Using the LTFF to analyse unpacking of the representation revealed the importance of improvisation in a live representation. FE3 planned several questions in advance, which focused almost exclusively on FE1 and FE2's planning, in order to make their decisions and rationales visible to participants. However, equally important were the questions she asked that she had jotted down during the live representation, which made the facilitator educators' in-the-moment decisions and rationales visible. In reflecting on the representation and its unpacking, we also realized that participants' questions differed according to their prior experience facilitating TPD. Based on this insight, we plan to elicit contributions from participants with a range of prior facilitation experience in future FPD sessions, as that could impact the focus of the questions and relevance of the conversation for the facilitators. Finally, we saw that by explicitly asking facilitators to "wear a facilitator hat" in each unpacking, we were implicitly supporting their development of what was a new identity for many, that of facilitator.

Analyzing activities from our respective FPD programs using the LTFF allowed our team to see how the framework's four pedagogies – selecting, representing, approximating, and unpacking – appear in our work and support our diverse goals as facilitator educators. Reflecting on these analyses also resulted in several insights about both the LTFF and FPD programs in general. For example, we realized that although all four pedagogies are relevant and essential for supporting facilitators' learning, they may not all be present in a particular FPD activity. They may occur either in a single activity or a coordinated set of activities within a FPD session, or even across several sessions in a FPD program. The PSC's FPD session we analysed is illustrative. All four pedagogies were present over the course of planning and enacting the FPD session, however, no activity included all of them. During the initial planning for the session, the central TPD task of leading a video-based discussion was selected as the focus of the entire FPD session. Then, the morning portion of the session included

only representing and unpacking, while the afternoon included approximating and unpacking.

A decade ago, McDonald et al. (2013) called for scholars and practitioners in teacher education "to collaborate in the development of a common language for describing (a) how teachers learn to practice and (b) the pedagogies teacher educators enact to support teachers in learning to practice" (p. 381). The LTFF serves a similar purpose in the more nascent field of facilitator education by offering designers and researchers a common language for discussing the pedagogies of FPD. Prior to developing this framework, we recognized that our respective FPD programs had several similarities and differences, but we lacked the language necessary to capture and describe those program features. In our conversations, it felt at times as if we were talking past one another, struggling to convey our ideas in terms that our colleagues would understand. The LTFF provided the language we needed to describe and compare our FPD programs, and we have gained important insights in our broader research program by using it to analyse similarities and differences in the enactment of the four pedagogies in our work. We hope that other facilitator educators will find the LTFF useful in designing or researching their own FPD activities. And we look forward to it supporting communication between FPD designers and scholars in diverse contexts, to foster a shared understanding of the complexity of FPD and help the field to move forward.

Studio Facilitators' Learning on the Job

Rebekah Elliott[1] and Hannah Nieman[2]

[1]Oregon State University, USA, rebekah.elliott@oregonstate.edu

[2]University of Washington, USA, hnieman@uw.edu

Abstract: Limited research has examined facilitators' learning on the job to support teacher learning in professional learning (PL). We examined how two facilitators' practices pressed for PL goals and were responsive to teachers' contributions in instructional conversations and what guided those practices. Our analysis identified shifts in facilitator and teacher interactions across PL cycles using these practices guided by four principles of teacher learning: goal-directed facilitation is essential, teachers' ideas are sensible assets, rich representations of teaching are essential, and teacher learning is a process developed through teaching and reflection. We contribute to an emerging body of research on facilitators learning on the job and discuss implications for the adaptations of our theoretical perspective and future research.

Keywords: Facilitators, Professional learning, Principles for teacher learning

Introduction

Previous research highlights that professional learning (PL) conversations centred on the instructional system – content, student reasoning, and teaching practice – to enhance future practice are generative for teacher learning (Horn & Garner, 2022). Facilitating such conversation demands that facilitators simultaneously press for professional learning (PL) goals linked to this system and act responsively to participants' contributions for there to be significant opportunities for teacher learning (Jackson et al., 2015; Pöhler-Friedrich et al., 2024). However, limited research has examined the practices of facilitators who have learned on the job and have not been involved in leader PL, which often guides leaders to take up goals linked to the instructional system in responsive ways (Even et al., 2020). This study examines mathematics facilitators' learning on the job to lead teachers in instructional conversations in Studio, a classroom-embedded PL model. Studio facilitators and teachers use lesson artefacts and live enactment to examine how the nexus of content and pedagogy afford and constrain student learning (Lesseig, 2016). We sought to understand *how two Studio facilitators pressed for PL goals and were responsive to teachers' contributions in instructional conversations and what guided their practices*.

Literature Review and Framing

Because of the limited studies of facilitators' practices learned on the job, we review expert facilitation and facilitators enrolled in leader PL research. In one of the most widely-cited facilitation studies, van Es et al. (2014) identified facilitators coordinating across practices[1] to reach their goals, which led to productive discussions. Coles (2019) similarly identified connected practices that supported his goal of teachers describing features of the instructional system that lead to productive instructional conversations. Jackson et al. (2015) identified facilitators' practices of pressing teachers

[1] Of note, the field does not use consistent terms for practices and underlying principles. For clarity, we have modified terms to align meanings and to create consistency across studies.

to articulate their reasoning and build on contributions while attending to the PL activity goals. This is similar to numerous facilitator studies using various leader PL designs (Borko et al., 2021; Elliott & Lesseig, 2023; Pöhler-Friedrich et al., 2024). Jackson et al. also identified a set of principles that guided facilitators' decision-making, providing a rationale for moves made in–the–moment linked to general principles for teacher learning. These authors found that leaders ascribed to modelling instructional practice rather than creating a series of experiences that built, pressed, and sustained focus and dialogue on core features of the instructional system. As a result, their analysis showed that leaders made progress but still needed support with the principle that *teacher learning is a progression.*

Limited extant research examines the facilitation practices learned on the job. Lewis' (2016) study of novice Lesson Study facilitators showed how facilitators' practices shifted across PL cycles to include more content-specific conversations involving the instructional system. The facilitators were challenged to balance redirecting, standing back, and pressing for goals. Gibbons and Nieman (2024) studied facilitation practices in teacher workgroup conversations. They identified that a facilitator's *press* to specify students' mathematical reasoning, like Jackson et al. (2015), was linked to broader principles. Studies of facilitators' practices across PL activities and designs document the importance of pressing on teachers' reasoning, focusing on the instructional system, and responsively building on contributions to support innovative future practice. These practices are generative for teacher learning. Fewer studies reveal the principles guiding facilitators' practices.

Building on Coles (2019) and Jackson et al. (2015), *principled facilitation practice* guides facilitators' decisions for supporting teacher learning. This framing comes from lifting a widely used construct of *principled teaching practice* to frame how researchers talk about what guides classroom instruction (Horn & Garner, 2022; Prediger et al., 2019). For example, a facilitator's decision to press teachers to specify teacher-student interactions may be driven by different purposes, such as to clarify mathematical ideas or to examine how a teacher's actions build on students' ideas and align with the lesson goal. Such purposes may be guided by different principles for teacher learning, such as *specifying and describing instruction, which allows for deeper subsequent teacher conversations* (Coles, 2019), or *teacher learning is a process of reorganising teachers' current practices to orient them to new practices* (Jackson et al., 2015). Studies of principled practice show that we gain insights into these principles underpinning decisions by analysing the facilitators' and teachers' contributions over multiple teacher conversations (Gibbons & Nieman, 2024; Jackson et al., 2015). We use the construct of *principled facilitation practice* to examine *what* guided facilitators' practices.

Methods

Mesa High School (9th–12th grade, students aged 15–18) Studio PL was the site of this one-year study. Faculty "detracked" classes, so students were not assigned to mathematics classes based on presumed ability. Two teacher-leaders, Georgia and Jasper, who had taught for nearly 15 years, facilitated five of the past 10 years of Studio. Studio is a predictable cycle of lesson planning, rehearsing with peers, enacting with students, debriefing, and generalising to future practice. Two *Studio teachers*, Oliver (online Studio 1, fall 2020) and Benson (in-person Studio 2, spring 2021), volunteered to teach. Seven other faculty (called *residents*) participated. In 2020, Oliver was a first-

year teacher; the faculty had a range of seven to 26 years of teaching experience. Six of the 11 current faculty members participated in Studio for 10 years, and only one teacher was new to Studio.

Mesa's Studio cycles centred on a data literacy lesson involving slowly revealing parts of a data representation. In the lesson, students first notice and wonder about a limited view of the data representation. As the representation is revealed, students reflect on how their thinking changed. Finally, seeing the whole representation, students make sense of the data's quantities and variables and reflect on their data literacy. Students work individually, in pairs, and as a whole class to discuss their ideas and reflect verbally and in writing.

Facilitators named two PL goals for the two Studio cycles: to support students' data literacy, which meant that students learned to describe and interpret data representations and reflect on changes in their reasoning. A second goal was to support teachers in lesson development focused on data literacy. By rehearsing, enacting, and debriefing multiple times across Studio cycles, facilitators aimed to support teachers using students' data literacy contributions to move lesson goals forward. Facilitators aimed for teachers to adapt the data literacy lesson, meaning they would select data representations aligned to their course's data reasoning goals and use the lesson in their classrooms. In Studio 1, facilitators and a Studio teacher rehearsed the lesson and debriefed the rehearsal to refine it. The Studio teacher taught the lesson online due to COVID-19. Residents observed and took notes to support debriefing the lesson afterward. In Studio 2, a Studio teacher rehearsed the lesson; everyone debriefed it to refine it, and the Studio teacher enacted it with students in a classroom, followed by the lesson debrief.

Data Collection and Analysis

Primary data sources include field notes, transcribed video records, and artefacts from two Studio cycles (9 h). We first reviewed field notes and applied structural codes to mark cycle activities (e.g., rehearsal). We segmented the data by topic changes that directed the conversation to a new observation, claim, or idea. Each segment was coded for *elements of the instructional system* (content, pedagogy, or student reasoning), *discursive practices* (e.g., eliciting reasoning, building on contributions, offering different perspectives; van Es et al., 2014), and *conversation forms* (e.g., replaying, rehearsing, anticipating students' responses; Horn & Garner, 2022). To reach inter-rater agreement, we coded a subset of the data and discussed coding disagreements to resolve them.

We then looked for patterns and shifts in facilitators' practices to uncover the *principles* underpinning their contributions. We wrote memos (Miles & Huberman, 1994), tracing patterns and shifts in their discursive practices and conversation forms across the two cycles. We pressed ourselves to articulate purposes for their contributions (e.g., norm-setting, pressing on goals; Coles, 2019; van Es et al., 2014). We then used an iterative process to identify principles associated with these purposes; we share these in the Results.

Results

We illustrate patterns of interaction and shifts in how Studio facilitators pressed for PL goals and were responsive to teachers' contributions in instructional conversations through excerpts across Studios 1 and 2. In doing so, we highlight four *principles* guiding facilitators' practices: (1) goal-

directed facilitation is essential for teachers' learning; (2) teachers' ideas are assets to connect to; (3) rich representation of teaching is essential for teachers' learning; and (4) teacher-learning is a process developed by teaching and reflecting.

One key pattern concerned a series of facilitator interjections to make explicit the PL goals of the data literacy lesson. Midway through the facilitators' rehearsal introducing the residents to the lesson, Jasper highlighted residents' mathematical contributions: "I'm noticing that people are thinking about a couple of different variables here: the size of the circle and the numbers inside the circles, and attempting to make some sort of connection or relationship between those." Jasper's description modelled how a teacher might highlight students' data literacy, which is a PL goal. Later, Jasper asked residents in the debrief to reflect on a PL goal of how to support students' data literacy: "What else do we need to say …in terms of …the goals, the language we use when we're talking to kids about how do we get them better [at] reading graphs and interpreting graphs?". Resident Tyson responded, "We're seeing graphs that are …not traditional,... multiple variables and multiple things going on." Georgia added, "Tyson said the multiple variables, that was what Jasper had talked about…. taking all these multiple variables and essentially putting them together to make a conjecture." Georgia made explicit the PL goal for the lesson, building from Tyson's comment and enacting Principle 1, goal-directed facilitation. Her building on residents' ideas is also linked to Principle 2, which states that teachers' contributions are assets. Georgia followed up, asking residents to reflect as a segue to the next Studio activity, "So, really, how do we support kids in coordinating variables?" Residents planned a data literacy lesson, followed by Studio teacher Oliver rehearsing before teaching his lesson.

In Oliver's rehearsal debrief, facilitators' practices were shaped by Principle 1; they attempted to make PL goals evident by asking about data literacy contributions and teaching moves. However, in Oliver's rehearsal debrief, residents focused on the social nature of eliciting students' discourse. In an attempt to shift from the social focus to PL goals, Jasper, guided by Principle 1, said, "I'm going to pause us," and asked, "What's Oliver saying to help [us] focus on data literacy?" Residents continued highlighting Oliver's social scaffolds. Jasper made one last interjection in the rehearsal debrief, asking Oliver and resident Henry, who planned with him, to elaborate on how their design leveraged data literacy ideas. Jasper's prompting oriented the group toward a PL goal (Principle 1), also creating a rich representation of mathematics (Principle 3) related to that PL goal.

In the lesson debrief, residents initially *replayed* how Oliver elicited and positioned students' contributions, again a social focus. For several contextual reasons, residents' contributions made sense. Oliver was a novice teacher, and the students had limited opportunities to interact due to online learning during COVID-19. Midway through the debrief, resident Brooke inquired about two students, one who revised their thinking based on the complete graph (a key idea in the lesson) and one who did not. Jasper leveraged Brooke's inquiry, explaining how the students were being data literate. This sparked resident Justine to interject on how she saw students revising their thinking based on a deeper look at the graph.

> In [the second reveal], Oliver, you were really encouraging them to revise their thinking, and you brought reference to the sentence frame. This was that piece of establishing purpose, and that part

about why we're even asking students to revise their thinking, and this being a place that we can help instill that.

Justine highlighted the lesson goal and an element supporting students' data literacy, the sentence frames for students' sense-making of the graph. After others reflected on Justine's comments, Jasper recentred her ideas, elaborating now on the teaching moves that supported data literacy.

> Like Justine is saying, be really explicit about telling them that the next time you interpret this, I want you to ask yourself, what do you notice? What do you wonder? How has your thinking changed? When you look at it a second time more closely and ask yourself, what's the data telling us?

Across Studio 1, facilitators' practices shifted in response to residents' contributions. For example, Georgia and Jasper initially made the PL goals explicit since the lesson and its content were new to residents. In response to residents' focus on students' social interactions in Oliver's rehearsal debrief, Jasper paused the conversation to re-orient residents to the PL goals. Because this interjection did not connect to residents' contributions, residents did not take it up. Later in the cycle, during the lesson debrief, Jasper built on residents' contributions to orient them toward the PL goals. This shift in Jasper's practice appeared grounded in Principle 4: Teacher learning is a process developed by teaching and reflecting, and it led to conversations grounded in PL goals and connecting aspects of the instructional system.

