes important. Instead of remaining on the surface of the pattern as a perceptible phenomenon, algebraic thinking is characterised as thinking processes to understand the underlying structure of the pattern and to use that structure to justify the emergence of the pattern. “Structural thinking is much more than seeing a pattern, such as ‘when one number increases by three the other goes down by three’” (Mason et al. 2009, p. 23). *Understanding structures* thus forms the core of algebraic thinking and can be defined as the process of recognizing and comprehending mathematical properties and relations.

Kieran (2018) emphasises the desideratum for more precise clarification of the term *structure* because of its importance in algebraic thinking. In their literature review, Venkat et al. (2019, p. 13) note that the term structure is defined very differently and that “we were comforted to find ourselves in good company in terms of our confusions”. It is understandably challenging to define such an important term precisely and, above all, soundly when it is used so differently in the literature. This is where a closer analysis of the development of algebra as a mathematical discipline is helpful, as has been explored in the previous section. With reference to structural algebra and following Mason et al. (2009) and Schifter (2018), Akinwunmi and Steinweg (2024) describe structures as mathematical properties and relations that define mathematics itself as characteristics of abstract objects of thought. Mathematical structures, according to Schifter (2018), refer to characteristics and properties that

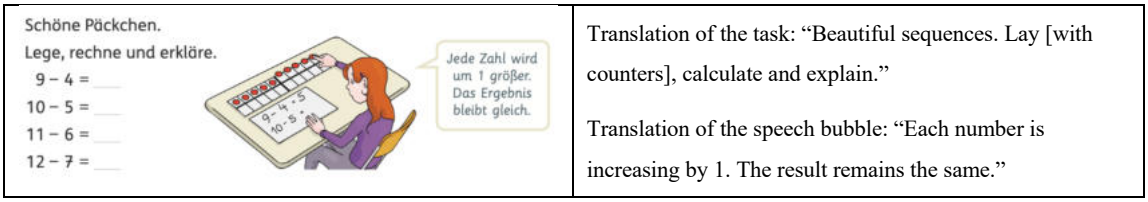
remain constant for all cases. Akinwunmi & Steinweg (2022) list four key ideas of algebraic thinking in arithmetic: understanding structures within *numbers*, *operations*, *equations* and *functions,* each one holding specific mathematical properties and relations to be explored. For example, the central properties of operations in primary school arithmetic are commutativity, associativity, distributivity, neutral elements and inverse operations (which are later extended by inverse elements within rational numbers). This list of central structures (here in the key idea of operations) is manageably short and can therefore be repeatedly addressed throughout the various grades of primary school. Some studies on early algebraic thinking investigate the understanding of such structures, especially in operations (e.g. Pitta-Pantazi et al. (2022) speak of *generalized arithmetic*). The empirical data for various numerical and operational structures have been expanded by Akinwunmi & Steinweg (2024). In summary, brief definitions of patterns and structures can be given:

- Patterns are regularities in visible phenomena.
- Structures are mathematical properties and relations.
- Patterns and structures are inextricably linked: Patterns provide access to structures and structures form the basis of patterns.

Fostering the understanding of structures

In German mathematics education, a fundamental, firmly established didactic principle is the *Operative Principle* (Wittmann, 2021 (original 1987)). According to this, the understanding of mathematical objects includes "to observe which effects properties and relationships are brought about by the operations according to the guiding question "What happens with ..., if ...?"" (Wittmann, 2021, p. 153). At the pattern layer, children can perceive phenomena, for example: the result remains the same if you switch the order of factors in multiplication. To understand, why the pattern occurs and holds for all cases (Schifter, 2018), an *Operative Proof* (Wittmann, 2021) is needed. With appropriate representations, students can e.g. understand that any rectangular array of counters (representing a multiplication) can be rotated by 90 degrees (representing the commutative multiplication) without changing the number of counters. An Operative Proof therefore has an epistemological character and leads to the understanding of structures. Similarly, Blanton et al. (2019) refer to this idea as representation-based proofs (Schifter, 2009), which are useful for *justifying generalizations*.

Akinwunmi and Steinweg (2024) confronted students with visual impulses from German textbooks (for example Figure 1). The students were first asked to re-enact the girl's action and then addressed with the question: Can you use the counters to explain why the result always remains the same?



Translation of the task: "Beautiful sequences. Lay [with counters], calculate and explain."

Translation of the speech bubble: "Each number is increasing by 1. The result remains the same."

Figure 1: Impulse to justify the constancy of difference (Nührenbörger et al., 2017, p. 89, © Klett)

The results of the study show that students use the impulse to move from focusing on number patterns to relating to the operation of subtraction. Nils' explanation is an example:

> Nils: So, if something is added to both, it's one more (*places another tenth counter*), but you also have to subtract one more. So, you can actually take this one straight away (*takes away the tenth counter*).

Some children also generalize, that "if you had more counters, you could always continue like that". With the focus on the general properties of subtraction, i.e. structures, children understand and thus also provide an Operative proof on why the constancy of difference holds for all numbers.

The results of this and further studies (Akinwunmi & Steinweg, 2024) show that suitable representations and impulses from the teacher are sufficient to enable children to reason on the basis of structures. Representations seem to play a crucial role in enabling students to understand structures. Moreover, the studies provide information about possible stimuli (e.g. Figure 1) to encourage children to take a structural view. This does not necessarily imply that every statement made by students can be assigned to the pattern or structure layer. Nevertheless, this distinction has important consequences for the promotion of algebraic thinking. It can promote teachers' awareness of generalisations with a focus on patterns or focus on structures and therefore help to create suitable learning opportunities and make mathematical structures the main focus of classroom communication. The aim of mathematics lessons should always be to go beyond the pattern layer and to understand the underlying structures.

Russell et al. (2011, p. 58) present some impressive successful answers from children to the question "Can you come up with a representation that shows this will always be true, no matter what numbers you start with? Make a picture, draw a model, but don't use any particular numbers". However, one should not underestimate the challenge of selecting a suitable representation. It is precisely the critical point that the children not only represent the numbers from the tasks that are linked with a symbolic sign in between. Instead, they have to find a suitable representation for the embodiment of the operation (e.g. a rectangular array of counters to represent a multiplication). If the children only find patterns in the changing numbers, they cannot think about the property of the operation. Constancy can only be understood as a property of subtraction if subtraction is perceived as an object. The subtraction in this example can be thought of in different ways, such as *taking away* or *determining the difference* (Selter et al., 2012). The impulse presented here uses taking away. A justification based on determining the difference would also be possible but would require different visual impulses (e.g. equidistant intervals on a number line).

Therefore, it is a challenging but essential task of the teacher whilst planning mathematics lessons, to select a suitable representation and to think through possible reasoning and generalising processes, rather than expecting the children to invent it themselves. This makes these challenges an important topic for research in teacher education. The role of the teacher was also recorded as a research desideratum at CERME12 by Hewitt et al. (2022, p. 464), because "the nature of the teacher-student interactions […] can be just as, or even more, significant as the tasks themselves." On the basis of one structure, a variety of patterns can be created for the students to explore. Tasks, suitable representations and impulses can then be developed to lead to the identified structures. It is the

responsibility of mathematics education to identify the essential structures, that are approachable for primary school students.

Consequences for the relation between algebraic and arithmetic thinking

Summarising the discussions at CERME12, Hewitt et al. (2022) raised important questions about the relation of algebraic and arithmetic thinking.

> There was much discussion about the relationship between arithmetic thinking and algebraic thinking. Sometimes these were mentioned as a transition from one to the other. If that were to be the case, then is there a type of continuum between the two or is there an abrupt shift from one to the other? […] Alternatively, are these seem as running in parallel with each other, or are they actually more separate than sometimes imagined? (Hewitt et al., 2022, p. 464).

It is apparent that on the basis of this theory it cannot be a matter of separating algebraic thinking from arithmetic thinking. Arithmetic involves, among other aspects, the conscious and flexible selection of calculation strategies depending on concrete numerical values in order to determine numerical answers to calculations. These strategies only work because of and on the basis of number properties (such as the decomposability of numbers into their place values) or mathematical relations between numbers. Numbers, operations, equations, etc. thus become representative examples that offer patterns for discoveries in order to understand structural properties and relations as universally valid concepts (Akinwunmi & Steinweg, 2024). In this sense, algebraic thinking refers "to think about arithmetic in an algebraic way" (Malara & Navarra, 2003, p. 9). Rather, algebraic thinking can be regarded as a specific way of thinking that contributes to the various areas of mathematics from a meta-perspective and is inextricably interwoven with them - as it is with arithmetic thinking. Algebraic thinking is inherent in other disciplines, just as variables, equations, etc. occur in all fields. Therefore, algebraic thinking should not be considered contrary to, but rather complementary to other fields of mathematics. It is important not to degrade arithmetic, trying to distinguish algebra from arithmetic, as if arithmetic was always just a matter of performing calculations. Algebraic thinking does not replace arithmetic thinking and is not only taught in elementary school as a precursor to algebra in secondary school. Algebraic thinking provides a deeper and richer understanding and is thus at the benefit of arithmetic (Winter, 1982).

This paper is to be understood as *one* possible view in the discourse on the nature of algebraic thinking. It defines algebraic thinking as thinking processes for the understanding of structures based on the term structure as opposed to pattern. Finally, the diversity of possible perspectives on algebraic thinking contributes to a fruitful, lively discourse to enable constant further development.

Mathematics teachers' correspondence and covariation approaches to quadratic functions in relation to their covariational reasoning

Mervenur Belin[1], Gülseren Karagöz Akar[1] and Işıl İşler-Baykal[2]

[1]Boğaziçi University, Faculty of Education, İstanbul, Türkiye; mervenur.belin@bogazici.edu.tr

[2]Middle East Technical University, Ankara, Türkiye

As part of a year-long multi-case study, in this paper, we investigated two high school mathematics teachers' correspondence and covariation approaches to quadratic functions in relation to their covariational reasoning. We conducted clinical interviews about quadratic functions. Analyzing the data from both teachers' reasoning processes using the code list developed throughout the study based on literature and the data, we found that these teachers showed distinct reasoning in relation to their covariational reasoning. Specifically, the teacher reasoning covariationally up to direct coordination and gross quantification, showed the correspondence approach in explanations of quadratic functions. The teacher reasoning covariationally up to direct and systematic coordination and extensive and intensive quantification, used correspondence and covariation approaches to explain quadratic functions. These findings were discussed in terms of teacher knowledge.

Keywords: Mathematics teachers, correspondence and covariation approaches, quadratic functions.

Introduction

Algebra is a broad branch of mathematics from primary school to college that students need to learn conceptually. In high school mathematics, algebra, as studying relationships between quantities, is the most emphasized conception as students learn functions and families of functions. The literature emphasizes two conceptions of functions: static (correspondence) and dynamic (covariation) (Thompson & Carlson, 2017). The static conception of function relies on the set-theoretic structure and correspondence of the elements in the sets with the criteria that every element in the set of domain should match with one and only one element in the set of range. On the other hand, the dynamic conception depends on covariation, focusing on how variables change together, satisfying the specific criteria between domain and range mentioned previously (Lloyd et al., 2010).

Oehrtman et al. (2008) pointed to the correspondence approach's (action view) indicators in someone's mathematical activity. First, a person might consider that functions are related to a rule. This also leads to considering a single value at a time as input or output by doing calculations (Oehrtman et al., 2008). In relation to this, while finding the sets of domain and range, the person might consider specific rules such as for a rational function, the denominator needs to be different from zero, and for a square root function, the inside of the radicand needs to be greater than or equal to zero. Similarly, the person might tend to relate the inverse of a function to the algebraic and geometric properties. This consideration might stem from the idea that the graph provides a geometric figure of a function rather than representing a simultaneous relationship (Moore, 2016). For instance, a person might have the idea that a quadratic function with real coefficients has a U-shaped curve rather than explaining how the values of the function are changing with respect to the input values of the function. Precisely, the person might reason on the effect of parameters on the function's graph

through the change in the shape of the graph, such as 'the graph opens up/opens down depending on the change in the value of the leading coefficient of the quadratic function.

Oehrtman et al. (2008) also explicated the indicators of someone's actions operating from a covariation approach (process view) while working on functions. Specifically, considering the definition of a function, someone might see a function as a process and a dynamic relationship between input and output values. In relation to this, the person considers that process without the necessity of a formula. This further leads to imagining and explaining the process and relationship between input and output values without calculating single values of the function at a time. Since the person does not need to focus on discrete values, s/he can imagine how inputs and outputs change together and continuously. This is important because the person might be aware that "A function is a transformation of entire spaces" and "Domain and range are produced by operating and reflecting on the set of all possible inputs and outputs" (Oehrtman et al., 2008, p. 10). That is, not one element in the domain, but all the elements produce output values depending on the functional relationship. Additionally, the person might consider the inverse of a function as a relationship between input and output where the process is reversed. Therefore, functions are considered to be dynamic entities. Moreover, a person reasoning with the covariation approach might consider that the graph of a function represents the traces of the points, which are multiplicative objects that refer to the dynamic relationship between variables (Thompson & Carlson, 2017).

Regarding the correspondence approach, Thompson and Carlson (2017) importantly commented that "although the correspondence meaning of function solved problems that arose for mathematicians, introducing it in school mathematics made it nearly impossible for school students to see any intellectual need for it" (p. 422). In this regard, the covariation approach might provide students with the intellectual need to learn functions by considering them through real-life situations. Therefore, there is a need to support students' learning of functions through covariation in secondary school. More importantly, the way teachers reason about functions needs to be investigated. In this study, quadratic functions were taken into consideration for several reasons. First of all, it is the first family of nonlinear functions teachers teach to high school students. It is essential to differentiate it from other function families, such as linear functions, based on their behavior by emphasizing having a linear rate of change (Lloyd et al., 2010). Secondly, none of the research studies included information about teachers' consideration of the covariation approach as a prerequisite to understanding quadratic functions. This is reasonable as Thompson and Carlson (2017) pointed out that "most researchers were operating from the perspective of a set-theoretic meaning of function, so they felt little incentive to attend to… covariational reasoning" (p. 445). In this regard, the findings of the study aim to provide a picture of teachers' understanding of quadratic functions in relation to teachers' covariational reasoning by answering the research question: How do teachers with distinct levels of covariational reasoning reason about quadratic functions through correspondence and covariation approaches?

Method

This study is part of an extensive one-year-long multi-case study investigating how two teachers' covariational reasoning processes support their knowledge of mathematics and teaching practices in quadratic functions. The whole research process included intensive interaction with teachers via a

series of interviews (approximately 17 hours in total) and classroom observations (24 class sessions in total). The participants were two mathematics teachers with distinct teaching experience, educational background, and demonstrating distinct levels of covariational reasoning. Specifically, Deniz, a graduate of a mathematics department, has taught secondary school mathematics for twenty-five years in high-ranking public high schools. Miray, a graduate of a teaching mathematics program, has five years of teaching experience at a high-ranking private high school. Regarding their covariational reasoning, Deniz frequently showed the following pattern: use of secondary variables, uncoordinated way of reasoning, and gross quantification. However, Miray frequently showed the following pattern: use of primary variables, direct and systematic coordination, and extensive quantification (see Belin et al. (2023) for details on teachers' covariational reasoning).

In this paper, with reference to their covariational reasoning, we specifically present the findings of a clinical interview that focused on teachers' knowledge of quadratic functions. The interview questions probed into the teachers' conception of quadratic functions, the properties of the graph of quadratic functions, and the relationship between the rate change and quadratic functions. Teachers were both asked about their definitions of the concepts and given specific cases regarding the graphs of quadratic functions to reason about. Their interpretations were intended to reveal their reasoning processes rather than focusing on their answer for students.

Table 1: Codes for correspondence and covariation approaches

Theme	Category	Codes
Correspondence Approach	Explaining functions through correspondence	Imagining a single value at a time as input or output, function as a relation, focusing on set properties of functions (1-1, on to, etc.), function as a mapping between two sets, function as a rule
	Static interpretation of the relationship between variables	Considering a point (x, y) as static, considering f(x) as a name, focusing on the geometric properties of the graph, finding a pattern through tabular values, using algebraic operations
Covariation Approach	Explaining functions through covariation	Focusing on invariant relationship, considering the inverse of a function as a reversal process, emphasis on the rate of change
	Dynamic interpretation of the relationship between variables	Determining the quantities in problem context as variables
		Variation, covariation, quantification

During the analysis, the researchers categorized teachers' explanations as having both approaches or having one of them. The unit of analysis was a single sentence or a paragraph depicting the teacher's reasoning in detail. Researchers coded the data using an initial list of codes stemming from the literature on functions and quadratic functions and a pilot study with two prospective mathematics teachers regarding quadratic functions interview. While coding the data from Deniz's and Miray's interviews, some codes were merged, some codes were moved to other categories, and some codes were deleted during this process. The final list of codes which are shared in Table 1 were formed in three rounds of the data coding process. Especially codes in the covariation approach had also sub-codes. However, due to the limited space, they are not shared in this paper.

Findings

Table 2 explains teachers' frequency of using functional approaches during the interview. Specifically, for all the content, Deniz's explanations through correspondence and static

interpretation of the relationships between variables were the dominant characteristics of the reasoning. Although scarce regarding quadratic functions, he could dynamically interpret a given functional relationship through direct coordination and gross quantification. In contrast, Miray used correspondence and covariation approaches to explain quadratic functions. Also, while interpreting a functional situation considering the properties of quadratic functions and the relationship between the rate of change and quadratic functions, although she used explanations pointing to a static view, such as explaining geometric properties of a graph and use of algebraic expressions, she mostly dynamically explained the relationships by focusing on the amount of changes in the values of independent and dependent variables and making additive simultaneous comparisons.

Table 2: Teachers approaches for reasoning on quadratic functions

Theme	Category	Explanation of quadratic functions		Properties of the graph of a quadratic function		Relationship between a quadratic function and its rate of change		Total	
		D	M	D	M	D	M	D	M
Correspondence Approach	Explaining functions through correspondence	5	1	0	2	1	0	6	3
	Static interpretation of the relationship between variables	8	7	9	10	0	2	17	19
Covariation Approach	Explaining functions through covariation	0	7	0	0	0	2	0	9
	Dynamic interpretation of the relationship between variables	3	8	0	12	0	21	3	41

The following subsections elaborate on teachers' explanations of quadratic functions, properties of quadratic functions, and interpretations of the relationship between variables, emphasizing the rate of change.

Explanation of quadratic functions

Deniz defined quadratic functions as $f(x) = ax^2 + bx + c$ where a is non-zero and expressed that the graph of a quadratic function is called a parabola. For the content, related to quadratic functions in the mathematics curriculum, he first mentioned quadratic equations and algebraic operations such as factorization since they were necessary to find the zeros of the quadratic function for drawing the graph. Similar to Deniz, Miray gave an algebraic definition of quadratic functions as "the polynomial function… $y = ax^2 + bx + c$ where a is a nonzero real number, b, and c are real numbers because we want the highest degree to be two. x and y represent independent and dependent, respectively." Notably, she thought of correspondence and covariation approaches together in the continuum of her reasoning. Different from Deniz, even though Miray defined quadratic functions emphasizing their algebraic form, she kept in mind how they differ from other functions considering the simultaneous change between independent and dependent variables. She stated:

> Miray: I would say the function is a relationship between two variables, variation and covariation. Since variation is to look at how x value changes, how y value changes so to compare change in x or for every same amount of unit change in x, the corresponding amount of change in the y value will be analyzed... How $ax^2 + bx +$

> c looks in general, what kind of relationship it is, in which situations we use it to represent the relationship between variables, what is the difference between linear functions, what is the rate of change, why we actually think of the function in daily life. When we use it to describe the relationship between two variables, they should be able to distinguish and recognize it. We need to discuss how having two (degrees) affects this rate of change, that is, how degree affects the rate of change so that when I make it three (degrees), s/he will understand what it is.

As the data indicated, Miray expressed that she thought of function as the relationship between variables and emphasized reasoning to analyze the change in y values with respect to the equal changes in x values. This refers to her consideration of the direct and systematic coordination of two variables, which might also be supportive of the additive comparison of changes between variables, leading to extensive quantification of changes in the values of variables. It is also essential that she also included the rate of change as a necessary component for quadratic functions. Miray was aware that seeing that the algebraic expressions differ in terms of the degrees of the function is not enough to interpret the function behavior. For Miray, to understand how the change in the degree of the function affects the function's graph, consideration of the rate of change is essential.

Properties of the graph of a quadratic function

When teachers were asked about the effect of parameters $a, b,$ and c on the graph of a quadratic function $f(x) = ax^2 + bx + c$, teachers' reasoning differed. Specifically, Deniz considered figurative aspects of drawing graphs as he explained geometric properties such as directions and shapes (being narrower or wider). For instance, Deniz thought of the leading coefficient 'a' by saying "Now, for example, a determines the openness and closedness, how open and how closed…If a is bigger than 0, the arms are upward. If a is less than 0, the arms are downward." Similarly, regarding the effect of 'b,' he considered that b determines the place of the vertex together with the values of a. He exemplified that when both a and b are positive values, the value of r, which is $-b/2a$, is placed on the negative side of the x-axis. Therefore, he inferred that the b value changes the place of the parabola to the right and left. Similar to 'b,' for the effect of c, he considered that the graph moves up or down when c is bigger or smaller respectively. His explanations pointed to the fact that he considered the behavior as a rule without explaining its reason. It could be deduced that the only focus was on the appearance of the graph instead of the relationship between x and y. Therefore, it is related to static shape thinking referring to the figurative aspect of a graph.

Miray, on the other hand, first considered the vertex form of the function as $a(x-h)^2 + k$ and by taking the square of the expression she wrote $a(x^2 - 2hx + h^2) + k = ax^2 - 2hax + ah^2 + k$. Then, she matched the coefficients in the standard form with those in the vertex form as $b = -2ah$ and $c = ah^2 + k$. It is important to mention that Miray's writing for the correspondence between coefficients in the standard form and the vertex form is valuable since it shows that she can use both forms simultaneously by relating them to each other. Specifically, she can deduce that $h = -b/2a$ and $k = c - a(-b/2a)^2$. Using both algebraic expressions helped her comment on what happens to the graph of a quadratic function when b is changed since examining the change in parameters a and c is more straightforward than examining the behavior of the function by changing the coefficients b. In contrast, while explaining the effect of changing 'a' on the graph of a quadratic function she focused on the amounts of changes in y values for the same x values. In particular, Miray focused on

the geometric aspects of the graph and the reasons behind them by stating the rate of change characteristics in relation to the change in 'a.'

Miray: Now when I change a, the function... if I think of it as y equals x squared, when a is greater than 1, well, for the same x values, because I'm multiplying the y values by a positive number greater than 1, it's like the y points are actually coming up higher. There is a vertical stretch in the graph. On the one hand, the rate of change also increases. So, the rate of change of x's is increasing. It starts to change faster, x's and y's change together. If a is between 0 and 1, then I decrease the rate of change with the same logic. I decrease the rate of change, and it starts to increase more slowly. While x's change, y's change more slowly.

As the data indicated, Miray had the following knowledge: When the leading coefficient 'a' in $f(x) = ax^2 + bx + c$ changes between 0 and 1 magnitude-wise, the changes in y values with respect to the successive changes (such as unit changes) in x values lead to the conclusion that the changes in y values slowly increase. Therefore, values of the average rate of change get smaller values. Also, when the leading coefficient 'a' in $f(x) = ax^2 + bx + c$ gets values more than 1 magnitude-wise, the changes in y values with respect to the successive changes (such as unit changes) in x values leads to the conclusion that the changes in y values rapidly increase. Therefore, values of the average rate of change get higher values. For reasoning about 'c', Miray considered $y = x^2$ as the parent function, took a point $(1, 1)$ on the parabola, and specified the zero of the function. Then, she took the c value as positive. She concluded that the parabola shifts c units upward, and the new point on the graph is $(1, 1 + c)$, and also $(0, 0)$ becomes $(0, c)$ in the new function. Similarly, she considered c as negative by saying that the graph is shifted downward by c units. Then, she compared the distance between the points in the parent function and the corresponding points in the new function. She concluded that all the y values increased with the same unit as c. For this reason, she considered that the changes were the same. With her explanations, she supported her idea that the rate of change of the function does not change when the parabola shifts upwards and downwards.

Relationship between a quadratic function and its rate of change

Two cases 'The change of rate of change is positive and the function has two zeros' and 'The change of rate of change is negative and the function has no zeros' were given to teachers for their interpretation and drawing for the general structures of the graphs. Deniz stated that there was no special relationship between the rate of change and quadratic functions. However, by using the formula $f(b) - f(a)/b - a$ to find the rate of change, Deniz explained that one could conclude that the value was the slope of the line for a linear function and slope at a point for a second-degree function as follows:

Deniz: Well, I think there is no special relationship, but the formula can be done by using $f(b) - f(a)/b - a$, but the relationship with the coefficient... well, for example, if it is 1st order, for example, when it is a 1st order function, the rate of change is equal to the slope. If the slope is positive, the function is an increasing function. If the slope is negative, the function is a decreasing function. Now when we consider the slope at that point, for example, 2nd order functions, if the slope at that point is positive, it is increasing in that range. If it is negative, it is decreasing in that range.

For both conditions, Miray's overall reasoning indicated that she had the knowledge that 'the change in the rate of change is positive when the leading coefficient of a quadratic function is positive' and

'the change in the rate of change is negative when the leading coefficient of a quadratic function is negative'. To illustrate, for the condition that the change in the rate of change is negative and there are no real roots, Miray directly stated that the leading coefficient is negative by referring to her reasoning on the effect of the parameter 'a' on the graph. Then she drew a graph (see Figure 1) for the given condition. She explained the algebraic properties as follows: a and c are less than zero, and the discriminant is less than zero.

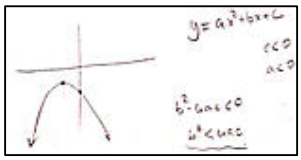

Figure 1: Miray's written work

Furthermore, she interpreted by tracing the graph after reaching the maximum point that as x increases, the y values decrease. She further commented on her explanation for the simultaneous change in x and y values after the maximum point was reached by coordinating the additive changes in x and y as follows:

R: So, uh, can you explain how did you decide?

Miray: ... If I think about the point where it is symmetric, that is if I think about the x coordinate of the vertex, when I increase the x values, that is, the differences between the y values will already open magnitude-wise in the intervals where I increase the x values one by one... In both conditions, let the x's increase one by one, and the y's change for the first example 1 3 5 7. Here, something like -1 -3 -5 -7 is related to the increase and decrease. In other words, nothing about it being quadratic does not change; only that it is looking down, that is, its arms are looking down or up. I highlight that it affects it.

As the data showed, Miray focused on one unit changes in x values to coordinate the changes in y values. She showed an additive simultaneous comparison of changes in x and y values for both conditions. It is important that she compared and contrasted concave up and concave down graphs considering the sign of change in y values as x values change in one unit.

Conclusion and discussion

The study's overall finding revealed that differences in teachers' covariational reasoning predicted their explanations for functions and quadratic functions as they differed in their attention to the correspondence and the covariation approaches in reasoning processes. Specifically, Miray's reasoning covariationally up to direct and systematics coordination and extensive and intensive quantification depicted in her explanations of both correspondence and covariation approaches. Furthermore, she pointed to the covariation approach while explaining her understanding of the quadratic functions. This might provide insight into her primary inclusion of the covariation approach along with the correspondence approach in her explanations (Ayalon et al., 2017). It can be argued that Miray considered the covariation approach as complementary to understanding correspondence approach. Specifically, while explaining the properties of the quadratic function graph, such as openness, symmetric nature, maximum/minimum points, and their relation to the rate of change, she used the changes in the values of dependent variables with respect to the changes in the values of

independent variables. Her explanations also supported her focus on the geometric properties of the graphs. On the other hand, Deniz's reasoning covariationally up to direct coordination and gross quantification is depicted in his explanations as only the corresponding approach. For quadratic functions, while explaining the properties of the graphs, he mainly focused on the geometric properties of the graph, which represented rules for him. This is reasonable as the dominant approach in teaching functions and textbooks is the correspondence approach (Ayalon et al., 2017). From both teachers' data, it might be inferred that covariational reasoning is essential to teacher knowledge (Tallman & Frank, 2020; Thompson & Carlson, 2017). Moreover, Miray's explanations pointed to her flexible reasoning with different forms and representations of quadratic functions, her making sense of quadratic functions linking with rate of change ideas, and the depth of her justifications behind her explanations indicating operational rather than figurative thought (Moore, 2016).

A 6th grade teacher's and students' togethering in the algebra classroom: A process of overcoming emerging dialectical contradictions

Jorunn Reinhardtsen[1] and Martin Carlsen[2]

[1,2] University of Agder, Faculty of Engineering and Science, Kristiansand, Norway;
jorunn.reinhardtsen@uia.no; martin.carlsen@uia.no

The aim of this paper is to shed light on the sociocultural process of togethering as a teacher and students in the middle-school classroom attune to each other as they generalize patterns. We address this issue through analyses of data from a Californian 6th grade algebra classroom. Learning algebra is multifaceted because the students are expected to shift their reasoning with respect to both form and function, i.e. from arithmetic to algebra syntax (form) and from calculational to analytical (function). It is crucial to the development of algebraic thinking that students shift from inductive work with numbers and manipulatives to the formulation of deductive arguments. In this paper we discuss how togethering manifests itself as dialectic contradictions in this shift, in terms of how emotions and meaning making permeate the space of joint action in the classroom.

Keywords: Algebraic reasoning, dialectic contradictions, introductory algebra, space of joint action, togethering.

Introduction

Algebra thinking is advocated as a central goal for mathematics teaching and learning as a way for students to learn the algebraic symbolism meaningfully and as a way of bridging different topics in the mathematics curriculum (Kaput, 1998; Kieran, 2018; Mason, 1996; Radford, 2010). Patterning activity, in which students are asked to generalize the growth of figural and numerical sequences, offers students opportunities for developing algebraic thinking (Lannin, 2005; Ellis, 2007). However, research point out challenges in achieving algebraic thinking in the classroom.

Reinhardtsen and Carlsen (2022) showed that the grade 6 students' "previously met calculational perspectives interfere when trying to reason analytically about number patterns and figural patterns" (p. 601). Three characteristics of the students' calculational perspective were discerned: (1) viewing numbers as the main objects of mathematical activity and operations as actions to perform; (2) using problem solving strategies that rely on consecutive series of calculations (not bypassing intermediate calculations); and (3) relying on examples for justification. Analysing the same data, we investigate the opportunities for developing algebraic thinking that arise as participants' perspectives come to the fore when coordinating their efforts solving patterning tasks (involving different mathematical structures such as proportional, linear non-proportional and quadratic).

The reported study stems from an algebra research project called VIDEOMAT (see Säljö & Kilhamn, 2019). Classroom discourse data from patterning activities in Finland, Norway, Sweden and the USA (California) were analyzed. The analyses showed, for instance, that the students, across countries, pursued surprisingly similar approaches to the patterning activities. Furthermore,

the students adopted calculational approaches over analytical ones, irrespective of the fact that the latter had been the object of newly teaching (Reinhardtsen & Givvin, 2019).

We take an activity perspective (Leont'ev, 1978) on the role of interaction in learning. Radford and Roth (2011) argued that interaction is a key component of classroom activity in which participants share and develop their thinking. Students learn by being exposed to cultural forms of thinking as they engage in the activity in which it is actualized through the participants' interactions. The teacher has a central role in bringing algebraic thinking to the fore as the students, left to their own devices, will mainly resort to previously encountered forms of thinking. Radford and Roth explained that for objectification to occur a deep exposure to "dialectic contradictions in the activity is required - one exposing in more detail participants' different perspectives" (p. 237).

Contradictions are neither problems nor conflicts that might be rapidly solved. Rather, they are manifestations of systemic tensions that emerge and are inherent to the situation in question, for instance emerging tensions in teaching-learning situations in mathematics manifested as contradictions between individual and collective perspectives and contradictions between the teacher's guidance and the student's agency. As such, a dialectical contradiction is understood dynamically as a unit of opposites.

Therefore, to investigate the learning potentiality in inviting and making student ideas central in classroom discussions of patterning tasks, we have formulated the following research question: *In what ways do the dialectical contradictions that emerge during Grade 6 students' engagement with a patterning activity facilitate the development of algebraic thinking?*

A sociocultural approach to the study of classroom interactions

We adopt a sociocultural approach to the students' learning of algebraic thinking. Thus, we view learning as a process of appropriating cultural tools, such as algebraic symbols and concepts, collectively nurtured and unfolding through the use of mediating artefacts (Vygotsky, 1986). Radford and Roth (2011), on a sociocultural ground, analyzed the interaction of the teacher and the students in the algebra classroom through two lenses, space of joint action and togethering. According to them, the space of joint action is "a space of relations and embodied reciprocated tunings in the concrete space of interaction" (p. 231). Radford and Roth's lenses are rooted in their theoretical position of the inseparability of individual consciousness and the consciousness of others. An inseparability mediated by language and other sensuous multimodal means of interaction. (Algebraic) thinking is thus viewed as a collective phenomenon.

The space of joint action conceptualizes the inseparability of consciousness, which embeds intercorporeal coordination through artefact- and sign-mediated actions (Radford & Roth, 2011). Students participating in a joint, goal-directed activity (such as developing algebraic thinking) think and act together, contributing to and building on each other's ideas through "tuning of speech, gestures, gaze, and actions" (Radford & Roth, 2011, p. 235). The space of joint action is thus a space in which intersubjectivity and collective thinking among the actors are accomplished.

The complex process of coordination involved in establishing a space of joint action, does not guarantee that students attain the object of the (algebraic) activity. The (mathematics) teacher's

involvement certainly plays a role. Radford and Roth (2011) addressed the involvement of the teacher through the concept of togethering. Togethering addresses ethical issues involved as students and their teacher tune to each other overcoming cognitive and emotional differences. The teacher and the students work inherently together to attain the object of the activity. However, the object appears differently to the teacher compared with the students due to their differing asymmetric positions in the classroom. The teacher approaches the mathematical topic as an expert, while the students solely rely on previous mathematical experience. Learning is therefore seen as the grasping and overcoming of such differing perspectives (Radford & Roth, 2011).

Teaching and learning are from a sociocultural perspective seen as two sides of the same coin. These are not separate, but rather a double-sided, irreducible process. The students and the teacher do shared work in the space of joint action. However, due to their differing positions, it is the students who have to appropriate the culturally bound mathematical meanings. Nevertheless, the teacher has to attend to the students' contributions. In our study, thinking about patterns from an algebraic perspective exemplifies a historical and cultural form of thinking.

For learning to happen, the inevitably inherent dialectic contradictions in the teaching/learning activity have to be exposed, through togethering. As such, togethering becomes "the committed engagement in joint activity with a common ideal/material object" (Radford & Roth, 2011, p. 242), indeed an ethical commitment by all participants to make the object a common object. These dialectical contradictions, opposing tendencies, materialize as different perspectives, calculational versus analytical, counting versus multiplicative structure, words versus signs, etc.

We include affect as intrinsic to cognition and learning, and view emotions as originating in activity. Roth and Radford (2011) argued that "Changes in activity are reflected in changed affective tonalities of the situation as a whole" (p. 21). In its movement the activity shapes the emotions, needs and feelings and the expectations of success culminating in individuals' motivation to act. Roth and Radford emphasized that students' emotions are rooted in the affective tonalities of the situation. Thus, emotions are fundamental as a first step for learning to occur. In analyzing classroom interactions in terms of algebraic learning opportunities using dialectic contradictions, we see these as consisting of affective moments as well as cognitive ones.

Methods

The data presented below come from an international study involving participants from four countries. Data were collected by local research teams and from four introductory algebra classrooms (self-reported by the teacher) in each country and included video-recordings from four consecutive lessons in each classroom. The teachers were asked to teach as they had planned without interference from the researchers. We present data from one Californian classroom in which an experienced teacher, who has a good report with her students, and 30 students worked on eight patterning tasks during the four lessons.

The first four tasks were numerical sequences, the sixth task included a numerical sequence presented in a function table, while the other tasks presented figural sequences. The first task had a proportional structure, tasks 2-4 and 6-8 had a linear, non-proportional structure, while the fifth task had a quadratic structure. In the lessons analyzed the teacher pursued an approach to patterns that

can be seen to involve three main phases of activity: (1) classroom exploration of a pattern; (2) making a function table and developing an explicit generalization based on systematic exploration of the relationship between two sets of numbers; and (3) extending the generalization to all subsequent terms and expressing the explicit generalization using alphanumerical signs.

The four lessons were transcribed, and salient episodes identified. The salient episodes analyzed involve situations in which participants' different perspectives are made evident in the classroom discussion, sometimes leading to tensions and abruption in the flow of interactions, and sometimes passed by as if unnoticed by the participants. We found that the affective tonalities of the situations needed to be considered. We take the same approach to analyze affective tonalities in classroom interactions as we take to analyzing the meaning making of participants. That is, taking an insider perspective to interpret subjective intent and collective meaning making relying on ourselves as fellow human beings and participants in human discourses, and taking an outsider perspective (professional) when determining learning opportunities in algebra. In particular, we study how dialectic contradictions manifest themselves in the shift from inductive work with numbers and manipulatives to the formulation of deductive arguments, a crucial process in the development of algebraic thinking (Ellis, 2007).

Results

There are several dialectic contradictions in the classroom patterning activity that are exposed in the teachers-student interactions: recursive versus explicit generalizations, multiplication in proportional situations versus linear non-proportional situations, functional perspective versus calculational perspective or factorization perspective. In our analysis we found that Ms. Lee's and the students' attunement to each other lead to different exposures of dialectic contradictions: (1) contradiction involving conflicting conclusions, ensuing discussion but not exposing the root causes; (2) contradiction without conflicting conclusions, no ensuing discussion of different perspectives; and (3) contradiction without conflicting conclusions, ensuing discussion that further expose the different perspectives. Due to space constraints, we only present and analyze episodes concerning the first dialectic contradiction in terms of opportunities for algebra learning.

A contradiction involving conflicting conclusions

Leading up to the four algebra lessons recorded, the class had worked with factorization. Presented with the first patterning task (the sequence 4, 8, 12, 16, ...) the students used their knowing of number structure to formulate an explicit generalization as they described the sequence as "multiples of four". The episode analyzed here occurred in the exploration phase of classroom work with the second patterning task (the sequence; 9, 14, 19, 24, …). The affective tonality of the classroom situation appears to change as the activity changes to include a sequence with a non-proportional structure and the students' factoring discourse no longer is sufficient to make meaning of the structure in terms of an explicit generalization.

As the students only presented recursive generalizations in the follow-up discussion, Ms. Lee tried to push them beyond a recursive approach and reminded them that in the previous sequence "they added 4, now they're adding 5." Carlos attuned to the teacher both when comparing the two problems and when attempting to apply a multiplicative approach. He argued: "In this problem, I

saw that you can't multiply anything… Like, uh, like from the beginning it was adding 5, but like, you can't multiply anything to 5 because it's a prime and odd number".

Carlos seems to indicate, using factorization (like the students did in Task 1), that the numbers in the sequence are not multiples of five, neither is it possible to factorize five as it is a prime number and thus multiplication cannot be involved in this number sequence. His argument seemingly is founded on a strong association between multiplication and proportionality. He also points out structural differences between the two sequences, raising the issue of non-proportionality in the latter sequence. Ms. Lee attunes to Carlos in that she confirms that a lot of what he said is correct, but she also voices the possibility of looking at the problem differently:

> I'm not sure if I agree with you. Let's take a look at this information in a different way, and let's see if we, we'll have this conversation in a minute. Okay. I hear what you're saying, you're talking about 5 being prime. You guys agree with that? Yes. 5 is prime, isn't it? And you're saying that because it is prime, and did you say also because it's odd? Then we're not going to be having some sort of multiplying thing going on. Okay, we'll come back to it in a minute and we'll take a look and see if we agree with that. Okay?

Ms. Lee decides to postpone further discussion of Carlos' statements and creates a common point of reference by setting up a function table. To do so, she expresses a possible disagreement with Carlos' conclusion. She reformulates the problem in terms of determining the relationship between two sets of numbers. She takes the lead and shows how two operations are involved and that one of them can be determined from the recursive generalization of the sequence. The strong connection students have formed between proportionality and multiplication is thus only implicitly addressed.

Although the same dialectic contradiction, a factoring perspective versus a functional perspective on a sequence of numbers, also emerged in the solving of the first problem, it was not marked by tension and conflicting ideas as the conclusions formed aligned. In the case of the second task Carlos and Ms. Lee became acutely aware of their very different ways of approaching the problem. Facing a non-proportional structure, Carlos is at a loss for how to involve multiplication as a tool for solving the task, describing 5 as prime and odd only tells him it is not possible. Ms. Lee is committed not only to solving the problem but also to expose the students to a culturally appropriate way of thinking about it. The teacher returns to Carlos' statements in the following lesson, but he is reluctant to participate.

Ms. Lee: Yesterday when we had this pattern, we took the numbers and we put it in our chart, our function table, and we came up with an adding five problem. And we realized that as we did our work, we're going to have to not only, um, use that five like we've been doing by multiplying, but then we had to add on four to get to the first number. So, we had to keep on adding four. You recognize this from yesterday? And so we came up with an expression that looked like that. Yeah? Now I remember Carlos yesterday you had a question. One of the things you had asked about, and I wanted just to come back to it really quickly because we never really answered it. You were saying yesterday you weren't sure that we were going to have any, multiplication happening with five because, you were saying, that five was a prime and five was odd. And so I want you to kind of think back at this, and did we answer your question or do you still have a question about that?

Carlos: Yeah, you answered it.

Ms. Lee: So what do you think? What you now know about this number five and how it works in this problem that maybe you weren't quite sure about here?
Carlos: Um…Um.
Ms. Lee: How is the 5 being used in the math problem here?
Carlos: Um, by multiplying, and I said that you couldn't use multiplication.
Ms. Lee: We are using as multiplication, and can you see why we're doing that?
Carlos: Um-hmm.
Ms. Lee: Can you tell us why?
Carlos: Because, um, I said that, um you can only—the-- for this problem you can only add, but that when you added it didn't work so you had to multiply.
Ms. Lee: Ok, and notice we're adding five over, and over, and over, again. And if I do it over and over and over again it's faster to do it as multiplication. Ok. Okay? It is true that 5 is a prime number? Yes. Is it true that five is an odd number? Yes; but does that mean that we won't use multiplication with five over here? Not necessarily. Okay? So that's-- I kind of just wanted to come back to that, because I know we didn't really address that yesterday.

Although Carlos expresses agreement with the teacher, he is not making an accurate connection between his previous argumentation and the acceptance of multiplication being involved. Carlos seems to have concluded that the factoring discourse, and the issues he raised regarding the nonproportional structure, are irrelevant to patterning activity (indeed, factorization is not mentioned again by anyone in the whole classroom discussions in the following lessons recorded). The affective tonality of the situation is manifested by Carlos' avoidance and compliance rather than curiosity and commitment, in spite of Ms. Lee's eagerness to follow up his previous contribution. Consequently, he does not enter the process of togethering, and meaning making regarding connections between a factoring discourse and the new functional discourse is suspended.

The dialectic contradiction, a factoring discourse versus a functional one, was revealed in the conversation. The participants were made acutely aware of a discrepancy in perspectives because of the conflicting conclusions. However, further commitment was needed to make the differences explicit, a need intuitively understood by Ms. Lee.

Discussion

We set out in this study to come up with answers to the question: In what ways do the dialectical contradictions that emerge during Grade 6 students' engagement with a patterning activity facilitate the development of algebraic thinking? We observed that the dialectic contradiction discussed led to limited opportunities for developing algebraic thinking. Carlos did not enter the process of togethering (Radford & Roth, 2011) and meaning making regarding connections between a factoring discourse (number structure) and the new functional discourse was suspended. Even though Carlos responded to the teacher's questions, he neither addressed nor returned to the nonproportional structure of the number sequence. A reason for this may be, in accordance with Stacey (1989), that students' strong association between multiplication and proportionality (seemingly the root cause for Carlos' and Ms. Lee's differing conclusions) was only implicitly addressed when the activity changed (to involving a non-proportional structure). In an exposure of this dialectic contradiction, there is an opportunity for learning to discern between proportional and non-proportional structures, i.e. thinking algebraically. This could bridge the students' meaning making regarding the two different sequences and a factoring and functional discourse.

The nature of the activity changed from a proportional structure to a non-proportional one, in which the factoring discourse was no longer sufficient. Therefore, the affective tonality of the classroom changed from commitment to avoidance and compliance. Carlos had no more clarity regarding why his initial meaning making led to a wrong conclusion after Ms. Lee's treatment of the problem. Thus, Carlos was not motivated to find out why his previous conclusion did not follow from his true statements regarding the number five. As Radford and Roth (2011) argue, affect is intrinsic to cognition and learning. Thus, the dialectic contradiction without exposing the root causes provided limited opportunities for developing algebraic thinking.

Emotions and meaning making permeate the space of joint action in the classroom, as students and the teacher immerse themselves in a sophisticated evolving coordination of actions (Radford & Roth, 2011). In general, it is in this space of joint action that intersubjectivity and collective thinking are accomplished. However, as we observe in our analysis, the emerging inherent dialectic contradictions cause tensions and violate the students' opportunities to learn, a result that goes beyond the results of Reinhardtsen and Carlsen (2022). The students and the teacher, in their togethering, "engage, respond, and tune to each other" (Radford & Roth, 2011, p. 236). Nevertheless, at least Carlos does not seem to attain the shared object of activity, to discern between proportional and non-proportional structures and thus bridge a factoring discourse held by the students and the functional discourse aimed for by the teacher.

Employing erroneous examples in refutational text to address misconceptions in equations and inequalities

Konstantinos P. Christou[1], Courtney Pollack[2] and Eleni Karagiannidou[1]

[1]Aristotle University of Thessaloniki, Greece; kchristou@nured.auth.gr

[2] Harvard University, USA

This study tested the hypothesis that errors in equations and inequalities may occur due to a tendency to misinterpret the phenomenal sign of the expressions involved (e.g., that $-2x$ can only stand for negative numbers). It also tested if an intervention with incorrect examples presented in a refutation text could help students address their misconceptions better than correct examples. Pre-, Post- and Retention tests were administered to 119 9th grade Greek students. The Experimental Group (N=44) was presented with erroneous examples in refutational text and the Control Group (N=65) with correct ones in non-refutational text. The results showed that students' misinterpretations of the phenomenal sign can influence their errors with equations and inequalities. Although the gains were not maintained over time, both incorrect and correct examples were effective in helping students to address some of their misconceptions.

Keywords: Erroneous examples, phenomenal sign misconception, equations, inequalities.

Introduction

Equations and inequalities are core concepts in algebra, which students often struggle to understand. Many different reasons for these mistakes and difficulties have been suggested in the literature. Inadequate transfer of knowledge acquired in arithmetic to the algebraic context and a deficient understanding of rational and negative numbers as well as the symbolism used in algebra may explain some of students' main misconceptions (Kieran, 1992).

Grasping the meaning and use of literal symbols to stand for numbers is sufficient for students' conceptual understanding of equations and inequalities. However, although variables are introduced in the mathematics curriculum at elementary school (at least in Greece) as letters used to represent any number in a given set, students tend to think of them as natural numbers only (Christou et al., 2022). This tendency may result in the *phenomenal sign misconception* (PSM), which is the tendency to think of the phenomenal sign of a given algebraic expression to be the actual sign of the numbers it may only represent. For example, to think that expressions with positive phenomenal sign, like *5y*, represents exclusively positive arithmetical values, while expressions with negative phenomenal sign, such as *-3x*, represents only negative values. This tendency would be expected to affect students' considerations about the possible solutions, creating specific mistakes, in equations and inequalities that involve algebraic expressions with different phenomenal signs on each side.

Theoretical and empirical background

Natural number bias and phenomenal sign misconception

Understanding the solutions of equations and inequalities are essential skills in mathematics. However, students experience many difficulties when trying to determine their solutions, even when

they know how to solve them using the algorithms (Resnick, 1984). In the process of acquiring conceptual understanding of what an equation and an inequality are and what their solutions actually mean it is essential to understand that there are certain number values which may be substituted for the literal symbols that appear in them that would make the given relation hold. Therefore, students' conceptions about the number values of the literal symbols that are used in algebra to represent the generalized number (i.e., indeterminate number values, one at a time) is regulatory in understanding the solutions of the equations and the inequalities (Christou, 2017).

When introduced to the use of literal symbols to stand for numbers in algebra, students have been usually explicitly told that literal symbols are used to represent any number within a given set, which entails that they may stand for natural as well as rational numbers, positive as well as negative numbers, etc. However, previous studies that focused on the way students understand the specific algebraic symbolism have provided evidence about students' tendency to associate literal symbols only with natural numbers (Christou, 2017; Christou et al., 2022). This tendency has been explained as a byproduct of a more general *natural number bias* (Ni & Zhou, 2005), which is the phenomenon that characterizes students' tendency to use their prior knowledge of numbers, that has been organized around their initial knowledge and experience with natural numbers, in situations where rational number knowledge should be applied. This tendency very often results in specific mistakes and low performance such as in the case of determining the size of rational numbers or performing operations with them (Ni & Zhou, 2005). There is evidence that this bias may also affect students' restricted conception that literal symbols stand only for natural numbers which may also lead them to consider the sign an algebraic expression appears to have as a superficial characteristic of its form (phenomenal sign) to be the sign of the numbers it can only represent, i.e., the *phenomenal sign misconception (PSM)*. Students who would think of literal symbols (e.g., the y in the expression $-4y$) as natural numbers only, they would consequently think that the algebraic expression which contain them would represent only specific kinds of numbers (e.g., negatives in the case of $-4y$) (Christou et al., 2022).

Both the natural number bias and its byproduct, the PSM, may affect students' performance in many different mathematical domains, such as in understanding functions, and may also have certain consequences when trying to reason about the solutions of equations and inequalities (Christou, 2017). For example, students would incorrectly think of *4* as the only possible solution of the quadratic equation $x^2 = 16$, due to a natural number bias that would prohibit them from thinking of x as standing also for the negative number *-4*. Additionally, the solution to $-y = 5$ is *-5*, since $-(-5) = 5$. However, due to a PSM someone could argue that this equation has no solution because a negative number (i.e., $-y$) could never equal a positive (i.e., *5*). In the same line, the PSM could cause students to conclude that the inequality $-y > 5$ is impossible, because, in their head, a *negative* number ($-y$) could not be bigger than a positive one. Thus, students may respond incorrectly because of PSM, especially in cases where expressions with different phenomenal signs appear in the two sides of the relation. A main focus of this study is to investigate such errors in these specific types of equations and inequalities. A second aim is to test the possibility of intervening in a way that might help students to address some of these misconceptions.

Previous studies have shown that such misconceptions are deeply rooted in students' prior knowledge and are therefore difficult to change, especially because students are not aware that they hold these

misconceptions (Christou et al., 2022). Therefore, it is often suggested in the literature that exposing students to their own contradictions that arise from their misconceptions might help them to become aware of their misconceptions and also to address them.

Erroneous Examples in Refutational Text

In recent years, cognitive conflict as a learning strategy has gained renewed interest among researchers exploring instructional methods to address students' misconceptions in mathematics. One approach to creating this conflict is through refutational argumentation, which explicitly identifies and refutes misconceptions while presenting the correct concept (Mason et al., 2019). Refutational texts have been effective in helping students overcome misconceptions and improve performance in both science and mathematics (Lem et al., 2017). A study using refutational texts targeting misconceptions about signs in equations and inequalities showed that cognitive conflict can help students partially overcome these errors (Christou, 2012). The current study builds on this work by adding erroneous examples to refutation texts, focusing on reasoning about solutions to commonly encountered equations and inequalities.

Erroneous examples, which are characterized by intentional errors, are used as learning tools to challenge students and promote deeper understanding (Adams et al., 2014). By studying errors, students can better understand mathematical concepts by analyzing the mistakes of others, an approach that has previously been applied to other mathematical domains such as rational numbers and word problems (Adams et al., 2014; Große & Renkl, 2007). Although there is still some debate about the relative effectiveness of erroneous versus correct examples, studies suggest that erroneous examples can enhance learning, especially when paired with traditional examples (Zhao & Acosta-Tello, 2016). The present study contributes to this discussion by examining erroneous examples in refutational texts to address misconceptions in equation and inequality tasks.

The present study

The purpose of the present study was to investigate whether there are errors that students make when reasoning about the solutions of certain types of equations and inequalities that could be explained by their tendency to misinterpret the phenomenal sign of the expressions that appear in the tasks. Specifically, we hypothesized that a PSM would lead to certain types of errors in reasoning about the solutions of equations and inequalities. In addition, we hypothesized that an instructional intervention with erroneous examples presented in refutational texts would help students address errors in equations and inequalities that reflect a PSM better than correctly solved examples.

Method

Participants

Participants were 119 9^{th} grade students from a public high school in Greece (14-15 years old, 57 girls). The Experimental Group (N=54) and the Control Group (N=65) were from four randomly selected classes. The participants were introduced to equations with literal symbols to represent the unknown from 7^{th} grade, and inequalities from 8^{th} grade. Thus, by 9^{th} grade they had acquired significant experience in both areas.

Materials

There were a pre- and a post-test before and immediately after the intervention, respectively, and a retention test one month later. All three tests had the same structure: nine equations and nine inequalities, with problems that had the same form but used different numbers. Students selected among two alternative given responses whether each equation and inequality had solutions or not, and were also asked to briefly justify their response. Specifically, the question was "Can you find numbers that make the equation/inequality below hold?" There were presented two alternatives: a) Yes, the solutions are…., and b) No there are no solutions because…The questions were posed in this way as a means to direct students to reason about possible solutions of the given equations and the inequalities without necessarily using the typical algorithm for solving them. All tasks were designed to elicit mistakes from students who systematically misinterpreted the phenomenal sign or thought of variables as natural numbers only by presenting algebraic expressions with different phenomenal signs in the two sides of each given relation, or by giving equations which have both positive and negative solutions.

Specifically, the first part of each test included nine equations: a) three with one solution (e.g., $-x = 17$); in these cases it was expected that students with PSM would respond that there is no solution, because a positive could never equal a negative quantity, b) three quadratic equations with two integer solutions (e.g., $y^2 = 25$, with solutions: $y = \pm 5$); in these cases students who showed a natural number bias towards the numbers associated with the literal symbols would erroneously answer by providing only positive numbers as possible solutions, and c) three quadratic equations with no solution (e.g., $-y^2 = 16$; these tasks were used for the alternative response "No there are no solutions because…" to be correct in some cases.

The second part of the test involved nine inequalities with the same structure as the first part presented above. Three inequalities had multiple solutions (e.g., $-y > 7$), and three had no solution (e.g., $3x^2 < -3$). We expected that due to the PSM, students would think that there are no solutions in cases where, for example, a positive-like quantity was smaller than a negative-like one (i.e., in the case of $2 < -y - 2$). The internal consistency of the initial test was acceptable (Cronbach's alpha=0.75).

Teaching intervention

During the intervention, the experimental group read four erroneous examples of a hypothetical student's incorrect response to a solution in inequalities with different phenomenal signs on each side, presented in a refutation text. The incorrect answer would be due to the PSM. The control group read analogous correctly solved examples of inequalities (see Figure 1), which also reminded students that both positive and negative numbers can be associated with literal symbols. It was decided to include only inequalities in the intervention because they are generally more difficult for students (Kieran, 1992). Also, the solution to inequalities can be a range of numbers, which is a useful context for students to better understand literal symbols as a generalised number that can take a variety of

arithmetic values, rather than one or two currently unknown values. This knowledge could be applied to equations, provided that this knowledge is transferred to that domain.

Erroneous example in refutational text	**Correctly solved example in non-refutational text**
Find the possible solutions for: $x + 1 < -x - 1$ A student claimed that the inequality had no solutions because they believed that the positive quantity x + 1 could not be smaller than the negative quantity $-x - 1$. However, this student's answer is incorrect. The variable *x* can have positive values when positive numbers are assigned to it. However, this assumption does not hold true when negative values are assigned to x. For instance, if we consider the value of $x = -5$, then we have: $x + 1 = -5 + 1 = -4$ In this case, $x + 1 = -5 + 1 = -4$ which is indeed smaller than $-x - 1 = -(-5) - 1 = 4$. Thus, $x = -5$ is a possible solution.	**Find the possible solutions for: x + 1 < - x - 1** Keep in mind that the variable *x* can be assigned both positive and negative values. For example: For $x = -2$: $-2 + 1 < -(-2) - 1$ or $-1 < +2 - 1$ or $-1 < 1$, which holds true. Thus, x = -2 is a possible solution. But, if $x = 4$: $4 + 1 < -4 - 1$ or $5 < -5$, which is not true. Thus, $x = 4$ is not a solution.

Figure 1: Examples of the texts used in the intervention *(Text is translated from Greek to English)*

Procedure

The questionnaire was piloted with four 9th grade students from different public schools, which allowed us to finalize the test format and determine the completion time. In the main study, students completed the revised tests in their classrooms in the presence of their math teacher and a researcher. Each test took 20 minutes, which was a reasonable amount of time. The instructional intervention, which took place immediately after the pretest, lasted approximately 15 minutes. During this time, students received individual transcripts (see Figure 1) and reviewed the texts independently. The researcher answered questions and clarified the text as needed.

Data Analysis

Students' responses were scored as incorrect (0), partially correct (1), or correct (2). Answers were rated as partially correct if they provided only one solution for equations with two solutions (e.g., $x^2 + 1 = 5$ has one solution: $x = 2$), or if they gave incomplete justifications for correct answers in equations and inequalities. For example, responses indicating that $x < -x$ has solutions, even without specifying any, were considered more sophisticated than those indicating that there are no solutions or giving no answer, and thus received a higher score. We calculated separate mean scores for the experimental and control groups across equations, inequalities, and each test (see Table 1).

Students' incorrect responses were placed into three main categories: a) PSM mistakes, where students mentioned explicitly the phenomenal sign of the expressions in their justifications (e.g., "*the two terms of the equation have opposite signs and two opposite numbers cannot be equal*);" b) "Trials with integers," where students tested solutions only with natural numbers (e.g., *"the inequality* $2 <$

$-\frac{2}{2x}$ *has no solutions, I tried values such as: 1, 2...*)"; c) "Other," when we could not identify the reason for the mistake.

Results

Categories of incorrect pre-test answers

To address the first hypothesis of the study, we examined the types of incorrect answers the students gave in the pretest as a means to identify the most common causes of students' errors in reasoning about the solution of certain types of equations and inequalities. As shown in Table 1, more than 80% of the incorrect answers in the pretest were PSM errors or trials with integer errors, i.e., errors due to their natural number bias, in both the experimental and control groups, for both the equation and the inequalities. Another interesting finding was that PSM errors decreased between pretest and posttest, while the errors students made by trying only integers increased.

Table 1: Percentages of each category of incorrect responses in the Pre-/Post-/Retention tests

		PSM (%)			Trials with integers (%)			Other (%)		
		Pre-	Post-	Ret-	Pre-	Post-	Ret-	Pre-	Post-	Ret-
Equations	Exp. Group	44.8	34.8	40.8	41.4	47.8	41.4	13.8	17.4	17.8
	Con. Group	50.0	32.5	38.8	31.4	38.6	42.5	18.6	28.9	18.7
Inequalities	Exp. Group	62.3	39.3	45.7	23.2	46.7	24.1	14.5	14.0	30.2
	Con. Group	62.4	32.8	38.4	17.3	57.0	32.3	20.3	10.2	29.3

Effects of the intervention over time

To address the second hypothesis, we calculated mean scores for each test separately for the experimental and control groups (see Table 2). Mixed ANOVA tests were conducted for equations and for inequalities, with mean performance as the dependent variable, group as the between-subjects factor (experimental vs. control group), and test time (pretest, posttest, late posttest) as the within-subjects factors. Analysis revealed a main effect of test time, with students in both groups showing improvement from pretest to posttest on equations, $F(1.84, 196.44) = 15.02$, $p < .001$, $\eta_p^2 = .12$ (Huynh-Feldt corrected for sphericity violation), and inequalities, $F(2, 214) = 34.97$, $p < .001$, $\eta_p^2 = .25$ (see Table 2). The moderate-to-large effect sizes for test time on equations and inequalities (.12 and .25 respectively) indicate a positive trend over time for both groups. There were no significant differences in mean performance between the experimental and control groups for equations, $F(1, 107) = 0.03$, $p = .86$, or inequalities, $F(1, 107) = 0.51$, $p = .48$ across the time points.

We conducted additional paired sample *t*-tests to examine in more depth the effect of the intervention. The *t*-test showed an overall increase in students' mean scores from pre- to post-test in the experimental group on both the equation [($t(43) = 3.109$, $p < .001$] and inequality tasks [$t(43) = 5.560$, $p < .001$]. The same was observed for the control group's mean scores on the equation [$t(64) = 6.894$, $p < .001$] and inequality tasks [$t(64) = 6.351$, $p < .001$]. However, the experimental group did not perform significantly differently in the retention test than in the pre-test on equations [$t(43) = 1.393$,

p = .171] or inequalities [t(43) = 1.499, p = .141], and the control group performed significantly higher in the retention test than in the pre-test only on inequalities [t(64) = 3.281, p = .002] and not on equations [t(64) = 1.658, p = .102].

Table 2: Means (and standard deviations) for each group and task at each phase of the experiment

		Pretest		Posttest		Retention test	
		Mean	S.D.	Mean	S.D.	Mean	S.D.
Equations	Exp. Group	0,74	0,31	0,90	0,33	0,82	0,40
	Con. Group	0,72	0,26	0,92	0,24	0,80	0,36
Inequalities	Exp. Group	0,61	0,28	1,02	0,42	0,71	0,44
	Con. Group	0,58	0,25	0,90	0,32	0,77	0,37

Discussion

The results support the hypothesis that students' reasoning in solving equations and inequalities with different phenomenal signs may be affected by their tendency to misinterpret these signs. This study contributes to the literature by highlighting specific algebraic challenges. In the pretest, students often assumed that expressions such as $-y - 1 = y + 1$ and $-x = 17$ had no solutions, mistakenly believed that expressions with opposite signs could not be equal, and rejected inequalities such as $-y > 7$ based on the misconception that a negative value cannot exceed a positive value. These findings are consistent with previous research showing that students often misinterpret literal symbols as natural numbers and use the phenomenon sign as the actual numerical sign (Christou et al., 2022). In addition, these findings extend previous research by highlighting the consequences of these misconceptions in the specific domain of equations and inequalities.

The results also suggest that presenting erroneous examples in refutational texts helped students address aspects of their phenomenal sign misconceptions in equations and inequalities, consistent with previous studies on erroneous examples (Adams et al., 2014; Große & Renkl, 2007; Zhao & Acosta-Tello, 2016) and refutational reasoning (Mason et al., 2019). However, the experimental group's lower retention test scores suggest that the brief intervention did not significantly alter their underlying misconceptions about arithmetic values in algebraic expressions. This may be because students were not encouraged to self-explain or compare the erroneous examples with correct solutions, as recommended in previous studies (Große & Renkl, 2007). Future research could test the effects of these strategies on addressing these misconceptions. Against our second hypothesis, both erroneous and correct example interventions yielded similar results, consistent with findings that both approaches effectively address misconceptions in equations (Zhao & Acosta-Tello, 2016). This may suggest that reminders through both types of examples can help students overcome the phenomenal sign misconception. The increase in trials with integers from pretest to posttest suggests that after the intervention, students may be more inclined to test with numbers rather than relying solely on the phenomenal sign of the expressions. However, even with this shift, they remain influenced by the natural number bias, which leads them to use only integer trials and not other rational numbers.

Despite their temporary impact, this study provides evidence that using examples of students' errors in reasoning about equations and inequalities- while making students aware of common misconceptions- can partially address these misconceptions and improve task performance. These results contribute to the ongoing debate on the effectiveness of interventions using erroneous examples by providing empirical evidence on their utility, particularly in the domain of equations and inequalities. Students' extensive experience with natural numbers can lead to persistent misconceptions about algebraic expressions, even after exposure to non-natural numbers (Christou et al., 2022). To address these deeper-rooted issues, long-term learning designs are necessary. Incorporating examples that directly target specific misconceptions, such as those used in this study, into textbooks and regular classroom practice could be a promising approach which however, warrant further empirical investigation.

From Inductive to Deductive Reasoning: Investigating Grade 6 Students' Algebraic Thinking Abilities

Demetra Pitta-Pantazi, Maria Chimoni and Constantinos Christou

University of Cyprus, Department of Education, Cyprus; pitta-pantazi.demetra@ucy.ac.cy

This study examines algebraic thinking among Grade 6 students transitioning from primary to secondary grades. Two tests were administered: the first assessed algebraic thinking through tasks involving questions that prompted students to use inductive and deductive reasoning, while the second assessed the basic mathematical knowledge expected by the end of Grade 6. The results revealed a significant performance gap, with students performing better on inductive reasoning questions than on deductive reasoning questions. This indicates challenges in advancing from inductive arguments to logical deductions. Additionally, it was found that deductive reasoning significantly predicts performance on the basic mathematical knowledge test, whereas inductive reasoning does not. These findings suggest that deductive reasoning is less developed than inductive reasoning by the end of Grade 6, despite its critical role in students' overall mathematical development.

Keywords: Algebraic thinking, inductive reasoning, deductive reasoning, variables.

Introduction

Over the past 30 years, many researchers supported that early exposure to algebra can help mitigate the well-known challenges students face in secondary grades (Kieran, 2018). Consequently, algebraic thinking may progressively develop across all grade levels and become increasingly complex and sophisticated (Ellis & Özgür, 2024; Kaput, 2008). This idea led to the incorporation of early algebra in various mathematics curricula (Radford, 2018), but also sparked discussions about the nature of algebraic thinking and how to make it accessible to younger students (Kieran, 2022).

Despite the various definitions found in the literature, researchers generally agree that algebraic thinking is multi-dimensional (Kieran, 2022). To comprehensively understand algebraic thinking, different dimensions must be considered, including algebra content, mathematical processes that serve the investigation of related concepts and procedures, and forms of reasoning that support these processes (Chimoni et al., 2018). According to Kaput (2008), there are three basic algebra content strands from K to 12: generalized arithmetic, functional thinking, and modeling languages. The mathematical processes related to algebraic thinking involve conjecturing, generalizing, expressing generalizations, justifying, and proving (Kaput, 2008; Blanton et al., 2019; Mata-Pereira & da Ponte, 2017; Stylianides, 2008). Different forms of reasoning unfold within these processes, with inductive and deductive reasoning influencing students' algebra performance across different grade levels (Chimoni et al., 2023). As Blanton et al. (2019) emphasized, algebraic processes are interwoven with reasoning forms that supports justification and proof. Specifically, students often use inductive reasoning to form conjectures and draw generalizations from observed patterns (Radford, 2006; Rivera & Becker, 2007). As they advance, they increasingly rely on deductive reasoning to derive logical inferences based on established premises (Harel & Weber, 2020), which is essential for constructing justifications and proofs (Martinez & Pedemonte, 2014). Similarly, Radford (2014)

suggested that a distinct characteristic of algebraic thinking is "analyticity," referring to the deductive treatment of quantitative relationships that involve variables.