In Studio 2, facilitators continued to press for PL goals, and we saw more residents' contributions shift to reflect on goal-focused ideas. This opened up ways for facilitators to be responsive to them. Studio 2 focused on the same data literacy lesson (using a new data representation) and PL goals. Studio teacher Benson rehearsed and taught the lesson. Georgia and Jasper pressed the group during the rehearsal debrief to specify how the lesson supported students' data literacy, guided by Principle 1. When responses moved away from data literacy, facilitators continued to press, inviting the group to consider how the lesson could take up data literacy goals. As a result, the group engaged in conversation, making robust connections between the data literacy goals, pedagogy, and anticipated student reasoning related to the data literacy lesson.

While Studio 2 rehearsal debrief was a shift from Studio 1, there were still bumps or stumbles. Benson initially focused on "tweaking the task" based on the rehearsal. However, residents and the facilitators encouraged him to take up the data literacy purpose rather than focus on his stated goal of students' arguments. Jasper and Georgia invited him to consider data literacy goals through multiple interjections. Residents Brooke, Kay, Tyson, Justine, and Zandra supported these ideas by unpacking the lesson and discussing how students might use data reasoning as the lesson unfolded. Jasper reflected, "When I see this stuff, I naturally tend to, and I think we all tend to, leave the data literacy off. And it's partly because we're still developing [our reasoning on the topic]." Jasper used personal and plural pronouns to create a sense that this was collective work to understand data literacy. Georgia said to Benson as she encouraged him to consider students' arguments related to data literacy, "Why don't we try? …[T]hat is why we are here, to try it, because it doesn't have to be an exemplar." Facilitators keenly pressed Benson, a seasoned teacher who was a part of the statistics team and who was teaching data science the following year. Through the support of residents and the facilitators,

Benson designed a path informed by two goals: data literacy and students' argumentation. During the Studio lesson, the facilitators coached Benson to take up students' contributions without assessing them. Jasper interjected with Benson's invitation when a student reflection prompt was sidestepped, eliciting students' data literacy reflections.

Resident Justine started the lesson debrief and focused on the lesson's purpose, elaborating on how students were prompted to think about what they would do the next time they saw a graph. "And all of a sudden, they all started talking about [what] we would want them to do every time they look at graphs." Jasper used that as an opening to elicit residents' replaying specific student contributions related to data literacy. Residents then shared what they heard from students (e.g., considering the context of the data and looking at the representations' features).

Across Studio 2, Jasper and Georgia were responsive to residents' contributions by building on their ideas (Principle 2). In doing so, they oriented the group toward students' data literacy and the PL goal of teachers lifting and describing students' contributions to demonstrate data literacy (Principle 1). As a result, the group's conversation made connections between students' data literacy contributions, discussion prompts, and how they could build on students' contributions in future instruction. The facilitation shifts across Studio cycles evidenced how these practices were guided by t*eachers' learning is a process developed by teaching and reflection (Principle 4).*

Discussion and Conclusions

We provided an image of facilitators' learning on the job as they pressed for PL goals linked to the instructional system responsive to teachers' contributions guided by principles for teacher learning. Findings indicate that as facilitators' interjections shifted within a Studio cycle and across cycles, building on and connecting to residents' contributions, more residents' contributions linked to the core goals of data literacy, supporting generative conversations at the nexus of content, pedagogy, and student reasoning (Borko et al., 2021; Horn & Garner, 2022). Studio 1 facilitator interjections lifted mathematical and pedagogical ideas to highlight how they were related to PL goals. Across the cycle elements, we saw residents' attention to data literacy slowly grow. Studio 2, carried out with the same PL goals, allowed facilitators to elevate students' data literacy, which empowered residents to contribute to generative conversations focused on mathematics, pedagogy, and students' reasoning.

Like in other research studies, Georgia and Jasper faced tensions as they pressed on PL goals and were responsive to teachers' contributions to support generative teacher learning (Elliott & Lesseig, 2023; Karsenty et al., 2023; Lewis, 2016). They were responsive to the experiential realities of Studio teachers, positioning new teacher Oliver as competent to build trust and pressing Benson, a seasoned teacher, to experiment, collaborate with residents, and take up classroom coaching to uncover students' reasoning (Gibbons & Nieman, 2024; Jackson et al., 2015; Lesseig, 2016). The interjections guided by overlapping principles for teacher learning showed how facilitators may be goal-directed and frame teachers' contributions as assets as they press for specificity and rich descriptions. By tracing facilitators' practices across activities within and across cycles, we illustrated how they were also guided by Principle 4, teacher learning as a process supported by teaching and reflection.

The four principles guiding facilitators' practices are well-rooted in PL research. Principle 1 is rooted in the goals of the instructional system and reflects numerous studies of facilitation that highlight the

challenges of goal-directed facilitation (e.g., Elliott & Lesseig, 2023; Jackson et al., 2015; Karsenty et al., 2023; Pöhler-Friedrich et al., 2024). Principle 2, teachers' ideas are assets, links to studies of teachers' asset-based language on students' reasoning (Horn & Garner, 2022). Principle 3, rich representations, echoes Coles' (2019) and Horn's and Garner's (2023) ideas that specifying and describing instruction leads to deeper teacher conversations, and Principle 4 is similar to Jackson et al.'s (2015) teacher learning is a process which was facilitated by the Studios' coherent design where residents developed and reflected on multiple lessons with similar goals and structures within and across cycles. These linkages to previous research validate the importance and utility of the principles guiding the Studio facilitators' practices to press for goals responsive to teachers' contributions supporting generative teacher learning.

Our study contributes to the growing body of literature on facilitators' efforts to press for PL goals and be responsive to teachers' contributions by providing an image of facilitators' learning these practices on the job and identifying the principles guiding that practice. We show how these experienced facilitators of classroom-embedded PL have transcended some of the tensions of being goal-directed *and* responsive to teachers' instructional conversations, a persistent challenge documented in facilitation research (Elliott & Lesseig, 2023; Jackson et al., 2015; Schwarts et al., 2023; Pöhler-Friedrich et al., 2024).

This study's limitations include its narrow focus on instructional conversations and one PL context. Future research should examine whether and how the principles identified might support future facilitator PL design and the scaling up of research on facilitators' learning on the job. In addition, future research should explore facilitators' principled practice in other PL contexts.

Self-perception of facilitators in PD

Ralf Erens[1,]

[1]Mathematics Department, University of Education, Freiburg, Germany; erens@ph-freiburg.de

Professional development (PD) courses are developed by researchers and PD designers who are often not the persons who conduct the PD course (Borko et al., 2014). The facilitating of teacher educators is commonly the means of scaling up PD courses to in-service teachers. The professionalization of in-service facilitators is an intervention to promote facilitators´ learning and their development of knowledge, as the facilitators' realizations vary according to their professional views and beliefs relating to PD programs and teaching practice. However, little empirical insights exist about facilitators´ self-perception as educators and their beliefs. This contribution presents some empirical results on the way facilitators perceive their role in the process of adapting and implementing of a PD program for in-service teachers. The goal of this study was to explore the self-perception of the facilitator, based on the underlying and connected beliefs that were reconstructed.

Keywords: Beliefs, professional development, teacher education, roles.

Professional development (PD) of facilitators

Design principles of content-related professional development (PD) courses for in-service mathematics teachers have become a vivid research area (Karsenty et al., 2023). The professional behaviour and beliefs of facilitators have been identified as an almost blind spot of PD research (Jackson et al., 2015). Some pioneering existing research studies focus on facilitators´ professional knowledge (Jaworski & Huang, 2014) and practices (Borko et al., 2014). Given the consensus on the decisive function of facilitators in the process of scaling up, the present study investigates the professional roles and beliefs of facilitators who educate in-service teachers with the aim of supporting their professional development.

As a first step, the concept of a facilitator will be shortly outlined. Based on a review of the literature, Lunenberg et al. (2014) broadly defined the heterogeneous group of facilitators to consist of teacher educators who are responsible for the continuing professional development of in-service teachers (in contrast to teacher educators for pre-service teachers). Like in-service teachers, facilitators face many challenges. They come from different backgrounds and work in different settings of teacher education. Their personal interpretation of their position as teacher educators is based on expectations from the environment (personal and institutional) which defines the concept of professional role (Dengerink et al., 2015). This definition of the professional role of facilitators should not be mingled with concepts of professional identity (ibid.).

Learning and especially lifelong learning is and has always been a fundamental issue in professional development (Jacobs et al., 2017). In research about models of teacher professional competence, knowledge as one dimension is complemented by the notion of beliefs (Philipp, 2007). As beliefs potentially guide decisions and aspects of practice (Fives & Buehl, 2012), it is therefore significant

to encompass beliefs in inquiries about decision-making and the professional behaviour of facilitators (Karsenty et al., 2023).

Synthesizing what is known from research about beliefs in education literature, this report adopts Philipp´s definition of beliefs as "psychologically held understandings, premises, or propositions about the world that are thought to be true" (Philipp, 2007, p. 259). Beliefs tend to be context dependent and differ from knowledge in that beliefs are thought to be true (while knowledge is known to be true or false). Moreover, beliefs serve as filters through which information is interpreted, influencing what one notices and how one interprets it (Philipp, 2007). Thus, beliefs about mathematics and its teaching play an important role in teacher learning and professional development.

This research on facilitators´ roles and beliefs is motivated by relevant adaptation processes similar to teachers on the classroom level. With their professional knowledge (on both: teacher PD and classroom level) facilitators might be seen as experts initiating appropriate learning processes to achieve specific targets in their PD sessions. Subjectively expressed beliefs as a part of facilitators' competence are of particular importance in trying to better understand what exactly determines their decisions in planning and performing PD sessions (selection of content and methods in PD). These decisions are to a large degree determined by what they think about the PD content and additionally by their individual perceptions (e.g. roles and beliefs) and goals (cf. Karsenty et al., 2023).

When facilitating the learning processes of schools and teachers, facilitators may have various roles which may also depend on the relevant expectations of the target group. Distinguishing various professional roles of facilitators, each requiring relevant skills, the differentiation of Fransson et al. (2009, p. 80f) of the following role descriptions is used as a starting point:

- Catalysts: who make people move, who bring about change, who inspire.
- Experts: knowledgeable and competent in acquiring or producing new knowledge.
- Problem solvers: who help learners identify and solve problems they are facing.
- Process helpers: who support learners in their learning processes.
- Developers: capable to develop learning environments, material, and tools.

The descriptions above do not completely cover the various roles of facilitators as a role can be an object of discussion. In practice several roles may often be combined. It seems obvious that facilitators indeed combine several roles and role combinations can possibly be a source of tensions, even conflict and modifications, because facilitators have to meet expectations from the setting of PD programs which may sometimes be hard to combine. Facilitators in this study were encouraged to communicate their own descriptions of professional roles as in-service educators. The deductive descriptions above thus serve as a mirror scope for facilitators' personal interpretation of their role which may then be derived inductively from the data in this study.

Research context and research questions

With the above considerations in mind, facilitators select and adapt PD materials to their own PD course within the given setting and context (specific teacher group, content of PD, cf. Dengerink et al., 2015) with respect to their personal choices, professional views and beliefs.

Within this research context, the aim was to examine how PD facilitators perceive their own double-role as educators and learners, and to reconstruct underlying beliefs with respect to their role. Among others in this project, the main research questions addressed in this paper are thus:

a) How do facilitators see their specific role in the PD courses regarding the target group?

b) What are facilitators´ beliefs with respect to the implementation of their own PD sessions?

To prepare and further qualify the facilitators for their PDs, a qualification course for these facilitators was conducted which consisted of continuous sessions over a period of one and a half years. Facilitators were provided with course material as well as possible design principles for PD sessions, video studies and relevant research literature. The participating facilitators in this project are all teachers who still teach at school and work as teacher educators simultaneously. Their task in the institutional context also contains the implementation of PD sessions concerning competence-based teacher education and the transmission of new principles of the curriculum (e.g. core practices).

Methodology of the study

For pursuing the research questions, a qualitative survey instrument in the form of a problem-centred interview (PCI), one of many techniques within the landscape of qualitative interviewing, was used as the PCI has an explicit interest in reasons why particular views, opinions or beliefs are prevalent (Witzel & Reiter, 2012). The individual interviews were conducted by the first author with N=10 facilitators, who voluntarily participated in this study. Various clusters of questions concerning relevant subjects (content and goals of particular PD session, self-perception) were used as well as narrative prompts concentrating on making facilitators aware of beliefs by means of reflection on intended action in their PD sessions. As an example, one activity in the PCI was a prompt to make participants comment on their priorities and views on design principles (e.g. participant-orientation) of their professional practice in PD sessions which guide their decisions from an individual perspective.

The interviews were transcribed verbatim, and the data was analysed following established conceptions of qualitative content analysis (Mayring, 2021). Especially an open content analysis seemed to be appropriate to maintain an openness approaching the research questions described above. The facilitators´ remarks on the selection and prioritization of contents for their PD courses, their strategies, underlying beliefs, and their roles as facilitators were reconstructed by a systematic comparison of cases.

Methodologically the PCI aims to facilitate a structured dialogue which allows to uncover views and perspectives of participants on particular issues. Additionally, the orientation on relevant subjects makes it possible to pose follow-up questions and precisely address the research focus (on particular roles and beliefs). The reconstruction of beliefs is thus furthered by the participants' capability and motivation of self-reflection.

Results

The results show that all facilitators considered appropriate learning activities and settings important in prioritizing various adaptions of the PD content resources provided. Facilitators mentioned several

issues (e.g. community and context), considering holistic challenges and multi-facet complexities of their PD sessions. Identifying specific facilitators´ views is always established in various parts of a single interview. We report only facilitators´ views that are coherent throughout the whole interview. In general, facilitators have to be able to adopt multiple roles, each requiring a high level of competence and skills (cf. Dengerink et al., 2015). Based on our data, some major roles and connected beliefs have been identified: three roles are highlighted exemplarily, appearing in most of the sample.

Facilitators consider their coaching role as very influential. They see themselves as process helpers who support teachers in their professional learning. In particular, facilitators try to meet the needs of the participants which they first have to analyse and identify themselves:

> Mr R: These are precisely the topics I mean. You come across certain things with participants in your PD sessions, then you can identify problems and possibly move them to reconsider their existing paradigms. And here I can accompany them in this process with research-based approaches. […] But being a problem solver, no, I wouldn´t presume to do that.

In terms of participant-orientation Mr. R. considers different orientations of the participants and intends to mediate between teachers´ interests and the need to communicate ideas based on PD resources, encourage reflection, and give productive feedback to participants in their learning community. Facilitators can reflect on their own actions and associated beliefs regarding the limit of one´s expertise and area of responsibility, as the example of Mr R. shows, who additionally mentions that he does not see his task description to be a problem solver as a facilitator. In meeting the needs of participants and with an explicit approach in trying to stimulate the learning process with an adaptation of the PD material, a clear belief can be reconstructed that Mr. R sees his role as a cooperating facilitator and coach. Offering research-based knowledge and professional support are key factors for this facilitator and shows that he determines his role as coach in an aspired symbiosis of various points - providing subject matter knowledge, experience in professional support and skilful communication.

The role and belief of a facilitator as a transmitter of input can clearly be found in the data. In their self-perception, some facilitators consider themselves to be competent in producing new knowledge and underline these beliefs with regard to the role as an expert, as the following examples illustrate:

> Mr S: Yes, I am definitely a provider of new ideas and try to give fresh impetus and impulses to my PD participants. […] Whether this results in any changes in teaching practice it remains to be seen.
>
> Mr B: …then [I see myself] as a source for transmitting input by raising relevant issues and questions, or stimulate discussions by outlining various teaching scenarios along with a critical reflection.

Both facilitators claim to be an initiator and catalyst who want to bring about change and who want to be a source of inspiration for teachers in their PD sessions. A connected belief to this role is that facilitators draw upon a sound knowledge base and their PD activities seem to be closely linked to the provided PD resources. However, the subjective evaluation of Mr. S. demonstrates the awareness of potential dilemmas between transmitting and PD efficacy. Sometimes facilitators try to model the implementation of both – content and teaching methods – in their PD sessions. Regarded as being particularly effective within the context of a PD session and as an adaptation of the PD material, Mr

B. enacted a discussion in one of his sessions about raising student awareness of thinking processes in teachers' classroom lessons:

> Mr B: We want our students to be able to use and choose between different problem-solving strategies, but first they need to learn to generate alternatives for any given mathematical problem or task. So, don´t we need to practice that for our own teaching methods in PD? […] When we design our actual [PD] courses, we must consider the goals and activities so that participants can promote thinking of students by critically considering various pedagogical approaches in actual teaching.

The modelling of learning approaches in PD sessions shows that Mr B. tries to be both – a transmitter of input and an initiator by transferring a specific issue from the discussion in PD sessions into the classroom that is one of his main concerns in professional learning. Thus, it can be reconstructed one of his beliefs is that modelling learning processes is one way of transferring research-based theory into practice. His role as a facilitator certainly includes being an initiator.

The adaptation of curriculum materials and content on the teacher PD level to the classroom level tries to combine research-based expectations with participating teachers' knowledge of practice. The goal of developing and fostering interactions between facilitator and participants becomes apparent here. The remark about critical reflection shows that Mr B. articulates his role as an initiator to create a community of learning and shows his belief that with an initiated focus on specific PD themes and content, the potential of his PD sessions can lead to consolidated joint insights and product on the classroom level. Of course, this is a case-specific individual perception of being an initiator which is rather questionable in terms of efficacy as can be seen by the remark of Mr S above. It should be noted that both facilitators seem to fulfil the role of a broker in the professional development and learning of in-service teachers. This role implies that a facilitator needs communication and negotiation skills to transfer and mediate curriculum material and content from a PD level to a classroom level using expertise on both levels. Stimulating inquiry and a joint attention on specific themes as a defining feature of the facilitator role as a broker confirm this interpretation (cf. Lunenberg et al., 2014, p.58f).

As a linking pin in the transfer of methods and content from research-based PD design to teacher adaptation in heterogeneous classroom the facilitators in this project contribute to the necessary process of theorizing and adaptation. However, they do not see themselves in the role as a developer who is capable to supplement materials and tools:

> Mrs K: I wouldn´t see myself as a developer. I would not have sufficient skill or knowledge to develop materials, but rather implement findings from research into practice.

With respect to the principle of participant-orientation facilitators stress that they want to fulfil teachers´ expectations in their PD sessions and some facilitators rather tend to focus on task examples as a form of transmitting practical knowledge. This does not exclude brief processes of theorizing, but participants in this sample rather hold the belief that their competence profile as a facilitator needs further qualification in this respect. The knowledge domains of facilitators in our sample are dominated by knowledge of practice with a focus on skills and teaching practice as well as an awareness of reflective beliefs and orientations in which facilitators go beyond a mere consideration of teaching skills and core practices towards a better connection between theory and practice.

Participating teachers' concerns and needs are more central than compliance issues about curriculum development or enactment in their adaptations of the PD curriculum materials.

> Mr C: ...well, if this [being a developer] was successful, this would be really good, but regarding myself this is not a direct objective and certainly this is not covered by my role in the system.

It could be argued that one principle for the design of education curricula is the common principle of linking theory with practice. In a role of being a "seconding developer" the facilitator needs to have a clear vision of the relevant knowledge and professional learning (being acquired on a facilitator PD level). Then facilitators adapt and model facilitator PD curriculum materials about teaching and learning approaches, which are advocated in the PD program, in their own PD sessions.

Yet this potential role of a "seconding developer" cannot be found at all in the data of our sample as the quotation from Mr. C. exemplarily shows – with an implied limitation. The potential role of being part of a development process or a developer seems to be restricted by institutional norms and role assignments in the educational system. Further hints of a desired role of being a developer cannot be found in Mr. C.'s interview data. The one given, however, is an indication that an active adaptation process between the different levels is taking place. It supports the argument given by Cochran-Smith (2006) who contents that any teacher educator or facilitator is a "public intellectual" who should play an active role in debates and processes about curriculum development and adaptation. Our data rather confirms the hypothesis that in this respect facilitators are more likely to be following the role they have been assigned by education institutions and authorities.

Discussion and conclusion

Based on the literature and our findings, it can be said that facilitators in this study consider themselves adopting a role of being professional learners. They achieve to attain an individual level of being a role model in professional learning in which facilitators hold a set of beliefs concerning their roles which they try to organize in a way that makes sense to the individual and is thus subjectively coherent (Leatham, 2006). The different roles, however, imply both, the challenge of how to cope with these and making decisions when a particular role is appropriate in the specific setting of a PD context.

The beliefs of facilitators which could be reconstructed in this sample illustrate a variety of role models and challenges which are perceived and reflected by our participants with different modes of experience in facilitation. The identification of facilitators' roles and beliefs is important in considering the adaptation processes of practices on a teacher PD level. These beliefs and their connection to enacted PD practices is however a tentative one.

Although the presented study is limited in scope it already provides some interesting answers to the research questions. The results show that all facilitators considered participant-orientation and stimulating cooperation as highly important design principles for their various adaptions of the PD content resources provided in their qualification course. These beliefs and associated role reflection are seen as an important and characteristic competence of facilitators in their capability to incorporate the needs and expectations of in-service teachers (target group) in several stages of the facilitation process. Facilitators usually have different backgrounds and have different paths how they found their

way into being in-service teacher educators. All participants of our sample are or have been active classroom teachers and are thus experienced in the profession. As teachers as clients in PD sessions prefer to be supported by someone who knows the profession from the inside, it is an expected result that facilitators subjectively hold beliefs that emphasize their preference for a cooperative setting and want to provide rich learning opportunities for their clients.

Using research-based textbooks and hands-on material was a major facilitator goal to support in-service teachers in coping with heterogeneity in the classroom. Participants see themselves as tutoring process helpers, experts, and transmitters of input, who provide impulses for innovations rather than being problem solvers or developers. This is consistent with their beliefs with respect to their own PD sessions and their roles therein.

What becomes apparent in the data of this study is that facilitators experience various tensions when they report about their beliefs and roles. Combinations of roles and potentially conflicting beliefs can be a source of tensions – be it in teaching at school or in professional development settings. Facilitators must meet various expectations and norms which are sometimes hard to combine. Dilemmas which have been mentioned by participants in this study are: the tension between theory and practice as well as the tension between approaches being advocated in the teacher PD curriculum material and their personal adaptation processes in relation to their beliefs and role reflections as an actor in this professional development program. In dealing with such tensions and dilemmas, facilitators require comprehensive theoretical knowledge as well as experience and reflective decisions. By finding the right balance between the factors causing the tensions, facilitators can make sense of their role of a teacher of teachers.

The limitations of this study are obvious: a small sample of facilitators can only illustrate facilitators' beliefs and roles exemplarily and should be taken as some illuminating cases for investigating significant factors of professional development practices in any other PD context. Overall, the results suggest that further connections between facilitators' competences, their role in adult education, their self-perception, beliefs, and efficacy should be identified in future research.

Learning to broach potentially difficult discussions about teaching through meta-coaching

Michael Jarry-Shore[1], Meghan Smith Durkin[2], Hilda Borko[2], Marsha Ing[3] and Thomas Smith[4]

[1]North Carolina State University, College of Education, USA; majarrys@ncsu.edu

[2]Stanford University, Graduate School of Education, USA

[3]University of California – Riverside, School of Education, USA

[4]University of California – Davis, School of Education, USA

Coaches can help teachers improve their teaching, yet little is known about how coaches broach potentially difficult discussions with teachers about aspects of their teaching to improve or how they learn to do this work. We examined a coach learning initiative, in which a mentor coach, or meta-coach, helped a coach broach difficult discussions with teachers about their teaching. We analyzed meetings between the meta-coach, coach, and one teacher before and after the teacher's lessons. Analysis revealed that the coach was unsure how to talk with the teacher about a lack of student engagement in her lessons. The meta-coach played a crucial role in helping the coach broach a potentially difficult discussion of this topic using "entry points" in the form of classroom data. This approach led the teacher to reflect on her teaching, absent the negative emotions that may arise when discussing improvements to one's teaching. We discuss implications for coach and teacher learning.

Keywords: coaching, meta-coaching, professional development, responsive coaching

If teachers are to make the substantial shifts in practice they are currently urged to make (Cobb & Jackson, 2021), they will require access to sustained professional learning opportunities. One approach to supporting teachers' professional learning that has become increasingly prominent of late is coaching, in which a mentor teacher, or *coach*, helps teachers develop their teaching practice in ways likely to enhance students' learning (Desimone & Pak, 2017; Gibbons & Cobb, 2017).

To support teachers' learning, coaches must engage teachers in potentially difficult discussions about aspects of their practice to improve. In observing a teacher's lesson, a coach might recognize an aspect of a teacher's practice that may be in need of growth, yet merely pointing this out to the teacher could seem evaluative and engender negative emotions like frustration or shame (McGugan et al., 2023). Coaches may thus avoid such discussions, maintaining the coach-teacher relationship (Anderson et al., 2014), but leaving the practice in need of improvement unchanged.

The field has begun to examine how coaches navigate such tensions in their work, yet still lacks knowledge of productive approaches coaches may implement in broaching difficult discussions with teachers. Also lacking is an understanding of how coaches learn to broach these sorts of difficult discussions. We examined an approach to supporting coaches' professional learning we call meta-coaching, in which an experienced coach, or *meta-coach*, helped a coach learn to broach difficult discussions with a teacher about her teaching. We addressed the following questions: 1) How did a coach broach difficult discussions with a teacher about aspects of her teaching to improve? 2) How did a meta-coach prepare a coach to broach difficult discussions with a teacher about her teaching?

Conceptual framework

Supporting teachers to develop their teaching practice through coaching

Coaching is an increasingly common approach to helping teachers develop their teaching practice in ways likely to enhance students' learning (Desimone & Pak, 2017; Russell et al., 2020). With regard to teaching mathematics, coaches can help teachers implement an ambitious and equitable instructional approach (Cobb & Jackson, 2021), in which they: a) launch a cognitively demanding task, b) ask students to solve the task in small groups, and c) select student strategies to be compared in a whole-class discussion. As this teaching approach is quite unfamiliar to many who teach mathematics (Ball et al., 2001), teachers may need help implementing it. Coaches can offer such help.

To support teachers in implementing this instructional approach, coaches may enact various routines (Gibbons & Cobb, 2017). For instance, they may facilitate a coaching cycle (Kochmanski & Cobb, 2023), in which they: a) co-plan a lesson with the teacher, b) observe the lesson and gather artifacts from it (e.g., video; student work), and c) examine these artifacts with the teacher in a lesson debrief.

Supporting coaches to develop their coaching practice through meta-coaching

Coaches must learn a great deal to support teachers in developing their teaching, yet with few exceptions (e.g., Russell et al., 2020; Saclarides & Kane, 2021), little work has studied approaches to supporting coaches' professional learning. In this study, we show how a new approach to supporting coaches' learning that we call *meta-coaching* supported a coach in developing her coaching practice.

The role of meta-coach is something we conceived in collaboration with our district partner. For us, a meta-coach is a mentor coach who supports individual coaches in developing their coaching practice. A meta-coach is also an experienced coach with substantial prior teaching experience. As meta-coaches are experienced coaches, they are likely to have prior experience broaching difficult discussions with teachers and can thus share lessons learned from these experiences with coaches.

To understand the work of meta-coaching, we draw on Prediger et al.'s (2019) Three-Tetrahedron Model, which describes learning at three levels. At each level, there are learners and someone supporting the learning. At the classroom level, the learners are students, whose learning is supported by a teacher. At the teacher professional development level, the learners are teachers, whose learning is supported by a facilitator. Finally, at the facilitator professional development level, the learners are prospective facilitators, whose learning is supported by a facilitator educator. A meta-coach is like a facilitator educator in that they prepare others to support teachers' learning.

Much as a facilitator educator can draw upon their experience as a facilitator, a meta-coach may draw upon their experience as a coach. For instance, they may lift the practice of facilitating coaching cycles with teachers to enact a variation of the coaching cycle with a coach, leading a planning session with the coach before a coaching cycle, then debriefing the coaching cycle with the coach afterwards.

Conversational stances in coaching cycles

Coaching cycles are one coaching routine a meta-coach might support coaches in implementing. As part of these efforts, a meta-coach may support a coach in adopting a directive or responsive conversational stance (Heineke, 2013; Ippolito, 2010). These stances position the coach and teacher

in different, and consequential, ways. With a responsive stance, a coach places a teacher's ideas center stage, thereby positioning the teacher as knowledgeable while decentering their own thinking, ideas, and opinions as a coach. Such a stance also allows teachers' interests to guide the coaching process (Dozier, 2006). With a directive stance, on the other hand, a coach offers advice to teachers about which teaching practices to enact and how, thereby positioning themselves as the primary knower, centering their own thinking, and setting the focus for the teacher's learning.

Both stances have affordances and limitations. While a responsive stance may enhance teachers' participation in coaching (Gillespie & Amador, 2024; Ippolito, 2010), it could result in discussion of an aspect of teaching practice other than the one on which a coach may wish to focus. A responsive stance may thus maintain a sense of comfort, but could leave an aspect of a teacher's practice in need of growth remaining unchanged (Dozier, 2006; Ippolito, 2010). With a directive stance, this is less of an issue, as such a stance allows a coach to explicitly name the teaching practice they would like to discuss. Such explicitness, however, may understandably elicit negative emotions (McGugan et al., 2023) and leave a teacher feeling judged, potentially withdrawing from the discussion or even choosing not to work further with a coach (Heineke, 2013). Given this, some have suggested moving between these two stances or adopting a combination of the two (Heineke, 2013; Ippolito, 2010).