While all dimensions of algebraic thinking are important, and the need for their development as early as primary school is no longer a contentious issue (Freiman & Fellus, 2021), there remains insufficient empirical evidence to assess the effectiveness of early algebra approaches in fostering all of them (Kieran, 2018). Specifically, the transition from inductive reasoning, where students generalize patterns from specific examples to deductive reasoning, where they apply general principles to solve problems, remains a critical challenge in mathematics education. This study addresses this gap by analyzing quantitative data from 75 students who had just completed Grade 6, having been taught a mathematics curriculum and textbooks that emphasized the development of algebraic thinking since Grade 1. Specifically, the study focuses on the dimension of reasoning forms, aiming to understand whether these students can successfully employ inductive and deductive reasoning to solve algebra tasks and whether these abilities are linked to their basic mathematical knowledge. To achieve this, student responses to questions prompting them to induce generalizations are compared with those requiring them to deduce logical inferences. Additionally, students' basic mathematical knowledge is assessed with the aim to examine its relationship with their abilities in inductive and deductive reasoning. Ultimately, the study aims to provide insights into students' achievements as inductive learners and deductive thinkers just before entering secondary school.

In the following sections, we first explore the theoretical underpinnings of inductive and deductive reasoning, highlighting their meaning and roles in the context of algebra education. Then, we present the study's method and the main results from studying students' responses. Finally, these results are discussed, and pedagogical implications are suggested.

Theoretical Framework

Definitions of inductive and deductive reasoning vary across disciplines, but for educational purposes, they can be framed as follows:

(a) Inductive reasoning involves generalizing rules from specific observations to draw broad conclusions from individual cases (Van Vo & Csapó, 2023).
(b) Deductive reasoning involves deriving new information from a set of premises, where these premises establish a rational basis for drawing true conclusions (Harel & Weber, 2020).

In algebra learning, inductive reasoning is often evident when students recognize patterns and regularities within specific instances, formulate a conjecture about a general rule, verify this conjecture with additional examples, and, if the conjecture holds for multiple examples, establish a broader generalization (Rivera & Becker, 2007). For instance, by investigating the sum of three consecutive numbers, such as $1 + 2 + 3 = 6$, $2 + 3 + 4 = 9$, and $4 + 5 + 6 = 15$, students might conjecture that "the sum of three consecutive numbers is always a multiple of 3." To validate this, however, they need deductive reasoning, rather than additional concrete examples. By expressing a general number as n, and then the general structure of its next two consecutive numbers as $n + 1$ and $n + 2$, students can extract a true conclusion: the sum is $n + (n + 1) + (n + 2)$, which, based on properties of operations, equals $3n + 3$ or $3(n + 1)$ where 3 is a factor. In this sense, students move

beyond initial observations to justify the general structure of the sum and prove that it is always a multiple of 3 (Knuth et al., 2019). This approach involves denotation since the symbol n is used in a meaningful way, utilizing the interpretation of a variable as a general number (Usiskin, 1988). Additionally, this process involves analyticity, since students use the properties of operations (i.e., commutativity and associativity) and operate on unknown quantities in the same way they would if these were known (Radford, 2014)). In this sense, the structure of three consecutive numbers is taken as a known premise, from which new information is logically derived— namely, the expression for their sum—ensuring that the conclusion, that this sum is a multiple of 3, is true.

Both the reliance on specific examples to verify general statements and the use of logical reasoning to derive conclusions from axioms, definitions, and previously established results are considered essential proof schemes when examining the truth of mathematical statements (Harel & Sowder, 1998). However, students often struggle with developing deductive proofs (Martinez & Pedemonte, 2014). This difficulty has been attributed to their preference for using arithmetic-based arguments that are immediately evaluable, often excluding algebraic methods (Healy & Hoyles, 2000).

Aim of the Study and Research Question

The current study aims to investigate students' abilities in inductive and deductive reasoning within algebraic contexts, particularly considering that these students graduated from an elementary school that implemented an early algebra program. As a result, they are expected to be better prepared for a smooth transition to secondary-grade algebra. The specific research questions are:

1. What is the students' performance on algebra tasks that require inductive and deductive reasoning steps?
2. How do students' abilities in inductive and deductive reasoning relate to their basic mathematical knowledge?

Method

The study involved 75 Grade 6 students (mean age 11.5 years). This grade level was considered appropriate as at this stage students are expected to begin engaging with both inductive and deductive reasoning. The students received instruction that followed the national mathematics curriculum and textbooks. According to these documents, algebra is a core component of the mathematics curriculum. The topics covered up to Grade 6 include: the equals sign as a relational symbol, properties of numbers and operations, repeating and growing patterns, the concept of variable (unknown quantity, quantity that varies, a general number), algebraic expressions, and one-step and two-step equations.

The data collection took place during the last month of the academic year. Therefore, it was expected that students had the opportunity to develop the mathematical knowledge that was outlined by the national mathematics curriculum and textbooks. Two paper-and-pencil tests were administered. The first test included five algebra tasks, each consisting of two questions: question (a) prompted students to think inductively, while question (b) prompted students to think deductively. By pairing each inductive question with a corresponding deductive question within the same algebraic context, the test aimed to provide insights into students' transitioning from identifying patterns or generalizations

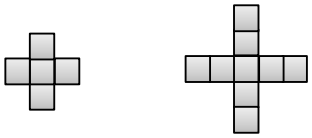
(inductive reasoning) to applying logical rules and principles to reach true conclusions (deductive reasoning). These tasks were adapted from the NRICH website (https://nrich.maths.org), where they are characterized as suitable for students aged 7 to 14 and categorized as medium-level challenges. The algebra test covered all the basic algebra concepts and procedures that students had been taught previously and involved the interpretation of different conceptions of variables: as an unknown quantity, as a quantity that varies, and as a general number (Usiskin, 1988). Figure 1 presents two sample tasks from this test. The first one refers to the sum of three consecutive numbers, described before: question (a) prompted students to observe that the sums of three consecutive numbers are multiples of 3, while question (b) prompted them to validate this conclusion. The second task refers to a figural pattern task: question (a) prompted students to inductively generalize the relationship between the number of the shape and the number of the squares in the shape, while question (b) prompted them to express a general structure that can be used to deduce the number of squares in any shape.

Below the sum of three consecutive numbers is presented.

Consecutive numbers	Sum
2, 3, 4	9
3, 4, 5	12
4, 5, 6	15

(a) Choose three other consecutive numbers and calculate their sum. What do you observe? What is common about these sums?
(b) How can you be sure that your observation is valid for the sum of any three consecutive numbers?

Shape 1 is made of 5 squares.
Shape 2 is made of 9.



Shape 1 Shape 2

(a) Can you predict the number of squares in Shape 5?
(b) Are you sure your prediction is correct? How can you be sure that you can calculate the number of squares for any shape in the pattern?

Figure 1: Examples of tasks included in the algebra test

In the algebra test, question (a) of each task was scored as follows: 0 points for an incorrect answer and 0.5 points for a correct answer, i.e., an answer that demonstrated a correct observation. Question (b) of each task was scored as follows: 0 points for an incorrect answer, 0.25 points for a partially correct answer, and 0.5 points for a fully correct answer. For example, in the task concerning the sum of consecutive numbers, 0.25 points were awarded for a partially correct answer that included a valid argument referring to the structure of three consecutive numbers through verbal explanations, and 0.5 points were awarded for a valid argument that used variables to represent the structure of three consecutive numbers and their sum. The second test assessed students' mastery of basic mathematical concepts and procedures expected by the end of Grade 6, covering numbers and operations, algebra, measurement, and statistics. In this test, 0 points were given for an incorrect answer and 1 point for a correct answer. Figure 2 presents sample tasks: one from the area of numbers and one from the area of algebra.

Which of the following fractions have 24 as a common denominator?
(a) $\frac{1}{20}$ and $\frac{1}{4}$ (b) $\frac{1}{14}$ and $\frac{1}{24}$ (c) $\frac{1}{3}$ and $\frac{1}{8}$ (d) $\frac{2}{3}$ and $\frac{6}{7}$

What is the result of $8.5 - 4.3 - k$, if $k = 3.5$?
(a) 0.7 (b) 1.3 (c) 7.7 (d) 9.3

Figure 2: Example of tasks included in the basic mathematical knowledge test

To analyze the data, we used the SPSS statistical package (SPSS27). Descriptive statistics were used to obtain an overview of students' performance on both tests. We also conducted a paired sample t-test to examine whether students' mean score in the algebra test as an overall is significantly different from their mean score in the basic mathematical knowledge test. To answer the first research question, we employed a paired sample t-test, which allowed the comparison of the mean scores of the students in the two types of questions (inductive and deductive). To answer the second research question, we used regression analysis which allowed the examination of whether students' performance in each type of question predicted their performance the basic mathematical knowledge test.

Results

Table 1 presents students' overall performance on the algebra test and the basic mathematical knowledge test. The results show that students' mean score in the algebra test (M = .35, SD = .18) was lower compared to their mean score in the basic mathematical knowledge (M = .64, SD = .21), while this difference was statistically significant (t = 10.62, p= .00).

Table 1: Students' Overall performance in the algebra test and the basic mathematical knowledge test

	N	*Mean*	*SD*
Overall algebra test	75	.35	.18
Basic mathematical knowledge test	75	.64	.17

Table 2 presents students' mean scores in each set of questions (inductive and deductive). The results show that students' mean score in the inductive questions was higher (M = .55, SD = .26) compared to their mean score in the deductive questions (M = 0.13, SD = 0.10), while this difference was statistically significant (t = 14.77, p= .00). This finding suggests that students had greater difficulties in deductive questions compared to inductive ones.

Table 2: Students' performance in the inductive and deductive questions of the algebra test

	N	*Mean*	*SD*
Inductive questions	75	.55	.29
Deductive questions	75	.13	.10

Table 3 presents the results of the regression analysis, which was conducted to examine whether inductive and/or deductive reasoning abilities in algebra influence students' performance on the basic mathematical knowledge test. This model accounts for 24.7% of the variance in students' basic

mathematical knowledge test performance. The results show that deductive reasoning abilities (β = 0.17, p = 0.02) is a significant predictor of students' performance on the basic mathematical knowledge test. However, inductive reasoning is not a significant predictor (β = 0.37, p = 0.26).

Table 3: Regression analysis results with the forms of reasoning as predictors

Intercept	*B*	*SE*	*β*	*p*
(Constant)	45.39	5.89		<.01
Inductive	.14	.12	.17	.26
Deductive	.84	.35	.37	.02

Discussion

This study provides insights into students' algebraic thinking abilities just before their transition from primary to secondary education, with a focus on inductive and deductive reasoning. A key finding is the significant difference between students' performance on inductive versus deductive questions, highlighting a gap between students' abilities related to these two forms of reasoning. Inductive reasoning, which involves identifying patterns and forming generalizations, seems more accessible to students at this stage. This finding aligns with previous studies indicating that inductive reasoning plays a crucial role in early algebra learning, as it allows students to make conjectures based on observable regularities (Radford, 2008). However, the lower performance on deductive reasoning questions underscores the challenge of progressing from inductive generalizations to logical deductions, revealing that algebraic thinking abilities are only partially developed by the end of Grade 6. One probable interpretation is that deductive reasoning requires a deeper understanding of formal proof structures—abilities that students often struggle to master without targeted instruction (Martinez & Pedemonte, 2014). Another important finding is the lower overall performance of students on the algebra test compared to the basic mathematical knowledge test. This aligns with existing literature suggesting that algebraic thinking is cognitively demanding (Kieran, 2018; Chimoni et al., 2023). A final finding is that deductive reasoning significantly predicts students' basic mathematical knowledge, while inductive reasoning does not. This underscores the crucial role of deductive reasoning for a solid mathematical understadning, including, but not limited to, algebra.

Overall, these findings suggest that there is a significant cognitive shift between inductive and deductive reasoning. Simply incorporating an early algebra approach into the mathematics curriculum and textbooks is not sufficient to ensure the effective development of all dimensions and sub-dimensions of algebraic thinking. Additionally, students' deductive reasoning abilities are crucial predictors of their overall mathematical performance and, therefore, their readiness for more advanced concepts. The weaker predictive power of inductive reasoning indicates that, while essential for early conjecture and pattern recognition, it may not be adequate for successful performance in broader mathematical tasks.

Given the difficulty students experience with deductive reasoning, more emphasis should be placed on developing this ability from the early stages of mathematics instruction (Stylianides & Stylianides, 2008). This could involve integrating more opportunities for students to engage in algebraic processes

that require justification and proof, even in the context of basic mathematical problems (Blanton et al., 2019). By encouraging students to think deductively alongside their inductive exploration, teachers can help them build the logical structures needed for success in advanced algebra and beyond (Martinez et al., 2011). To conclude, this study contributes to the growing body of research advocating for a progressive, well-rounded approach to algebraic thinking in early mathematics education. While inductive reasoning is essential for early algebra, the ability to make deductive inferences is critical for students' overall mathematical development. Future research should continue to explore how these two forms of reasoning interact, especially how students manage to assign meaning to algebraic symbols and use structural properties to deduce conclusions, exhibiting analyticity in their thinking.

The development of a reference epistemological model of upper secondary school algebra in Sweden

Matilda Hällback and Olov Viirman

Uppsala University, Sweden; matilda.hallback@edu.uu.se

Reference epistemological models (REM) are employed as analytical tools in research within the Anthropological Theory of the Didactic. This paper provides a methodological description of how the development of a REM of upper secondary school algebra in Sweden has proceeded, and the result of this development. We conclude that the REM gives an accurate and ample description of what upper secondary school algebra in Sweden consists of. The REM is discussed in the light of the opportunities this kind of analytical tool entails, and how this methodological and theoretical approach answers the purpose of the study.

Keywords: Algebra, REM, praxeology, methodology, analytical tool.

Introduction

Epistemological models are employed within many theoretical approaches and fields of research. Already Foucault (1982) discussed the importance of tracing and mapping a specific knowledge area: "We must question those ready-made syntheses, those groupings that we normally accept before any examination, those links whose validity is recognized from the outset" (Foucault, 1982, p. 24).

In mathematics education research, epistemological models are employed for instance in APOS (action-process-object-schema) theory, where they are called *genetic decompositions*, often based on "results from literature, historical knowledge or the experience of teachers" (Bosch et al., 2017, p. 42; see also Dubinsky, 1991). In the Anthropological Theory of the Didactic (ATD), which this study is built on, these models are denoted *reference epistemological models* (REMs) and are "formulated in terms of a dynamical relationship between praxeologies, describing the researchers' interpretation of mathematics and the relation of this interpretation to specific school content domains." (Bosch et al., 2017, p. 43). REMs are models of the given mathematical domain under study, and therefore serve as references for didactic analyses by providing a more unbiased view of the material.

Several REMs in a wide range of mathematical domains have been elaborated by researchers in the ATD community internationally throughout the years (see for instance Barbé et al., 2005; Bosch, 2015). In many cases, the REM is used as an analytical tool to engage with empirical data. In the Swedish context, there are only a small number of empirical studies using REM as an analytical tool (e.g. Asami-Johansson, 2021; Viirman et al., 2022), none of them focusing on the case of school algebra at upper secondary level, the topic of the doctoral project of the first author. We therefore found it necessary to develop such a REM; to fill the knowledge gap, but also to be able to carry out our proposed study. The focus of this particular paper is on the elaboration of a REM of Swedish (upper secondary) school algebra and is therefore of methodological character.

Education is largely characterised by the cultural and social settings and norms of a country. Developing a REM for the Swedish context also helps us distinguish unique phenomena in the Swedish mathematics education, making comparative investigations across countries possible. By

extension, we want to be able to discuss what kind of algebraic knowledge different student groups are offered and how that may affect the teaching and learning of algebra in schools.

Consequently, the main aim of this paper is to describe the elaboration of this REM of school algebra. Correspondingly, the main aim of the REM is to provide a description of what school algebra in Swedish upper secondary school is, from which to analyse text books for the first two courses at upper secondary level. Since the paper is of methodological character, we only provide one example of how the REM is used as an analytical tool. To fulfil the aim of the paper, a detailed and thorough description of the development procedure is presented, followed by a discussion focusing on this procedure and methodological inquires connected to the theoretical framework.

Different methodological approaches to textbook studies

A number of textbook studies in algebra have been conducted around the globe. Since this study is situated in a Nordic context, we focus on a few significant studies from the Nordic countries and contrast them with our methodological approach. There are many possible ways of approaching textbook analysis, depending on the purpose of the study. As the purpose of our forthcoming analysis is to map and characterise the algebra content in Swedish upper secondary textbooks, to be able to make a sociological analysis of what knowledge different student groups are offered, we needed an epistemological ground that captured all nuances of upper secondary school algebra. Hence, we find the ATD (Bosch, 2015), and specifically the REM, particularly useful in this case. Jakobsson-Åhl (2006), for instance, instead used phenomenography to study algebra in mathematics upper secondary text books. Instead of developing an analytical tool to guide the analysis, Jakobsson-Åhl (2006), used grounded theory to detect phenomena in the text books, and form categories inductively. Another example of a similar approach, is Kongelf (2015), using inductive content analysis. Bråting et al. (2019), instead used Blanton's et al. (2015) big ideas of algebra as a base for their analytical tool. Rather than developing a more technical analytical tool, like our REM, they describe how they interpreted these big ideas in the analysis of the textbooks, and adopted these interpretations when examining their units of analysis.

Mathematics in Swedish upper secondary school

To support understanding of the REM and its context, we here outline the structure of mathematics education at the upper secondary level in Sweden. In the upper secondary school curriculum, there are both HEP (higher educational preparatory) and VET (vocational education and training) programs. As a result of a major curricular reform in 2011, Lgy11 (Swedish National Agency for Education, 2011) mathematics as a subject is divided into five courses (six if you count a specialisation course). For the first two courses there are three alignments, according to study programs; a, b, and c, aimed at vocational (VET), social sciences-oriented (HEP), and natural sciences-oriented (HEP) programmes, respectively. In VET programs, Mathematics 1a is compulsory and 2a is optional. In social sciences-oriented programs (HEP), 1b and 2b are compulsory and 3b is optional (compulsory in the economy program). In the technology program (HEP), 1c, 2c, and 3c are compulsory, and 4 and 5 optional, whereas 1c, 2c, 3c and 4 are compulsory in the natural science program (HEP). Mathematics 1a, 1b, 1c, 2a, 2b, and 2c are under consideration in this study.

The national tests in mathematics in upper secondary school are mandatory only for the highest final course within the student's program. This means that the only mandatory national test in mathematics for students in VET programs is for the course Mathematics 1a, whereas the mandatory test for students in the natural science program (HEP) is for the course Mathematics 4. However, a high proportion of upper secondary schools implement the national test for each course and each year, since they are well designed to test the course's core content. They also have thorough assessment instructions for teachers, since they are graded by the mathematics teachers themselves, and results are then reported to the Swedish National Agency for Education.

Theoretical underpinnings – ATD

The ATD is a "programme of research" (Bosch, 2015, p. 52) engaging with mathematical knowledge, such as (school) algebra, from an institutional perspective. A central assumption of the ATD is that the taught knowledge (see Figure 1), is not invented in the school institution (Bosch & Gascón, 2006). Rather, the scholarly mathematical knowledge needs to be made teachable in order to make sense in the school institution and for the learners. To this end, didactical and mathematical choices need to be made, affecting the body of knowledge (school algebra, in this case) in different ways. This process is called *didactic transposition* (Chevallard & Bosch, 2020).

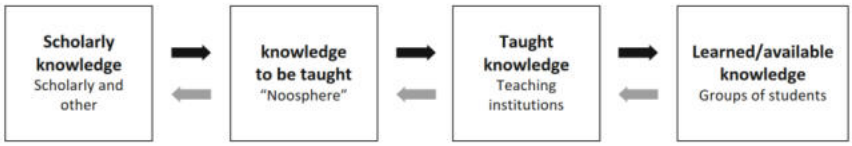

Figure 1: The didactic transposition process (Chevallard & Bosch, 2020, p. 171)

We view the three different course alignments in the curriculum as the result of three different didactic transposition processes, since different objects from the body of knowledge that is (school) algebra are being selected by the "noosphere" – people that have an interest in education (Bosch, 2015) – and put in the curriculum in the different course alignments for the different program types. Using ATD, and specifically didactic transposition, allows us to make differences between the transpositions visible. It also allows us to examine the data material in an unbiased way, since the REM broadly describes upper secondary school algebra in Sweden. The epistemological character of school algebra is epitomised in the REM in a way that makes it easier to detect the specific didactic transpositions in the different programs in Swedish upper secondary school and hence what kind of knowledge different student groups are being offered.

Praxeologies and scale of levels of didactic codetermination

From an ATD perspective, mathematics, like any human activity, can be described in terms of *praxeologies* (Bosch, 2015). The word *praxeology* is built from the Greek words *praxis* and *logos*, praxis being the practical part (k*now-how*) of a mathematical (human) activity and logos being the justifying or knowledge part (*know-why*) (ibid.). The assumption is that one needs both praxis and logos for an activity to hold and make sense. The praxis block is made up of a type of task (T) and one or several techniques (τ) connected to the Ts. The logos block is made up of technologies (θ) supporting and justifying the τs, and a set of overarching theories (Θ) supporting the θs. A praxeology is consequently made up of the quadruple [T, τ, θ, Θ]. This is also called a *point praxeology* (PP) of

an institution. Praxeologies centred on a technology θ are called *local praxeologies* (LP) whereas praxeologies centred on a Theory Θ are called *regional praxeologies* (RP) and can contain several types of tasks, techniques and technologies. Most REMs are formulated in terms of PPs, LPs and RPs, with the aim of giving an overall view of the mathematical domain analysed. By describing the content in terms of praxeologies, we get a REM that describes even how the smallest mathematical elements are linked together. By extension, we get an "aerial photo" of the contemporary discourse of school algebra. The REM in this study is built around PPs and RPs.

As mentioned, there are many factors outside the school institution that influence the teaching and learning, and consequently also the praxeological organisations. To identify what these factors and conditions are, ATD proposes the *scale of levels of didactic codetermination* (Bosch, 2015). In the forthcoming textbook study, we take society, school, pedagogy, discipline, domain, sector, theme and subject levels into consideration when analysing and interpreting the didactical constraints of school algebra, as it is proposed in the REM.

Method – developing the REM

We began the development of the REM by extracting all the algebraic content from the core content for the courses 1a, 1b, 1c, 2a, 2b and 2c in the national curriculum (Swedish National Agency for Education, 2021). The rationale for picking out a specific content area was based on previous studies of what school algebra in Swedish upper secondary school consists of (e.g. Hällback et al., 2022). After extracting the algebraic content from all six courses (1a, 2a, 1b, 2b, 1c and 2c) into a list, a table comparing all of the content was made. Thus, we could detect similarities in content over the three alignments and the two courses. For example, we found content regarding solving equations, but on different levels, in all courses and alignments. This type of content was placed on the same row in said table.

The reason for compiling all three alignments together, rather than developing a different tool for each alignment, was that we needed an analytical tool that captured all aspects of the algebra content, and not just one. Additionally, with one tool for each alignment, detecting nuances of differences between the three alignments in the analysis would not have been possible. This is a serious drawback since the raison d'être of the REM is to be able to make an accurate and close examination of the algebra content in the textbooks.

After compiling all algebraic content, we began formulating type of tasks (T) and corresponding techniques (τ), that corresponded to the core content. After this step, technologies (θ) and theories (Θ) were formulated, so that we had (almost) complete praxeologies. This work was also presented in a table, for the sake of clarity of the analytical tool. At this stage of the development, we noticed that in some cases, detecting techniques (τ) and technologies (θ), and anticipating how the practicing teacher will arrange the teaching, can be difficult. Therefore, we thought of adding national tests from all courses and alignments to the source material. Unfortunately, our analysis of the national tests did not add more details than the core content. We could detect some arithmetical properties, like the distributive law or the commutative properties. However, these were neither mentioned in the task formulations, nor in the assessment instructions for teachers, and therefore we chose to exclude these.

We detected two RPs in the development of the REM; algebra and functions. As a last step in the development procedure, we therefore grouped the PPs in accordance with these RPs.

The REM

The REM was developed in Swedish, since we followed the Swedish syllabi and national tests. As an analytical tool, it will also be used in its Swedish form, as the textbooks that will be analysed also are in Swedish. However, we translated it into English for the sake of academic diffusion. In the illustration of the REM as an analytical tool below, we also translated the analysis into English.

TYPE OF TASKS (T)	POINT PRAXEOLOGY (T)	TECHNIQUE (τ)	TECHNOLOGY (θ)	THEORY (Θ)
T_1: Manipulate algebraic expressions		• Factorisation and multiplication • Managing exponentiation	Arithmetic properties, such as: the difference of two squares, identities of binomial squares, rules for exponentiation, commutative property etc.	RP_1: Algebra
T_2: Express and motivate algebraic relationships	$T_{2.1}$: Formulate general relationships			
	$T_{2.2}$: Motivate the laws of logarithms			
	$T_{2.3}$: Motivate the laws of exponentiations			
	$T_{2.4}$: Motivate the identities of binomial squares and the difference of two squares			
T_3: Solve equations	$T_{3.1}$: Solve linear equations	• Digital methods (to make equation solving more effective) • Graphical and algebraical methods (unspecified)	• Arithmetic properties, such as: the difference of two squares, identities of binomial squares, rules for exponentiation, commutative property etc. • Equivalence, implication and the meaning of the equals sign • The concepts interval and linear inequality	
	$T_{3.2}$: Solve equations with square roots, cube roots etc.			
	$T_{3.3}$: Solve equations with exponentiations			
	$T_{3.4}$: Solve exponential equations			
T_4: Solve inequalities	$T_{4.1}$: Solve linear inequalities			
T_5: Comparisons of different equations	$T_{5.1}$: Comparisons of exponential equations and equations with exponentiations			
T_6: Tasks related to functions	$T_{6.1}$: Create graphs to functions	Digital methods for creating graphs to functions	• The concept of functions (including domain and range) and, representations and properties of functions (in words, function expressions, tables and graphs) • Especially linear, quadratic, exponential and functions with exponentiations o The concept of linear functions (räta linjens ekvation) • Quadratic functions: line of symmetry, extremum and zero of a function	RP_2: Functions
	$T_{6.2}$: Determine linear functions	Graphical and algebraical methods (unspecified)	The concept of linear functions (räta linjens ekvation)	
	$T_{6.3}$: Determine the value of a function	Graphical and algebraical methods (unspecified)	The concept of functions (including domain and range) and, representations and properties of functions (in words, function expressions, tables and graphs)	
	$T_{6.4}$: Comparisons of exponential and linear functions			

Figure 2: The REM, translated into English

In the leftmost column in the REM, we present the types of tasks (T). These Ts are overarching and are our interpretation of the more precise formulations in the syllabi. Next to the overarching type of tasks are the point praxeologies (PP). These are also tasks, but more specific and closer to the actual formulations in the syllabi. Note that T_1 and T_2 are not complete praxeologies. Since T_1 – manipulate algebraic expressions – already is so specific, we could not break it down into PPs. The τ's connected to T_1 are also in line with the formulations in the syllabi, whereas the θ is our interpretation of what mathematically justifies these τs. In T_2, on the other hand, we were not able to detect any τs in the syllabi or the national tests. We decided to leave this space blank, since the θ explains the assumed τs satisfactorily. As visible in the REM, most τs are relatively vague. There were no mentions of specific methods beyond algebraic, graphical and digital, in either the syllabi or the national tests.

In Swedish secondary school, the concept of linear functions is prominent in the teaching and learning of algebra. This concept as a whole is denoted "räta linjens ekvation" ($y=kx+m$ in the slope-intercept form), which would translate to "the equation of the straight line". Consequently, teaching and learning regarding "räta linjens ekvation" not only concerns the straight line, but also gradient, y-

intercept and how analytic geometry is connected to coordinate systems and graphing. This is why we put "räta linjens ekvation" as a θ in our REM.

Illustration of the REM as an analytical tool

In this illustration, we show an example of an exercise from each alignment. Each exercise belongs to the same PP, but we can see how the mathematical content still varies depending on the course alignment. The example shows content from RP_1 (Algebra) and T_1 (Manipulate algebraic expressions). All three exercises are taken from the same book series, Mathematics 5000+ from the publisher Natur & Kultur, belong to similar chapters and have the same level of difficulty.

Table 1: Example of exercises in each alignment, translation done by the first author

Course	Exercise	Interpretation
Mathematics 1a (VET)	2106: A taxi ride costs (75 + 40x), where x is kilometres. a) How much does it cost to go 3.5 km? b) How much more expensive is it to go 2.5 km instead of 1.5 km?	T_1 τ: multiplication θ: arithmetic properties
Mathematics 1b (social science HEP)	1311: Linnea has x kr (Swedish crowns, SEK). Write an expression that describes how much money she has if she a) gets 50 kr, b) gives away 20 kr, c) gets the double amount of what she already has.	T_1 τ: multiplication θ: arithmetic properties
Mathematics 1c (natural science HEP)	1313: A small salmon fry in a fish farming weighs 20 grams and increases its weight by 2.5 g/week. a) Write an expression that describes the fry's weight in grams after x weeks. b) Examine how many weeks it takes for the fry to double its weight.	a) T_1. τ: multiplication. θ: arithmetic properties. b) T_2, and explicitly $T_{2.2}$. τ: Graphical and algebraical methods (unspecified). θ: arithmetic properties and equivalence, meaning of the equals sign.

Note that in 1b and 1c exercises, the student is not only required to manipulate a given expression, but also to construct one. Since this type of task is not explicitly mentioned in the syllabi, it has been introduced by the textbook authors. The 1a textbook, on the other hand, did not contain any such task at this level of difficulty. It appears that the level of mathematical difficulty increases from alignment 1a to 1c. Moreover, the exercise from 1c not only contained T_1, but also $T_{2.2,}$ thus intertwining several praxeologies in the same exercise.

Discussion

In the development process it became obvious that the formulations in the mathematics syllabi are not complete praxeologies, which goes in line with the results of the previous study in this doctoral project, where we found that praxeologies in the VET programs are much more praxis-oriented, compared to praxeologies in the HEP programs which are more evenly distributed between praxis and logos (Hällback et al., 2022).

The core content is generally open for interpretation by teachers and text book authors. However, some paragraphs and some algebraic content are more explicitly written; in the core content covering linear functions, the equation of a straight line is mentioned several times. Content regarding quadratic functions is also relatively explicit; extremum and the zero of a function are for example mentioned explicitly. This suggests that some pieces of content are more important than others, which is not a problem per se, but it raises the question of factors outside the school institution that codetermine the teaching and learning situation. From this study, we cannot say anything about *how* these different levels of codetermination are influencing the school algebra content. We can only suppose that the society, school, pedagogy and discipline levels have influenced the content somehow, making some content appear more prominently. In the forthcoming textbook study, we will be able to discuss these factors more deeply and also to discuss them in the light of the different didactic transposition processes; VET, social sciences HEP and natural sciences HEP.

Jakobsson-Åhl (2006) and Kongelf (2015) demonstrate a more inductive methodological approach to textbook analysis, where the data material gives rise to a number of different categories, whereas Bråting et al. (2019) use a more deductive approach with predetermined categories guiding the analysis. Using a REM as an analytical tool takes the deductive approach even further, since it is a pure composition of mathematical content. On the other hand, although the REM is built around praxeologies, the theoretical framework is less visible in the REM itself, making the analysis less rigidly dependent on the theory. This also shows in the way the data material is approached. Bråting et al. (2019) use their theoretical framework to build categories, thus predetermining which exercises to choose and not to choose. Our analytical tool is instead built on the content in the syllabi, and then formulated in terms of the theoretical framework (praxeologies). Taking this approach, we need to consider every exercise that contains any algebra in any way. If we exclude exercises, we might miss some valuable information about the didactic transposition process (Chevallard & Bosch, 2020). If an exercise displays an incomplete praxeology, that does not correspond to the praxeologies, as expressed through the REM, that result is still valuable in terms of didactic transposition and the levels of didactic codetermination.

To sum up, we do not argue for one right way of conducting a textbook study. The aim and the research questions must, as always, guide the methodological approach. In this case, the ATD and developing a REM proved useful for the kind of inquiries that we had. What the actual textbook analysis will reveal, will be summarised and presented in a forthcoming article.

Acknowledgments

This paper reports on research conducted within the graduate school RelMaS, funded by the Swedish National Research Council. We also acknowledge the contributions made by professor Kajsa Bråting, who was part of developing the REM, but who tragically passed away before this paper was authored.

Assessing students' emerging awareness of algebraic structures

Anna Holmlund[1] and Johanna Pejlare[1]

[1]The University of Gothenburg and Chalmers University of Technology, Sweden;
anna.holmlund@gu.se

To solve linear equations, students need not only to understand algebraic procedures and concepts but also to identify relevant features of the equation and interpret the structure to be able to begin the solving process. This can be challenging if the equation is presented in an unfamiliar format, such as with non-natural numbers or new symbols. In this paper, we explore the features that 16-year-old students in vocational education focus on when sorting equations. The results show that students focus on a diversity of features when grouping equations together. We also discuss the potential of the task to assess students' algebraic structure sense.

Keywords: Algebra, linear equations, algebraic structure sense, sorting task.

Introduction

Students' awareness of structural properties of algebraic expressions, also known as algebraic structure sense, has been identified as an area in need of more research (Rojano, 2022a). This includes both investigating its importance for algebra learning and developing teaching methods that take it into account. This paper explores a sorting task to better understand its potential to reveal what features students consider relevant in linear equations, and its potential as a tool to assess students' awareness of structure.