Methods

Setting and participants

We examined a meta-coaching initiative that took place in the 2019-2020 and 2020-2021 school years in a large district in the western United States. In total, three coaches and six teachers took part in this study. We focus here on data for only one coach and the teachers she worked with in 2020-2021, as the problem of coaching practice integral to this study – broaching difficult discussions – was most salient to this coach and came increasingly into focus for her in 2020-2021. We present our analysis here of a coaching cycle with one of the coach's teachers in which this problem was especially salient.

The meta-coach was an experienced coach and former teacher. She was previously responsible for ensuring coherence across the district's professional learning initiatives and for supporting implementation of the district's new mathematics curriculum. She then began serving in the role of meta-coach, a role we conceived together and that was funded by a grant to our research team. The coach, on the other hand, was a former teacher with five years of coaching experience. The teacher taught 7th-grade mathematics and was in her 4th year in the classroom. All participants were familiar with one another through their prior participation in other district professional learning initiatives.

The meta-coach helped the coach facilitate coaching cycles with several teachers, including the focal teacher. In the cycles, the coach worked alongside teachers in planning a lesson, before then observing the lesson and debriefing it with the teacher; the meta-coach also attended these phases. In this work, they supported the teachers with student engagement, launching tasks, and fostering student discussion. The meta-coach and coach met together at the start and end of each coaching cycle, as well as between the observe and debrief phases of the coaching cycle in what we refer to as the *meta-coaching cycle.* The coaching cycle was thus embedded in the meta-coaching cycle (Figure 1).

Data collection

The meta-coach collected audio-recordings of each phase of the cycles except the lesson enactment. She had been provided an audio-recorder and a brief script to read at the start of each audio-recording stating the date and phase of the cycle being recorded. This generated audio-recordings of the following phases: plan for the coaching cycle, plan for the lesson, prepare for the lesson debrief, debrief the lesson, and debrief the coaching cycle. Phases 1, 4, and 6 involved the meta-coach and coach. Phases 2, 3, and 5, on the other hand, involved the meta-coach, coach, and teacher. The recordings of each phase were 20 minutes or longer. Transcripts were created for all audio-recordings.

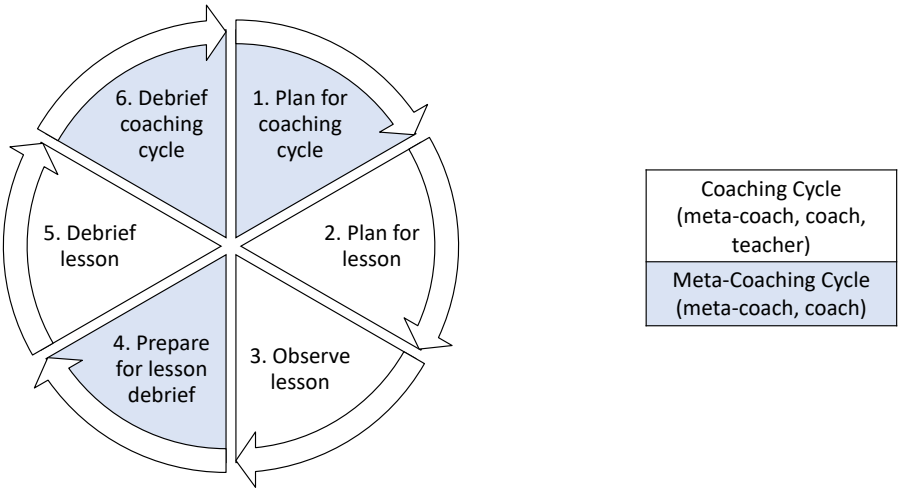

Figure 1: The meta-coaching cycle

Brief student surveys figured into the coach's work and were a secondary data source in this study. These surveys were short, took fewer than five minutes to answer, and consisted of questions asking students about their experiences of lesson launches and small-group or whole-class mathematics discussions (Nieman et al., 2020). The surveys were developed to offer teachers feedback that could be referenced during ongoing, job-embedded professional development like coaching. With their coaches, the teachers in this study identified a specific survey and survey items to focus on in each coaching cycle related to the goals they had set for their teaching.

Data analysis

The first and second authors began analysis by reading transcripts of the lesson debrief preparation phase for the coach's 16 coaching cycles in 2020-2021. Their goal was to identify cycles where the coach mentioned an aspect of teaching practice she wanted to discuss with a teacher in the debrief, but was unsure how to broach. This led them to identify one cycle where this problem and efforts to address it were especially salient. They next read transcripts for all phases of this cycle to see if the aspect of practice was discussed elsewhere, before writing and comparing analytic memos (Maxwell, 2013) in which they reflected on discussion of this aspect of practice in the cycle. This allowed them to identify: 1) the nature of the teaching practice the coach wanted to discuss, 2) how the meta-coach supported the coach in preparing to broach discussion of this aspect of practice, 3) how the coach broached discussion of this aspect of practice in the lesson debrief, and 4) how the coach and meta-coach felt things went. Throughout, the first and second authors attended to the conversational stance advocated by the meta-coach and adopted by the coach in broaching discussion with the focal teacher.

Results

To illustrate how the meta-coach prepared the coach to broach difficult discussions, we present excerpts from phases 4, 5, and 6 of the cycle we analyzed, in order, starting with the lesson debrief preparation phase. We chose these excerpts as they were especially illustrative of key elements of the meta-coach's approach to broaching difficult discussions and her efforts to help the coach enact it.

In preparing for the lesson debrief (i.e., phase 4), the coach expressed disappointment regarding a lack of student engagement she had perceived in the teacher's preceding lesson, stating the following:

> We kind of planned on putting a premise [i.e., a problem context] for kids to get excited about the math problem. I thought the teacher was going to make it more engaging about splitting pizza, like an actual story. I imagined visuals and pictures and here's these three groups of friends and, I mean, honestly, the question that – I know I can't ask this – but I really want to ask this question, which is, "what would make you excited in your own classroom, when were you excited in this classroom?" Because I was not excited in this classroom.

The coach seemed disempowered here to do much about the lack of engagement she had perceived. She also noted that, while she wanted to speak to this issue directly, she could not, implying that such a directive approach might come across as evaluative and result in an unproductive lesson debrief.

The meta-coach agreed that student engagement had been low and that this should be the focus of the ensuing lesson debrief. To help the coach broach discussion of the lack of student engagement, the meta-coach suggested the following to the coach:

> The teacher gave you an entry point to that. I know you're not going to say those words, but she gave you an entry point because she said, "hey, let's look at the [survey] question that asked, 'Were you excited about the problem?'" The teacher asked to look at that specific question. And the results were close to 50-50 … so, she gave you, she opened the door for you to have that discussion … So, I would open the conversation with her in the lesson debrief with something to surface that.

The meta-coach then provided additional suggestions for what to do in the lesson debrief depending on the teacher's response to being asked to examine students' responses to this survey question:

> And if we don't get, "[the results are like that] because the lesson was boring for me, too," if we don't get that statement from her, [but instead get], "oh yeah, I should have expected that," [we can ask], "why do you say that, what made you say that?" And I think, with asking those two questions in that sequence, I think that'll get her to say, "because it wasn't exciting" and then you can say, "well, what could we do differently to hook the kids?", because the kids weren't hooked.

In the lesson debrief (i.e., phase 5), the coach followed the meta-coach's advice, saying to the teacher:

> There was a question on the survey that you were wanting to look at … and I think it was the last question of the survey, ["Were you excited about the problem?"]. And I just wanted to hear more about your thoughts about what drew you to that particular question.

A conversation about student engagement ensued, in which the teacher acknowledged the importance of engagement, but also expressed concern that making every lesson exciting is unrealistic:

> So, I'm going to be really honest right here that, yes, I truly do believe that getting kids curious about math problems is a really good way to up engagement. But I also think that it is one of several hundred responsibilities that I have going on right now.

Later in the debrief, the teacher shared a similar sentiment, saying, "I feel that the problems in the lesson were as engaging as dividing with decimals ever gets." As the conversation continued, however, she described how, alongside a colleague, she had developed a different lesson for students related to Escape Rooms, also noting that students found that lesson very engaging. In response, the coach stated, "when you started talking about Escape Rooms, did you notice that your face physically lit up and you started to smile and you just got really excited?" The coach continued by stating:

> I think the kids will follow you in your passion. So, whatever you find that is exciting and new about a problem, even if it's the same old dividing decimals, like you're saying, I can make something in here be new and exciting. I think our kids get excited about whatever you're excited about, I think, is my theory.

As the preceding shows, the coach managed to broach a prolonged discussion about student engagement – the topic she wanted to discuss – using student survey data as an entry point. She also did so in a way that did not seem to elicit negative emotions on the part of the teacher.

In debriefing the coaching cycle (i.e., phase 6), however, the coach expressed doubt about whether she had managed to accomplish much in debriefing the lesson with the teacher. She reflected on her efforts to encourage the teacher to increase student engagement and display more enthusiasm in her lessons, saying, "I think that's when she called me a Pollyanna." The meta-coach then stated:

> I know you probably feel like you have not had an impact on her, but I feel like you have. Even from last year to this year. She agreed to do this. She could have easily said, "no, not this year." And then, when you said, "for our next cycle," she said, "okay, alright." There was no resistance to you being with her, for us being with her, no resistance whatsoever.

Discussion

We make two primary contributions to the growing literature on coaching. First, we describe a productive approach to initiating potentially difficult discussions with teachers about aspects of their teaching to improve. This approach was directive in that the aspect of practice in focus was something the coach had identified (Gillespie & Amador, 2024; Heineke, 2013; Ippolito, 2010). However, it was also responsive as the coach did not bring up this aspect of practice directly, but allowed discussion of it to emerge through the use of "entry points" in the form of classroom data. As this approach resulted in the teacher reflecting on an aspect of practice the coach believed could be improved, but without the experience of negative emotions like frustration or shame, we would regard it as particularly productive. Scholars have argued that the experience of negative emotions may be a necessary part of the process of developing one's teaching via coaching (McGugan et al., 2023), yet coaches may understandably be reluctant to engender such emotions with teachers. Why such emotions were absent in the current study, yet present in the work of others, seems related to differences in the responsiveness of each approach. In the work of McGugan et al. (2023), the coach broached discussion of students being overwhelmed with a challenging problem, something the

teacher had not previously identified as an aspect of her practice to work on. As such, when this topic came up for discussion with the coach, it seemed to catch the teacher off-guard. In the current study, by contrast, the teacher had previously identified student curiosity as a topic of interest, so was perhaps less taken aback when a discussion of student engagement arose in the debrief. It was somewhat fortuitous that the aspect of practice of interest to the teacher aligned with that which the coach believed needed improvement, and we wonder how the discussion would have played out had the teacher not already expressed interest in students' curiosity.

This study also demonstrates the crucial role of meta-coaching in helping a coach learn to broach difficult discussions with teachers. It thus adds to the field's growing understanding of approaches to supporting coaches' professional learning (Russell et al., 2020; Saclarides & Kane, 2021). The meta-coach's support seemed especially critical in preparing for the lesson debrief. During this phase, the coach expressed disappointment with the lack of student engagement in the preceding lesson, seeming disempowered to address this with the teacher. In response, the meta-coach provided encouragement to the coach and reminded her that the teacher had provided an "entry point" into a discussion of this topic by having previously expressed interest in the survey question about students' curiosity. The meta-coach was very adept at recognizing such conversational entry points. With regard to teaching, experienced teachers have been found to be particularly attuned to student contributions that can be leveraged in steering a lesson toward consideration of a lesson's key objective (Ghousseini, 2015). Likewise, the meta-coach seemed particularly attuned to *teacher* contributions that could be leveraged as entry points into a discussion of an aspect of practice set as a goal for the teacher's learning. Had the meta-coach not been present to offer encouragement and identify such entry points, we question whether the ensuing discussion of student engagement would have even taken place.

This raises questions about the infrastructure required for meta-coaching to become established and sustained within districts. Moreover, while we argue that the teacher in this study reflected on important shifts in her teaching practice, we lack the evidence to say that the teacher indeed made such changes. Future research could examine these and other unanswered questions as the potential of meta-coaching to support both coaches' and teachers' learning is examined further.

Mapping structural characteristics of preparation and support programs for mathematics PD facilitators

Ronnie Karsenty[1], Hilda Borko[2], and Susanne Prediger[3]

[1]Weizmann Institute of Science, Israel, ronnie.karsenty@weizmann.ac.il

[2]Stanford University, USA

[3]IPN Leibniz Institute for Science and Mathematics Education / TU Dortmund, Germany

In recent years, facilitator professional development (FPD) programs have increasingly been institutionalized to prepare and support mathematics PD facilitators in many different ways, which have not yet been systematically compared. In this paper, we suggest a map of structural and institutional characteristics of FPD programs, aiming to make external and internal structural decisions for FPD programs explicit, to compare programs across contexts and to provide a tool to support decisions about new programs. We illustrate relevant characteristics in three programs from Israel, USA, and Germany and discuss interesting differences and commonalities the maps revealed.

Keywords: Facilitators' Professional Development (FPD) programs, FPD characteristics, support.

Introduction

The past decade has seen an advancement in researching professionalization trajectories of those who lead professional development (PD) programs for mathematics teachers, namely, mathematics PD facilitators (Karsenty et al., 2024). Ten years ago, Even (2014) noted that professionalization processes of facilitators are commonly not the result of organized activities but rather occur as a byproduct of the projects that facilitators work in. She pointed to the need to better understand how facilitators should learn and develop as professionals. Since then, several institutionalized efforts of preparing and supporting facilitators, in the form of facilitator professional development (FPD) programs, have been reported (e.g., Borko et al., 2021; Bruns et al., 2022; Valoyes-Chavez & Felmer, 2021). However, as stated by Karsenty et al. (2024), there is still much need for expanding our knowledge about FPD programs, how they are constructed, what purposes they serve and the affordances and limitations involved in decisions made while designing them.

One way to gain such knowledge is by comparing existing FPD programs, in order to distill possibly relevant characteristics that shape these programs. Whereas another paper submitted to this TWG presents the Learning to Facilitate Framework (LTFF), a tool that focuses on the *content* and *agenda* of FPD activities (Jarry-Shore et al., 2024), our aim here is to focus on *structural* and *institutional* characteristics of FPD programs. This paper is therefore a conceptual contribution, rather than an empirical one. We draw on experiences gained from three different FPD programs in three countries, posing the following research question: *Which structural and institutional characteristics shape FPD programs?*

Potentially relevant structural and institutional characteristics of FPDs

Existing publications on FPD programs allow us to identify various aspects to consider when attempting to map structural and institutional characteristics: First, we assume that the nature of the

teacher professional development (TPD) program in which facilitators work may affect how the FPD is structured. For example, research points to the difference in facilitating highly-adaptive TPD programs vs. highly-specified programs (Koellner & Jacobs, 2015). Second, facilitators might act differently if they had a first-hand experience with the TPD as learners, or if they were themselves involved in the development and/or adaptations of the TPD materials (e.g., Valoyes-Chavez & Felmer, 2021). Third, projecting from our knowledge about how work conditions shape professionalization processes at the teacher level (e.g., Brodie & Borko, 2016), it is reasonable to assume that professionalization processes at the facilitator level may also depend on the conditions in which facilitators work. Fourth, research on FPD programs (e.g., Borko et al., 2015), shows that they can emphasize teacher learning of mathematical content knowledge, teacher learning of pedagogical content knowledge or particular facilitation skills, all of which are needed yet can be prioritized differently. Fifth, it is significant if the FPD program targets novice or experienced facilitators, or both, as novice facilitators encounter unique challenges (e.g., Schwarts et al., 2021). Finally, a crucial question concerns the issue of sequencing: are facilitators introduced to the TPD program simultaneously to, or before, the FPD program? While we already intuitively assumed that all these aspects might impact decisions about structural and institutional characteristics, only the systematic comparison of the three FPD programs allowed us to articulate them concisely.

Approach and context for comparing structural and institutional FPD characteristics

Context of inquiry

The research question we pose and the need to develop a language for structural and institutional characteristics of FPDs emerged during an intense collaboration between three FPD design research teams from USA, Germany, and Israel. While conducting comparative empirical research on facilitators' learning in two FPD programs (Schwarts et al., 2021) and on the ways we design and enact FPD activities (Jarry-Shore et al., 2024), we became increasingly aware that some structural and institutional commonalities and differences between our FPDs substantially shape the professional learning experiences we provide for facilitators. Thus, we tried to articulate what exactly these characteristics were, by comparing the structures and institutional aspects of the FPDs we work in.

Comparative approach

The three FPD research teams met in two intensive workshops, led by the authors of this paper. In the workshops we discussed the structure of each FPD program and identified seven elements that we agreed are necessary for capturing the essence of FPD structures. For each element, we identified the different categories of choices made or external conditions provided, for the three programs, and possible options in each category. By comparing the program structures, we were successively able to refine the initial elements into finer-grained characteristics that seem important for distinguishing among FPDs. The outcome is a comparative tool, the *FPD Structure Map* which we introduce here, and a first tentative discussion of its potential contribution to our understanding of FPD structures.

Three FPD programs to be compared and contrasted with respect to their institutional settings

The Problem-Solving Cycle FPD program. The Problem-Solving Cycle (PSC) is a TPD program for middle-grades mathematics teachers, implemented in the USA. It typically consists of two cycles per

school year, each cycle including three workshops that revolve around a focal mathematics problem (Borko et al., 2015). The FPD program, designed to prepare prospective facilitators to lead PSC workshops, consists of three sessions that precede the three TPD workshops in a given cycle. FPD activities are led by mathematics facilitator educators who may be university researchers or district mathematics specialists. The sessions include modeling of facilitation tasks around the focal mathematical problem (e.g., leading a discussion of a classroom video) by the facilitator educators, collectively unpacking the modeled facilitation tasks, and rehearsing versions of leading the task by the prospective facilitators (Borko et al., 2021).

The VIDEO-LM FPD program. VIDEO-LM (Viewing, Investigating and Discussing Environments of Learning Mathematics), is a TPD project implemented in Israel. Its central aims are to enhance the reflective skills of secondary mathematics teachers and to enrich their mathematical knowledge for teaching. In the TPD, typically a 30-hour course, videotaped lessons serve as objects for teachers' peer-discussions, directed by a framework of analysis developed for this purpose (Karsenty & Arcavi, 2017). The FPD for preparing facilitators to lead VIDEO-LM TPDs was designed as a one-year course, consisting of seven 4-hour sessions, facilitated by two facilitator educators. The course included activities such as simulations, "Live Labs" of facilitation, and session planning.

Mastering Math FPD program. Mastering Math is a TPD program implemented in Germany, aimed at developing mathematics teachers' expertise to foster students' understanding of arithmetic concepts in Grade 5–7 (Prediger et al., 2023). The TPD, consisting of six 3-hour sessions followed by classroom experiments, focuses on teachers' practices in specifying, monitoring, and enhancing students' understanding. During the FPD program, preparing Mastering Math leaders, the participants also experienced the TPD as teachers and reflected on what teachers should learn. To establish facilitation practices and their underlying rationales, the FPD workshops focused on selected situational demands related to leading the TPD, with reference to noticing and leveraging teachers' typical practices and underlying knowledge and orientations about fostering students' understanding.

Outcome: The FPD Structure Map as a tool for comparing and planning programs

In Figure 1, we present the *FPD Structure Map* which depicts the structural and institutional characteristics that we have identified as crucial in shaping FPD programs. As noted, this mapping tool pertains to seven elements, each with one or more categories that include different options - either design decisions made or external conditions to be taken into account when FPD program structures are developed. In the following we detail these elements in the order they appear in the rows of Figure 1. The various categories and options are indicated in corresponding rows of the map. Importantly, we note that options are not mutually-exclusive. The list below identifies the elements and categories.

1. *Target group of facilitators*. This element includes four categories pertaining to the FPD participants: their experience, the nature of their employment, whether they are expected to work alone or in teams, and by whom they are recruited.
2. *Nature of the TPD program*. This element pertains to the TPD that facilitators are being prepared to lead, in terms of duration, degree of specification of the TPD materials, and the TPD orientation.
3. *Facilitators' initial involvement with TPD materials*. This element refers to facilitators' familiarity with the TPD content and materials when they enter the FPD program.

4. *Form of integration of facilitation experience in TPD*. This element maps five different options for sequenced vs. parallel phases of facilitators' participation in TPD, FPD, and their own TPDs.
5. *Focus of the FPD content*. This element refers to design choices about the nature of what facilitators learn in the FPD.
6. *Duration of preparation and support period*. This element specifies the nature of the FPD length, and the model of preparation and support for facilitators.
7. *Certification and attendance*. This element refers to choices regrading whether formal certification is granted upon completing the FPD, rules referring to facilitators' attendance in the FPD, and the work expected from participants between FPD sessions.

Target group of facilitators:	Novice facilitators	Experienced facilitators	Long-term contracts in well-defined institutions	Freelancers	Appointed specifically for the PD program	Working alone	Working in teams	Selected by PD team	Selected by external authority
Nature of the TPD program:	Short term program (one or just a few sessions)	Long term program along at least several months to a year	Long term program along several years	Highly specified PD materials	Basic PD ideas can be used in an open-ended manner	Instructionist	Adaptive to teachers' starting points	Content-oriented	Process-oriented
Facilitators' initial involvement with TPD materials:	TPD content new to prospective facilitators when entering FPD		TPD content well known by prospective facilitators when entering FPD				TPD materials are developed in collaboration with facilitators		
Form of integration of facilitation experience in TPD:	Successive TPD⇨FPD⇨own TPD: First facilitators participate in the TPD, then in FPD, then they start their own TPD		Successive FPD⇨own TPD: Facilitators participate in the FPD, then they start their own TPD		Simultaneous TPD | FPD⇨own TPD: Facilitators experience the TPD as part of the FPD, and after the FPD they start their own TPD		Simultaneous FPD | own TPD: Facilitators are prepared during already giving their own TPD		Simultaneous TPD | FPD | own TPD: Perhaps with mini-successions within the FPD
Focus of the FPD content:	Mathematical content		Pedagogical content knowledge and teaching practices		Processes that teachers need to engage in (e.g., reflection)		Facilitation knowledge and practices		
Duration of preparation and support period:	Short term preparation FPD (one or just a few sessions)		Long term preparation FPD – along at least several months to a year		Few or no opportunities for support once the preparation period is over		Support through continuous FPD	A combined model of preparation and support	Personalized support by experienced facilitators
Certification and attendance:	Formal certification	No formal certification	Attendance in FPD sessions is mandatory		Attendance is expected but not mandatory		Participants' work in between sessions is expected		No or very little work is expected in between sessions

Figure 1: The FPD Structure Map

Figure 2 depicts small versions of three filled-in FPD Structure Maps for the three FPD programs (note that these are not meant to be read; the purpose here is to understand the procedure of personalizing the FPD Structure Map for a specific FPD program).

VIDEO-LM FPD Structure Map | Mastering Math FPD Structure Map | Problem-Solving Cycle FPD Structure Map

Figure 2: Filled-in Structure Maps of three FPD programs

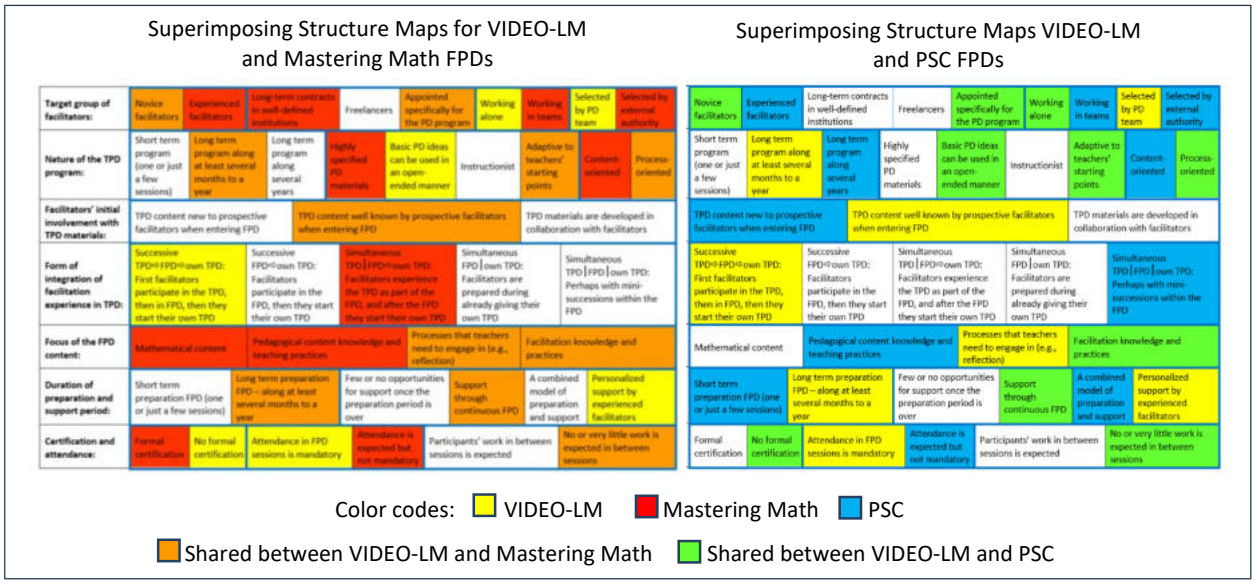

Figure 3: Bilateral comparisons by superimposing filled-in FPD Structure Maps

The two maps presented in Figures 3 were created by superimposing the Structure Maps of two FPDs. The superimposing reveals that the VIDEO-LM and the Mastering Math FPDs have several commonalities (orange colored cells), for example with respect to target groups and length of the TPD and FPD programs. However, there are differences in the nature of the TPD: while the Mastering Math TPD program is highly specified and offers TPD materials with detailed TPD activities (thoroughly designed to work towards TPD content goals in clearly planned processes), the VIDEO-LM TPD program is adaptive and process-oriented, emphasizing reflection on classroom videos with a high degree of flexibility regarding the contents for which the reflective lenses are used and the specific activities offered to teachers. As a consequence, although both programs focus on facilitation knowledge and practices as well as processes that teachers need to engage in (row 5 in the Structure Map), only the Mastering Math FPD focuses also on particular mathematics contents and specific pedagogical content knowledge and teaching practices to be leveraged with the teachers. These programmatic differences lead to different forms of integration of TPD and FPD experiences (row 4 in the Structure Map): whereas VIDEO-LM adopts the successive model of "TPD⇨FPD⇨own TPD", Mastering Math adopts the simultaneous model of "TPD|FPD⇨own TPD". This means that in VIDEO-LM, only teachers who have previously participated in the 1-year TPD program are invited to be novice facilitators for the FPD program. Thus, they go through the modules first as teachers, and only at a later year as prospective facilitators focusing on how to lead reflective VIDEO-LM sessions themselves. In contrast, in Mastering Math the novice facilitators have mini-successions in working through the TPD as teacher participants, then reflecting on these experiences with respect to what they are expected as facilitators of the same sessions, taking into account the backgrounds of teachers' professional learning. After a year of this simultaneous TPD | FPD experience, the facilitators start their first own TPD. These differences resonate with the respective TPD focus: for unpacking the details of the TPD content in Mastering Math, the conjoint TPD and FPD experience is more suitable. In VIDEO-LM, for establishing norms of reflection and high-quality processes in which teachers shall engage, one year of TPD participation and a second year of FPD participation

gives more opportunities for socializing into, and gaining ownership of, the intended reflection processes.

Sometimes, however, it is not the inherent characteristics of the TPD that determine the form of integration of TPD-FPD experiences, but rather external conditions, for example a district under pressure to start the program immediately. In the case of implementing the PSC program in one district in California, such external conditions necessitated that FPD designers choose the model of simultaneous TPD|FPD|own TPD ("on the job" model), preceded only by a 3-day summer institute and with mini-successions during the year. Thus, the induction into the TPD program, the FPD unpacking, and the facilitators' own first TPD experiences were all taking place in the first year.

The superimposing of the VIDEO-LM and PCS FPDs (see right-hand side of Figure 3) reveals a different set of commonalities (green colored cells) and differences between these two programs. The greatest similarity is in the nature of the TPD program. In both programs, the TPD ideas can be addressed in an open-ended manner and are adaptive to the teachers' experiences and needs, although whereas VIDEO-LM focuses only on process, the PSC centers both content and process. Neither program provides formal certification and neither expects much work between sessions. Interestingly, for several elements the two FPDs show *both* overlaps and differences, in the sense that VIDEO-LM choices are subsumed within those of PCS: for example, both programs recruit novice facilitators, however the PSC additionally targets experienced facilitators; in both programs facilitators work alone, yet in the PSC program the possibility to work in teams is also available. For the latter element, external conditions necessitate that FPD designers be flexible. Since the PSC program is designed to work with facilitators who conduct PSC workshops in their own schools, and since schools within the district vary in size, it follows that in smaller schools it is not possible (or necessary) to have more than one facilitator.