The term *algebraic structure* is used to denote the internal order in an algebraic expression, referring to the relationship between the parts of the structure, that is either apparent or can be revealed by transformations (Hoch and Dreyfus, 2004). This algebraic structure can be interpreted in different ways, depending on how it is transformed or which parts are focused on; when parsing a linear equation we can either focus on the equality of two expressions $(5x + 3) = (7x + 1)$, or on the grouping of terms $(5x) + (3) = (7x) + (1)$, or on the relation between numbers, variables and operations $(5) \cdot (x) + (3) = (7) \cdot (x) + (1)$ (cf. Rüede, 2013).

When students learn algebra, it is natural that they focus on solving one linear equation at a time. However, as they become more proficient in solving equations, they start to notice general aspects that are central to the solving process. Mason (1996) describes this algebraic awareness as the ability to shift attention – not only to see values and operations but also regard them as expressions and objects. In this process, students need to move their focus from features that might have initially been their primary concern (e.g., the numbers) to the observed generalities, such as the combination of symbols and the relations they represent (English & Sharry, 1996). Hence, as students develop their algebraic thinking, that is the analytical dealing with indeterminate quantities (Radford, 2018), they should also learn to notice features important for the algebraic context. This can be compared to the notion of "saming" described by Sfard (2008) as a central process in learning new mathematical discourses, which involves finding commonalities in what was not previously considered the same.

In line with this, Rüede (2013) found different interpretations of the structure of fractional expressions among 12 novices and 12 experts. Some of the novices looked for visual similarities (syntactical structuring), while others wanted to change the expression (operational structuring). Some saw an initial structure but re-interpreted it (first-order structuring), while all experts considered several structures from the start (second-order structuring).

It is natural that students' awareness of structure is influenced by their previous mathematical knowledge, for example their familiarity with the algebraic sign system and their ability to transform expressions to reveal structure (Rojano, 2022b). Moreover, it has been proposed that students' initial learning of algebra is significantly influenced by surface features they are already familiar with (English and Sharry, 1996). Furthermore, several aspects of equation solving that research has identified as conceptually challenging for students are related to concepts that students already have some understanding of. For example, there is considerable evidence showing that the equal sign is often perceived as something "to do" rather than a symbol for equality (Bush & Karp, 2013). This misunderstanding can make an equation with the equal sign at the beginning (e.g., $480 = 12 \cdot x$) confusing, as the "answer" appears first. Another example, which has been studied extensively (Bush & Karp, 2013), concerns the various ways students interpret letters in algebra (e.g., as labels for objects). Coefficients in linear equations can also serve as a visual feature that guides students toward seeing structure (Rojano & Palmas, 2022), but they also represent an aspect with which students have prior experience, potentially influencing their interpretation of structures (Holmlund, 2024).

This paper is part of a PhD project aiming at developing teaching on structural awareness through a research lesson, in the form of a learning study. The project involves three teachers and one researcher who collaboratively design and evaluate teaching strategies and improve it through three cycles based on variation theory (Marton, 2014). Variation theory explains learning as the discernment of aspects that constitute an object of learning. In this context, *identifying the structures of linear equations* is the object of learning. This is taught by varying other aspects of the equations, such as the coefficients, the letter used for the variable, and the position of the variable, while keeping the operations constant within a specific structure (e.g., $a = b \cdot x + c$, $a = x + c$, or $a = b \cdot x$). One of the tasks used in the pre-test is analysed in this paper. The purpose of the task is to assess how students recognise equations as familiar structures – one of the abilities of structure sense according to the definition of Hoch and Dreyfus (2004) – by asking them to justify their sorting of linear equations. Sorting tasks have previously been used for both teaching and evaluating algebraic understanding. When used for assessment, sorting tasks can observe whether students notice irrelevant or relevant features in equations (English & Sharry, 1996; Rüede, 2009). English and Sharry (1996) used a sorting task to orally assess which features three secondary school students focused on in first- and second-degree equations. They found that, beyond features indicating the degree of the equations, students' attention was drawn to several other aspects: the use of different letters for the unknowns, the presence of one or more unknowns, whether one side contained only a number – particularly linking zero to second-degree equations – denominators with or without variables, and computational aspects, such as the need to group letters. In their study, extra

proficient algebra students identified more features related to the equations' structures compared to less skilled students.

Identifying the features students focus on at an early stage can assist teachers in guiding students towards a more algebraic understanding of equations and helping students to engage with the algebraic context. In this paper, we will discuss the features students attend to in a sorting task and explore the potential of this task as an indicator of students' awareness of structure in the previously mentioned learning study. The research question guiding the study is: What can we learn about students' awareness of structure regarding linear equations from a sorting task?

Method

In this paper we focus on a sorting task in the pre-test of the learning study, answered by students in their first year of upper secondary school in Sweden. 40 students signed a written consent, and the results displayed concern their answers. The students are approximately 16 years old (age was however not controlled in the study). They attend three different schools in two cities and are therefore taught by separate teachers. The students are all in vocational education, focusing on electricity and will likely use linear equations with both decimal and negative numbers as coefficients in their future profession as electricians. They have previously, in lower secondary school, learnt to solve linear equations, but mainly using natural numbers as coefficients. In the present study, the sorting task was adapted to focus specifically on linear equations (see Figure 1). Twelve equations were designed to vary in features that might be relevant for students' attention. Some equations were inspired by equations that had proved useful in probing students' understanding for structure in previous studies, for example $0.12 = 0.4 \cdot x$ and $0.657 = 0.045 \cdot x$ (Holmlund, 2024) and $-24 = 6 \cdot x$ (Vlassis, 2002). Inspiration was also taken from the task by English and Sharry (1996), for example including a zero on one side and varying the letter used for the unknown. Other features were varied among the equations, based on previous research indicating them as central to students in their understanding of linear equations, for example the position of variables on one or both sides of the equal sign (Vlassis, 2002). The task instructed students to "sort the equations you think 'belong together' and resemble each other. Encircle the ones you think belong together and mark the first group as A, the second as B and so on." After sorting, students were asked to justify why they grouped the equations as they did. The response field was divided into four sections, so while students were encouraged to create as many groups as they wanted, the task did not support more than four groups. Also, the task did not encourage students to encircle one equation several times. The free sorting asked for in the task was intended as a tool to learn about the features that students immediately look for in the equations – without there being any wrong answers – and thus not intended to display their understanding of the structures in more depth. However, the open formulation of the task was mentioned as confusing by two students.

A qualitative content analysis was conducted on the output of the sorting task in the pre-test, using students' justifications as the unit of analysis (Graneheim & Lundman, 2004). To identify categories that describe the features students focus on, all answers were carefully reviewed, looking for similarities and differences, and a list of commonalities in students' justifications was compiled. The analysis focused on the meanings conveyed in the students' answers.

Sometimes, a student provided multiple reasons for considering equations as similar, such as noting both the letter used and the operation (e.g., "they have y in the equation and a multiplication sign"). These features were categorised based on shared characteristics. The goal was to identify categories that encompassed all the justifications while remaining mutually exclusive. The first analysis was conducted by the first author. The second author reviewed all student answers and categorizations. A few disagreements were discussed with a third researcher until consensus was reached. The intention was to let the students' perspectives guide the categorization, minimising the influence of the researchers' perspectives.

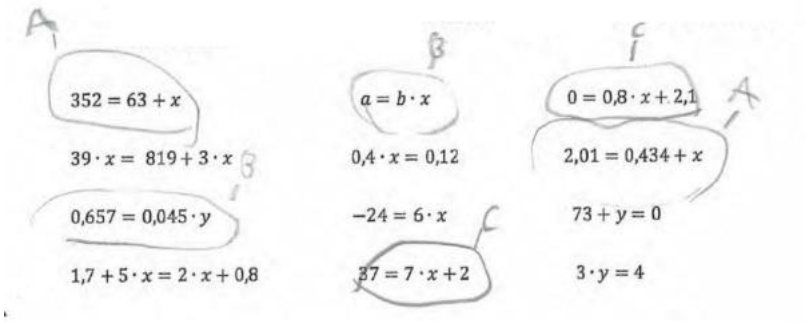

Figure 1: The analysed task with a student's encircled equations

Results

The qualitative content analysis of students' justifications resulted in seven categories, which give an overview of the structural properties of algebraic expressions that the students attend to. The properties, inherent in the equations, are what students notice in their search for characteristics. In parallel with the presentation of each category below, examples from students' answers will illustrate the potential and shortfalls of the sorting task to indicate and describe students' awareness of structure.

Separating different operations

Similarities of operations is a frequent feature that students use to group equations together. Making the type of operations explicit in their justification is distinctive of this category. As an example, one student explains the group of equations as "containing" either addition, multiplication or both addition and multiplication. It is possible to group equations in different ways based on the operations: for example, seeing equations with both addition and multiplication as a third structure or as belonging to the structure of multiplication. Generally, this feature occurs in students' answers with at least the distinction between equations with (only) addition and equations with (only) multiplication. One student explains $a = b \cdot x$ as a formula for multiplicative structure that other equations with multiplication match with.

Separating number of steps

A related feature, that some students mention, is the number of steps required to solve the equation. As an example, one student describes the common feature in group A in Figure 2 as the need for only one calculation on one of the sides to find x or y. In contrast, for group B "two calculations are required on one of the sides if there is no negative number on one of the

sides which can complicate the solution somewhat". Operations are thereby noticed but sorted according to how many they are, rather than by their type (as in the previous category).

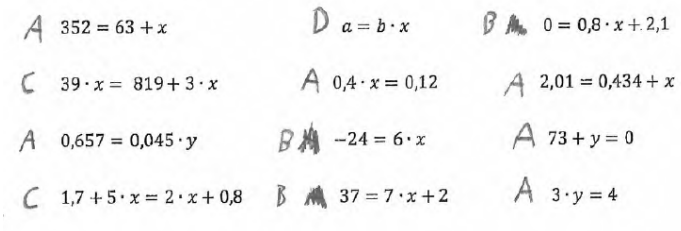

Figure 2: Encircling with justifications based on the number of steps

Variable on one or both sides

A feature considered by some students is whether x is on one or both sides of the equality sign. For example, one student describes one of his groups by stating “There are equations [expressions] on both sides”. Looking at Figure 3, this student explains his choice of group C as “Because you have to calculate on both sides” which also focuses on the variable being on both sides, rather than on the number of calculations (as in the preceding category).

Specific positions

As in the example in Figure 1, several students identify the position of components within the equations as a defining feature. This feature appears in two distinct ways. For some, the position is described, with a focus on either the right or left side of the equation, mentioning whether the side in focus contains only a number, an expression involving a variable, or an expression involving a particular operation. In other cases, students focus not only on one side of the equation but on a specific position within it, such as the final position, sorting equations based on the symbols present at this position (e.g., a number or an unknown). One student places $1.7 + 5 \cdot x = 2 \cdot x + 0.8$ in the same group as $3 \cdot y = 4$ because “they end with numbers”.

Letters

For some students, features concerning the unknown play a central role in sorting the equations. Their justifications involve the specific letter used to denote the unknown, leading them to categorize equations with y separately from those with x. For example, one student groups $0.657 = 0.045 \cdot y$, $73 + y = 0$, and $3 \cdot y = 4$ together, noting “they have y instead of x”. Another aspect of using the letter is to look at the number of unknowns. It is not uncommon for the students to see the equation $a = b \cdot x$ as a category on its own, observing that this equation features multiple letters and “contains only variables”.

Numbers

Some students base their grouping of equations on numerical features. These justifications sometimes involve certain numbers. For instance, some students sort equations that contain only decimal numbers separately from those with whole numbers. One student sorted equations involving negative numbers in one group, explaining that “then you need to calculate and think in a different manner than in the other groups”. Another student identified odd numbers as a common characteristic of one group of equations. Other students focus on more specific

numerical features, such as one noting that "they have very similar digits 3, 5, and 7" or another observing "they are equal to 0". In one instance, the presence of many digits was used as a justification for grouping or excluding equations.

Length of equation

Some students use the length of the equations as a criterion for categorization. Usually, longer equations are those that involve multiple operations, have the variable x on both sides of the equality sign or contain numbers with many digits. For example, one student sorts $0 = 0.8 \cdot x + 2.1$ and $2.01 = 0.434 + x$ together because they are "very long compared to the other [equations]". Another student sorted $352 = 63 + x$ and $3 \cdot y = 4$ in the same group with "short" as the only justification.

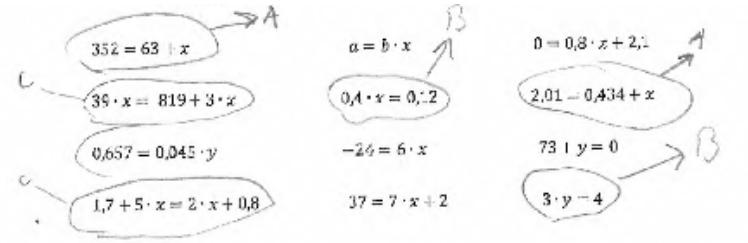

Figure 3: An example where a student focuses on different features

A limitation of the sorting task is occasional weak alignment between students' encircling of equations and the accompanying justifications. For example, some students mention operations as a criterion for the groups but do not encircle all relevant equations, sometimes due to conflict with other features they noticed. This can be seen in Figure 3 where one student justifies groups A and B by mentioning the specific operations without encircling all additive equations for group A, nor all multiplicative equations for group B, as positions of "solutions" and "answers" (which he also mentions) seems to be an important feature to him. On the contrary, the student behind Figure 1 does not mention operations in the justifications but examining the encircling reveals that this is a relevant feature to him. It appears that additional features, such as the positioning of the variable in relation to the equal sign, are significant to this student. Another example is given by a student in Figure 4. He describes group B as "has decimal numbers as an answer and in solution and has one variable" underscoring the importance of numerical features to the student. Group C is characterized as "they look the same, the only difference is that one is integer and the other decimal number". Comparing groups B and C indicates that positioning likely plays a central role in the students' awareness of structure, which is not clear from the justifications.

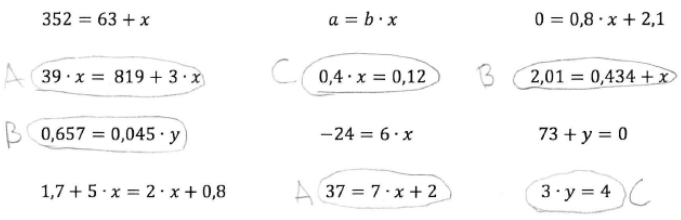

Figure 4: An example where specific numbers guide the sorting

Discussion

To learn more about students' awareness of different features in linear equation, and to be able to use this when assessing how they improve in recognising equations as familiar structures, students in the study were asked to sort a set of equations. When reviewing the seven categories found in students' justifications, we see three features that indicate an emerging focus on algebraic structures. Based on Radford's description of algebraic thinking as analytically handling unknown quantities, it is reasonable to consider the feature of "Variable on one or both sides" as algebraic: as it makes a distinction between equations that requires handling the unknown and those that do not. Focus on the first two features, operations and number of steps, indicates that the students noticed the different parts of the equation. This does not necessarily imply algebraic thinking but could at least show that they are on the way. Focusing on these features can be compared to the operational focus and first-order structuring found in the study by Rüede (2013). However, we interpret the other features mentioned by students (i.e., specific positions, letters, numbers and length of the equation) as not showing algebraic thinking or an emerging awareness of structure. These categories are visually salient, and they are of relevance to students' previous understanding of familiar mathematical concepts. For example, justifications related to specific positions can be partly related to students' view of the equality sign as indicating something to compute, often placing the answer on the right side, without seeing the equality as symmetric. Many of these justifications are similar to those described by English and Sharry (1996). References to the length of the equations generally indicate that the student struggles with these equations, as they rarely solved many equations elsewhere in the pre-test. Students' focus on numbers is supported by earlier research suggesting that numbers are a key feature that students attend to in equation solving (Holmlund, 2024). Thus, regarding saming as a central activity to enter the discourse of algebra (Sfard, 2008), students also need to be guided into what is *not* the same.

To summarize, the analysis of the sorting task has revealed that aligning students' encircling (or lack thereof) with their justifications can be challenging. However, it can display signs of emerging awareness of structure and to effectively use the sorting task to assess students' awareness of structure, it is important to consider both the encircling and the justifications.

Overcoming the *letter-as-object* misconception in 4 weeks? An analysis of latent class transitions and contributing teaching practices

Katrin Klingbeil[1] and Filip Moons[2]

[1]University of Duisburg-Essen, Germany; katrin.klingbeil@uni-due.de

[2]Freudenthal Institute, Utrecht University, The Netherlands

While misconceptions regarding algebraic letters have been researched for decades, they still seem to be very prevalent among students learning algebra. Therefore, this study aims to investigate teaching approaches that support students overcome erroneous thinking patterns related to the letter-as-object misconception. Based on latent classes that had been identified for 2220 German Year 7 and 8 students, students' transitions between latent classes were examined and connected to self-reported teaching practices from three interviewed teachers. The results suggest that explicitly focussing on the meaning of variables in the context of algebraic expressions can help students overcome the letter-as-object misconception.

Keywords: Algebra, variables, letter-as-object misconception, online formative assessment.

Introduction

One of the fundamental concepts in algebra are variables. However, students often struggle to grasp this concept, bringing previous knowledge about letters into the classroom that can hinder learning (Arcavi et al., 2017). In addition, also inadequate teaching can foster misconceptions. One of the well-known misconceptions regarding variables is the *letter-as-object* (LO) misconception which is highly prevalent among students (e.g. Akhtar & Steinle, 2017, Lucariello et al., 2014 (termed 'label for an object' there)). Its high prevalence and its potential impact on further algebra learning raises the question how students can be supported to overcome the LO misconception. To investigate the development of students' thinking patterns regarding the LO misconception, we have conducted a Latent Transition Analysis (LTA) based on the SMART test 'Meaning of letters'. For three classrooms, student development was then linked to reported teaching practices.

Theoretical background

Similar to other researchers, Arcavi, Drijvers and Stacey "distinguish five facets of the concept of variable: a placeholder for a number, an unknown number, a varying quantity, a generalized number, and a parameter" (2017, p. 12). Across these facets, variables stand for or refer to one or more numerical values. Yet, algebra learners often struggle with this numerical interpretation, and various typical errors and misconceptions have been identified. One of them, the *letter-as-object* (LO) misconception, has been described already in 1981 by Küchemann as the letter being "regarded as a shorthand for an object or as an object in its own right" (p. 104). Misleading teaching materials and practices, such as 'fruit-salad-algebra' where, e.g., a is used as 'apples' and b as 'bananas', can reinforce this interpretation of algebraic letters as abbreviations for objects (MacGregor & Stacey, 1997). Several varieties of the broad LO misconception can be identified: Küchemann (1981) found that some students seemed to believe they should incorporate a solution into an initial equation, rather than formulate an equation that describes the situation, thus arriving at an equation similar to $35b +$

$10t = 100$ in the *Bikes* item (Figure 1). Here, the letters are used as abbreviations for the involved objects and the coefficients stand for a possible solution ("35 bikes and trikes have 100 tyres altogether"). Hence, we will refer to this LO-subtype as the *solution-as-coefficient* (SAC) misconception in the following. Another special form of LO is called *letter-as-unit* (LU) when the algebraic letter is interpreted as an abbreviation for a unit (Akhtar & Steinle, 2017), e.g., in the *Ducks* item (Figure 1) d in $6d = 12$ would be misinterpreted as standing for dollars (not realising that this would not be a correct equality).

Sometimes, the LO misconception is explicitly taught through inadequate instruction including in textbooks (MacGregor & Stacey, 1997), and sometimes, it arises naturally when students read an algebraic sentence through the lens of natural spoken language and writing conventions. The LO is a significant misconception especially because it leads students to make mistakes when formulating algebraic equations and hence deprives them of the benefits of being able to use algebra to solve problems. As with other misconceptions, conceptual change is necessary (e.g. Strike & Posner, 1985). However, conceptual change is not easily achieved, but "requires particular instructional strategies, such as raising student metacognition and creating cognitive conflict" (Lucariello et al., 2014, p. 32).

The Current Study

In our current study, we have explored typical patterns regarding the *letter-as-object* misconception among 2,220 German Year 7 and 8 students by means of a Latent Transition Analysis (LTA) (Klingbeil & Moons, submitted). Based on the six-multiple-choice item SMART ('Specific Mathematics Assessments that Reveal Thinking') test 'Meaning of letters', we were able to describe five response patterns in terms of latent classes with their particular item response probabilities. For this study, 103 teachers from six federal states of Germany were asked to administer the online SMART test, first, 1–2 weeks into their regular teaching sequence about variables, algebraic expressions and/or equations, and second, after another 4 weeks of teaching. Teachers were encouraged to use the test results from the first test for their teaching. In total, 2220 Year 7 and 8 students (aged 12–14) completed at least one of the tests (877 in Year 7, 1343 in Year 8); 1219 students completed both pre- and post-test. In the following, we briefly describe the used test items and the identified response patterns.

SMART test 'Meaning of letters'

The SMART online test 'Meaning of letters' was designed to assess the *letter-as-object* (LO) by means of six multiple-choice items (see Figure 1 for items of Version A). Evidence for the validity of this test was presented elsewhere (Klingbeil et al., 2024). The first item type (Meaning items) uses only one algebraic letter and asks students to decide on the meaning of this letter in a linear equation in a given context. While the *Ducks* item uses the initial letter of the involved objects and units, the *Bricks* item uses the letter y. The second type of item (Additive items) uses two algebraic letters (corresponding to the initial letters of involved objects), which are additively connected and restricted by the given situation. Students are supposed to choose the correct linear equation for the described context. In the equation of the *solution-as-coefficient* (SAC) option, coefficients correspond to a possible solution to the problem (that has not been required) so that the equation can be read as a solution sentence. The third item type (Proportional items) comprises two variables that are directly proportional to each other. Students are again asked to choose the equation matching the given situation.

While *Biros* contains concrete objects, *Racetrack* deals with more abstract racetrack rounds and the unit minutes.

Meaning items	Additive items	Proportional items
Ducks	*Garden*	*Biros*
Lucy bought 6 ducks for \$12. She wrote the equation $6d = 12$. What does d in Lucy's equation stand for? d stands for... ☐ the cost of one duck (COR) ☐ one duck (LO) ☐ ducks (LO) ☐ dollars (LU)	Payam bought r red rose bushes and l lilac lavender bushes for his garden. One rose bush costs €4. One lavender bush costs €5. Which equation says that the total cost of the plants was €70? ☐ $4r + 5l = 70$ (COR) ☐ $r + l = 70$ (LO) ☐ $10r + 6l = 70$ (SAC)	Biros are sold in 3-packs. Sam bought p packs and has now b biros altogether. Choose the correct equation: ☐ $3p = b$ (COR) ☐ $p = 3b$ (LO) ☐ $p = 3$ (LO) ☐ $b + p = 4$ (LO) ☐ $30b = 10p$ (SAC)
Bricks	*Bikes*	*Racetrack*
Tina stacked 9 identically sized bricks on top of each other making a 99 mm high tower. She wrote the equation $9y = 99$. What does y in Tina's equation stand for? y stands for... ☐ the height of one brick (COR) ☐ one brick (LO) ☐ the bricks in the tower (LO) ☐ millimetres (LU)	At a bike shop there are b bikes (with 2 tyres each) and t trikes (with 3 tyres each). Which equation says that there is a total of 100 tyres in the shop? ☐ $2b + 3t = 100$ (COR) ☐ $b + t = 100$ (LO) ☐ $35b + 10t = 100$ (SAC)	A car takes 12 minutes for one round of the racetrack. In m minutes a driver drives the round r times. Choose the correct equation: ☐ $12r = m$ (COR) ☐ $12m = r$ (LO) ☐ $r = 12$ (LO) ☐ $5r = 60m$ (SAC)

Figure 1: Items of 'Meaning of letters' test (German A version) translated back into English

Identified Latent Classes regarding the *letter-as-object* (LO) misconception

The five identified latent classes are shown in Figure 2 together with their item-response probabilities for each item as well as prevalence in pre- and post-test. Although the order of the latent classes does not play any role in a LTA, they are presented in ascending order based on the average probability of having items correct.

SAC in additive, LO elsewhere is characterised by very high probabilities for *solution-as-coefficient* (SAC) responses in Additive items and high probabilities for LO responses in all other tasks. This indicates a rather consistent interpretation of letters as abbreviations for involved objects in combination with an interpretation of coefficients as solutions in additive equations.

Mostly SAC is characterised by high probabilities for SAC responses. In the Meaning items that do not offer a SAC option, LO is most likely; a correct response in *Bricks* is possible. Since this is the class with the highest probability for SAC in Proportional items, students in this class seem to be quite convinced that coefficients stand for (possible) solutions also in different equation types.

Mostly LO, possibly correct in additive is characterised by LO responses being most likely in Meaning and Proportional items. Even when the initial letter of the involved object is not used (*Bricks*), LO is much more likely than a correct answer. However, in Additive items, correct responses are about as likely as LO responses.

Correct in meaning is characterised by high probabilities for correct responses in Meaning items, high probabilities for SAC in Additive items, and high probabilities for LO in Proportional items. Students in this class seem to be able to identify the correct meaning of an algebraic letter when

directly being asked for it. However, when choosing equations, they still fall into the trap of interpreting letters as abbreviations.

Mostly correct is characterised by correct responses being most likely in almost all items. Only in *Racetrack*, LO is clearly more likely than the correct response. In *Ducks* and *Biros*, LO is also possible but only about half as likely as the correct response. This indicates at least a partial understanding that algebraic letters do not stand for abbreviations.

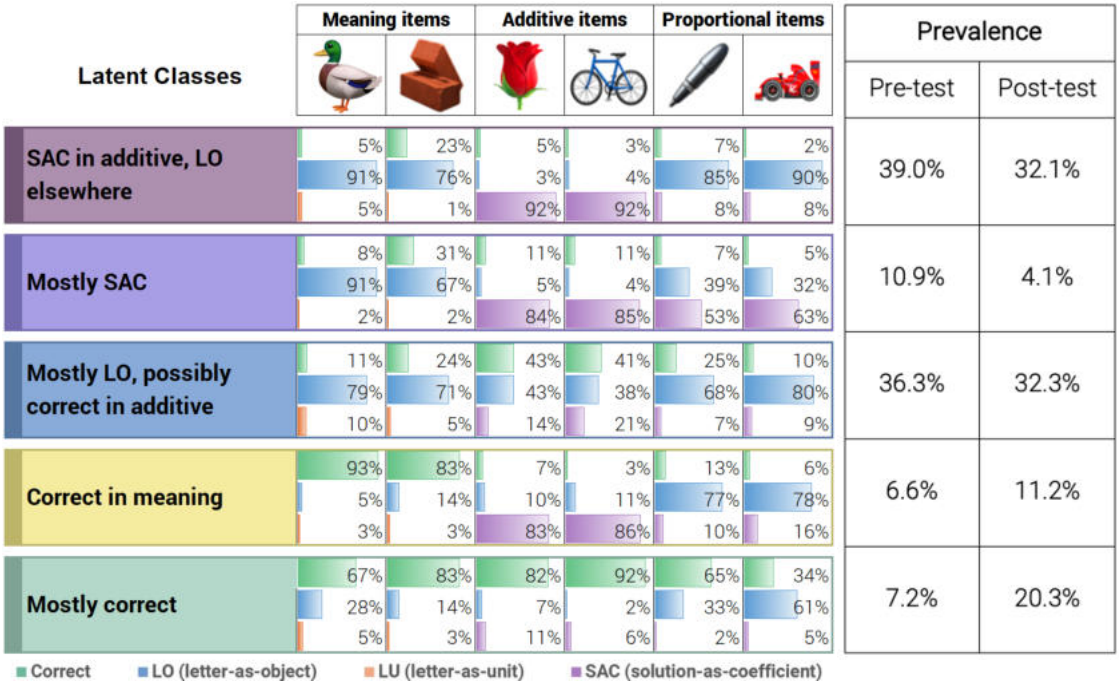

Figure 2: Latent classes with their response probabilities for each item and prevalence

Alarmingly, we found that only 7.2% of students are most likely to belong to the *Mostly correct* class in the pre-test. From there, probabilities for being in *Mostly correct* increased to 20.3% after the 4-weeks teaching period (with 5.8% of students staying in this class and 14.5% transitioning into it). However, 53.6% of all students stayed in one of the other latent classes and 26.1% moved to a latent class other than the best. This observation prompted us to further investigate the question *how (self-reported) teaching during the 4-week period might have influenced different transitions (or stagnations) between latent classes regarding the 'letter-as-object' misconception among students.*

Methods

To answer this question, we were able to draw on information from 9 of our 103 teachers who had volunteered to be interviewed twice. In order to be able to compare the reported teaching and its influence on students' latent classes transitions, we selected a subset of three classrooms from these interviewed teachers who fulfilled the following criteria: same Year level (7), similar distribution of latent classes in pre-test, different distribution of latent classes in post-test. In the following, we are describing the selected classrooms in terms of the students' transitions in more detail.

Figure 3 shows the transitions between latent classes within the three selected Year 7 classrooms in

form of alluvial diagrams. These illustrations of the transitioning between the latent classes at the time of pre- and post-test are based on transition probabilities from the LTA (only including probabilities larger than 3% for better readability).

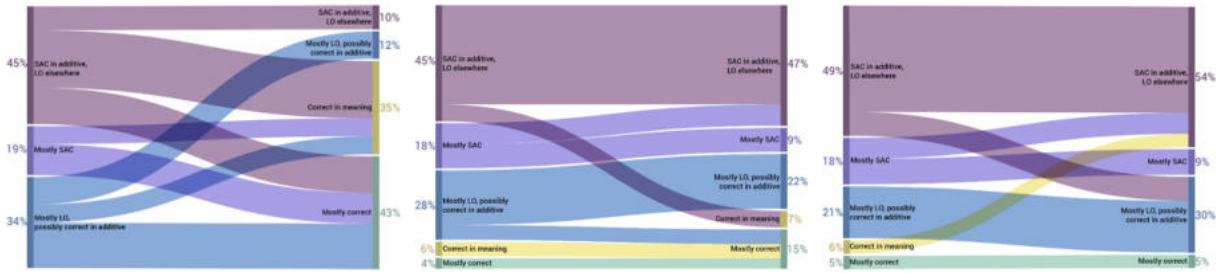

Figure 3: Transitioning between latent classes from pre- to post-test

The three selected classrooms show a similar distribution of latent classes in the pre-test: *SAC in additive, LO elsewhere* is the most prevalent class (45-49%), followed by *Mostly LO, possibly correct in additive* (21-34%) and *Mostly SAC* (18-19%). In addition, Classrooms 2 and 3 each have a single student with *Correct in meaning* and *Mostly correct* as best-fitting class.

In the post-test, however, the distribution of latent classes differs considerably between classrooms. While Classroom 2 and 3 see only a few changes in latent classes from pre- to post-test, Classroom 1 students almost all transition to a different latent class. In the post-test, most of Classroom 1 students correspond to *Mostly correct* (43%), followed by *Correct in meaning* (35%), *Mostly LO, possibly correct in additive* (12%) and *SAC in additive, LO elsewhere* (10%). In Classroom 2, students are less likely to transition, hence *SAC in additive, LO elsewhere* (47%) and *Mostly LO, possibly correct in additive* (22%) are still most prevalent in the post-test. However, *Mostly correct* has increased to 15% with newcomers stemming from *Correct meaning* and *Mostly LO, possibly correct in additive*. In Classroom 3, most students (73%) do not transition with *SAC in additive, LO elsewhere* (54%) and *Mostly LO, possibly correct in additive* (30%) staying the most prevalent latent classes. Unlike in Classroom 2, students do not transition into *Mostly correct* (5%); not even students from *Correct in meaning* who are most likely to transition to *SAC in additive, LO elsewhere* here.

The teachers of these three classrooms took part in two semi-structured interviews each conducted shortly after teachers had deployed the pre- respectively post-test. The questions most relevant for the investigated research question were: Please elaborate on what you have done in the classroom regarding variables and algebraic expressions before the pre-test. What are you planning to do with your students' test results? What has happened during the last 4 weeks in your classroom? To what extent have the test results influenced your teaching? The interviews were inductively analysed for various information on their teaching and case summaries were created (Kuckartz, 2018).

Results

The teacher interviews revealed several differences between reported teaching (see Table 1 for a comparative overview). Teacher 1 administered the pre-test after only one lesson about substituting values and formulating algebraic expressions during which they stressed the importance of defining

what the used variable stands for. Based on the test results, they decided to spend more time on these contents and not to move on to equations yet. In the following weeks, they strongly focussed on the meaning of the variables and required students to be explicit and precise about this (even if tasks from the textbook would not require it on their own). They initiated classroom discussions on differing formulated expressions and variable definitions stemming from group work. For choosing further tasks, they emphasised the importance of switching between different representations and connecting to contexts. As feedback on the test, Teacher 1 discussed the test items of the pre-test in their classroom and addressed substitution as a strategy to check given or formulated equations.