Looking at both superimposed Structure Maps in Figure 3, we can also see that each FPD program has several unique characteristics. The PSC program is unique in that it is designed to work with a single school district for several years, with the aim of building both TPD and FPD capacities within that district. External conditions resulting from this design characteristic led to several ways in which it differs from both the VIDEO-LM and the Mastering Math FPD programs. For example, it is the only program of the three in which the TPD content is possibly new to prospective facilitators when they begin the program. The program takes that possibility into account by providing a combined model of preparation and ongoing support, beginning, as mentioned, with a summer institute to introduce new facilitators to the TPD program. Throughout the simultaneous TPD|FPD|own TPD experience, the design of mini-successions allows the facilitators to engage with the TPD as learners prior to enacting it as facilitators in the workshops they lead.

The Mastering Math FPD is unique in several features, which we suggest are related to the systemic and large-scale implementation of the program (Prediger, 2022): it is the only FPD of the three that grants facilitators formal certification, and the only one that offers long-term contracts in well-defined institutions. The choice to have facilitators use highly-specified TPD materials may also be linked to the institutionalized nature of the project.

The VIDEO-LM is the only one of the three FPDs where prospective facilitators are selected by the design team, and the only one where experienced facilitators provide personalized support to novice facilitators. This may be due to scale considerations in more than one sense: Israel is a much smaller country than the US and Germany; the community of mathematics leaders is relatively small, and there is a sense that 'everyone knows (almost) everyone'. Selecting candidates to lead PD on the basis of prior acquaintance is a very common practice in the Israeli Mathematics Education community. In addition, the scale in which VIDEO-LM was implemented (about 70 TPD courses given, by about 30 facilitators), although quite large in Israeli terms, still allows for personalized support.

Discussion

This paper is not an empirical one. We do not claim that the comparison of three FPD programs in which we (as FPD designers and facilitator educators) engaged, is highly methodologically controlled, or that we would not come to other results if other programs were in view. We emphasize that the results of this comparison are tentative and preliminary, and we hope that the suggested Structure Map will further develop through the contributions of other FPD design experiences.

However, we are convinced that already in its first version, the FPD Structure Map can be of value for other FPD designers and FPD researchers, as it has been for us, for several different tasks:

- *Communication.* The FPD Structure Map (perhaps in further iterations in the future) can provide a descriptive language for structural and institutional characteristics, that can enable an efficient exchange of ideas among FPD designers and researchers when they report their research contexts, processes and program effects. This will help in comparing different FPD research findings.
- *Systematized catalogue of typical models.* We envision a catalogue of different FPD models made explicit according to the FPD Structure Maps, so that, as a field, we can learn from other contexts.
- *Reflection.* The Structure Map, together with a catalogue of realized examples, would help FPD designers not to take the familiar structural and institutional settings in their own context (program / country / district) for granted, but to consider (at least some of) them as design choices that may be taken differently in other contexts.
- *Deliberate design.* The specified characteristics and the catalogue of other examples can support FPD designers in taking design decisions more deliberately when planning a new FPD program.
- *Understanding complexities and dependencies.* When we start to investigate the emerging catalogue, we can aspire to deepen our understanding about how some external conditions, as well as the inherent nature of the TPD program, may have consequences for the design decisions regarding both the structural aspects of FPD we discussed here and others to be revealed in future research.

In particular for the last point, we will need many more comparisons, with higher methodological control, to investigate possible complexities and dependencies more explicitly and systematically.

Ten years on: The learnings from a project nurturing collaboration between mathematicians and mathematics educators

Margaret Marshman and Merrilyn Goos

University of the Sunshine Coast, School of Education and Tertiary Access, Australia; mmarshma@usc.edu.au

The IMSITE project provided significant funding to six Australian universities to nurture partnerships between mathematicians and mathematics educators who educate prospective teachers and to foster integration of mathematics content and pedagogy in university coursework. This longitudinal study explores how the IMSITE initiatives have survived, focusing on one of the participating universities. Valsiner's zone theory was used to analyse project publications and a recent interview with a mathematician still working at the university. Whilst ten years later the last of the IMSITE initiatives was still in place, it will soon be discontinued. Nevertheless, the mathematician who brokered interdisciplinary collaboration still works with mathematics educators, albeit subversively. Maintaining lasting institutional relationships remains challenging, even when being championed.

Keywords: Mathematics teacher educators, Valsiner's zone theory, disciplinary boundaries, identity.

In Australian universities, as in many other countries, there are strong disciplinary boundaries in initial teacher education. Prospective teachers are generally taught mathematics content in the university's mathematics department and how to teach mathematics in the education department: often, there is little or no communication between these departments. Prospective teachers describe the tensions caused by the conflicting beliefs and practices of mathematicians and mathematics educators who teach them in their initial teacher education program (Marshman, 2021).

In 2013 the Australian Government funded several projects as part of the *Enhancing the Training of Mathematics and Science Teachers (ETMST)* Program. The *ETMST* Program aimed to lead:

> a major improvement in the quality of mathematics and science teachers by supporting new preservice programs in which faculties, schools or departments of science, mathematics and education collaborate on course design and delivery, combining content and pedagogy so that mathematics and science are taught as dynamic, forward-looking, and collaborative human endeavours. (DET, 2016, as cited in Goos et al., 2017, p. vi)

The *Inspiring mathematics and science in teacher education* (*IMSITE*) project, conducted between 2013-2017, provided significant funding to nurture partnerships between mathematicians and mathematics educators who educate prospective mathematics teachers and to find new ways for mathematicians and teacher educators to integrate mathematics content and pedagogy and embed these practices in their institution. Mathematicians and mathematics educators at six Australian universities were involved. While the project was successful in supporting new forms of collaboration between mathematicians and mathematics educators (Goos & Bennison, 2018, 2019), its longer-term impact has not been monitored. Our current project exploring the identity trajectories (Wenger, 1998) of Australian mathematics teacher educators (MTEs) provided an opportunity to consider a longitudinal study of one mathematician ten years after she was interviewed as part of the *IMSITE*

project. We used zone theory (Valsiner, 1997) as a lens to explore this MTE's identity as she moved along her professional path to becoming an experienced MTE. The analysis also allowed us to identify changing institutional conditions that enabled or constrained the survival of *IMSITE* initiatives. Our research question is: What is the long-term impact of interdisciplinary collaboration between mathematicians and mathematics educators on one MTE's identity?

Theoretical perspectives

Collaboration between mathematicians and mathematics educators is increasingly recognised as valuable for improving initial teacher education (Marshman, 2021) and whilst collaboration can enhance the quality of mathematics teaching and learning, it is often complex and challenging (Marshall et al., 2023). The *IMSITE* project (Goos & Bennison, 2018) identified *personal qualities* including "included open-mindedness, trust, mutual respect, and shared beliefs and values" (p. 265), working towards *common goals,* and a *common or shared problem* as sustaining collaboration whilst the *physical separation* of buildings, "*workload formulas or financial models* that did not recognise or reward interdisciplinary collaboration" (p. 267) and entrenched *cultural differences* hindered collaboration. Successful collaborations required acknowledging the personal and professional experiences of all participants, centring identities and humanness (Marshall et al., 2023) as well as motivation, acknowledging each other's strengths, trusting that each person wants to improve student learning, and helping each other to reach their mutual goals (Sultan & Artzt, 2005). These interdisciplinary efforts can lead to more coherent experiences for prospective teachers, promote better student outcomes, offer personal and professional rewards for the collaborators involved (Marshall et al., 2023: Marshman, 2021) and lead to changes in beliefs about and practices of teaching and learning mathematics (Inch & McVarish, 2003). Collaboration can also lead to new learning and practices including: *confrontation* (forcing a reevaluation of current practice); *hybridisation* (combining practices from different contexts); *crystallisation* (embedding new procedures into practices); and *continuing to negotiate practices* that work against collaboration (Goos et al., 2017).

This study is underpinned by a sociocultural perspective, utilising Wenger's (1998) ideas about identity development and an adaptation of Valsiner's (1997) zone theory. Wenger (1998) stated that identity development entails a temporal learning trajectory connecting the past, present, and future. This trajectory can be traced by using zone theory to examine the changing interactions between an individual's learning environment and the people within it.

Extending Vygotsky's Zone of Proximal Development (ZPD), Valsiner (1997) integrated the goals, social environment, and actions of participants by introducing two additional zones – Zone of Free Movement (ZFM) and Zone of Promoted Action (ZPA). The ZFM denotes what the environment allows whilst the ZPA denotes activities or resources within the environment with respect to which a person's actions are promoted. For a MTE, the ZFM includes characteristics of teacher education students (e.g., students' beliefs about mathematics and how it is best taught and learnt and the depth of their mathematical knowledge), structural characteristics of teacher education programs (e.g., extent of connections between mathematics content courses, mathematics teaching courses and other general education courses), organisational structures (e.g., timetabling, workload, budgets), and university culture (e.g., lack of value placed on teaching) (Goos & Bennison, 2019). Similarly, the

MTE's ZPA might include reflections on practice (e.g., Chapman et al., 2020), research with teachers (e.g., Jaworski, 2001), professional development (e.g., the professional diploma for mathematics teacher educators offered by the Norwegian University of Science and Technology), and informal interactions with colleagues. For example, the informal collaboration between Bass and Ball (2014) focused on the interplay between mathematical and pedagogical aspects of classroom practice. Similarly, Jaworski (2001) described the interplay between mathematical, pedagogical, and educative reflection when teachers and MTEs work in a community of inquiry. The ZFM and ZPA work as a ZFM/ZPA complex that represents the affordances offered by people and resources within an environment, thus shaping an individual's developing identity as a MTE, whilst acknowledging individuals' agency to change their environment or their interactions with the people in it.

Research design and methods

This longitudinal case study is part of a larger study exploring the identities of Australian MTEs, both university-based mathematicians and mathematics educators, using a survey and semi-structured interviews. The interviews were designed to reveal the MTEs' identity trajectories using Valsiner's zone theory, and thus asked questions about their ZPD (Can you tell me about your background? Can you tell me about your teaching?), ZFM (Can you tell me about your professional context?), and ZPA (How have your knowledge and practices as a mathematics teacher educator developed over time?). One of those interviewed had participated in the *IMSITE* project ten years ago (Goos et al., 2017), and so this provided an opportunity for monitoring of the project's impact. Ethical clearance was provided by the university Human Ethics Research Committee (A242040), consent was given, and a pseudonym used to refer to the participant.

In this paper we report on one MTE, Carol, a mathematician who acted a broker between the mathematics and education discipline communities. Carol's interview from this current study, interview transcripts in the *IMSITE* project report (Goos et al., 2017), and a publication (Goos & Bennison, 2018) from the *IMSITE* project were analysed using Valsiner's zone theory to explore the temporal development of her identity from *past* to *present* to *possible future* as in Goos and Bennison, (2019). Data were analysed by identifying excerpts that clearly identified examples of ZPD, ZFM, and ZPA (listed above) from the interview, publication, and project report. The MTEs' responses were inserted in a table with columns for ZPD, ZFM, and ZPA and rows for past, present, and possible future. Inspecting the table horizontally, within time periods, enabled us to identify alignments and misalignments between the zones within that time period, whilst inspecting the table vertically enabled us to identify incidents that sparked changes from past to present or could potentially trigger a future change within the ZPD and ZFM/ZPA complex. From this table we could identify the enablers and constraints for collaboration between the discipline communities. The findings are summarised in Table 1 and discussed below. Interview excerpts are tagged with the year in which they occurred and categorised as relating to the MTE's ZPD, ZFM, and ZPA to illustrate the data/theory relationship.

Findings

Beginning with the ***past*** temporal dimension, Carol studied a mathematics degree and a Diploma of Education, followed later by a PhD in mathematics. She said that she identifies as a mathematician.

Reflecting on her background, Carol said she began collaborating with Tess, a mathematics educator, in 2011 when she was assigned to teach into the primary teacher education program. Thus, her *past ZPD* offered possibilities for her development as a teacher educator.

> Carol (2024); About 2011, I was assigned to teach preservice primary. Oh, that was interesting. And then I started working with Tess from education in that space, in that primary Ed space, and then Merrilyn's big *IMSITE* project came on. (ZPD)

Carol's *past ZFM* was largely structured by her perception of student characteristics. She recognised that many had mathematics anxiety and poor mathematical knowledge from school.

> Carol (2024); I had no idea that people knew so little mathematics coming out of year 12. So, I was somewhat flabbergasted by my experiences. The first time I taught, … I had my tutorial class, and I could not get them to answer questions for love nor money. I had all the classic avoidance symptoms of leaning over their work so I couldn't see it. I gave them hands on things, and they wouldn't try, necessarily. I'm drawing them out to get them to do anything, and this almost a resistance to learning. (ZFM)

Carol "did a bit of research" to understand the issue of mathematics anxiety and the "whole I can't do it. I don't want to show anybody that I can't do it." This was confronting for Carol – the "maths anxiety, maths phobia, and how our education system is failing people." The following year she made lectures compulsory, encouraged students to work with materials, explained concepts in multiple ways to build "relational understanding" and introduced mastery exams, indicating that Carol had the *personal qualities* needed to work in this interdisciplinary space.

Although Carol successfully shared teaching of the primary mathematics course with Tess, a mathematics education academic, she nevertheless observed *cultural differences* arising *within* the education discipline, where the non-mathematics educators did not understand or like mathematics.

> Carol (2024); The non-maths people in education, … they have a real interest in how students learn … When it comes to mathematics, they've got no idea. They were not good at mathematics. They don't like it either, and they feel for the students. (ZFM)

In the secondary teacher education space, the *IMSITE* project offered a ZPA providing the time for Carol and Tess to collaborate, during which they identified a *common or shared problem* in that prospective teachers did not have a good conceptual understanding of secondary school mathematics.

> Carol (2024); Tess and I identified in *IMSITE* was that they were not good with their high school mathematics, our preservice secondary maths teachers, that they're weak with their maths skills from high school. And partly it was because while they could do it, they had never investigated the whys or the wherefores or they've not made links. So, they just could do it their way. They couldn't do it any other way. (ZFM/ZPA)

IMSITE allowed Carol and Tess to codevelop and coteach a course integrating content and pedagogy - *Reflective Communication in Mathematics* to overcome *common problems* of poor student conceptual understanding of school mathematics and increase the number of students studying teaching. Originally designed for noneducation students and studied by education students as an elective, the course aimed for students to be able to analyse their own understanding of mathematical concepts, demonstrate pedagogical content knowledge by explaining mathematical concepts and explain mathematical ideas in creative ways (Goos & Bennison, 2018). The course became part of the Bachelor of Mathematics Education (Goos et al., 2017).

Carol (2024): I did succeed in getting one subject up and running through *IMSITE* that we've held on to. And that's a taste of teaching subject. So, I do talk about instrumental versus relational understanding. I do talk about reflective communication. (ZPA)

Carol (2014): We both realised that [these students] had not made the connections between their maths subjects, their pedagogy subjects, and the maths that they were going to be teaching at school. This was the first subject that they'd had where we were talking about both at the same time, taking it further than anything had been taken – like take the syllabus from high school, push it into where it goes to university where they come back and talk about how might you teach it so that you get those outcomes. (Goos & Bennison, 2018, p.264) (ZFM/ZPA)

Carol and Tess developed an understanding of the different cultures in mathematics and education:

Carol (2015): We broke down some of the skepticism that both sides can have. (Goos et al., 2017, p.15) (ZFM/ZPA)

When coteaching the mathematics subject they developed *hybrid* practices that recognise the "uniqueness of their established practices as a mathematician and mathematics educator" and their "complementary expertise" (Carol in Goos et al., 2017, p.15):

Carol (2015): We go to class and there are times when she says to me 'That's all yours because it's beyond what I understand' and that's fine. Likewise, she'll come in and talk about the greats of education and I'm just going blank, no idea. (Goos et al., 2017, p.15) (ZFM/ZPA)

Carol and Tess continued to work together at the boundary between their disciplines, shaping their shared ZFM/ZPA with weekly project meetings, attending and teaching into each other's tutorials in mathematics and mathematics education subjects, co-supervising honours students, and conducting professional development for practising teachers together (Goos et al., 2017).

Moving to the ***present*** temporal dimension, Carol's credibility in both disciplines continues to be recognised by mathematics educators at her university, potentially nurturing her development (ZPD).

Carol (2024): I've had lots of influence on the maths ed here. … I regularly get, oh, we need to catch up. … they go in to fight for these things that they truly believe in. And then they come out of the meeting, wondering … Should I keep fighting for it, … And they get from me, okay, these are the reasons why this is a good thing to fight for, okay, because of this and because of that. … I'm behind them, but it's tough. (ZPD)

In a recent review of teacher education programs the Education department decided that mathematicians were not suited to teaching mathematics to prospective teachers. At the same time, a Mathematics department review of programs decided to discontinue *Reflective Communication* course.

Carol (2024): Unfortunately, next year, with the new changes, I'm out, they've kicked me out. I think they've been trying to find a way to do it for 10 years. (ZFM/ZPA)

Carol (2024): That's where I come up against my culture, right? … They [mathematicians] just want to, it's almost like they want to open students' head and cram in as much information as they possibly can, and then sit on the head while they sew it, zip it back up again, right? ... There's so much maths to teach. (ZFM/ZPA)

The entrenched *cultural differences* between education and mathematics that had been partially mitigated by the *IMSITE* project have now become a much more significant constraint on Carol's development as a MTE. Yet she continues to seek out new ZPAs that affirm her MTE identity, such as the First Year in Mathematics network for mathematicians who are interested in teaching.

Table 1: Zone theory analysis of Carol's MTE identity trajectory

	ZPD	ZFM	ZPA
Past	- Mathematician with secondary mathematics teaching qualifications -Interested in teacher education	-Teacher education programs generally separate content and pedagogy. -One mathematics and two pedagogy courses cotaught -Prospective teachers poor conceptual understanding of secondary mathematics	-Some Mathematics Department support for co-teaching and mathematics education research -Reflections on MTE practice -*IMSITE* project provided resources for collaboration (ideas, funding, time, encouragement)
Present	-Credibility in mathematics and mathematics education communities -Most research in education	*TENSION: Disciplinary cultures prevail over interdisciplinary collaboration once IMSITE* resources end -Education academics do not understand mathematics -Mathematicians no longer value education	**Change** -Retains & increases respect of mathematics education colleagues -First Year in Mathematics
	TENSION: Institutional cultures discourage collaboration		
Possible Future	-Maintains MTE identity -Continue education research	-Cultural differences between mathematics and education	-Develop further mathematics teacher professional development
	TENSION: Carol and mathematics educators continue to collaborate		

Despite Carol's rather discouraging situation, we can catch glimpses of an optimistic ***future*** temporal dimension in her MTE identity development. She continues to pursue her goal of developing her teaching practice by reflecting on student feedback and what she has heard at conferences:

> Carol (2024): I do self-reflect lots and lots, … thinking about how I can do it better, … I regularly go to the First Year in Maths network. So, I need to go to those and get ideas from other people. Mind you, … most of the time I sit there and pull them apart and go, "Well, this is a problem with that, and this is a problem with that." But is there some gem that I could take that will help me improve. (ZPA)

Thus, Carol, is attempting to navigate through her increasingly constrained university ZFM by seeking external ZPA where she can interact with like-minded people from both the mathematics and the mathematics education communities.

Discussion and conclusion

Having qualifications in both mathematics and education, Carol's ZPD positioned her to value interdisciplinary collaboration. However, it was the realisation that many prospective primary school teachers had so little mathematical knowledge after completing twelve years of schooling (ZFM) that provided the *confrontation* between the school mathematics and university mathematics (Goos et al., 2017) that perhaps strengthened Carol's commitment to collaboration between the disciplines, similar to the co-learning of mathematics teachers and MTEs through collaborative critical inquiry (Inch & McVarish, 2003; Jaworski, 2010). Carol was perhaps driven to improve the schooling experience that was failing so many students (ZFM/ZPA).

IMSITE provided time (ZPA) for Carol and Tess to collaborate in transforming secondary mathematics teacher education so that there were education and mathematics courses that were cotaught and contained cross-disciplinary content, providing a *hybridised* practice (Goos et al., 2017). New cultural dialogues had *crystallised* (Goos et al., 2017), so that after Tess retired Carol continued to collaborate with the mathematics educators who seek her advice (ZFM/ZPA).

Whilst Carol's ZPD and strong *personal qualities* have allowed her to build sustained relationships with mathematics educators that are focused on the *shared problem* of improving student learning, this cross-disciplinary *trust* and *valuing* has not extended to all education academics where *cultural differences* mean she is seen as being on the margins. Although Carol had developed a successful primary mathematics education course, the education academics felt threatened by her presence. The Education department decided that the primary mathematics course needed to be taught by someone from the education discipline as they couldn't "rely on the mathematician to do a good job." Carol gave her course resources to Tess and continued to work with her so that the primary prospective teachers were well supported, and connections were made between mathematics and pedagogy, similar to the work of Bass and Ball (2014).

More recently, the *cultural differences* between mathematics and education arose in the review of the education pedagogy courses: the Education department no longer wanted to share course *workloads,* meaning there was no space for the mathematics discipline expert to contribute to teaching. Similarly, the mathematics program review means that, from next year, the *Reflective Communication in Mathematics* course will be discontinued. Carol's teaching is not valued by either community.

Ten years later there is still a strong sense of community between Carol and the mathematics educators who have continued the collaboration. This relationship is built on working towards the *common goal* (Goos & Bennison, 2018) of improving the learning of prospective mathematics teachers – both primary and secondary – and the "*personal qualities* of open-mindedness, trust, mutual respect, and shared beliefs and values" (Goos & Bennison, 2018, p. 265). However, within the wider mathematics and education communities, *workload formulas* and the entrenched *cultural differences* between the disciplines have not recognised or rewarded disciplinary collaboration (Goos & Bennison, 2018). Hence interdisciplinary collaborations need to be worked on continually because their success depends on more than just those who are collaborating.

Structuring deep and specific conversations: The work of mathematics teacher educators in professional learning

Kelly McKie[1], Lynsey Gibbons[1] and James Hiebert[1]

[1]University of Delaware, School of Education, Delaware, United States; kmckie@udel.edu

This paper explores how mathematics teacher educators routinely structured examination of educative curriculum materials that led to detailed, fine-grained analyses of teaching in order to support teachers' development. The study examined lesson analysis cycles, which involved lesson planning, enactment, and reflection. We found that the structure supported mathematics teacher educators to leverage curriculum materials to orchestrate discussions with teachers that focus on pedagogy, mathematical content, and student thinking. Implications for the practices of mathematics teacher educators are discussed.

Keywords: Mathematics teacher educators, professional development, MTE practices

Introduction

The goal of this paper is to describe a design for professional learning that enables mathematics teacher educators (MTEs) to lead conversations among teachers shown to support teacher learning and, in turn, more ambitious teaching (Lampert et al., 2013). Central to the design is an intense focus on the details of individual lessons from an educative curriculum (Ball & Cohen, 1999). In the United States curriculum refers to published student textbooks with teachers' manuals and accompanying materials, including unit overviews and lesson plans, designed to meet jurisdictional educational standards. Many different curricula are created and sold to school districts; often with neighboring districts teaching from different curricular materials. Curriculum materials are not all created the same. Educative curriculum materials, such as the one used in this study, support teachers in developing deeper understanding of mathematical content and pedagogy, which in turn supports students' deeper understanding of mathematics (Remillard, 2000).

In this paper, we describe an aspect of a project aimed at understanding the ways in which professional learning activities supported teachers' learning and changes in practices. We focus on the role of MTEs as they led groups of same-grade level teachers to collaboratively plan to teach a lesson from their curriculum. We provide examples that show how MTEs used a structured routine to analyse curricular lessons in a way that encouraged detailed, fine-grained analyses of teaching.

Our thesis is that deep and specific conversations about mathematical content provide rich learning opportunities for teachers (Russell et al., 2020) and that MTEs play a crucial role in the orchestration of these conversations. In the U.S., these conversations are difficult to support as teachers are necessarily trained to teach their subject apart from a particular curriculum, owing to the plethora of different materials used across the country. As Cohen observed, teachers in the U.S. typically "are taught how to teach no particular version of their subjects" (2010, p. 45). We aim to show how MTEs can leverage the analysis of a well-designed lesson to create opportunities for teachers to learn to teach a very specific version of mathematics.

Background and conceptual framework

MTEs providing coaching and expert support to teachers has become more common in the U.S. However, uncertainty exists about the optimal work of this role (Peters-Dasdemir et al., 2023). While research on the incorporation of MTEs in professional learning shows promise for improving teaching and student outcomes (Russell et al., 2020), this is not always the case (Witherspoon et al., 2021). Evidence indicates that effective facilitation is complicated work, with some approaches more effective than others (e.g., Karsenty et al., 2023; Şahin-Gür & Prediger, 2023).

One area of research has focused on conversations among MTEs and teachers that lead to more ambitious teaching (Ferreira et al., 2023). A significant finding is that the most productive conversations are deep and specific (e.g. Lefstein et al., 2020) and "focus on the interactions between teachers, students, and mathematics" rather than on "what the teacher will do" (Russell et al., 2020, p. 443). Imagine teachers slicing an individual lesson into thin pieces, identifying a critical piece, and spending significant time examining the key mathematical idea, the way students might think about that idea, and teachers' role in supporting the richest thinking possible. Examples of such conversations exist in the literature (e.g., Melville, in press; Stigler & Hiebert, 1999).

Building on this work, we examined the nature of conversations that MTEs facilitated that reached this standard of depth and specificity about mathematics content, student thinking, and pedagogy, with special interest in the conditions that supported these conversations. In our view, an important question for the field is: How do MTEs structure planning conversations that facilitate deep and specific conversations among teachers?

Context

We report preliminary findings from a project seeking to understand how teachers translate experiences during professional learning into teaching that ultimately improve student learning. The project, which emerged from a partnership between MTEs at a statewide mathematics coalition and researchers at a state university, employs a lesson analysis cycle guided by MTEs using educative curricula to engage Grades 4-7 teachers in a video-based professional development (PD) program.

The lesson analysis cycles include a highly structured process, developed by the MTEs, and centred on lessons from the *Bridges in Mathematics* curriculum (Math Learning Centre, 2019). Each cycle involved three phases: (1) planning (2) enacting and (3) reflecting. The planning involved MTEs and 3-5 same-grade level teachers collaboratively analysing and planning to teach a lesson (approx. 3.8 hours). The enactment involved the MTE videotaping a teacher teaching the lesson (approx. 45 mins). The reflection involved the MTE and each teacher watching video clips from the lesson, discussing student thinking, teacher moves, and reflecting on any changes to improve teaching of the lesson the following year (approx. 45 mins). The cycle occurred three times throughout the school year; the project was in its second year of implementation when this data was collected. Our analysis focuses on the first phase of the cycle, when the MTE facilitated planning with the teachers.

Methods

Participants

The project included 13 MTEs. For this study, we shadowed three MTEs working with 4th and 5th grade teachers. All three are considered expert MTEs with an average of 30 years teaching experience

and a range of facilitating experience from 4-20 years. As we explain below, although we analysed data for three MTEs, we pulled examples from one MTE to describe our findings—Nina, a former elementary teacher with four years of facilitating experience, and her group of three 5th grade teachers, Carla, Dana, and Tracy, with a range of teaching experience from 2-17 years.

Data collection

Researchers collected audio recordings, observational notes, and artefacts such as the planning structure, curriculum documents, the group's written record of the planning process, and the final annotated lesson plan. Recordings were collected using audio recorders.

Data analysis

All data were uploaded, transcribed, and marked using Vosaic software. We were interested in understanding how MTEs structured planning conversations. Therefore, we listened to audio recordings of the planning sessions and carried out direct content analysis (Hsieh & Shannon, 2005) by marking segments that captured interactions about content, pedagogy, and/or student thinking. We then came together and compared selections and agreed on segments that focused on at least two of these aspects (e.g., the MTE facilitated a conversation about anticipating how students thought about using money to understand decimals). We then created memos that identified specific components of the structure and moves that the MTE employed to orchestrate these interactions.

Findings

In each of the planning sessions, we repeatedly observed how MTEs used the structure they designed to orchestrate a detailed and comprehensive analysis of the lesson the teachers were preparing to teach. We first describe the MTEs' collaborative lesson planning process they co-developed (Table 1), then we provide two examples from the data to illustrate the considerable specificity with which the MTE supported teachers to analyse teaching. In our view, these conversations enabled teachers to learn to teach a specific version of mathematics.

Table 1: Planning structure used by MTEs

Duration	Components of planning structure
60 mins	Study the unit overview
20 mins	Read the lesson and engage in the mathematics in the lesson (individual)
20 mins	Identify and agree on the lesson learning goal(s)
20 mins	Unpack the key mathematical understandings and connections they want students to make
20 mins	Identify the critical moment, where the learning goal will come to life
90 mins	Anticipate student thinking and identify the pedagogical strategies that will support students to make connections and reach the learning goal

The planning process began with participants individually reading the unit overview and then collaboratively discussing how the lesson fit into a larger sequence. Following this, MTEs asked

teachers to engage with the mathematics of the lesson and identify the learning goal(s) and the critical moment of the lesson–the point of the lesson at which students would have an opportunity to grapple with the mathematical idea identified in the learning goal. After individually considering these ideas, the MTEs supported the group to reach consensus on the learning goal and the critical moment. MTEs then facilitated a longer discussion among the group, unpacking the mathematical understandings and key connections they wanted students to make. MTEs would prompt teachers to anticipate students' responses and formulate questions they could ask students to support the intended mathematical connections. Teachers identified points in the lesson where they wanted to create and foster discussion among their students, and they planned how to record students' thinking to orient other students toward the mathematical ideas.