Table 1: Comparison of reported teaching before and after the pre-test

	Teacher 1	**Teacher 2**	**Teacher 3**
Contents before pre-test	formulating algebraic expressions, substituting values into expressions match figure patterns		
	importance of defining what the variable stands for, idea of using variables for generalisations	fruit-salad-algebra used to help, connecting expressions to context situations, no explicit correction of LO statements	simplifying expressions, equality of expressions, variables stand for numbers, same letters stand for same values
Teaching between pre- and post-test	*Contents:* substituting values into expr., same letters for same values, formulating expr. with stating the meaning of the variable, simplifying expressions NO equations	*Contents:* equation solving (scales model & match boxes), equivalent transforming, substituting to check results, facets of variables NO formulating equations	*Contents:* equation solving (scales model), equivalent transforming, formulating equations from a given situation, mostly x used as variable NO focus on meaning of var.
	Tasks: connecting representations: alg. expr., verbal description & table, formulating expr. for patterns and situations	*Tasks:* formulating alg. expr. for variables which stand for letters in name (+ other tasks from SMART teaching suggestions)	*Tasks:* tasks from textbook, e.g. age tasks
	Feedback: no individual feedback, test items discussed, strategy to check by substituting	*Feedback:* no individual feedback, test items/solutions NOT addressed	*Feedback:* no individual feedback, test item solutions shown in classroom

Teacher 2 administered the pre-test after teaching substituting values, and formulating and matching algebraic expressions for two weeks. Reflecting on the SMART test, they acknowledged having used 'fruit-salad-algebra' and handling students' d0efinitions of variables as objects as imprecisions by not explicitly correcting students, but just using a correct formulation themselves. Prompted by the test results, they dedicated two lessons to work on selected tasks from the SMART teaching suggestions focussing mainly on substituting values for letters and facets of variables (unknown, generalised number, varying quantity). Because Teacher 2 was afraid to distort results of the study, they did not discuss the test items with their class before the post-test (afterwards they did and deemed it utterly helpful). For the rest of the 4 weeks between tests, the lessons focussed on equation solving and checking results by substituting, but not formulating equations yet.

Teacher 3's students completed the pre-test after 8 lessons on substituting values, formulating and simplifying expressions, and equality of expressions. While it was addressed that variables stand for numbers, no tasks were included which required deciding what the variables are being used for in a given context. Since the test results were not unexpected for Teacher 3 (because this kind of tasks had not been addressed), they did not adjust their further teaching except for briefly showing the

solutions of the pre-test. Accordingly, the lessons between tests dealt with solving equations, equivalent transforming and formulating equations from a given context without focussing on the meaning of variables. Teacher 3 reported generally using the letter x and no initial letters for variables. They assumed that an understanding of variables would develop in the course of time, e.g. in Year 8 when taking up algebra again, and being able to solve tasks would be sufficient at the moment.

Discussion

As can be seen in the results, Classroom 1 students have improved the most after 4 weeks of teaching. Apparently, Teacher 1's focus on the meaning of variables has indeed helped students to transition to *Mostly correct* (43%) and *Correct in meaning* (35%). Interestingly, equations had not been addressed in lessons yet; thus, a proper understanding of the meaning of variables might be more important than knowledge of equations and equality in order to avoid a *letter-as-object* (LO) interpretation.

Despite dedicating two lessons on tasks from the teaching suggestions, only a few Classroom 2 students progressed to *Mostly correct* (15%) or *Correct in meaning* (7%). This could, on the one hand, be attributed to the focus on substituting values and on facets of variables rather than on explicitly addressing that algebraic letters do not stand for abbreviations of objects. On the other hand, the use of fruit-salad-algebra in previous lessons and the acceptance of students' "inaccuracies" might have made it more difficult to overcome a LO misconception for many students. However, for a few students the reported teaching was sufficient to avoid this interpretation in more test items than before.

Teacher 3 did not change anything in their teaching apart from showing item solutions. Although they are aware of the importance of variables standing for numbers, and avoid initial letters in their teaching, moving on with equation solving and formulating is not enough for their students to improve their understanding of the meaning of variables. The one student with *Correct in meaning* as best-fitting class for the pre-test even deteriorates to *SAC in additive, LO elsewhere*.

Conclusion

Comparing reported teaching with the development of students' latent classes, we can infer that explicitly addressing the meaning of used variables (again and again), discussing the importance of a precise definition (raising metacognition), and comparing different definitions of variables (probably creating cognitive conflict) and their implications for formulating expressions was a successful approach to facilitate conceptual change for many learners. For this purpose, also the discussion of the SMART test items might be helpful since they comprise different subtypes of this misconception (diverse instruction). These findings seem to be in line with instructional recommendations to achieve conceptual change (e.g. Lucariello, 2015). Learning about equations, on the other hand, seems not to be as crucial; on the contrary, moving on to equations too quickly and without stressing the meaning of variables could actually hinder students' improvement since no conceptual change is initiated. Of course, for teachers to be able to employ such helpful teaching, they need to be aware of potential misconceptions in general and amongst their students, but also of appropriate teaching approaches. While our findings are certainly limited by the small number of interviews analysed and the nature of self-reports, we nevertheless were able to gain further information on how teachers could be advised to help students overcome the *letter-as-object* misconception.

While research in algebra education has provided rich insights and designs that focus on open-ended exploration activities, instructional designs that support teachers and students in the phase of active knowledge organization after initial explorations have received less attention. This paper explores how interactive instructional videos can enhance students' understanding of variables as generalizers when the videos are used at the beginning of a knowledge organization phase prior to a teacher-led discussion. Snapshots from design experiments with eighth graders in the third cycle of a design research project show that interactive features and follow-up tasks that build on (sometimes only partially correct) student solutions from the exploration phase can enhance students' understanding of the generalizer by making them question prior deviant solutions, helping them distinguish between generalizer and placeholder, and providing helpful language means.

Keywords: Variables as generalizers, instructional videos, interactive features, two-phase instructional designs, design research.

Introduction

Ellis and Özgür (2024), in their review of recent trends in algebra education research, emphasize the need to investigate instructional approaches and materials that help teachers deliver high-quality algebra instruction. Research in algebra education has long supported the use of open-ended inquiry tasks in an initial *exploration phase* in which students re-invent algebraic concepts (Kieran, 2006). While teachers often succeed in initiating such phases, many struggle to productively implement the subsequent *phase of active knowledge organization*, which aims to collect and connect students' ideas from the exploration phase and to organize them into a coherent network of knowledge that conforms to the norms of mathematics (Prediger et al., 2021; Stein et al., 2008): Some teachers lose students' cognitive engagement by simply "telling" the final mathematics after collecting ideas, while others, reluctant to "tell" anything, collect students' ideas but fail to connect them to regular mathematics.

Algebra education research paid little attention to instructional designs for the knowledge organization phase. These designs can draw on effective teaching practices for this phase to maintain students' cognitive engagement (Stein et al., 2008), but should be supplemented with topic-specific materials to support teachers in moderating focused whole-class discussions around typical student solutions. This paper addresses the case of variables as generalizers, a concept essential for generalizing relationships but often difficult to understand for students (Küchemann, 1981; Usiskin, 1988). We report on a design research project investigating the potential of interactive video as an instructional material that incorporates interactive features such as open-ended gaps or self-explanation prompts and can enhance students' knowledge organization after an initial exploration phase in preparation for a teacher-led whole-class discussion (Atkinson & Renkl, 2007; Mayer, 2021).

The research question of this paper is: *To what extent can interactive videos enhance students' understanding of variables as generalizers in a phase of active knowledge organization before entering a whole-class discussion?* After sketching the theoretical background on variables as generalizers, the use of interactive video in the knowledge organization phase, and supporting design features of effective video, and outlining the methods, empirical snapshots of learning processes from the third design research cycle are presented and discussed.

Theoretical background

Understanding variables as generalizers

Generalizing is central to algebra (Kieran, 2006). Students who can use letter variables and algebraic expressions to generalize relationships between quantities and explain their meaning (as in the generalization tasks in Figure 1a) understand letter *variables as generalizers*, i.e., they have constructed the meaning of the letter as representing *all possible* numbers (e.g., driving times). This understanding can be developed in sense-making activities that promote generalization experiences aimed at describing relationships for all relevant cases at once (Usiskin, 1988).

(a) E-scooter task on algebraic expressions

Target task: Till occasionally rents an e-scooter and pays different prices as he drives, sometimes longer, sometimes shorter. Find an algebraic expression with a variable that determines the total price to be paid for every arbitrary chosen driving time.

E-scooter rental
Price per minute 0.15€
Price to unlock 1 €

(b)

Date of e-scooter ride	Driving time (in min)	Costs driving time (in €)	Expression for total price (in €)	Total price (in €)
May, 16	20	20 × 0.15	20 × 0.15 + 1	4.00
May, 19	12	12 × 0.15	12 × 0.15 + 1	2.80
May, 24	27	27 × 0.15	27 × 0.15 + 1	5.05
May, 25	18	18 × 0.15	18 × 0.15 + 1	3.70
May, 29	33	33 × 0.15	33 × 0.15 + 1	5.95
June, 2	42	42 × 0.15	42 × 0.15 + 1	7.30
For every arbitrary driving time:	x	x × 0.15	x × 0.15 + 1	

(c)

Date of e-scooter ride	Driving time (in min)	Calculation	+ unlock costs	€
May, 16	20	20 × 0.15	20 × 0.15 + 1	4.00
May, 19	12	12 × 0.15	12 × 0.15 + 1	2.80
May, 24	27	27 × 0.15	27 × 0.15 + 1	5.05
May, 25	18	18 × 0.15	18 × 0.15 + 1	3.70
May, 29	33	33 × 0.15	33 × 0.15 + 1	5.95
June, 2	40	40 × 0.15	40 × 0.15 + 1	7.00
For every arbitrary driving time:	150	150 × 0.15	150 × 0.15 + 1	23.50

Figure 1: Exploration task for re-inventing variables as generalizers (a), table as instructional support (b), and a typical improvable student solution before working with the video (c)

Developing understanding of generalizers has long been identified as challenging for students (e.g., Bardini et al., 2005, Küchemann, 1981), who often (initially) interpret letter variables through an "arithmetic frame of reference" (Kieran, 2006, p. 25) focused on calculation. Within this frame students tend to interpret *variables as temporally indeterminate placeholders* into which one can put a number to "finally" calculate something (Bardini et al., 2005). Hence, students mistakenly transfer the idea that variables represent something *not yet known* – typical of unknowns in equation-solving activities ($3x+5 = 7$) – to generalization activities. But generalizers do need no further determination, because a general statement is the epistemic purpose (Usiskin, 1988).

Instructional support for understanding the generalizer typically elicits students' calculation-dominated interpretations and then contrasts them with the meaning of the generalizer (Prediger & Krägeloh, 2016). A table can help students appreciate the subtle contrasts (Figure 1b): They initially fill in the e-scooter table for several arithmetic expressions, mostly with a *horizontal* view along rows from left to right, and choose a driving time for June 2 (placeholder). In contrast, the last row calls

for every arbitrary driving time and requires seeing the table *vertically*, using a generalizer to represent all possible numbers that could occur in the driving times column. Providing language that distinguishes between "every arbitrary number" and "a specific chosen number" further supports students in grasping the subtle conceptual differences (Prediger & Krägeloh, 2016).

Students with arithmetic reference frames often do not complete the table as intended. Figure 1c shows a typical improvable student solution that interprets every arbitrary number as a prompt to choose a specific number (e.g., 150min). The exploration phase aims to elicit such typical student ideas, while the knowledge organization phase builds on these ideas, e.g., by contrasting the meaning of the placeholder and the generalizer and leveraging them to understand the generalizer.

Design features of interactive videos that can enhance students' knowledge organization

Knowledge organization phases, typically teacher-led whole-class discussions, pose challenges for teachers and students (Prediger et al., 2021; Stein et al., 2008): Teachers must enact highly demanding teaching practices, such as connecting students' ideas from the exploration phase to the mathematical norms, while students must follow these rich discussions and process ideas not yet developed in their own prior exploration, potentially leading to cognitive overload (Mayer, 2021). Prediger et al. (2021) developed and investigated *knowledge organization tasks*, which are less open-ended tasks launched after students' explorations, that introduce typical student ideas from the exploration phase, explicate connections to regular mathematics, and can support teachers in implementing teacher-led knowledge organization phases. Such knowledge organization tasks, typically completed by students individually or in small groups before being discussed with the whole class, allow students to process typical student ideas at their own pace, can reduce the cognitive load of the subsequent whole-class discussion, and can help students focus on relevant topic-specific aspects.

In this paper, we use interactive videos as knowledge organization tasks and explore how such videos, used after students' individual exploration of the e-scooter task (Figure 1), can prepare a teacher-led whole-class discussion by enhancing students' understanding of the generalizer. In general, instructional videos can enhance understanding, but their effectiveness depends on students' *focused cognitive engagement*, i.e., students' deep processing of the video content with a focus on the relevant topic-specific content elements (Atkinson & Renkl, 2007; Mayer, 2021). Students' focused cognitive engagement with the video explanation can be supported by the following evidence-based *design features* (Atkinson & Renkl, 2007; Mayer, 2021): (1) The video content should build on *typical student solutions* from the exploration phase. (2) The *multimedia design* should take into account students' limited cognitive capacity. (3) Videos should use *interactive video features* and post-video *follow-up tasks* that elicit deep cognitive engagement and focus students' attention on relevant content elements of the video content, such as distinguishing between generalizers and placeholders.

While the general features are well articulated, their topic-specific realization requires design research to meet the key aspects of the topic in view, in our case, variables as generalizers. Therefore, we designed an interactive video on understanding the generalizer and investigate students' algebra-specific learning processes while working on the interactive video in a knowledge organization phase after exploring the e-scooter task (Figure 1).

Methods of the design research study

Research context and instructional design of the video

This paper presents snapshots from Design Experiment (DE) Cycle 3 of a design research project that investigates how videos can enhance students' understanding of variables. In DE Cycle 1, we identified typical improvable student solutions to the e-scooter task (e.g., Figure 1c) and investigated learning processes with a non-interactive video after exploring the e-scooter task. We found that students often overlooked important concept elements, even when they were extensively explained in the video, e.g., the generalizer in the last row of the e-scooter table (Figure 1b). Moreover, students struggled to connect the video content to their solutions from the exploration phase.

Based on these results, we improved the video for DE Cycle 2 by adding interactive features and follow-up tasks to help students process the relevant content elements (e.g., generalizer) and connect them to their prior solutions. For example, after explaining that you can choose a number (placeholder) in the penultimate row (June, 2 in Figure 1b), the video explicates the purpose of the last row as follows: "We don't just want to describe any chosen driving time here, but every arbitrary driving time, in general. So, we no longer specify how long Till drives." In DE Cycle 2, the video speech pauses after this explanation and a written explanation is introduced in silence: "Every arbitrary driving time means: There is no specific number fixed for the driving time." (Figure 2a). In DE Cycle 2, we found that this unusual silence allowed students to see the relevance of the written explanation, and that students who interpret "every arbitrary number" as a request to calculate column sums benefited from being prompted to reconsider the last row of the table after reviewing the written explanation. For DE Cycle 3, we added an interactive feature (Figure 2a) that allows students to enter an answer for the last row and, after pressing the check button, receive corrective color-coded feedback (red: wrong) and explanatory audio feedback by pressing the play button next to their entry.

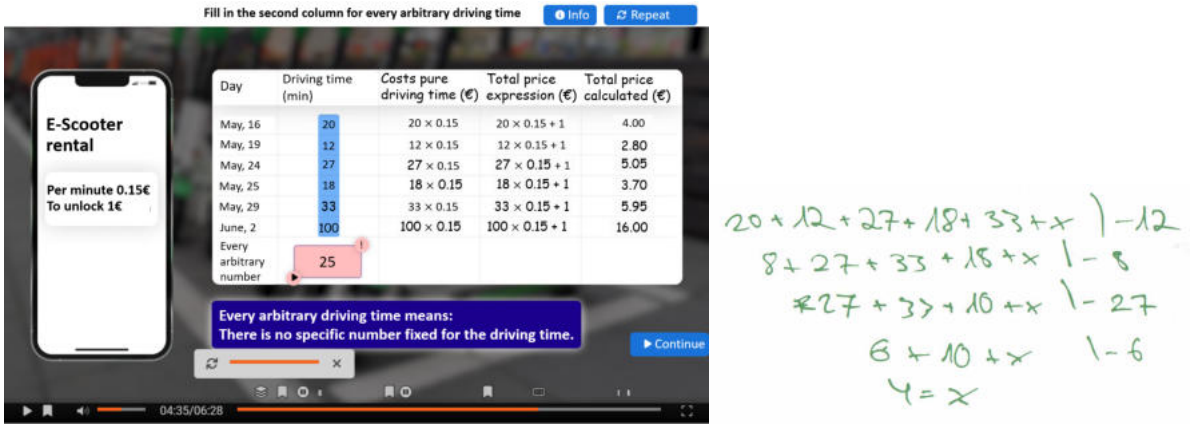

Figure 2: Example of an interactive video feature (a), Gamze's idiosyncratic calculation (b)

Methods of data gathering and data analysis

This paper reports on learning processes from DE Cycle 3 with focus on students' understanding of generalizers in contrast to placeholders. The first author conducted DE with three pairs of eighth-grade students who were selected because they had limited prior experience with letter variables from simple problem-solving activities, but had not yet developed an understanding of the generalizer. We

focus on snapshots of two pairs, Gamze and Arif, and Ilya and Serhat, during the first 90min session: in which they worked on the e-scooter exploration task and then as pairs on the interactive video and its follow-up tasks. Pairs and video screens were videotaped and videos fully transcribed.

To analyze students' learning processes, we identified transcript scenes where they worked on relevant interactive video features and follow-up tasks. Each student utterance was qualitatively analyzed to capture emerging ideas about variables, by deductively coding whether an utterance expressed (a) the generalizer (all possible numbers), (b) the placeholder (a specific chosen number), or (c) other content elements outside the study focus. Coding was done by a trained rater (first author) using a codebook developed in DE cycles 1 and 2 with substantial interrater agreement ($\kappa > .70$).

Empirical insights into students' algebra-specific learning processes with video

Gamze and Arif question their solution from the exploration phase

In the exploration phase, Gamze and Arif produced the improvable solution shown in Figure 1c. They interpret "every arbitrary driving time" as "the driving times that I drive every month", where "every" is interpreted as "throughout the whole month", so they write 150 in the last row of the table to express the sum of all their numerical entries in the driving times column. Their strong arithmetic frame of reference can be seen in their answer to the question of why their expression in the last row is correct for every arbitrary driving time: "Because these are all driving times that Till drives". Thus, Gamze and Arif's response replicates Prediger and Krägeloh's (2016) finding that, for many students, the meaning of the language provided to informally express generalizations ("every arbitrary driving time") is not automatically understood, but must first be constructed in rich generalizing experiences.

After the video introduces the written explanation in silence (blue box in Figure 2a), Gamze and Arif pause the video and write it down just below their own explanation that every arbitrary driving time means "every month". Thus, the design seems to allow them to superficially link the video content to their prior solution (interpreting "every arbitrary number" as a request to calculate column sums), but they do not seem to see any conflict between the two. Hence, they are in the target group that could benefit from the interactive feature shown in Figure 2a. They work on this feature as follows:

202 Gamze: I think it's 25. I added everything up and then divided by 6 [*types 25 into the cell*]
203 Arif: What do you mean? [*confused*] All together?
204 Gamze: Yes. [*Presses check, gets "wrong" as response, clicks on the audio feedback*]
205 Video: As with the other rows, you have entered a fixed number. Think about why this can't be right. Maybe the written explanation from the video will help you.
206-17 [*Students discuss whether they need to enter the sum of all entries, 150, or if the mean 150:6 is correct and they just made a calculation error, while Arif uses his calculator to check 150:6, Gamze listens again to the audio feedback (Turn 205)*]
218 Gamze: [*Reads the written explanation:*] There is no specific number fixed for the driving time. So- Oh my God! Do we have to reckon with this *x*? Because here [*points at 100 in video's e-scooter table*] the 100 is never fixed, it could be another number.

In her prior solution from the exploration phase, Gamze wrote "150:6" below the table (Figure 1c), i.e., the mean driving time, as a second interpretation of the unfamiliar "every arbitrary number". In Turn 202, she refers to this interpretation, while Arif still considers the sum of all entries as an answer (Turn 203). Although Gamze had already copied the written explanation from the video as an explanation for every arbitrary number, it is only after listening to the audio feedback a second time

that she thinks deeply about it (Turn 218) and links it to a vague idea of using "this *x*" – a phrase that, in German, suggests a certain distance. In this scene, we can see that there is a real need for targeted, topic-specific interactive features that elicit students' prior ideas, encourage them to challenge those ideas, and get them to think deeply about the relevant content elements.

Gamze processes the video explanation about the generalizer actively

In Turn 218, Gamze sees the problem that you could choose a number for June 2, so the 100 chosen in the video "is never fixed" and "could be another number", e.g., Gamze's 40. Here, we see how she slowly begins to appropriate the meaning of every arbitrary number, digesting the written explanation from the video. She then "reckons with this *x*" by performing the idiosyncratic calculation shown in Figure 2b. In the first line of her calculation, Gamze writes an expression for the sum of the driving times from the table, taking into account that one number "is never fixed". Yet, Gamze's understanding of "this letter" seems to be dominated by previous equation-solving activities aimed at finding a specific number. So somehow, she still thinks that *x* stands for a specific number. To determine this number, she uses idiosyncratic rules that resemble rules for manipulating equations. Having "determined" $x = 4$, Gamze and Arif proceed as follows:

234 Gamze: I'll try four [*types 4 in the field; presses check, gets "wrong" as response*] Why?
235 Arif: Try- Try 200 [*smiles*], just like that, let's see.
236 Gamze: [*Types 200 in the field; gets "wrong" as response*] Huh? [*clicks audio feedback*]
237 Video: You have entered a specific number again. In this row, we don't want to fix a specific number for the driving time.
238 Gamze: Ahh! *x*! [*types x in the field; presses check, gets "correct" as response*] Did you see, its *x*. I knew it, wait, wait, *x*. I knew it because I also calculated with *x* [*points to her calculation, Figure 2b*] Oh, yes! [*presses play to continue video*]
239 Video: As the driving time is no longer fixed, we cannot enter a specific number here.# Instead we use a variable, for example *x*. [...]## *x* also stands for all possible driving times that Till could ever drive.
240 Gamze: #Yes! ##[*nodes her head*]

In this scene as well as in the previous one, we can see that the interactive feature elicits all sorts of relevant prior ideas that Arif and Gamze have about the last row, ideas about calculating sums, finding unknowns (Figure 2b), and simply choosing a number (Turn 235). The audio feedback (Turn 237) allows Gamze in Turn 238 to finally step back from the idea of calculating column sums and to appreciate that *x* allows her to express that the number "is never fixed" and that this might be of value, even though no "reckoning with this *x*" is involved. What we find particularly remarkable about pairs such as Gamze and Arif, who work intensively on this interactive feature, is how actively they seem to process the video explanation about the generalizer immediately after the interactive feature (Turn 239), e.g., as indicated by Gamze' joy, nodding, and affirmative behavior (Turn 240).

Potentials of targeted, topic-specific follow-up tasks

Follow-up tasks that elicit self-explanations of relevant video content also aim to deepen students' focused cognitive processing (Mayer, 2021). In a follow-up task, which confronts Gamze and Arif with a solution similar to their own from the exploration (Figure 1c), students are asked to explain what is wrong with simply choosing 100min to express every arbitrary driving time:

327 Gamze: [*explains to Arif:*] You always have to use *x* when you think of a number and want to write a calculation [expression]. Then you don't choose a number like 50 or

> 100, because otherwise you get a wrong calculation – so it's not wrong, but it doesn't work because not everyone wants [to use] 50 or 100 or 40.

Gamze's explanation suggests that her understanding of letter variables seems to have changed in the course of working with the interactive video. It seems that she now sees a value in using a letter variable to express generality in the sense that "not everyone wants" to use the same number. This can be a very important first step in appreciating the epistemic purpose of the generalizer: The letter does not need to be specified, because we want an expression that is useful for all possible cases.

Snapshots of another pair, Ilya and Serhat, illustrate how targeted follow-up tasks can encourage students to return to specific video parts to find language means to express generality. For example, when Ilya is asked in a follow-up task to explain why the expression $x \times 0.15+1$ is always correct (not just for the numbers in the e-scooter table), he goes back to the video explanation that x stands for all possible driving times (see Turn 239) and writes: "The variable x [makes the expression] always correct, because x can stand for all [numbers]." Similarly, in a follow-up task where Serhat is asked to explain the structure of the e-scooter table, he returns to an interactive feature (not shown here) that deals with the purpose of letter variables (to distinguish changing quantities from fixed ones), which allows him to express the vertical structure of the table: "In the table, everything is the same except the driving time and the total costs. The total costs depend on the driving time."

Discussion

The empirical snapshots of students' work with interactive videos and follow-up tasks showed that such design features can indeed foster students' understanding of the generalizer. While generic design feature for supporting students' focused cognitive engagement are known (Atkinson & Renkl, 2007; Mayer, 2021), their algebra-specific realization requires design research to specify the relevant content elements that need focus: The *written explanation* introduced in silence took students' limited cognitive capacity into account while focusing a particularly relevant content (the generalizer) missed by students in prior DE cycles. The design of the *interactive feature* shown in Figure 2a was strongly influenced by a careful algebra-specific analysis of students' learning processes in previous cycles, which allowed to build on typical student ideas: In the case of Gamze and Arif, it elicited relevant prior interpretations of letters as placeholders, sums, and unknowns, and encouraged them to focus on the relevant content by articulating ideas about generalizations ("not everyone wants" the same number; "x stands for all numbers"). The design of the *follow-up tasks* was similarly informed by previous DE cycles and encouraged students to engage in cognitively demanding self-explanations focusing the generalizer and making use of algebra-specific language means provided in the video to grasp subtle conceptual differences ("you don't choose a number", "x can stand for all [numbers]").

Thus, interactive videos with targeted topic-specific interactive features and follow-up tasks can be a valuable resource at the beginning of the knowledge organization phase, if they are sensitive to typical student ideas from the exploration to be leveraged and allow students to process challenging algebraic ideas at their own pace and with focused support. Yet, for most students, understanding a concept as complex as the generalizer will require a discussion with the teacher at some point in the learning process, as some fine nuances can only be clarified through discourse. We see interactive video as a useful preparation for such teacher-led whole-class discussions, and initial responses from teachers

suggest that they themselves can benefit from this design by using typical student ideas in the follow-up tasks as a starting point for their whole-class discussion, and by drawing inspiration from the video for targeted language means and ways of connecting multiple representations.

Abstract

This study consisted of Grades 1 and 2 (ages 6-8) classroom teaching experiments (CTE) with a lesson sequence focused on graphical representations of algebraic relationships. We interviewed students before, during, and after the CTE. Here we report on the progression of one Grade 2 (age 7) student's thinking across the CTE. Prior to the CTE, the student had not previously interacted with representations of algebraic relationships. By the end of the CTE, the student was able to generalize about the functional relationships using graphs. This study illustrates how a learning trajectory modeling students' understandings of function graphs can be used to characterize one children's learning and provides evidence that young students are able to reason with function graphs.

Keywords: learning, learning trajectories, mathematics education, algebra.

Introduction

Prior work has illustrated that young students are capable of algebraic reasoning (e.g., Dougherty, 2008), including using variables (e.g., Blanton et al., 2017; Brizuela, Blanton, Sawrey et al., 2015); reasoning about functional relationships (e.g., Brizuela, Blanton, Gardiner et al., 2015), and representing algebraic ideas using tables (Brizuela et al., 2021). A key takeaway from this prior work is that functional relationships are opportunities for young learner to reason algebraically. We build on emerging work (e.g., Strachota et al., 2024) on students' understandings of Cartesian graphs to reason algebraically.

Our study builds on this previous work and assumes that if students have consistent experience with algebraic reasoning earlier in their K-12 schooling, then algebra would be less of a gatekeeper to higher education and subsequent job opportunities.

In this study, we will address the following research questions:

1. How does one student's understanding of function graphs develop over the course of a classroom teaching experiment (CTE)?
2. What aspects of the CTE lessons in which the student participated seem to be associated with shifts in that student's understandings?

Conceptual framework

We rely on the levels of students' understanding of graphs developed in our prior work (viz., Strachota et al., 2024). To develop these levels, Strachota et al. (2024) identified relevant literature on trajectories and progressions in related contexts (e.g., Brizuela et al., 2021; Battista et al., 1998; Gabucio et al., 2010; García-Milá et al., 2014; Martí, 2009; Martí et al., 2010, 2011; Piaget, 1970; Sfard, 1991) and described the ways of thinking about graphs that might occur in the context of functional relationships. Then, using grounded theory (e.g., Corbin & Strauss, 1990) we iteratively revised the levels based on data that was collected through interviews and CTEs with Grades 1 and 2 students. The process resulted in a description of an eight-level trajectory, modelling students' understandings of function graphs (see Table 1); we use these descriptions to characterize students' understandings as well as help explain the shifts we observed in their understandings over time.

Table 1: Descriptions of the levels in the graphing trajectory

Pre-structural	The student does not understand the representation is a graph. They can engage with the graph but not in a way that is unique to this type of representation or that indicates they understand graphs as different from another type of representation.
Interiorization of component(s)	The student understands what the graph is about, what it is referring to, and/or what information is being recorded. They have interiorized (Sfard, 1991) components, such as axes, variables, what quantities are represented by points, etc., but not the graph as a whole. Thus, they do not yet accurately interpret or plot points.
Emergent coordination of quantities	The student interiorizes the coordination of quantities. This might involve gesturing between two coordinated quantities or connecting two coordinated quantities with a line, but not plotting a point or putting their pencil on the point and indicating the precise location. This might include plotting a point at an imprecise, incorrect location.
Condensed coordination of quantities	The student interiorizes the Cartesian coordinate plane (Sfard, 1991). That is, they have or are developing a conceptualization of the graph as two coordinated axes (i.e., uniformed, structured rows and columns according to Battista et al., 1998) and have interiorized the coordination of quantities. Thus, they have condensed a point. They do not however do anything to provide evidence that they understand how two or more points are related.
Emergent recursive inferences	The student can relate two or more points on the graph by describing a recursive pattern. At the emergent recursive inferences level, students describe the change between points in terms of either the *x*-axis or the *y*-axis, but not in terms of both. That is, they describe either the "rise" and the "run" of the slope, but not both.
Condensed recursive inferences	The student can relate two or more points on the graph by describing a recursive pattern. They may interpret consecutive points as always going up by the same amount. They do not however describe the general functional relationship represented in the graph. At the condensed recursive inferences level, students describe the change between points in terms of both the *x*-axis and the *y*-axis. That is, they describe both the "rise" and the "run" of the slope.
Functional inferences	The student can relate two or more points on the graph and generalize about a functional relationship. When students generalize about a functional relationship, they describe a relationship that extends beyond consecutive points. The distinction between this understanding and making recursive inferences, is that students' recursive inferences rely on consecutive points, whereas students' functional inferences are general and connect across points.
Function graph as object	The student understands the function graph as something that extends beyond what is at hand and exists in relation to other function graphs. They can describe how the graph can be transformed or manipulated without having to recreate it or calculate specific values.

Method

We conducted CTEs in Grade 1 and 2 classes at an elementary school in the Northeastern United States. For this paper, we focus on one Grade 2 student's reasoning with algebraic relationships and representations in the CTE. The data collection consisted of videorecording 14 CTE lessons in each of the Grades 1 and 2 classrooms (ages 5-8). The CTEs lessons were about 40 minutes and taught by a former classroom teacher. We detail the development and content of the CTE lessons below. To track students' progress in the instructional sequence, we conducted interviews (Steffe & Thompson, 2000). The interviews took place before, during and after the lesson sequence and were conducted by at least two team members. Lessons and interviews were videorecorded.

Classroom Teaching Experiment

Over the course of the 14 CTE lessons, Grade 2 students reasoned with three different functional relationships within multiple problem contexts: 1) $y = x$; 2) $y = 2x$; and 3) $y = x + 1$. The instructional sequence was designed in the form of cycles of revisiting tabular and graphical representations. For instance, students reasoned with tables and graphs in both the "dog eyes" context ($y = 2x$) and the "cutting string" context ($y = x + 1$). The advantage to this cyclical approach is that it provides opportunities to revise our curriculum plans fluidly to support students in advancing their reasoning (Sandoval, 2014).

The lessons were chosen and adapted from prior research that had included CTEs and instructional sequences (Blanton et al. 2015, 2017; Brizuela, Blanton, Gardiner et al., 2015; Brizuela, Blanton, Sawrey et al., 2015). We intentionally chose lessons that focused on representing, including tabular and graphical, or lessons that could be modified to include these representations to create our instructional sequence. Lessons were piloted with other Grade 1 students prior to the CTE.

Individual Interviews

In addition to the lessons, interviews were conducted before, halfway through and after the CTE to document and understand the students' progress with 1) reasoning with algebraic representations and 2) ability to think recursively and functionally. In the interviews, students were asked to both reason with and create graphical representations to understand the function $y = 2x$ in the context of the relationship between number of birds and bird wings.

Here we report on three interviews from one Grade 2 student, Levi. We selected Levi's interviews for analysis because they supported us in answering our research questions. Levi provided rich verbal responses and a willingness to engage with graphs. For each of Levi's interviews, we noted the highest level within the graphing trajectory that he exhibited.

Data analysis

All of Levi's interviews were transcribed and coded line by line based on Levi's utterances and gestures. using MAXQDA software. Codes were applied irrespective of mathematical accuracy. The codes we used are outlined in Table 1. To ensure reliability, we used a primary/secondary coding approach and addressed differences using third-party resolution (Syed & Nelson, 2015).

Findings

In the following we report the most sophisticated level that Levi exhibited in each of his three interviews and provide examples that illustrate the levels.

First interview

Since students were not expected to have seen the graph before, the graph that Levi received in his first interview was pre-constructed with points representing one through seven birds and the corresponding wings. Figure 1 shows the representation that was given to Levi and his annotations.

Levi interpreted some components of the graph, namely that the x-axis represented the number of birds and that the number of bird wings is represented with the points. For instance, the following exchange occurred when Levi was asked to solve for the number of bird wings if there were three birds.

Levi:	Ok, so we started by three (draws line from [3,0] to [1,2] to [2,4] to [3,6]).
Interviewer:	Can you tell me what you're doing?
Levi:	I'm doing the three and then doing all the way up, with the counting by twos, which number we're starting with.
Interviewer:	Mhm, why did you stop at this point?

Levi: Because it (the point) has a six.
Interviewer: Does it have a three too, or just the six?
Levi: It has a six, you start with the three and then it goes all the way up to six.

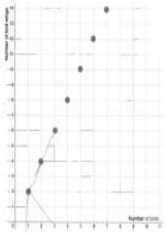

Figure 1: Levi's written work on the graph in his first interview

To solve for the number of bird wings if there were three birds, Levi first marked (3,0) with his pencil, indicating that it is represented three birds on the *x*-axis. Next, Levi drew lines from (3,0) to (1,2) to (2,4) in order to connect (3,0) to (3,6), indicating that (3,6) represented 3 birds and 6 wings. Notably, despite using the *x*-axis as a starting point for his lines, Levi never stated he understood the number of birds is represented by (3,6). When asked if the point "has a three too, or just the six," Levi never stated that three is represented by that point as well. Therefore, we infer that Levi has interiorized *part* of the point, specifically the number of bird wings, evidence of *emergent coordination of quantities* level. He also indicated *emergent recursive inferences* by describing the difference between points by counting up two from the *x*-axis.

At the *emergent coordination of quantities* level, students begin to interiorize how to coordinate quantities in the graph context, such as by drawing lines connecting two covarying quantities. Differing from *condensed coordination of quantities*, students that exhibit this level have not fully interiorized what the points represent.

Second interview

Once again working on the pre-constructed graph, Levi drew lines that connected values on the axes to points on the graph. For instance, when solving for the number of wings if there were two birds, Levi drew a line connecting the *x*-axis (2, 0) to the point (2, 4). This action suggested that he understood two birds were represented within the point (2, 4). When asked where four wings was on the graph, Levi gestured from (0, 4) to (2, 4) and stated that the four is "on this dot," suggesting that he also understood four wings were represented in the point simultaneously. Later in the interview, he drew a line connecting four wings to the point, providing evidence that he was thinking at the *condensed coordination of quantities* level. Levi then accurately coordinated quantities for one, three, and four birds by again drawing guidelines to connect to the points.

Third interview

Similar to his second interview, Levi drew guidelines from the axes to plot points (see Figure 2). The teacher-researcher asked Levi to plot (8, 16) without the use of guidelines. After he accurately plotted the point, the following exchange occurred.

Interviewer: How are the points helping you figure out where the next point is?
Levi: Cause they're going like in a pattern, like 1, 2, 3, 4, 5, 6, and they're going diagonal.
Interviewer: They're going diagonally?
Levi: Yeah, that's how I know.

Levi's statement reflected the *emergent recursive inferences* level, as he is thinking about the points in relation to each other. By stating "1, 2, 3, 4, 5, 6," Levi described a recursive pattern, indicating he has condensed the points and is now acting on the points, reasoning about they are related.

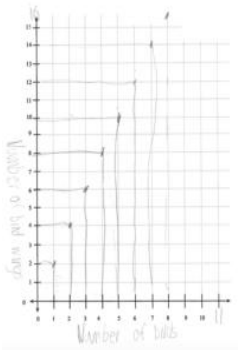

Figure 2: Levi's written work on the graph in his third interview

Summary of findings

To summarize our observations of Levi's progress, we present Table 2, which shows Levi's level of understanding of graphs in each of his three interviews. The table indicates that Levi demonstrated increasingly more sophisticated thinking over the course of the CTE.

Table 2: Levi's levels of understandings of graphs in his first, second, and third interviews

	Interviews		
	1	2	3
Function graph as object			
Functional inferences			
Condensed recursive inferences			
Emergent recursive inferences			
Condensed coordination of quantities			
Emergent coordination of quantities			
Interiorization of components			
Pre-interiorization			

Discussion

The goal of this paper was to describe how one student's understandings of function graphs shifted over the course of a CTE, and to highlight aspects of the lessons of the CTE that seemed associated with those shifts. In the results we presented Levi's understandings of function graphs. Here, we discuss characteristics of the lessons to illustrate how the lessons may have contributed to the shifts in his thinking. For the sake of brevity, we report on two lessons, 4 and 5, that we argue involved content that seemed related to the ways in which Levi reasoned about function graphs.

In lesson 4, students reasoned with a large, human-sized number line taped across the floor that represented the *x*-axis to represent the relationship between number of dogs and dogs' eyes. Students were familiar with a number line but had not yet used the Cartesian coordinate plane, so they practiced using a single number line representing the *x*-axis, with the intention of building on that representation. They reasoned about the relationship, plotting points and stating what quantity

represented. When students plotted points on the human-size number line, they walked them out and stood on the point. The goal was to help students *interiorize components* of the graph, namely the *x*-axis and points.

The lesson was also designed to create a need for the *y*-axis. The idea was that students would notice the challenges of representing two different quantities using a single number line and start experimenting with other ways of representing two quantities simultaneously.

In lesson 5, students continued reasoning about the relationship between the number of dogs and eyes. Students continued with the human-sized representation, but this time they used both the *x*- and *y*-axis. Each student had a paper graph as well to record their representation while the class interacted with the human-sized graph.

Because the axes were human-size, students walked out on the axes and Cartesian coordinate plane to represent quantities. We note this activity because we theorize that it may have contributed to developing a visual link between the axes and the quantities, which manifested as drawing guidelines to plot points on a paper graph.

In lesson 5, Levi plotted points on his paper by drawing guidelines from the axes and walked around on the human graph to represent points. Initially, we did not observe an indication that Levi was relating points or noticing a relationship between points. However, a group of students devised a new strategy of plotting new points based on the placement of previously plotted points. This strategy was shared with the whole class on the human-size Cartesian coordinate plane. We theorize that these moments may have helped students *interiorize the y-axis* and begin to think about the points in relation to each other, helping them reach the *emergent recursive inferences* level.

Later in this lesson we also observed that when Levi plotted the point (4, 8), he used the (3, 6) as a reference to "measure." Levi presented this method to the class, and the teacher-researcher asked the students to work individually and try Levi's method of "measuring." This moment affirmed that Levi's strategy was productive. This strategy also indicated that Levi was beginning to relate points.

We share these summaries of lessons 4 and 5 to highlight the ways in which these experiences contributed to developing Levi's reasoning about function graphs. We presume that students' understandings are intimately connected with the curricular progression in which these understandings were developed (Barrett & Battista, 2014; Clements & Sarama, 2014). That is, the trajectory that models Levi's reasoning is dependent on his engagement in the instructional sequence. Moreover, we highlight that these are just two of the 14 lessons in the instructional sequence while reminding readers that lessons were structured similarly throughout the CTE, using repeating representations and functions, but varying the context of the functional relationships.

Conclusion

Levi's thinking in each of his three interviews grew more sophisticated over the course of the CTE. We are impressed with the levels of sophistication of Levi's thinking throughout the CTE, as he only experienced instruction on graphs for a short period of time. We argue that if algebraic representations were woven more consistently throughout mathematics curriculum, we envision that students would more frequently demonstrate these sophisticated ways of algebraic thinking. Aligning with others, particularly those who have conducted longitudinal studies (e.g., Blanton et al., 2015; Dougherty, 2008), we argue that children would benefit from sustained opportunities to reason algebraically to develop "algebraic habits," such as mathematizing unknown quantities and relationships (Blanton et al., 2015, p. 545).

We also view these results as evidence of the power of representations as a tool for enabling students to see things they may not see otherwise. When incorporated properly into instruction, representations are tools that can help students do things more easily or do things they could not do alone (Hiebert et

al., 1997). In fact, Levi's reasoning confirms that representations "enable some thoughts that would hardly be possible without them" (Hiebert et al., 1997, p. 53). Consider his observations about relationships between points.

We also highlight the power of representations for cognitive scientists. We presume the representations mediated Levi's mathematical thinking and supported us to see Levi's "unseen" ideas (McCormick et al., 1987) about functional relationships. That is, in our study, the graphs were products and interpretations of ideas about how Levi advanced his understandings of functional relationships. With this lens, we can better understand students' developing understandings of the concept being represented through the representation itself.

Teachers' conceptualizations of slope in teaching Grade 8 students

Marios Pittalis[1] & Panagiotis Gridos[2]

[1]University of Cyprus, Department of Education, Cyprus; m.pittalis@ucy.ac.cy

[2]Mathematics Education and Multimedia Laboratory, University of the Aegean, Rhodes, Greece; p.gridos@aegean.gr

This study explores how Grade 8 mathematics teachers introduce the concept of slope and the specific conceptualizations they emphasize. The research involved observing six lessons from two Grade 8 teachers. The findings revealed that the teachers addressed six distinct conceptualizations of slope: geometric ratio, real-life physical property, parameter, linear constant, behavior indicator, and real-life functional situation. Teachers predominantly relied on a visual approach to teach the geometric ratio conceptualization. Despite introducing multiple conceptualizations, there was limited time for students to independently explore and connect these ideas. While both teachers covered the same slope conceptualizations, they differed in their emphasis on explanations, procedures, and connections, such as constructing triangles to visualize the ratio of vertical to horizontal displacement or using the algebraic formula.

Keywords: Slope, functional thinking, covariational reasoning.

Introduction

Slope is a fundamental concept in mathematics education, essential for understanding linear functions, graphical interpretations of functions, and rates of change (Diamond, 2020; Teuscher & Reys, 2012). It plays a critical role in the study of linear functions, typically introduced in Grade 8, and extends throughout secondary school to encompass the description of non-linear functions and pre-calculus concepts (Cho & Nagle, 2017). Grasping the concept of slope is closely tied to a covariational approach to functions, which involves viewing a function as a process of covariation—focusing on how the dependent variable changes in relation to the independent variable (Thompson & Carlson, 2017). Despite its importance, students often struggle with isolated meanings and misconceptions related to slope. These challenges are further compounded by the varying conceptions held by teachers and the procedural emphasis prevalent in many textbooks (Dolores et al., 2020; Lingefjärd & Farahani, 2018).

Although previous research has explored students' and teachers' conceptualizations of slope, there is limited knowledge about how teachers introduce and develop this concept in classrooms. This study aims to investigate how teachers conceptualize and introduce slope in Grade 8, focusing on their instructional strategies, the connections they emphasize, and their approach to balancing procedural and conceptual knowledge.

Theoretical Framework

Conceptualizations of Slope

Slope has been regarded as a measure of various attributes, depending on the quantities involved in the relationship, and involves constructing a ratio or rate to measure the given attribute (Lobato &

Thanheiser, 2002). In secondary mathematics curricula, slope is presented in multiple forms: geometrically as the $rise/run$ ratio, representing the steepness of a line; algebraically as the parameter m in the equation $y = mx + b$ or through the formula $\frac{y_2-y_1}{x_2-x_1}$; trigonometrically as the tangent of the angle of inclination of a line; in calculus as a limit; and in real-world contexts as a measure of the steepness of physical situations, such as mountain roads and ramps, or in functional scenarios where slope represents the rate of change (Stump, 2001). Moore-Russo et al. (2011) expanded on Stump's (2001) model and identified eight different conceptualizations of slope: geometric ratio, algebraic ratio, physical property, functional property, parametric coefficient, trigonometric conception, calculus conception, and real-world situation, along with determining property, behavior indicator, and linear constant. Nagle and Moore-Russo (2013) further refined this framework, distinguishing between procedural and conceptual understanding, as well as visual and analytic interpretations, to propose five general components of slope: constant ratio, trigonometric conception, behavior indicator, calculus conception, and determining property.

The constant ratio component encompasses geometric ratio, algebraic ratio, and linear constant conceptualizations (Nagle & Moore-Russo, 2013). The geometric ratio involves visual methods like $rise/run$ or $vertical/horizontal$ change in a line graph, while the algebraic ratio focuses on the nonvisual expression $\frac{y_2-y_1}{x_2-x_1}$; , independent of specific points on the graph. The linear constant conceptualization, crucial for understanding slope as a constant rate of change between two varying quantities, highlights recognizing slope as a consistent ratio for linear functions. Visually, this is represented by the uniform straightness of a line on a graph, regardless of the segment chosen, and by distinguishing between constant and varying rates of change (Johnson, 2015).

The behavior indicator conception of slope includes a visual approach, identifying whether a linear function increases, decreases, or remains constant, and correlating the slope's sign with the directions of rise and run (Stump, 2011). The non-visual approach links the slope's sign to the relationship between changes in y and x. Additionally, the parametric coefficient, m, in the slope-intercept form $y = mx + b$, represents a non-visual approach to this conception. The determining property conception involves visually assessing whether linear graphs are parallel, intersect, or how they intersect, while algebraically, it assesses whether two linear relationships form a solvable system and the number of solutions. The calculus conception, related to limits and derivatives, is typically studied in upper high school. In real-world contexts, slope is conceptualized as either a measure of physical situations, such as the steepness of roads and ramps, or functional situations where it represents the rate of change between covarying quantities, like in distance-time scenarios (Stump, 2001).

Researchers have highlighted the need to connect different conceptualizations of slope to build a deep conceptual understanding (Hoban, 2021). Each conceptualization of slope is a crucial component of a broader network of understanding (Nagle & Moore-Russo, 2013). Teuscher and Reys (2012) emphasized the importance of helping students distinguish between slope, rate of change, and steepness, and to make the correct connections among them by exploring both visual and non-visual approaches and applying these concepts in real-world contexts.

Teachers' Conceptions of Slope and Teaching Practices

Numerous studies have examined how preservice and in-service secondary school mathematics teachers conceptualize slope worldwide (Byerley & Thompson, 2017). Research by Mudaly and Moore-Russo (2011) found that the most common conceptualizations among practicing teachers were the parametric coefficient and behavior indicator, while real-world situations and physical properties were less emphasized. Similarly, Byerley and Thompson (2017) noted that most secondary teachers focused on additive and formulaic meanings of slope, with few addressing slope as a rate of change. Stump (1999) also noted that few teachers incorporate ratio in teaching slope and tend to prioritize procedural methods over conceptual understanding (Lingefjärd & Farahani, 2018). Consistent with Nagle and Moore-Russo (2013) and others, López et al. (2024) found that teachers often emphasize procedural aspects of slope, making it difficult for students to connect slope with concepts like rate of change and steepness. This focus on procedures, such as the "rise-over-run" mnemonic, contributes to a limited understanding of slope (Birgin, 2012).

Researchers have highlighted a gap between teachers' conceptual understanding of slope and its classroom implementation (Nagle & Moore-Russo, 2013). Although teachers intend to teach slope conceptually, they often default to procedural tasks in practice. Nagle and Moore-Russo (2013) revealed that teachers frequently emphasize algebraic ratios, parametric coefficients, and real-world applications in instructional materials, neglecting other important concepts like determining property and functional property. López et al. (2024) further found that teachers prioritize constant ratio and trigonometric conceptions while overlooking the variational aspects of slope.

Methods

Participants, Setting, Procedure, Data Collection and Analysis

Two Grade 8 teachers from an urban gymnasium in Cyprus participated in this study. Both recently completed pedagogical training at the University of Cyprus, had less than five years of public-school experience, and around 15 years of private tutoring experience. They voluntarily agreed to have their lessons on slope observed. The researcher did not influence lesson planning, allowing the teachers to design their lessons independently. Each teacher taught three classes, involving 116 students. Students were informed about the study's goals and encouraged to freely share their thoughts during lessons. Parental consent and student assent were obtained.

The Cyprus mathematics curriculum for Grade 8 includes attainment targets that emphasize understanding the slope of a line as the ratio of the vertical displacement (Δy) to the horizontal displacement (Δx). It also explores the role of the parameters a and b in the graph of the line $y = ax + b$. The official school textbook defines slope as the ratio of the vertical displacement (Δy) to the horizontal displacement (Δx), referring to this as the rate of change. Additionally, the book provides the formula $\frac{y_2-y_1}{x_2-x_1}$ for calculating the ratio $\Delta y/\Delta x$ and defines the slope for the special cases $y = a$ and $x = b$. Furthermore, the book states that the slope of the line $y = ax + b$ is equal to the coefficient of x. Finally, it illustrates the graph of a line with positive and negative slopes. According

to the official guidelines, three to four teaching hours can be used for the teaching of slope. Slope is part of a larger unit, consisting of around 16 teaching hours on functions.

The two teachers dedicated three lessons, each lasting 45 minutes, to teaching slope, followed by an additional hour for revision, which included linear functions. The researcher observed three consecutive lessons in one class for each teacher to maintain consistency in student interaction. Although both teachers taught multiple classes, they reported that all Grade 8 classes performed at a similar level, allowing them to use the same lesson plans across all groups. Classroom data were collected using an audio recorder placed centrally in the room during each lesson. Two researchers attended each session to take field notes, focusing on whole-class discussions, teacher explanations, and feedback, as group work was minimal. No formal observation protocol was used to preserve the authenticity of the teachers' language and actions.

The study collected audio recordings, observations, and field notes from six mathematics lessons, focusing on the depth and connections in teachers' conceptualizations of slope. Audio recordings were transcribed and enriched with observers' notes, capturing teachers' actions, selected materials, explanations, examples, and class discussions. A qualitative interpretive framework guided the data analysis (Miles & Huberman, 1994), using a coding scheme based on frameworks by Moore-Russo et al. (2011), and Nagle and Moore-Russo (2013). The scheme differentiated between various slope conceptualizations, including geometric and algebraic ratios, physical properties, and rates of change, and was enriched with teachers' explanations and examples.

Results

Analysis revealed that during the three lessons focused on the concept of slope, both teachers covered most of the slope conceptualizations introduced in Lesson 1. Teacher 1 primarily used the geometric ratio approach as the central theme, building upon it when introducing other concepts. In contrast, Teacher 2 initially engaged students with the idea of slope as the physical property of steepness, subsequently connecting this to slope as a geometric ratio through relevant examples.

In Lesson 1, the teachers introduced five different conceptualizations of slope: geometric ratio, real-life physical property, parameter, linear constant, and behavior indicator (see Table 1). Teacher 1 mentioned that slope could be analyzed as a rate of change, a concept to be explored in subsequent lessons. Teacher 2 implicitly referenced the rate of change by explaining that the ratio of vertical to horizontal displacement, as illustrated by a ramp, represents the height gained for every meter of horizontal displacement. Both teachers involved students in understanding slope as a physical property. The activities explored slope as a geometric ratio and as a parameter, while the linear constant was implicitly addressed through tasks involving calculating the slope of a line using different pairs of points. In the lesson's conclusion, the teachers introduced the behavior indicator to explain the slope of special cases of lines. Teacher 1 focused on demonstrating and calculating slope as geometrical ratio, by constructing a triangle on the graph. She introduced this method as the simplest to determine a line's slope. Using the graph, she illustrated that the triangle's vertical side represents the vertical displacement (Δy), while the horizontal one represents the horizontal displacement (Δx). She provided practical advice on how to calculate this ratio, recommending starting from left to right by first constructing the horizontal displacement, and then the vertical

displacement. For a line with negative slope, Teacher 1 noted that a negative sign must be added manually, as the final movement is downward. She emphasized that the triangle should always be constructed on the right side of the line. Teacher 2, on the other hand, emphasized that whether a line inclines or declines determines the sign of the ratio $\frac{\Delta y}{\Delta x}$. Contrary to Teacher 1's approach, Teacher 2 introduced the algebraic ratio as an alternative way to calculate slope. She explained that for any two points A(x_1, y_1) and B(x_2, y_2), the slope is calculated using the formula $\frac{y_2 - y_1}{x_2 - x_1}$.

In Lesson 2, no new slope conceptualizations were introduced. In the introductory activity, Teacher 1 connected the concept of slope as a physical property of steepness with the behavior indicator to explain the slopes of specific types of lines ($y = a$ and $x = b$). She illustrated how the sign of the ratio Δy/Δx correlates with the behavior of the line, indicating whether it is inclining or declining. Graphically and algebraically, she demonstrated that for the line $y = a$, the numerator in the ratio Δy/Δx is zero, resulting in a slope of zero. In contrast, for the line $x = b$, the denominator is zero, which means the slope is undefined. Teacher 2 also focused on the slope of these special cases, using slope as steepness to clarify. She pointed out that the line $y = a$ is flat, neither ascending nor descending, while the line $x = b$ is vertical to the horizontal axis, making it infinitely steep, and thus, the slope cannot be defined. Additionally, she stressed that if the equation of a line is given in the standard form $y = ax + b$, then 'a' represents the slope. She dedicated significant time to tasks that required transforming equations into the standard form to easily identify the slope.

Table 1: Conceptions of Slope as Introduced by Teachers

Slope Conceptualization	Teacher 1	Teacher 2
Visual Geometric ratio: Vertical displacement over horizontal displacement	Formal definition of slope is introduced based on this conceptualization. It includes constructing a triangle to visualize vertical displacement over horizontal displacement, defining vertical and horizontal displacement as Δy and Δx respectively. Students are tasked to calculate the ratio Δy/Δx for lines with positive or negative slope.	Students explore the concept through a textbook activity featuring skateboard ramps. While discussing slope as steepness, they connect it to the geometric ratio, concluding that with equal bases, the steeper ramp is higher, and with equal heights, the steeper ramp has a smaller base. **Linking steepness to the formal definition of vertical and horizontal displacement**, the ratio Δy/Δx represents the slope, indicating the steepness of the line or ramp.
Parametric coefficient	The ratio Δy/Δx is labeled as m. Students are tasked with observing that the ratio Δy/Δx equals the parametric coefficient in the standard form of the line $y = ax + b$.	If the equation of the line is given in the standard form line $y = ax + b$, then a is the slope. Students are tasked to identify whether given equations are given in the standard form to identify the slope.
Physical property – steepness	Students are engaged in the concept through an exploration activity from the school textbook, which presents skateboard ramps. Slope is related to real-life scenarios, such	Students discuss steepness by comparing the four ramps of the school textbook exploration activity. Students are prompted to consider steepness quantitatively as a measure of the meters of height

	as mountain roads, uphill and downhill terrains.	gained in relation to one-meter horizontal displacement.
	Special cases lines $y = a$ and $x = b$: A runner runs on a flat surface, so the slope is zero. A human cannot walk on a walk; thus, it can be supported that slope is undefined.	A line of a graph can be viewed as a large ramp, where the goal is to calculate and express the degree to which the line ascends or descends.
Behavior indicator	Connection of the sign of the ratio $\Delta y/\Delta x$ with the direction of the vertical vector when constructing the triangle that defines the vertical and horizontal dsiplacement.	An alternative method simplifies the process by first finding the absolute value of $\Delta y/\ \Delta x$ and then determining the slope's sign. The slope is positive if the line ascends from left to right; otherwise, it is negative.
Linear constant conceptualization	An implicit connection to linear constant conceptualization by concluding that the calculated slope is the same regardless of the selected points.	Clarification that the ratio of vertical to horizontal displacement is constant for any two points on a line, which is a characteristic feature. The algebraic ratio is provided
Real-word situation: Functional situation	Use of a real-life problem involving a functional relationship. The formula is given, and students are tasked to interpret the intercept and slope.	Students are tasked with identifying the variable and constant measures in the real-life problem make appropriate connections to the slope and intercept.

In Lesson 3, both teachers concentrated on applying the concept of slope to real-world functional situations. Students tackled two problems involving quantities connected by a linear relationship. In the first problem, they were given the formula and needed to identify and utilize the slope. The second problem presented a verbal description of a linear relationship, requiring students to write the corresponding formula. In both scenarios, the teachers emphasized interpreting the slope as the rate of change between the two quantities. They asked questions that encouraged covariational reasoning, such as calculating how the dependent variable changes in response to uniform increments in the independent variable. The increase in the dependent variable for each unit increase in the x-value was also illustrated on a graph. Teacher 1 aimed to link the concept of slope and rate of change specifically to the scenario at hand (e.g., the rate of height increase) by relating it to the vertical-to-horizontal displacement ratio while constructing the graph. Meanwhile, Teacher 2 described the slope as an indicator of how quickly the dependent variable increases within the scenario, while also identifying the intercept value as the constant parameter in the situation.

Discussion

The analysis revealed that teachers addressed six different conceptualizations of slope, either explicitly or implicitly: geometric ratio, real-life physical property, parameter, linear constant, behavior indicator, and real-life functional situation. This finding is consistent with previous research (Stump, 1999). Moreover, it was found that teachers predominantly used a visual approach to the geometric ratio conceptualization. This approach, which involved the ratio of vertical to horizontal displacement, was emphasized in several activities during the first two lessons. Although the teachers

introduced five different conceptualizations in the first lesson, there was insufficient time for students to explore and connect these different conceptualizations or form their own interpretations. The teachers attempted to link different representations and slope conceptualizations through their explanations. This included interpreting the slope's sign as a behavior indicator, calculating the geometric ratio as vertical to horizontal displacement, and then determining the sign based on the line's behavior. Most of the explanations, repetitions, and guidance focused on constructing the appropriate triangle to illustrate the geometric ratio. This finding supports Leong and Chick's (2011) claim that time constraints can lead to direct teaching approaches and reduce opportunities for students to engage in independent exploration.

Although both teachers used the same teaching material, lesson plan, and addressed the same slope conceptualizations, they emphasized different explanations, procedures, and connections. This could lead to students having fragmented or incomplete understandings of the concept and inconsistent comprehension among different groups of students. For instance, one teacher focused on constructing a triangle to demonstrate, calculate, and determine the slope's sign, while the other offered the algebraic ratio as an alternative method. Furthermore, the first teacher spent considerable time calculating the slope of a line using different pairs of values, whereas the second teacher concentrated on transforming the equation of a line into the standard form. Neither teacher's explanations included interpreting the geometric ratio as a rate, such as determining the vertical displacement for different changes in the horizontal displacement (Byerley & Thompson, 2017). This concept could have been reinforced by constructing triangles of different sizes. Additionally, in the third lesson, there was no connection between the contextual interpretation of the rate of change and the geometric ratio studied in the first two lessons. The findings of this study highlight key educational implications for teaching the concept of slope in Grade 8. Slope is fundamental in mathematics, and adequate teaching time is crucial. Rushing through multiple conceptualizations without providing sufficient time for exploration and understanding can lead to superficial learning and poor conceptual approaches.

Furthermore, professional development programs for teachers should emphasize the importance of connecting conceptualizations of slope to real-world applications and rates of change. Teachers should be encouraged to incorporate a variety of teaching strategies, such as connecting the geometric ratio to contextual problems and encouraging students to explore different representations through hands-on activities. Additionally, teacher education programs should focus on equipping educators with the skills to present the geometric, algebraic, and contextual interpretations of slope cohesively. This includes addressing how different approaches—such as graphical or algebraic—can complement each other, reducing the risk of fragmented student understanding.

Cartesian graphs and co-variational thinking in early algebra

Luis Radford

Laurentian University, École d'éducation, Sudbury, Canada; Lradford@laurentian.ca

The aim of this article is to contribute to the existing body of research on the understanding of graphs by young students. To this end, I draw on the theory of objectification and focus on the processes of conceptualizing co-variation between continuous variables when Grade 6 students, aged 11–12, interpret a given graph. The context is a dynamic one, namely, the interpretation of a Cartesian graph representing the movement of a body. The findings suggest that, initially, based on perceptual understandings, the students conceptualize the graph as a map, without co-variation being a central aspect of their analyses. Furthermore, the students' perceptual understandings give rise to some contradictions. However, these are gradually resolved as the teacher engages with the students in exploring the graph and new cultural-historical understandings of co-variation emerge.

Keywords: Motion graphs, theory of objectification, co-variational thinking

Introduction

Although research on early algebra has produced a wealth of results in recent years, research on young students' understanding of Cartesian graphs has not received much attention. Indeed, in their recent literature review, Cañadas et al. (2024) note that studies investigating how elementary students construct, use, or read graphs are almost nonexistent. Yet, graphs are known to provide rich functional contexts for learning about variables and their co-variation (Blanton et al., 2018; Kaput, 2008; Kieran, 2016; Robert, 2024). When studied, Cartesian graphs have often been featured in connection with a new functional mode of representing *discrete* data in x/y tables—see, e.g., Cañadas et al. (2024), Carraher et al. (2008), and Tierney and Monk (2008). In this case, graphs are constructed from a functional relation between x and y variables (e.g., $y = 2x+1$), instances of which lead to points (x, y) in the Cartesian plane. In this paper, I focus on a different type of Cartesian graph: a given Cartesian graph representing the *motion* of a body. Understanding such a graph requires *conceptualizing* the co-variation between the inherent *continuous* variables of time and space. Inspired by Carlson et al. (2002), I consider co-variational thinking as the embodied, semiotic, and material cognitive activity "involved in coordinating two varying quantities while attending to the ways in which they change in relation to each other" (p. 354). The research question I seek to answer is how students come to conceptualize the co-variation of two variables—time and distance—in a given Cartesian graph.

Theoretical framework

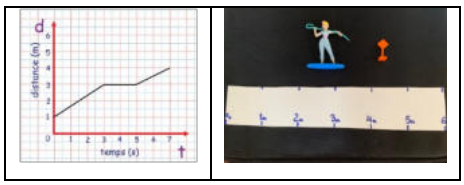
The theoretical framework followed in this paper is based on the Vygotskian theory of objectification (TO) (Radford, 2021). In accordance with the TO, the students' conceptualization is part of a sense-making process: the *process of objectification* (p. 86); that is, the social process in which teachers *and* students engage in sensuous and material activity as they proceed to encounter, examine, and explore cultural-historical mathematical meanings—in the case of this paper,

mathematical meanings related to Cartesian graphs. This teacher-and-students' sense-making process is a creative, imaginative, affective one entrenched in classroom teaching-learning activity. It finds support and expression in language, signs, artefacts, interactions, gestures, and the body more generally.

Methods

The method to investigate the research question is the dialectical materialist one proposed in the TO (Radford, 2015). This means that *the methodological explanatory category* is the *teaching-learning activity* that anchors the various multi-modal and material connections that teacher and students create as they produce ideas to explore and understand the cultural-historical meaning of Cartesian graphs. The teaching-learning activity is designed in a way that allows the students to work in small groups of three or four and encourages the students to work together in the production of what in the TO is called *une oeuvre commune* (a common artistic work): a collectively built idea about how—in the case of this paper—to interpret graphs. We use four or five video cameras and make transcriptions that are then subjected to multi-modal analyses (Radford, 2021). The data presented below come from a recorded lesson conducted in a Grade 6 class (11–12-year-old students) in a French public school in Sudbury, Canada. In this paper I focus on one of the small groups (chosen for its paradigmatic nature)—a kind of case study. Case studies are limited in terms of the generality of their results. However, they allow in-depth explorations of the research problem. The lesson was preceded by a lesson in which the students had access to a video showing a remotely controlled battery-operated train moving at constant speed in a graduated straight line. They were asked to produce a Cartesian graph of the train's motion. In the lesson featured in this paper (which is an adaptation of a lesson conducted in a Grade 8 class; see Radford, 2009), the graph was given. Here is the problem.

The problem and the first graph interpretations



"Tina is 1 metre from a fountain. She walks on a straight-line path. The graph represents her walk. Give a precise description of Tina's walk." Unlike the lesson in Grade 8, the teacher equipped each group with a kit containing a figurine representing Tina, an object representing the fountain, and a flat, graduated cardboard path to enact Tina's walk. I focus here on one of the groups of three students: D., L., and B.—two girls and a boy, respectively (see Fig. 1.1 below) (Fig m.n refers to pic n, from left to right, in Figure m).

The first interpretation:

D: Huh! Tina starts here (*pointing at (0, 1)*). Then the fountain is here (*pointing at (0, 0)) (Fig. 1.1)*).

L: Yes, but how do we find the time?

D: Time is here. (*She slides her finger along the t-axis*) (*Fig. 1.2*) ... So, from 1 (*she points at (0, 1*)) to here (*she points at (3, 3)*), she did 3s (*Fig. 1.3*). Then, from there (*she points at (3, 3), Fig. 1.4*) to there (*she points at (5, 3), Fig 1.5*), she did 5s .... And

then, from here (*she points at (5, 3)*) to there (*she points at (7, 4)*), *Fig. 1.6*) (*she lowers the pen vertically from (7, 4) to (7, 0)*), she did 7s.

Figure 1. Pic 1, from left to right, B., L., and D. The students' first interpretation

In this episode, D. offers a first explanation of the graph based on an interpretation of it as a *map*. She places the figurines of the fountain and Tina at points 0 and 1 of the cardboard, respectively. Then, the attention moves to the graph. The explanation is not clear to L: "You have to explain, I don't understand." D. responds trying to make more explicit her understanding of the graph as a map:

D: Since she came here (*she slides the pen from (0, 1) to (3, 3)*), she went 3m and 3s. She arrived here (*points at (5, 3)*) … 3m and 5s; then, she went straight (*points to graph horizontal segment*).

L: Ok, Ok! Wait! Wait, 1m, it's 7s.

D: No! ... From here (*points at (0, 1)) to there (points at (3, 3)),* it's 3m and 3s. Also, from here (*points at (3,3)*) to here (*points at (5,3)*) it's 5s.

L: Ahhh! So, what's 7s?

D: From here (*points at (5, 3)*) to there (*points at (7, 4)*), it's 7s.

In D.'s interpretation, the t-axis is not conceptualized as a Cartesian variable, the values of which are referred to as a starting point. In her eyes, the numbers on the t-axis are seen as labels or stickers that indicate the duration of the segments that comprise Tina's walk.

L. states that she remains uncertain as to the appropriate explanation for Tina's walk. The teacher comes to see the group. The students explain their current interpretation:

L: (*Referring to the first graph segment*) Tina walks … 3s.

T: So, at 3s, where is she?

D: At 3m. Then (*moving her finger along the horizontal segment*), she walks straight ahead 5s …

T: Does she walk straight ahead? (*She moves her finger across the graph's horizontal segment*) How long?

L: The distance? We can count (*counting horizontal lines on the grid*) 1, 2, 3, 4.

T: (*Pointing to the vertical axis, she calls the students' attention to the fact that the vertical axis indicates the distances. Talking to B. to involve him in the conversation*) What do you see here?

B: The actions Tina did … the meters …

The teacher echoes B.'s remark, emphasizing that the distance is measured along the vertical axis (Fig 2.1) and leaves. The students keep discussing.

The second interpretation: About 5 minutes later, B. suggests a new interpretation based on the vertical axis: "I'm confused, (but) I'll explain. Uh, uh, I don't know. But maybe it's like … like, Tina walked 1 (meter). (*He points at (0, 1*) *on the Cartesian graph; see Fig. 2.2*). She still goes like ... she goes here (*points at (0, 3)*). And then, she goes here (*points at (0, 4)*), and she's here now (*pointing again at (0, 4)*). Maybe it's like this."

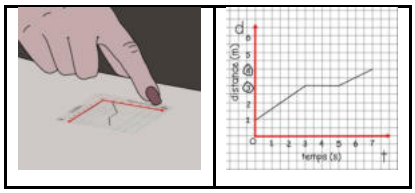


Figure 2. The second interpretation

B.'s interpretation speaks of distance and time in a new manner. Through verbs, B.'s interpretation involves the temporal dimension: Tina *walked*, she *goes here*, but in an unquantified manner. Distance, by contrast is quantified. On the d-axis, B. circles numbers 3 and 4 (see *Fig. 2.2*). It is perhaps the implicit role of time in B.'s interpretation that his teammates find unconvincing; D. and L. go back to the map interpretation of the graph again, as if trying to find something that would so far remain unnoticed.

Third interpretation: L. suggests a third interpretation: "[Tina] started at 1m (*Fig. 3.1*). Then, at three seconds (*she points at 3 on the horizontal axis (Fig. 3.2*) *and slides the pen vertically to point (3, 3); Fig. 3.3*), she continued to 3m (*she points at (0, 3)*) (*Fig. 3.4*); (*repeating*) she continued to 3m (*but now, inspired by what B. said, she moves the pen horizontally to the point (3, 3),*). Then, she continued straight on from 3s to 5s, (*moving the pen along the graph's horizontal segment*), but within 3m (*Fig. 3.5*). Then, she went up ... (*showing the end point of the graph*) to 7s" **(***Fig. 3.6***).**

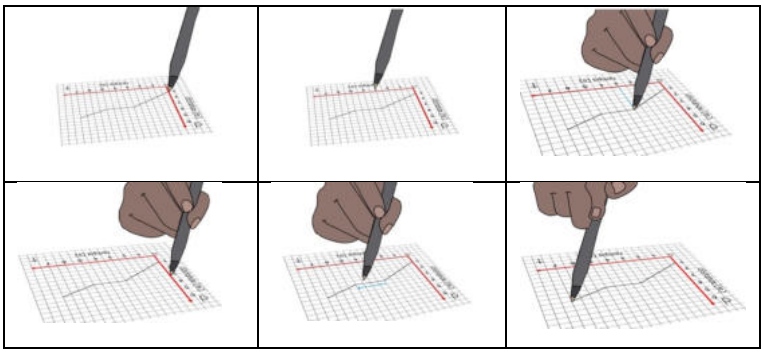

Figure 3. The third interpretation

The interpretation of the horizontal segment persists. But now, *time becomes the main organizer of students' thinking*: at 3s something happened; between 3s and 5s, something else happened, etc. However, the students are not yet satisfied. A few seconds later, L. produces a sharper interpretation: "She started at 1m, ok (*she points at (0, 1); Fig. 4.1*). That's the starting point; and now, at 3s, she was already at 3m (*places the pen between (3, 0) and (3, 3)*; *Fig. 4.2)*. Then, pointing to the horizontal segment, she continued straight on, right? Then at 5s, she started to climb to get to 4m, and at 4m, she is at 7s. Do you understand?"

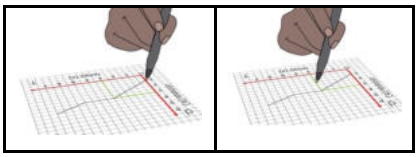

Figure 4. The third interpretation refined

Now, time and distance become related in what we can recognize as a nascent functional interpretation of the graph. Time appears for the first time as a variable; instantiations of the variable (e.g., "at 3 seconds," "at 5 seconds") are put into correspondence with instantiations of the distance seen also as a variable. Yet, the nascent functional interpretation is still haunted by the idea of the graph as a map: the horizontal segment keeps being seen as Tina walking straight on; and in the last segment, Tina is said to climb to 4m. The students start writing their interpretation: "In the beginning, Tina was at 1m and 0s. Then, she walked 3m at 3s. She is at 3m and 3s."

Dealing with the contradictions

When the teacher comes back to see the group, D. offers an explanation that makes the inherent contradictions more visible. D explains: Tina is at "3m and 3s (*she points at (3, 3)*) … Then in the middle of her walk (*she points at (4, 3))* she's still at 3m (*pointing to the horizontal segment*), but she's done 4s (*pointing at (4, 0)*). Then she continued to walk at 3m" (*She moves her pen from left to right on the graph's horizontal segment to indicate Tina's motion*). The contradiction is this: between 3 and 5 seconds, the students imagine that Tina keeps walking while still being at d=3. The teacher encourages the students to keep thinking: "I want you to tell me what happened here (*she points to the horizontal segment*). What do you notice here? What can we add to [the description of] the walk?"

Vygotsky suggested a systemic view of concepts: a concept is formed of dynamic connections between its parts (internal connections) and connections with other concepts (external connections). What distinguishes the concepts that children form in the course of subjective experiences (e.g., "spontaneous" or "quotidian" concepts) from "scientific" concepts is precisely the *nature* of their constitutive connections. Spontaneous concepts often exhibit a *syncretic perceptual understanding* of phenomena. These concepts are based on perceptual connections that form ad hoc *wholes* or *complexes.* Thinking in terms of these perceptual-based connections is what Vygotsky called "complexive thinking" (Vygotsky, 1987, p. 136). What lends "scientific" concepts their particular nature is the cultural-historical character of their internal and external connections. I want to contend that complexive perceptual-based connections are what lead to the perception of Cartesian graphs as maps. Understanding graphs in a Cartesian contemporary mathematical meaning entails

becoming aware of its parts: the meaning of the axis, the identification of variables and their co-variational nature (qualitatively and quantitatively)—among other things. The *movement* from complexive thinking to the Western scientific-mathematical co-variational thinking is not a natural process. In the theoretical framework followed here, the name of the process that makes this movement possible *is teaching-learning activity* (Radford, 2021). In teaching-learning activity, *the teacher works hand in hand with the students*; they collectively generate ideas and novel interpretations of the problem at hand. In this lesson, to help the students deal with the contradictions, the teacher suggested that they use the manipulatives. Initially considered by the students, the manipulatives were ultimately set aside. While manipulatives (or artefacts, more generally) are undoubtedly valuable, they may not always be a stand-alone solution for fostering cultural mathematical thinking. The efficacy of artefacts hinges not only on their intrinsic properties but also on their *integration* and use in the teaching-learning activity. Thus, encouraged by the teacher, the students started placing Tina at 1m from the fountain.

L: She moved forward 2m (*Fig. 5.1*)… at 3s (*The teacher moves Tina to the point marked 3*).

T: Ok, at 3s. Now, what's happening? She's here, isn't she? (*She points at (0, 3) on the graph while pointing to Tina in the manipulative model*). What happens with her walk?

D: She walks straight on, uh … she walks straight ahead in 3m and 5s.

T: She's still at 3m (*see Fig.5.2)*, but she moves forward …?

L: (*As saying something obvious*) At 3m she moves forward 2s!

T: (*Inviting the students to reconsider*) Does she move forward?

L: Yes! She moves forward 2s!

T: There is some time elapsing here (*she points at the t-axis*), but the distance (*pointing to the horizontal segment in the graph*), does it increase or decrease? … Tina is here (*Fig. 5.3*) … Time elapses (*pointing to the t-axis; Fig. 5.4*). But how long?

L: 2s …

T: Ok. 2s. And *here*, (*touching Tina (Fig. 5.5) and pointing at (0, 3) (Fig. 5.5)*); look at Tina's distance when she was at 3m (*making a sliding gesture pointing at the horizontal segment while keeping the figurine motionless (Fig. 5.6)*). Did she move?

B: No!

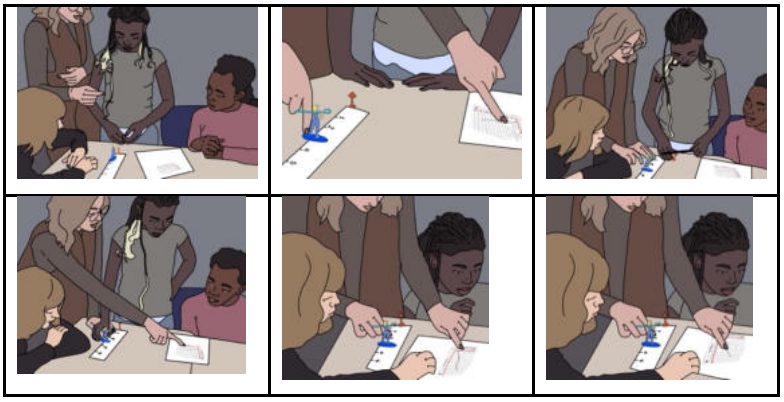

Figure 5. Teacher and students working together

At that moment, the students realized that, in the interpretation of the horizontal segment, changes in one of the variables do not necessarily lead to changes in the other. This new aspect of co-variational thinking had been hindered by the initial percetual sense of the graph as a map. Working hand in hand with the students, the teacher manages to open a new dimension in the conceptualization of Cartesian graphs through a fine-grained link of the enactment of Tina's walk on the cardboard path and the graph. The horizontal graph segment now appears to mean that time elapses while the distance remains the same, thereby overcoming a contradiction that haunted the students' first interpretations of the graph.

The text that the students produced in response to the activity requirements was the following: "In the beginning, Tina did (1m) and (0s). Then she ~~walked~~ advanced (2m at 3s) so she is at (3m and 3s) and 2s pass but she doesn't move so she is at (3m and 5s). Finally, she climbs (1m and 2s) which gives (4m and 7s)." Contradictions still remain. The text is still cast in the rhetorical style of the phenomenological apprehension of the graph as a map: for example, we are told that, in the last segment, Tina climbs. There is still room to move closer to a co-variational description of events. Yet, the ongoing students' encounter with a cultural-historical co-variational understanding of motion graphs paves the way to engage in further reflective mathematical experiences.

Concluding remarks

This paper seeks to contribute to a notorious underrepresented topic in early algebra: the students' understanding of graphs. Cartesian graphs possess an historical epistemological density that may hide its meaning from novice young students, as shown by the example discussed in this article. In our study, which featured a motion graph, drawing on syncretic perceptual understanding of phenomena, the students tended to interpret the given graph as a *map*. D. suggested a first interpretation. In it, thinking about the graph was not organized in terms of Cartesian variables—i.e., variables referred to a certain arbitrary spatial and temporal origin. As the teaching-learning activity unfolded, B. drew on D.'s ideas and on a teacher's hint to formulate a second interpretation where the focus is distance while time remains unqualified. In turn, L. drew on the previous interpretations and formulated a third one, where variables became better identified, although their co-variational nature remained obstructed by the persistent perceptual sense of the graph as a map. At the end of the lesson, drawing on the students' ideas, through a fine-grained link of the enactment of Tina's walk on the cardboard path and the graph, the teacher created room for the students to become conscious of a new meaning of co-variation that discloses the possibility that changes in one of the variables does not necessarily lead to changes in the other. It is this movement of collective ideas that teacher and students form and voice while engaging in teaching-learning activity that we call *l'oeuvre commune*, the collective artistic embodied-intellectual-material work of the participants. The collective idea still requires further refinements, for as noted above, the students' text is still a vivid evocation of the graph as a map walk, rather than a mathematical sign expressing *relations* between variables, the quantities of which "change in relation to each other" (Carlson et al. 2002). "The child's thought [still] must be raised to a higher level for the concept to arise in consciousness" (Vygotsky, 1987, p. 169). This tension between the *perceptual* as the basis of sense that underpins the understanding of the graph as a map, and the *relational* as the basis of sense intended in co-variational thinking is part of the ontogenesis of co-variational thinking. It is

not something to avoid, but rather something to help us, educators, to better work with teachers and students.

Linking a table and a graph of a function: Slovak case

Daniela Šabaková[1], Ingrid Semanišinová[1]

[1]Pavol Jozef Šafárik University, Faculty of Science, Košice, Slovakia;
daniela.sabakova@student.upjs.sk

This paper investigates whether Slovak high school students can infer properties from the table representation of a function that help them link it to the graph of a quadratic function. 124 students (16-18 years old) solved a task focused on linking a table and a graph of a quadratic function without axes after they had completed learning about functions. The analysis showed that almost 88% of the students link these two representations of a quadratic function incorrectly. Moreover, the students' solutions also showed that they still had some significant misconceptions after learning about functions. Possible reasons for this are discussed in the conclusion.

Keywords: Quadratic function, representations of function, linking representations of function.

Introduction

In the media, in many scientific disciplines, etc., we often come across various graphs and charts that visualise certain dependencies. Data is coded in tables, plotted, and scientists try to find a relationship that describes the data and predicts its behaviour. Various researchers (Duval, 2017; Ronda, 2015; Leinhardt et al., 1990; Pittalis et al., 2020) point to the importance of linking different representations of functions and show that this linking can be difficult for students to grasp.

> ... the teaching of mathematics brutally reminds teachers that the distinction between mathematical objects and their multiple representations constitutes one of the main difficulties of understanding in the learning process. (Duval, 2017, p. 15)

The topic of function is introduced to Slovak students in elementary school (10–15-year-olds). It usually starts with examples of linear functions. This concept is easy for students to follow, but it can create a prototypical image (Hadjidemetriou & Williams, 2002) of a function, which can lead to several misconceptions (e.g., a graph is a line, a function must be a one-to-one function, or it must be only increasing/decreasing, etc.; see Leinhardt et al., 1990; Hadjidemetriou & Williams, 2002; Parhizgar et al., 2021). Later in high school students learn about different types of elementary functions, their representations and properties. The analysis of textbooks used by Slovak teachers showed that the most used transition is from a function equation to a function graph; little attention is paid to the other links (Šabaková, 2024). Together with equations and verbal descriptions, tables and graphs are part of the mathematics curriculum in Slovakia and students are expected to be able to link them in various ways, although the document explicitly mentions only linking graph and equation (ŠPÚ, 2014). This may be the reason that most attention is paid to the transition between the equation and the graph, since the wording of curriculum documents is the starting point for textbook writers and also influences the design of school curricula (Jukić Matić et al., 2022). On the other hand, several researchers emphasise the importance of linking different representations. Duval (2006) explains that the complexity of mathematical thinking is not only due to the concepts themselves, but is influenced by the transformations of the semiotic representations used in mathematics. He identifies

two different types of transformations that are crucial for mathematical understanding, treatment transformations (which involve the manipulation of mathematical objects and representations that students are already familiar with) and conversion transformations (which require students to switch between different semiotic registers, which is more complex and challenging). Although the conversion transformations tend to be more difficult for students, understanding and engaging with both types of transformations is essential for improving mathematical comprehension and learning.

This paper is part of a PhD thesis that focuses on linking different representations of elementary functions. Here we focus on linking two representations from different semiotic registers (a table and a graph) and investigate the depth of this link. We conducted research to find out what is the state of this knowledge in Slovakia. Do our students have the same problems as those described in the works by Ronda (2015) or Leinhardt et al. (1990)? This motivated us to investigate the answers to the following research questions: Which solution method do students prefer when linking a table with a graph of a function? Will the students' solutions reveal misconceptions?

Theoretical background

Learning about functions also means understanding the function as an object with its unique properties that can be identified across its different representations, and successfully linking these representations (Ronda, 2015; Leinhardt et al., 1990; Duval, 2006; Parhizgar et al., 2021; Jukić Matić et al., 2022). Each representation has its strengths and limitations, and "… knowing how to work with different representations of the function does not necessarily lead to the understanding the function." (Ronda, 2015, p. 305). The real understanding of the function lies in knowing what remains the same in what is represented, and what changes when we link different representations. Understanding this is essential for applying mathematical concepts to real-life situations (Duval, 2017; Ronda, 2015). Different representations emphasise different aspects of the function, for example, a graph can show trends over time, or some invariant properties, whereas in a table we can clearly see individual values of a function. Pittalis et al. (2020) highlight four different aspects of a function: 1) **input-output** (e.g., generation of function values from function rule); 2) dynamic process of **covariation** (e.g., noticing constant and/or linear rate of change, or how does the dependent variable change when the independent variable changes by 1 unit); 3) **correspondence** relationship (e.g., the ability to create a function rule); 4) **function as an object** (e.g., using invariant properties of the function). Thompson & Carlson (2017) consider the covariation aspect to be crucial in functional thinking. They describe this aspect in more detail and divide it into two: variation and covariation, each with its own levels of understanding. Correspondence relationship is harder to see in a table independently of covariation. The ability to see different aspects in a given representation can be helpful in linking representations. All aspects are closely related to the task-solving strategies described by Ronda (2015). She describes the perception of links between representations through the process-to-object continuum, using interpretations of function properties. This is closely related to the strategies that students use when solving tasks that focus on linking representations of elementary functions: **strategy (i) –** usually involves generating values (e.g., creating a table) or identifying some of the local properties of the explored function; **strategy (ii)** – usually involves using trends, patterns and global properties and noticing monotonicity or rate of change; **strategy (iii)** – usually involves identifying and using invariant properties of the class of the function (e.g., function transformations). In general, we

associate strategies with aspects in the following way: strategy (i) with the first aspect, strategy (ii) with aspects 2) and 3), and strategy (iii) with the fourth aspect.

Various studies (e.g., Leinhardt et al., 1990; Hadjidemetriou & Williams, 2002; Parhizgar et al., 2021) describe common misconceptions that students can have when learning about functions and emphasise the importance for teachers to be aware of them. Most of them are related to the graphical representation of the function. Some of the reasons for these misconceptions may be the abstract nature of functions or the need to use and link different representations. To answer the research questions, we chose a task inspired by Ronda (2015) that focuses on linking a table and a graph of a function. Many authors (e.g. Leinhardt et al., 1990; Hadjidemetriou & Williams, 2002) deal with a function graph and a function rule, but rarely mention a function table and as far as we know, there is no research in this area in Slovakia. All these reasons motivated us to carry out the research presented in this paper.

Methods

The research consists of three parts:

1) The analysis of two newest Slovak high school textbooks. The analysis focused on links between different function representations. The results of this analysis can be found in Šabaková (2024).
2) Pilot research – pilot test consisted of 8 tasks.
3) Main research – the same test tasks as in the pilot with minor changes to make the tasks clearer.

The qualitative analysis of the data in the pilot and main test was based on the methodology used by Ronda (2015). 43 students (from 2 classes) participated in the pilot research and 124 students participated in the main research (both groups 16-18 years old). We will analyse only the results from the main test in the paper. 124 students were from 5 different classes in 3 different high schools:

- High school in a regional city with more than 10 similar high schools - 2 classes.
- High school in a city with 2 such schools - 1 class.
- High school in a town with only 1 such school - 2 classes.

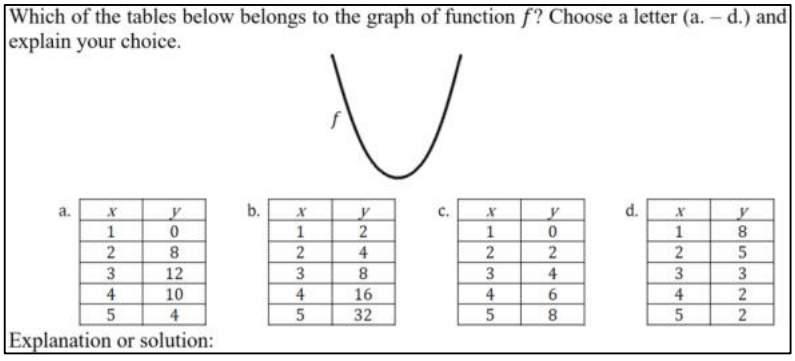

Figure 1: Task 2

All students have already completed the study of functions, including function properties, different classes of functions and their unique properties. Here we will focus on one task out of 8: task 2 (see Figure 1). Students were asked to link a graph of a quadratic function with no axes shown to one of

the four tables. By noticing the monotonicity or rate of change in the tables, we can see that option a) can represent a concave function, option b) an exponential function, option c) a linear function and option d) a convex quadratic function. The only option that fits the parabola is therefore option d).

Three possible strategies of solution were anticipated (as described in the Theoretical Background). In strategy (i) the student draws individual graphs using values from tables and then chooses the answer (see Figure 4) using the input-output aspect. Strategy (ii) concerns describing monotonicity, rate of change, or patterns using 2nd and 3rd aspect, e.g., describing the increase or the decrease of the values (see Figure 5) or noticing the rate of change in the tables (see Figure 2). Using strategy (iii) means understanding a function as an object, seeing invariant properties or, in this case, seeing that the derivation of the option d) is linear. This strategy only appeared in one student's solution in the pilot research (see Figure 3).

Expected solution	Expected description
	a. first it increases, then decreases – concave function b. exponential growth of values c. constant growth of values – linear function d. linear growth of values – quadratic convex function, first decreases then increases

Figure 2: Expected solution using covariation

Student's solution	Translation
	a. no, because firstly it increases, then decreases b. not, because it increases unevenly, and a graph constantly increases quicker c. not, because it is linear d. can be because the derivative is linear

Figure 3: Pilot test student's strategy (iii)

Results

106 students solved this task. 18 students did not choose any option or write anything. Most students completed the task within 10 minutes. The solution strategies used by the students to solve this task are shown in Table 1. Strategy (i) was used by 27 students. Within this strategy they evaluated individual points and plotted these points (input-output aspect; see Figure 4). 25 students used strategy (ii) (using a global property – monotonicity, rarely using correspondence; see Figure 5). As for this strategy, students most often mentioned monotonicity. On the other hand, concentrating only on monotonicity prevented many of them from excluding table b) as the correct answer. 15 students used both strategies (i) and (ii) (see Figure 6). Strategy (iii) did not appear in the main research. 8 students seemed to identify linear growth using covariation in option c). However, none of the students explicitly used this strategy for other options (see expected solution in Figure 2). 47 students

(44.34%) chose an option without explaining their solution strategy. Some students chose more than one option, an example of which is shown in Figure 6. 13 students (12.26%) solved the task correctly, of whom three used strategy (i), two used strategy (ii), six used both strategies and two students chose the correct option without any explanation. The rest of the students chose option d) as correct but used an incorrect explanation or did not choose this option as correct. Option b) – a table of the exponential rate of change – was chosen as correct by 57 students (53.77%).

Table 1: Students' answers (mathematics class students [∑=24] + standard class students [∑=82])

Option		Strategy (i)	Strategy (ii)	Both strategies	Without explanation	∑
a.		1	0	0	3	4
b.		15	13	5	24	57
c.		7	4	1	15	27
d.	correct	3	2	6	2	13
	incorrect	0	4	3	0	7
No option		1	2	0	3	6
∑		27	25	15	47	114

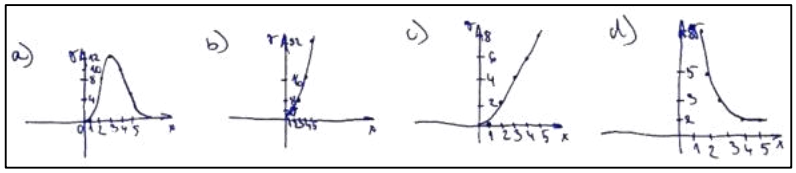

Figure 4: Student's strategy (i)

Student's solution	Translation
a stúpa, klesá, f klesá a stúpa b vyzerá ako 2^x, ku ktorého grafu nepristúpa graf f c vyzerá ako lin. funkcia d klesá a potom stúpa, čo sedí k f.	a. increases and decreases, f decreases and increases b. looks like 2^x, which graph does not belong to graph f c. looks like a linear function d. decreases and then increases, which fits with f

Figure 5: Student's strategy (ii)

Student's solution	Translation
 Vysvetlenie alebo riešenie:	d) can be => a function can acquire these values c) can be too I just imagined it
	theoretically – b) is a table of exponential function, but we don't know what values it acquires for negative numbers, so I don't know for sure if yes or no

Figure 6: More than one option, both strategies and inaccurate argumentation

The following misconceptions emerged from students' solutions:

A. The graph must be symmetrical with respect to the y-axis (∑=13). A student added axes to the given parabola assuming that the graph had to be symmetrical (see Figure 7).

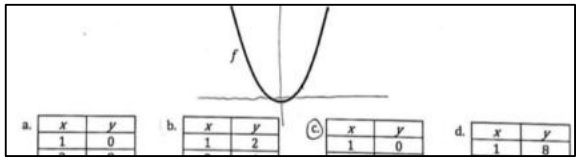

Figure 7: Student's solution – misconception A

B. For two different values of x there cannot be the same values of y, because the function would become constant in this interval (∑=10) (see Figure 8).

Student's solution	Translation
d.) to nemôže byť, pretože x=4 a x=5 nadobúdajú rovnaké y takže na jednom úseku by to bola konštantná funkcia; parabola nie je konštantná	d) can't be it, because x=4 and x=5 have the same y, so in one segment it would be a constant function; parabola is not constant

Figure 8: Student's solution – misconception B

C. Not distinguishing between the rate of change of a quadratic and an exponential function (∑=5). Students were assigned to this misconception if they explicitly wrote that the function is exponential, grows exponentially (see Figure 9) or based on this idea chose option b) as correct. Two students wrote that the function rule is $y = 2^x$.

Student's solution	Translation
Vysvetlenie alebo riešenie: b, aj d, pretože nevieme kde končia body x a vieme že funkcia rastie exponenciálne	b) and d) because we don't know where points of x are, and we know that function increases exponentially

Figure 9: Student's solution – misconception C

Discussion and conclusion

In general, students have difficulty linking a table and a graph of a quadratic function after learning about functions, even after they learned about their representations and properties. The results are in line with claims in Duval (2017) that the distinction between mathematical objects and their multiple representations constitutes one of the main difficulties of understanding in the learning process. Moreover, the results showed that none of the students demonstrated covariation thinking with the table describing the quadratic function (function table d)) and only 3 students showed it with the exponential function (function table b)). They did not explore the variation in the columns and consequently did not look for patterns in the table to link it to the function graph (as described in Pittalis et al., 2020). They limited their exploration to the monotonicity of the function, which was not sufficient for most of them to distinguish between exponential and quadratic growth. The analysis of Slovak curricula and Slovak textbooks (Šabaková, 2024) showed that the covariance aspect of the concept of function is not sufficiently emphasised in the development of concept of function,

therefore Slovak students are not used to work with the covariance aspect. This is in line with Jukić Matić et al. (2022), who stated that the curriculum has an influence on the students' personal definition of the concept. This is in contrast to the claim that covariance aspect is “epistemologically necessary for students to develop useful and robust conceptions of functions.” (Thompson & Carlson , 2017, p. 423). This could be possible reason of students' struggling with the task.

The research revealed three different misconceptions. The first two identified misconceptions point to similar problems of Slovak students as described in the literature. Misconception A is related to a misconception that a graph has to go through the origin and can also be related to the prototypical image of a quadratic function (Hadjidemetriou & Williams, 2002), which is the function $y = ax^2$ or $y = x^2$. Misconception B is related to the common misconception mentioned by Leinhardt et al. (1990) that a function is always a one-to-one function. The last misconception identified, together with the finding that most students chose table b) as the table representation for the parabola, shows that our students have difficulty distinguishing between different rates of change, especially when the function is not linear. This is a very important finding because distinguishing between different rates of change is one of the most important ideas about functions. As mentioned in Cooney et al. (2010, p. 8), “function's rate of change is one of the main characteristics that determine what kinds of real-world phenomena the function can model”.

Preferred solution methods together with the misconceptions identified point to the problems that remain with students after learning about functions and to the need to include tasks that require different strategies for their solutions and working with the table of values. Although we studied only one task involving the linking of table and graph representations of a function, our results showed that one of the important aims of teaching functions, namely that students should be able to characterise different kinds of relationships by noticing the rate at which one quantity changes with respect to another, was not being met in the review of the functions topic.

Limitations of this research lie in the fact that the research was conducted only in high schools in the eastern region of Slovakia, therefore further research needs to be conducted to draw conclusions concerning all high schools in Slovakia and to better understand how students understand these representations, how well they can work with them, and whether they are able to see and recognise differences between elementary classes of functions. The results of this research will be used in the professional development of teachers to help them understand their students' thinking and to better prepare them for the teaching aimed at development of their functional thinking.

Race among the number line: Functional thinking among primary school students

Stephan Tomaszewski[1] and Marcus Nührenbörger[1]

[1]University of Münster, Institute of basic and inclusive mathematics education, Germany; stephan.tomaszewski@uni-muenster.de

In an international context, algebraic thinking is an established subject area in mathematics lessons – even at primary school level. In German primary schools, however, the topic is often addressed unconsciously (Akinwunmi & Steinweg, 2024), which means that a wide range of potentials for stimulating substantive learning processes remain untapped. In the following, a case study will be used to illustrate the thematization of functional thinking in primary school. From an epistemological perspective, it is reconstructed to what extent primary school students demonstrate conceptual understanding with respect to the four function aspects in their engagement with the learning environment 'race among the number line'. Results show that learners as young as fourth grade can find access to functionally characterized situations and can develop and express ideas.

Keywords: Algebraic thinking, functional thinking, functions, primary school, function aspects.

Introduction

"The true mathematical wealth is created by the perspective of function" (Freudenthal, 1983, p. 511). Freudenthal's quote shows how important functional thinking is as part of algebraic thinking in mathematics. However, functional thinking is not only important from a mathematical point of view, but is crucial in society itself.

Although the importance of functional thinking is undisputed, it is far less clear what exactly functional thinking means. Smith (2008) describes functional thinking as a type of

> […] representational thinking that focuses on the relationship between two (or more) varying quantities, specifically the kinds of thinking that lead from specific relationships (individual incidences) to generalizations of that relationship across instances. (Smith, 2008, p. 143)

Functional thinking is therefore not limited to dealing with functions, but describes a broader way of thinking. In primary school in particular, it is of course not about a symbolic examination of functions, but about thinking in *functional relationships*.

> Functional relationships inevitably shift the focus of thinking away from individual solutions to the relationships themselves. The 'solution' of activities to functional relationships usually involves the description of this very relationship in the form of an equation, a term, a verbal rule. (Steinweg, 2013, p. 199; translated by author)

In the following, it is shown how fourth-graders can focus on such *functional relationships* using a suitable learning environment and how they express their intuitive approaches. To do so requires considerations on functions, notions of functions, and the epistemology of mathematical concepts.

Theoretical Background

A function defines a mathematical relationship (relation) between the elements of two sets (X, Y) (Rudin, 1964). An element of the domain (the independent value) ($x \in X$) is uniquely assigned to an element of the codomain (the dependent value) ($y \in Y$), such that $f: x \mapsto y$. A relation is a function if it is *well-defined* and *total on its domain*. Total on its domain: $\forall\, x \in X\ \exists\, y \in Y : (x, y) \in f$; Well-defined: $\forall\, x \in X, \forall\, y,z \in Y : (x, y) \in f \wedge (x, z) \in f \Rightarrow y = z$.

The function types of the linear function, the quadratic function and the exponential function are relevant for this study:

A function f with $f(x) = ax + b$ where $a, b \in \mathbb{R}$ is called a *linear function*.

A function f with $f(x) = ax^2 + bx + c$ where $a, b, c \in \mathbb{R}$, $a \neq 0$ is called a *quadratic function*.

A function f with $f(x) = a^x$ where $a \in \mathbb{R}_{>0} \setminus \{1\}$ is called an *exponential function*.

Understanding functions, however, is not limited to knowing their definitions and formal notations; rather, it involves the active engagement with functions — functional thinking — which constitutes the conceptual core of the concept of function (Warren & Cooper, 2005). Functional thinking is thus not tied to a formal concept of function and can already occur in primary school (ibid.), by "focusing on specific patterns that provide initial access to functions and their structures" (Akinwunmi & Steinweg, 2024, p. 306; translated by author).

Characteristic of this functional thinking are the so-called *function aspects*. In the international context, the four aspects of *input-output*, *covariation*, *correspondence*, and *mathematical object* have become established (Pittalis et al., 2020).

The *input-output* aspect of function is understood as a straightforward computation according to a predefined rule, which does not require the learner to understand the causal relationship between the input and the output. It is often perceived by students merely as a calculative operation, where the insertion of one variable (the input) leads directly to another variable (the output) (Pittalis et al., 2024).

The *covariational* aspect involves analyzing, manipulating, and understanding the relationships between at least two simultaneously changing quantities. This aspect emphasizes the conceptualization of how two or more quantities vary together, aiming to coordinate the changes in the values of these variables (ibid.).

The *correspondence* aspect, frequently employed to formally introduce functions at school, highlights understanding the structural conceptualization of functions. It focuses on grasping the relationship between independent and dependent variables (ibid.).

The *mathematical object* aspect views a function as a mathematical entity that can be depicted through various representations, including arrow chains, tables, graphs, formulas, and verbal descriptions. Each representation offers a unique perspective on the same mathematical object (ibid.).

According to Sfard (1991), there is a gradual shift from a process-oriented perspective, which emphasizes the input-output aspect, to a more structural viewpoint focusing on the object aspect. However, it is important to note that these different perspectives are often intertwined, posing challenges for teaching and learning (Pittalis et al., 2024). In primary school, students

will primarily engage with functions through input-output, covariation, and correspondence approaches.

Keeping these four function-aspects in mind, the research interest for the following case study is: *To what extent do primary school students demonstrate conceptual understanding with respect to the four function-aspects in their engagement with the learning environment 'Race among the number line'*?

Setting & Methodology

The learning environment 'Race among the number line' (Akinwunmi & Lang, 2017) allows learners in primary school to playfully gather initial experiences in handling functions. The basic task is as follows (Fig. 1):

A race is played on the number line with four game pieces. Each game piece moves forward according to specific rules. The game piece that first reaches the number 1000 wins.

- The red game piece is allowed to move 50 steps in each round.
- The blue game piece moves 10 steps in the first round. In each subsequent round, it moves 10 steps more than in the previous round.
- The green game piece moves one step in the first round. In each subsequent round, it moves twice as many steps as in the previous round.
- The yellow game piece moves 100 steps in the first round. In each subsequent round, it moves 10 steps less than in the previous round.

Figure 1: Basic task and specific movement rules

The focus of the task lies on the different movement rules for the game pieces, or the underlying concept of slope. Particularly, the function aspects of *covariation* and *correspondence* are relevant in this context.

The mappings between the number of rounds and the position on the number line represent different types of functions for each game piece (Table 1):

Table 1: Overview of the game pieces and the underlying functions

Red game piece	linear function	$f(x) = 50 \cdot x \; ; \; x \in \mathbb{N}$
Blue game piece	quadratic function	$g(x) = 5 \cdot x^2 + 5 \cdot x \; ; \; x \in \mathbb{N}$
Green game piece	exponential function	$h(x) = 2^x - 1 \; ; \; x \in \mathbb{N}_{>0}$
Yellow game piece	quadratic function	$i(x) = -5 \cdot x^2 + 105 \cdot x \; ; \; x \in \mathbb{N}$

The learning environment was conducted with three pairs of learners from a fourth-grade class (ages 9-10 years) at a German primary school, chosen by their teacher. As part of the survey, which lasted 3 times 60 minutes, the pairs were taken out of their regular lessons. The following will examine the work of the learner pair J. and T. They were described by the teacher as "rather high-performing". The actual survey addressed various follow-up tasks. The analysis only considers individual snapshots.

The sequences were videotaped and transcribed. For analysis, the *epistemological triangle* according to Steinbring (2005) was used. This involves reconstructing the understanding of mathematical *concepts* (e.g., linear functions) through the learners negotiation between specific *signs* (e.g., representations, statements) and *reference contexts* (conceptual reference points of the learners). New mathematical knowledge is ultimately understood as an extension of old knowledge through new, rich relationships, in that possible meanings are transferred from a relatively familiar, or partially familiar *reference context* to a new, as yet meaningless system of *signs* (ibid.). Content knowledge is constructed in interaction. Following this idea, negotiation processes and conceptions of the learners can be reconstructed by understanding expressions, representations, or notations as signs to be interpreted. For instance, conceptions of covariation can be elaborated through the interpretations made by the learners such as when a learner says, *it rises faster and faster*, indicating their perception of the rate of change, or *if this one speeds up, then the other value also rises*, demonstrating their understanding of the relationship between variables in a dynamic system. In this sense, the students processes of constructing new mathematical knowledge in the interaction are reconstructed with the help of the epistemological triangle.

Analysis & Selected Results

After the task was presented to the learners, they were initially asked to write down their first prediction about which game piece would win the race. Both agreed that the red game piece would win (J.: "I believe the red game piece will win because it runs 50 steps in every round."; translated by author) (T.: "I think the red game piece will go further because the yellow game piece runs 10 steps less each time."; translated by author).

Since human thinking and most everyday situations are based on linear processes, exponential growth is a phenomenon that is unfamiliar, especially for primary school students. Consequently, initial guesses are predictably as expected. The difference between repeated addition and repeated multiplication is likely not perceived by J. and T., and certainly not considered decisive. This is evident from the fact that at no point (before the start of the game) was there a discussion about whether the green game piece could win. The small number of "one step in the first round" seems too insignificant compared to the fifty steps of the red game piece. Instead, considerations are made about whether it is better to start with a high number and slow down (yellow game piece), or to run with a consistent stride length (red game piece).

If we consider the red set piece, the following epistemological triangle can be modeled (Fig. 2):

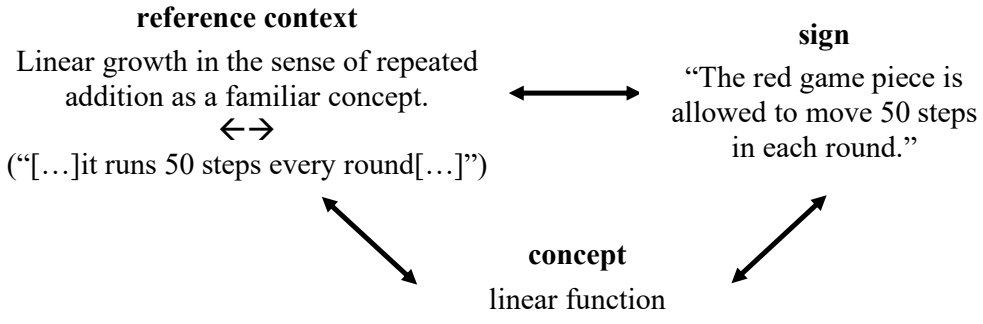

Figure 2: Mediation between specific rule and conceptual reference point for the red game piece

The specified moving pattern for the red game piece ("The red game piece is allowed to move 50 steps in each round.") serves here as the sign that the learners need to interpret. The direct reference to the number of steps per round of the game piece ("[…]it runs 50 steps every round[…]") suggests that J. and T. relate the number of steps to the number of rounds. The emphasis on the phrase *every round* indicates that they recognize the constancy of the slope and identify it as important. Even as their mathematical justifications remain at a more narrative level (see Krummheuer, 2013), they demonstrate conceptual considerations regarding the *correspondence* and, to some extent, the *covariational* aspect in terms of continued addition.

After the learners had noted down their predictions, they were asked to check which game piece would win. J. and T. decided to note the positions of the game pieces step by step for each round and to present them in a table (Fig. 3):

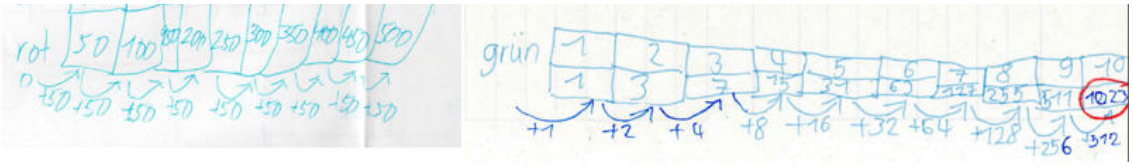

Figure 3: Tabular representation of the game pieces and their position (left: red; right: green)

This leads to the following situation, while J. calculates the position that the green game piece will reach in the 6th round:

J.	[…] and 31 plus 32 are (..) are 63 (*notes result*)
Int.	Mmh.
J.	(...) And doubling thirty-two is (..) well, if I think about it, I really don't know if, if (..) green will make it but (...) well, it could happen that it, it (unintelligible) (..) it will probably happen that, that green takes over a hundred steps.

This passage clearly shows that although J. initially approaches the problem purely arithmetically by calculating the concrete numerical values ("[…]and 31 plus 32 are (..) are 63"), he simultaneously detaches himself from these concrete values ("[…]well, if I think about it[…]"). He is already considering the increase in subsequent rounds without having specifically calculated it ("[…]it will probably happen[…]") and realizes that it grows much faster than initially suspected. This is a clear indication of thinking in *covariation*. After calculating a few more positions of the green figure, they confirm that the green game piece will in fact reach 1000 first. The green game piece not behaving according to their expectations leads to a strong urge to justify. The interviewer asks:

Int.	Why does the green game piece win now, how can that be?
J.	Because (..) eh, because it keeps increasing, if you're already at a hundred#
T.	# it always doubles. And (..) uh and then, you are, you are here (*points to the table*), then you are, then it keeps increasing and if#
J.	# you must not underestimate the smallest one!
Int.	(*laughs*) you must not underestimate the smallest one?
J.	One must not underestimate that if the smallest one, if one starts running very slowly, and then, and then does, then does, then suddenly goes into turbo mode (*laughs*).
Int.	What do you mean by he suddenly goes into turbo mode?
J.	Because, um (...) from one, you think that, you think you're not walking that far, but it doubles. From two to four, from four to eight, from eight to sixteen.
T.	And then suddenly the steps increase very quickly.

In their explanations, they repeatedly refer to "doubling" and “increasing” (*verb*), but the verbalization makes it clear how difficult this is, since the learners naturally lack the algebraic terminology like *slope* or *increase (noun)*.

At the same time, the choice of words (“[…]it keeps increasing[…]”) reveals that the focus is on the change in values (*covariation*), not on the specific values itself. Again they use narrative phrases like “you must not underestimate the smallest one!” or “[…]suddenly goes into turbo mode[…]” to bridge the gap between their available linguistic means and the conceptual ideas they wish to express.

Those phrases, as well as the emphasis on the word "doubling" in their statements, suggest that they see more than just the movement rule of the game piece in this term. They likely see the doubling (or the continued multiplication by two) as the reason for the rapidly increasing growth. This assumption is supported by phrases such as "then the steps increase very quickly", or by listing examples (“From two to four, from four to eight, from eight to sixteen”) that simultaneously have a generalizing character. It is apparent that the steeper slope of repeated multiplication compared to repeated addition is the conceptual core of their argument (function aspect of *covariation*).

If we consider the green set piece, the following epistemological triangle can be modeled (Fig. 4):

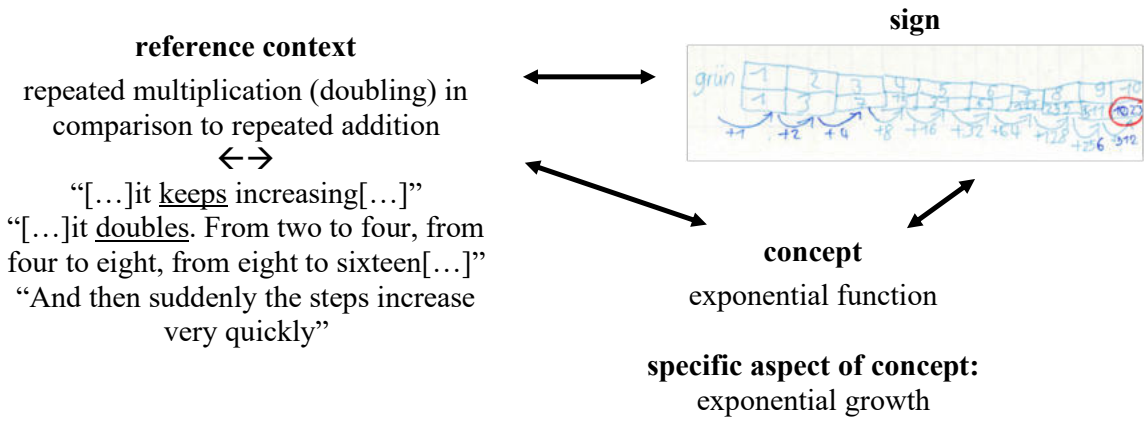

Figure 4: Mediating the irritation by referencing the differences between repeated multiplication and repeated addition

To test these considerations, J. & T. are confronted with a new game piece: this game piece moves 100 steps in the first round. In each subsequent round, it moves 50 steps more than in the previous round ($j(x) = 25 \cdot x^2 + 75 \cdot x$; $x \in \mathbb{N}$). The learners determine some positions of this game piece and quickly recognize that it will reach the 1000 faster than the green game piece. Then the interviewer asks whether this new game piece will also win if the game is played indefinitely, or whether the green figure will catch up again.

J. But it is now questionable (...) uh (...) so in ten rounds, the new figure would win, but if you continue running, then green would overtake again.
Int. Why is that?
[…]
J. Because, because then (*stands up from the chair*), because when you double, steps are, very, very often, are very, when you then, eventually (...) there

> (*points towards the table of the green figure*) you were already at five hundred twelve, and we had calculated that up to here (*points to round 11 of the green figure*), there (...) two thousand forty-seven, that would be, that (*points to round 10 of the 'new figure'*) is indeed more, but here (*points again at the table of the green figure*) the steps are then doubled, but since the steps there are doubled and there (*points towards the table of the 'new figure'*) only, there only fifty is added.

J.'s explanations very aptly underscore the considerations previously worked out: the arithmetic values provide the starting point for further thinking processes that, in the sense of functional thinking, detach from the concrete numbers. In terms of covariation, J. recognizes the difference between repeated addition and repeated multiplication and realizes that in the long run, the latter must always grow faster. His linguistically halting and simultaneously gesturally supported explanations once again show the attempt to express this complex relation with limited linguistic means.

Conclusion and Outlook

By adopting the epistemological approach, insights into students' processing and conceptualization of mathematical functions were gained, confirming the notion that fundamental algebraic concepts, typically introduced later, can be understood by young learners through contextually driven, discursively rich learning environments.

Considering the main research question of this paper "*To what extent do primary school students demonstrate conceptual understanding with respect to the four function aspects in their engagement with the learning environment 'race among the number line'?*", it is evident that fourth graders were able to make conceptually significant experiences with functionally defined situations within the provided learning environment. These experiences particularly allowed the students to express concepts of *covariation* and *input-output*. Although the learners lack the explicit technical vocabulary regarding functions, they are able to express their ideas using the linguistic resources available to them. Similarly, there were moments of generalization observed, indicating a shift from purely arithmetic considerations. The results also emphasize the importance of language (including gestures, objects, drawings, graphs, tables, etc.) for mathematical learning processes (e.g., Moschkovich, 2015), as well as the intertwined use of *mathematical language registers* and *everyday language registers* (e.g., "goes into turbo mode").

For future research, it might be interesting to continue focusing on the approaches and linguistic negotiations of primary school students, as well as to observe student teachers dealing with school-related algebraic tasks. It would be relevant not only to examine which subject-specific concepts the student teachers have developed themselves, but also how they pedagogically assess corresponding tasks for primary school, especially those that provide suitable interfaces for algebraic thinking in primary school.

Constructing varying relationships of quantities and writing equations with fractions: A preliminary analysis of representations produced by Japanese and Turkish teachers

Zelha Tunc-Pekkan[1], Keiko Hino[2], Hisae Kato[3] and Hiraku Ichikawa[4]

[1]University of Agder, Department of Mathematical Sciences, Kristiansand, Norway; zelha.t.pekkan@uia.no

[2]Utsunomiya University, Japan

[3]Hyogo University of Teacher Education, Japan

[4]Miyagi University of Education, Japan

We focus on production of representations by two Japanese and two Turkish teachers as they solve problems involving fractions and two types of varying quantities. We identified their multiplicative concepts (MC1-3) and investigated how these constructs could play a role in their problem-solving activities using video recorded semi-structured interviews. Two participants identified as MC2 level drew general pictures to show the problem situation and wrote equations, but they did not relate meaning of equation to production of pictures. Two participants were identified as MC3 level: One recalled the "double number line" (Japan) but struggled in writing equation. The other one correlated her drawing to make the relationship between the two varying quantities with "direct proportion" method (Turkiye) and solve it but did not write an equation. By analysing the process of producing representations, we report their challenges of units coordination in two varying quantities.

Keywords: Equation, multiplicative concepts, units coordination, representation, teachers.

Purpose of the study

The purpose of this study is to investigate the problem-solving strategies of both pre- and in-service teachers in Japan and Türkiye regarding algebraic equation writing that includes fractions. This exploration might be useful for us to understand how adults make connections transitioning to algebraic equation writing including fractions.

Algebraic equation writing involving fractions contains the process of "units coordination" (Norton et al., 2015). The reality of students at different stages of units coordination and the factors that influence their difficulties have been captured (e.g., Hackenberg & Sevinc, 2022) for only one type of quantities such as length. In this study, we aim to understand teachers' problem-solving activities when writing and solving algebraic equations with two varying quantities, dL and m^2. The main reason is that it has been recognized that teachers' content knowledge influences students' learning, and more specifically, that this quality plays a vital role in noticing and responding to students' thinking (e.g., Dindyal et al., 2021). With this in mind, we designed and conducted a qualitative study in Japan and Turkiye. This paper draws on an initial analysis of the video recorded semi-structured interviews with two Japanese pre-service teachers (no teaching experience) and two Turkish in-service teachers (20 years of teaching experience). The research questions are as follows: What kind of drawn representations do the teachers produce in formulating equations involving fractions? And

how are their multiplicative concepts related to teachers' actions and operations in formulating algebraic equations?

Related literature

This study is grounded on the theory of units coordination adopted by Steffe and other researchers (e.g., Hackenberg & Sevinc, 2022; Norton et al., 2015; Steffe, 1994). According to Norton et al. (2015), "units coordination refers to students' abilities to create units and maintain their relationships with other units that they contain or constitute" (p. 111). Researchers have characterized a progression in such abilities by stages that are determined by the number of levels of units students can coordinate in problem situations.

Norton et al. (2015, pp. 112–113) describe three stages of units coordination by using a task: "If the small red bar fit into the medium yellow bar three times, and the medium yellow bar fit into the long blue bar four times, how many times would the small red bar fit into the long blue bar?" Stage 1 students mentally iterate the short bar to know how many times it fits into the long bar. They can assimilate units of 1 and composite units as twelve 1s, but the relationship between these two levels is not multiplicative but additive and figurative. Stage 2 students mentally iterate the medium bar four times, with each iteration corresponding to a 3, by uttering "3, 3, 3, and 3" for example. They can take two-level multiplicative relations (medium and long bars, small and medium bars) as given, but they need to build up the third level of units (small, medium and long bars) in activity. Stage 3 students immediately understand that there are four threes in the long bar by responding "12" and stating that 12 is four 3s. They can assimilate the given relation into a unit of units of units (take three levels of units as given) and can flexibly switch between structures.

Hackenberg and Sevinc characterized students' units coordination in terms of multiplicative concepts (MC1-3), in correspondence with the three stages (Stage 1-3) introduced above. Considering that multiplicative concepts influence students' reasoning in fractions and algebra in middle school mathematics, they examined middle school students' reasoning with fractions and algebraic reasoning together. Concerning the length and fraction units, MC2 students are those who "can imagine a length partitioned into equal parts without making it" (Hackenberg & Sevinc, 2022, p. 179). They can use a unit of units structure. They have an iterable unit and create 3/5 of a bar by iterating three of the one part which was produced by partitioning a bar into five. MC 3 students are those who "can imagine a length partitioned into equal parts, each of which are partitioned into equal parts" (p. 179). They can use a unit of units of units. They can use multiplicative relationship between a unit fraction, the unit, and any fraction made from it, so they produce 5/3 as 5 times 1/3 by disembedding a unit fraction 1/3 and iterating it 5 times, while also maintaining relationship between 1 and 1/3. We are interested how MC levels might play a role in how teachers conceive and formulate equations including fractions and quantities with two different and varying types: dL and m^2.

Methods

We developed an interview protocol with series of 14 problems related to fractions and algebra (see Table 1). We wanted to understand how the knowledge related to multiplicative concepts might help

or hinder teachers to solve algebraic problems including making relationships between varying quantities and writing algebraic equations.

Table 1: Tasks used in the interview protocol

Bar Task	(Given the three bars in picture) Pretend that the small green bar fits into the long orange bar exactly 9 times. Pretend that the small green bar fits into the medium purple bar exactly 4 times. How can you use this information to figure out how many times the medium purple bar would fit into the long orange bar? (Task 7, Norton et al. 2015, p.134)
Seat Task	1. There are blue seats and yellow seats in a train. 1/5 of all the seats are blue seats. 2. There are blue seats and yellow seats in a train. 2/5 of all the seats are blue seats. Can you showcase this situation by drawing a picture? Can you write an equation to express these situations? What if there were 30 blue seats, how many seats would there be in the train?
Plant Task	1. The height of Leyla (Kaede)'s plant measure in cm is 1/5 the height of Serhat (Asahi)'s plant measure in cm. 2. The height of Leyla (Kaede)'s plant measure in cm is 2/5 the height of Serhat (Asahi)'s plant measure in cm.(adapted from Hackenberg & Sevinc, 2022) Can you demonstrate this situation with a picture? Can you write an equation to express this situations and relate to the pictures? What if Leyla's plant was 30cm, what would be Serhat's plant height?
Paint Task	1. With 3/4 dL of paint, I have painted 1 m^2 of a board. With 1 dL of this paint, how many square meters can I paint the board? 2. With 3/4 dL of paint, I have painted 1/5 m^2 of a board. With 1 dL of this paint, how many square meters can I paint the board? 3. With 3/4 dL of paint, I have painted 2/5 m^2 of a board. With 1 dL of this paint, how many square meters can I paint the board? (Fujii & Majima, 2020, p. 55)

The protocol consisted of four parts. Part 1 includes seven bar tasks developed for assessing units coordination structures (Norton et al., 2015: they were translated to Japanese and Turkish by authors): continuous quantities of same type. Part 2 comprises Seat tasks that deal with two unknowns and part-part-whole relationship between blue seats, yellow seats and all seats: discrete quantities of same type. Part 3 comprises Plant tasks that deal with two unknowns and comparison between heights of two plants: continuous quantities of same type. For the Plant task, we modified the tasks from Hackenberg and Sevinc (2022). Part 4 comprises three Paint tasks and deals with two variables and proportional relationship between the amount of paint (dL) and the size of area that can be painted (m^2). The problems in this group are called "third usage of ratio" (Japan Society of Mathematical Education, 2018, p. 314) in Japan. Even though it is taught at Japanese schools, National assessment results show that half of the 6^{th} graders have difficulty in this type of problems (e.g., NIER, 2022). We also hypothesize that the MC stages are contributing factors for students' performances in this type of ratio problems. For each task in Part 2, 3, and 4, we provided the following prompts: Q1 *draw a picture of the situation*, Q2 *write equations for this situation and explain the meaning of your equations in your pictu*re, Q3 *solve the problem*, Q4 *tell mistakes you expect of students making*, and Q5 *tell feedback you will give students who make mistake or have difficulties*. Due to space limitations for this paper, we only present the analysis of one Bar Task and Paint Task 1. We used the "Rubric for Assessing Units coordination Structures" (see Norton, 2015, p. 136) to analyze teachers' actions

and operations in the Bar Problem. Two researchers individually watched the interviews and coded using the Rubric, then researchers came together, discussed their coding, and reached a consensus.

Two Japanese participants were pre-service primary school teachers who would be certified to teach 1-6 grades in their Year-4 (last year) study and have already completed student teaching practice (internship). Two Turkish participants were middle school in-service teachers of at least 20 years of experience (teaching 5th -8th grade). Individual interviews were conducted during summer 2024. Each interview took about 45-120 minutes, and was videotaped; written work was also collected.

Analysis

Teacher A (MC 2 level, Pre-service)

Bar Task: Teacher A first wrote (9÷4=4/9), but she hesitantly said, "I may be wrong." She then drew a line that represented the long orange bar, and underneath, she drew a short line representing the small green bar and counted if the length fits into the orange bar 9 times. Then, she wrote two segments by counting 4 short lines (she first made a counting mistake). By looking at this drawing, she derived the solution "2 1/4." She then changed the answer from 4/9 to 9/4. We conclude that she is in the MC2 level because at the beginning she did not construct multiplicative relationship between three different units such as the purple bar is 4/4, and 9 times 1/4 (one green bar) is the long orange one. It was only after she drew the lines that she found the purple bar fitting into the orange bar 2 1/4 times. She did coordination of three levels of units in activity, so it is categorized as MC2 by referring to Norton et al. (2015).

Paint Task 1: Teacher A drew area diagrams with dL and m^2 (see Figure 1). Area diagrams only showed the problem situation. This tendency of less attention given to the quantitative relationship continued when she was constructing equations. She first wrote "x=," but erased it and wrote "y= ― (fraction bar)." She mumbled, "I don't know which is which (she is trying to decide between 3/4 and 4/3)." She again erased it, wrote "x= ― y," thinking a little while. Finally, she decided on "x=3/4y." When she was asked to explain what happened, she replied, "Since 3/4 dL would paint 1 m^2, I applied it." However, being asked how the equation relates to the diagrams, she replied: *"Relationship with the diagram, …, well, it is difficult*…" She did not explain the equation beyond the numerical correspondences. When asked to make another equation, she quickly constructed y=4/3x. When asked to find the area that can be painted with 1dL paint, she used y=4/3x, calculated y=4/3×1 and got the answer of 4/3 m^2. In this way, for this problem her attention remained numerical correspondences without engaging in units coordination either with amount of paint or with painted area to find the unknown quantity.

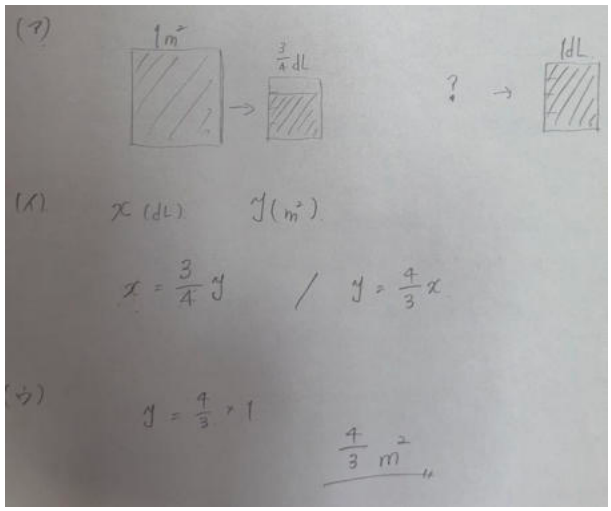

Figure 1: Teacher A's solution to Paint Task 1

Teacher B (MC 3 level, Pre-service)

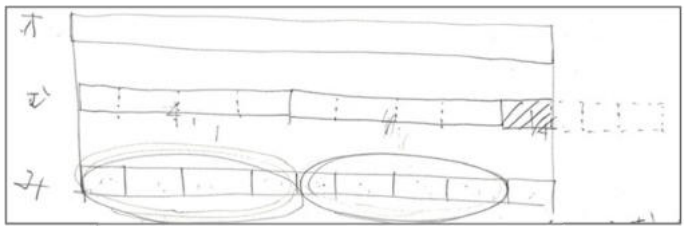

Figure 2: Teacher B's solution to Bar Task 7

Bar Task: Teacher B drew tape diagrams, which she had been drawing in the previous bar tasks and derived the answer: 9÷4=9/4=2 1/4. Compared to Teacher A, she drew three different bars explicitly with units and made relationships verbally, which showed her attention to the three levels of units. She did not conflate the leftover in the purple bar with 1/9. The leftover part was explained, "And this one (pointed the right leftover in the middle purple bar), too (traced the stretched part for emphasis), the one that goes in is green ..., purple (restated) ribbon divided into 4 pieces, and then it comes to the same length as the orange one, so 2 and 1/4 pieces go in" (Figure 2). She appropriately accounted for the leftover part in the middle bar without losing its relationship with the small bar, which we concluded indicated MC3 level by Norton et al. (2015, pp.136).

Paint Task 1: Teacher B quickly drew double number line (dL and m^2) and obtained the answer 4/3 dL (later, she corrected dL to m^2) by using a proportional relationship between dL and m^2 (Figure 3a).

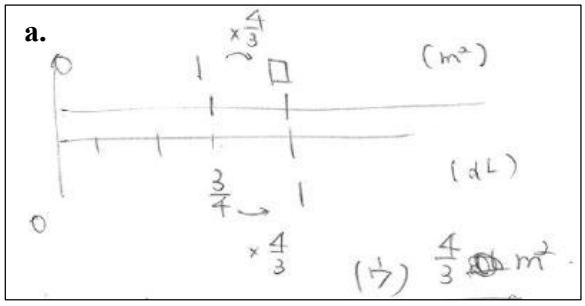

Figure 3: Teacher B's solution to Paint Task 1

However, it was difficult for her to express the relationship between x(dL) and y(m^2). She put x and y on the double number line but could not proceed further. She also drew a rectangle, shaded 3/4 of it, and began to develop parallel expressions between dL and m^2 (Figure 3b). However, in the middle of her writing, she crossed them all and said : *"It doesn't come out."* From her writing, we inferred that to find the whole (4/4 dL) she wanted to use the unit fraction 1/4 dL. However, she did not find the square meters that can be painted by 1/4 dL. Even though she did units coordination within the paint quantity, it was challenging to do it within the area quantity: first of all, she did not come up with 1/4dL equals 1/3m^2. This equality of two different quantities is important to find the solution. One needs to coordinate three levels of units first within the paint quantity and at the same time abstract that a third of 3/4 dL refers to a third of 1m^2. Later, one needs to use the result of this equality as the smallest unit for the m^2 to construct three levels of units coordination: 4 times 1/3 m^2.

Teacher C (MC 2 level, In-service)

Bar Task: Teacher C labeled "1 unit" for the green bar, "4 units" for the purple bar and 9 units for the orange bar, which is 9 times the green bar. She made two individual two-levels of units coordination.

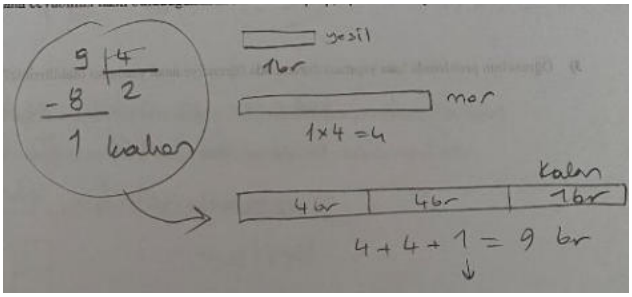

Figure 4: Teacher C's solution to Bar Problem

She also demonstrated these statements by drawing the bars (see Figure 4). To find out how many purple bars would fit into the orange bar, she divided the length of the orange bar by the length of the purple bar so she wrote 9 divided by 4. From the division procedure she had 2 in the quotient and the 1 in the remainder, she concluded that "the orange bar is 1 more than 2 times the purple bar." In her drawing, she indicated that the orange bar would be 9 units with 4 units of the purple bar + 4 units of the purple bar + 1 unit remainder. From Norton et al. (2015, p. 136), we concluded she was operating on level MC2 since she did not use any fraction in her results and especially, she did not articulate what "1 unit" would be in terms of the purple bar (supposed to be 1/4). She did not produce 9/4 as a fraction but she just divided 9 by 4; there was no units coordination other than the initial individual two-levels of unit coordination with whole numbers.

Paint Task 1: For this problem, Teacher C asked for help which was not planned. The interviewer gave help without any other choice. The help she received was as follows: she first had 3/4 dL drawn which was shown as the rectangle having 3 parts and she was told that "this amount painted 1 square meter, each part of the paint then painted 1/3 of the 1 m^2. Since 1 dL consisted of 4 equal parts, so it should be 4×1/3, which was equal to 4/3 m^2" (this was provided). After receiving this help, when she started solving it on the paper on her own, she drew the paint can (3/4) as a rectangle. She shaded 3 out of the 4 parts and assigned a variable "a" to each part (Figure 5). She then added: "*3a paints 1 square meter, so 1 dL…"* Here, since she thought of each part she called "a" as 1 dL, she was about to get confused again, but recalling the previously explained solution, she added: "*Then 'a' paints ⅓ of a square meter.*" She continued, "The equation for this is a + 3a = 4a; 4a becomes 1 square meter + 1/3 square meter," and finished the solution. Similar to what she did in the Bar problem (no coordination of units) she did not have units coordination within the painted area as a multiplicative relationship and she depended on the interviewers. Even though she produced a result of 1m^2 +1/3 m^2, this solution was not hers.

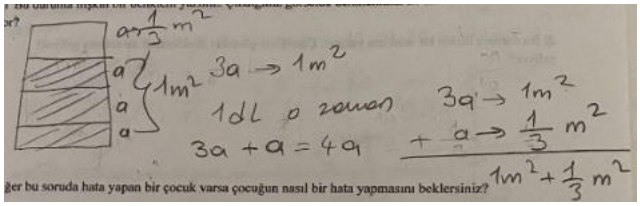

Figure 5: Teacher C's solution to Paint Task 1

Teacher D (MC 3 level, In-service)

Bar Task: Teacher D, after reading the question, stated that "*I am confused* " and re-read the question. On her second reading, she said the answer would be 9/4 times. She got confused again. She read the question as she was pointing out the colored bars: "*purple one is 4 times green; orange is 9 times green so it is 9 over 4 times*". She stated that the orange bar is 9/4 times the purple bar which she said less than 2.5 times and exactly 9/4 times. Here, since she explained how she made 9/4 by pointing to the pictures and she was explicit that the purple was the middle unit for coordinating smallest unit of

green and the biggest unit of orange bar, we categorized her actions as MC3 aligning with Norton et al. (2015, p. 136).