To illuminate how MTEs utilised the planning structure to engage teachers in analysing teaching in deep and specific ways, we consider two episodes. In these episodes Nina and the three teachers were analysing a lesson designed to support students' understanding of decimal quantities. These episodes demonstrate how the MTE supported teachers to consider what they wanted students to understand in relation to decimal quantities and how they could prompt students to think about these ideas. Prior to the analyzed episodes, teachers had reached consensus on the lesson's learning goal.

The team planned for a Grade 5 mathematics lesson titled *Draw and Compare Decimals.* This lesson was part of a module that focuses on adding and subtracting decimals and supporting students to "deepen their understanding of place value in decimal numbers, equivalencies between decimals, fractions, and money, and adding and subtracting decimals" (Math Learning Centre, 2019, p. 573). As written, the first part of the lesson involves the teacher leading the class through a decimal subtraction number string (Figure 1), one problem at a time, while asking students to share their thinking and model strategies students share publicly using a number line.

3.7 - 0.7
3.7 - 0.9
4.2 - 0.2
4.2 - 0.3
7.46 - 0.46
7.46 - 0.52
1.82 - 0.83
28.32 - 0.48

Figure 1: Number string

The team agreed upon the following learning goals for the lesson: "(1) when using the removal strategy for subtraction, the subtrahend can be decomposed and removed in parts in order to reach a friendly number, and (2) when comparing decimals, the value of the tenths digit determines which decimal is greater than or less than".

Example 1: Facilitation of unpacking the key mathematical understandings and connections teachers want students to make

Nina, the MTE, asked teachers what they needed to know in order to teach the lesson well. In response, Carla shared a problem that she had dealt with in the past. She explained that sometimes students will say "I subtracted one" without referring to the unit the one represents. Anticipating the language their own students might use, the group then discussed different ways they might respond.

Carla: I don't know…where this should be added [in our lesson plan], but this thought popped in my mind…I want to make sure I'm intentional when we're getting to these prompts. When…we're moving to the whole number, that when [the students] say "and then I removed one more" to be intentional [with our response]: "What do you mean one more?" But it's not one whole one… I've just been thinking about that as we're approaching unit three… that's always a misconception that I need to

	do better at, making sure when they say "one," do they mean one or one hundredth? Do they mean one tenth? Do they mean one whole?
Nina:	So, would you call that, the language of decimals?
Carla:	Yes
Nina:	…That kind of reminds me of the last lesson we did before: 30. Thirty what? Thirty minutes? Or thirty-sixtieths? How are you thinking of that?
Carla:	And I think that the work we did on that last lesson – like being intentional with my language did improve their understanding. I've been thinking about that with decimals about how I want to be intentional because like, of course, when they say "remove", I removed one more, I know what they mean. But I think I need to encourage that kind of talk so that when we get to other removal problems, there isn't a confusion there. Because I was just thinking about that with the critical moment. That, you know, hopefully, what we'll see is that they remove the 82/100 or the 82 cents. And my kids will, in previous years or even in this group, I could see them say "and then, so I knew that that got me into one whole. So, then I removed one more." And then I would be like, "yeah." And I would just put that, but if I don't show that to them and the [students] that aren't quite there are going to be removing a tenth instead of a hundredth. And in that problem, they're actually removing a hundredth, or a penny. So, I just kind of put a note for myself that I want to listen for that misconception and correct it in that moment.
Nina:	And question.
Carla:	Mm-hmm and question to get to it

In this excerpt, Nina prompted teachers to identify specific aspects of mathematics in the lesson which were essential for them to understand. This led to several outcomes. To anticipate students' thinking and plan their responses, the teachers reflected on previous ways students had engaged with similar concepts. Carla spoke in detail describing what students might do when subtracting decimal quantities and how she planned to respond when students say they subtracted "one more". Nina connected the problem Carla identified with a lesson they had discussed earlier in the school year–a lesson in which they explored different representations when solving addition or subtraction problems with unlike denominators. This led Carla to recall that, in that lesson, it was helpful to press her students to describe the referent to which the quantities referred. Nina's questions and responses prompted the teachers to consider student thinking, mathematical content, and pedagogy. Teachers anticipated that students would name a value without being specific about what the quantity represented. The specificity with which teachers anticipated students' responses allowed them to prepare to ask questions of the students that would help students use the appropriate decimal naming.

Example 2: Facilitation of the identification of pedagogical strategies that will support students to reach the learning goal

This example took place 7 minutes later, after the teachers negotiated and identified the following mathematical connection: "I can break apart decimals into parts that make it easy to subtract". Nina led a discussion on each expression in the problem string (see Figure 1). The group anticipated how students might interact with each expression, any challenges students might have, and what the teachers wanted to pay attention to as they introduced each expression. This conversation lasted approximately 37 minutes. The excerpt below came after Nina drew the group's attention to the expression: 7.46 - 0.52, the step in the lesson they had identified as the critical moment. Nina asked the group to anticipate how students might reason through the expression. Carla offered what she thought students might struggle with (related to removing 6 hundredths from 7).

Nina: So, what are you expecting then on the 7 dollars and 46 cents minus 52 cents? [long pause]. We'll be able to get that jump of 46 cents, right? To get to the 7.

Carla: I think that the struggle… could possibly come in when they then have to remove the other 6 hundredths. And that their starting point is the whole number 7.

As the conversation continued, multiple teachers agreed that students would struggle with removing the remaining 6 hundredths from 7 dollars, after removing 46 cents from the initial amount. Nina invited the teachers to think collectively and share ideas about possible pedagogical moves that could support students with this struggle. The group members offered different ideas: comparing 7.46 - 0.52 to an expression with whole numbers (746 - 52); asking students "What if you subtracted another penny?" from $7.00; using a number line to represent the values between 6.90 and 7.00; and, simply asking students "What is in between $6.90 and $7.00?". After three minutes of sharing ideas, Nina wondered if they should consider changing the expression so students could engage with the mathematics in a way that still met the learning goal and, at the same time, would be accessible to more students.

Nina: If it [referring to the subtrahend] was just 50 cents, would I then know it's 4 more pennies pretty easily? That gives some access but keeps the goal the same…Like if this wasn't 52 cents, and it was 50 cents [7.46 - 0.50], I definitely feel like kids know there's 4 pennies. I still have to subtract 4 pennies. Some will just struggle with knowing it's 6 pennies to subtract.

Carla: Right.

Nina: I think that could… give some access to kids with still that same goal. I still have to get from 7 and I have to subtract 4 more pennies, but at least for some of them it's not struggling with figuring out its 6 pennies. I just know it's 4 pennies. If taking away one little struggle

Dana: Um-hum.

Nina: But I still have that idea of $7, take away 4 pennies. I think that money's...

Tracy: Yeah.

Nina: going to be important for this one .... And Tracy…with your kids… it could be 47 cents. Now I'm just taking away 1 penny. That's still having to know it's $6.99. That's, that's accessible.

The group continued to discuss how best to modify the problem. Because anticipating students' thinking is part of the planning structure, Nina intentionally drew teachers' attention to the critical moment of the lesson. She pushed the group to consider how best to create opportunities for students to grapple with the mathematical ideas of the learning goal. They discussed modifying the problem because they predicted that students might struggle removing 6 hundredths if they did not yet understand the big ideas of the lesson. Nina's orchestration supported teachers in developing a deeper understanding of mathematics through their fine-grained analysis of the problem string.

Discussion

MTEs in this project supported teachers to engage in deep and specific conversations. What supported their facilitation of these conversations was following a highly structured planning process using educative curriculum materials aligned with ambitious teaching. This planning process contained repetitive, recognizable interdependent actions (Feldman & Pentland, 2003) that allowed them to make "the complex work of teaching visible" (Grossman, 2020, p. 8).

The planning process involved MTEs guiding teachers to first understand the mathematical content of the lesson. This foundational step identified the key learning goal and critical moment of the lesson. The structure next supported MTEs to facilitate conversations about how students would engage with the mathematics and what actions the teachers would take to support students' learning. This approach ensured that teaching decisions and discussions remain grounded in the mathematics, rather than being driven solely by pedagogical techniques or classroom management strategies. This finding aligns with accumulating research that suggests facilitating repeated conversations among teachers characterised by a focus on content, pedagogy, and student thinking at a specific, fine-grained level is one path toward teacher learning that yields important changes in practices (Russell et al., 2020).

The planning process enabled the MTEs to support depth and specificity in the conversations, which intentionally increased with each step. Over the course of the planning process, the MTEs pressed for more specificity as they anticipated students' mathematical thinking and considered what pedagogical actions they would take to enrich that thinking. This depth and specificity was evident in the time the group spent discussing the language they would use to name decimals in episode one (5 mins) and discussing an expression in the number string (8.5 mins). This dissection of lesson elements supported teachers to develop nuanced strategies focused on student understanding of mathematical concepts.

Our analysis revealed that MTEs can facilitate opportunities for teacher learning through a highly structured planning process in which teaching becomes an object of study (Stigler & Hiebert, 1999). When MTEs and teachers examine shared problems of teaching, they create a shared language with which to communicate. These MTE-facilitated interactions can lead to learning to teach very specific versions of their subject (Cohen, 2010). For U.S. teachers, this defines a learning opportunity strikingly different from the norm.

Mathematics teacher educators professional learning: Evidence from inquiry into their own practice

Helena Montenegro[1], Francisco Rojas[2] and Salomé Martínez[1]

helena.montenegro@uchile.cl

[2]Universitat Autònoma de Barcelona, Spain

Mathematics teacher educators play a crucial role in teacher education, and examining the opportunities that facilitate their professional learning is imperative. In this study, we report how inquiry into one's own practice can be a suitable strategy for this, characterizing the improvements that mathematics teacher educators identify when participating in an e–learning self–instructional course and workshops on inquiry into their own practice. We employed a quasi–experimental, mixed methods, pre–post design; data were collected through an online questionnaire and focus groups. Findings evidence that participants in this professional learning experience perceived they developed new research skills and expanded their knowledge and positioning about research, highlighting that inquiry into one's own practice is a valid genre of research that allows them to improve their prospective teachers' learning. Finally, the implications of these findings are discussed.

Keywords: Professional learning, mathematics teacher educator, inquiry, practice–based research.

Introduction

Teacher educators are seen as crucial agents of change in preparing teachers for increasingly complex and uncertain educational contexts. They ought to model effective teaching practices, engage in research, and navigate multiple roles as researchers, mentors, and career curriculum managers (Lunenberg et al., 2014). In addition, they are responsible for implementing educational policies, reforms, and quality teaching and learning experiences inside preservice teacher education programs (Cochran–Smith et al., 2020). Considering their crucial role in educating teachers, several studies have reported the relevance of supporting teacher educators' professional learning (Kelchtermans et al., 2018; Ping et al., 2018; Tack et al., 2018).

One way to improve teacher educators' professional learning is by developing their inquiry stance and development as scholars and researchers (Cochran–Smith et al., 2020; Murray et al., 2020). According to Willemse and Boei (2013), teacher educators' research is seen as a means to achieve professional development, improve their classroom practices, and contribute to the body of their knowledge. In terms of mathematics teacher educators doing research, there has been much interest in practice–based research (such as action research, narrative inquiry, and self–studies) to develop a deep understanding of their practice to enhance it (Chapman et al., 2020). When mathematics teacher educators inquire into their own practice, they can develop an inquiring mind, maintaining research-informed teaching and building awareness about the complex task of teaching future teachers (Cochran–Smith et al., 2020; Murray et al., 2020). In other words, practice–based research allows mathematics teacher educators to scrutinize their own practice and, therefore, to support their own growth and professional development.

The RedFID project is an original model of professional learning and development for Chilean mathematics teacher educators. It offers a comprehensive support system, featuring a technological platform with three distinct digital environments: Professional Learning, Communities, and Resources (https://www.redfid.cl/). These environments provide mathematics teacher educators with access to a self–instructional professional development course, synchronous workshops, various communities of practice, and a digital library of resources.

This proposal reports the professional development outcomes related to two activities of the Professional Learning environment: the e–learning self–instructional "Inquiry into teaching practice" course and six synchronous workshops to strengthen different teaching and research skills to inquire about their teaching practices. The following research question guides this study: What are the main gains of professional learning in mathematics teacher educators who participate in a formal program to improve their abilities to inquire into their own practice? The research on this topic becomes relevant because it will allow us to systematize the improvements mathematics teacher educators gain by participating in professional learning opportunities focused on strengthening their professional development as teacher educators.

Conceptual Framework

Professional learning for teacher educators

Professional learning for teacher educators encompasses a range of activities and processes designed to enhance their knowledge, beliefs, skills, and practices (Ping et al., 2018; Tack et al., 2018) and is essential for teacher educators to maintain and enhance their teaching practices, research skills, and overall professional growth. Several authors have identified various strategies for improving professional learning among teacher educators: participation in communities of practice that share common interests and goals (Ping et al., 2018), engagement in collaborative learning and reflective practice with other teacher educators (Tack et al., 2018), and conducting research on one's own teaching practices through practitioner research and self–study (Kelchtermans et al., 2018; Tack et al., 2018). Professional learning is more effective when it is participatory, situated in the workplace, and contextually relevant (Murray et al., 2020; Ping et al., 2018).

Furthermore, the professional learning needs of teacher educators are diverse, reflecting the multifaceted and complex nature of their roles. First, it is crucial to develop specific knowledge and skills related to their dual roles as teacher educators and researchers (Ping et al., 2018) and research skills associated with conducting research and integrating research into their teaching practices (Czerniawski et al., 2017). It is also essential to build a strong professional identity and confidence in their roles as teacher educators (Tack et al., 2018). Finally, staying updated with current research in mathematics education and understanding how to apply these findings to their teaching, ensures they are well–informed and knowledgeable in their field (Martignone et al., 2022).

Inquiry own practice as professional learning

Teacher educators' engagement in conducting research is a fundamental aspect of their professional development. Ping et al. (2018) in their study point out that many teacher educators highly value research knowledge as essential for their work. This ability to conduct research includes formulating

theoretical frameworks, developing research designs, selecting research methods, and publishing results. However, despite recognizing research's importance for professional development, teacher educators face several challenges. These challenges include a lack of time and insufficient support, knowledge, and skills necessary for undertaking research (Czerniawski et al., 2017; Lunenberg et al., 2014). On the other hand, Lunenberg et al. (2014) highlight another challenge: while institutions expect teacher educators to engage in research, many feel ambivalent about this role. Indeed, they often identify more with their role as educators of future teachers and tend to show greater confidence in this aspect of their work than in their research role (Lunenberg et al., 2014).

Self–study is highlighted as an essential type of practitioner research that enables teacher educators to reflect on and improve their teaching practices, helping them better understand the relationship between teaching and learning in substantive ways (Loughran, 2014; Tack et al., 2018). The outcomes of such inquiries often highlight the role of reframing taken–for–granted practices to become more informed and knowledgeable about teaching and teacher education. Similarly, Murray et al. (2020) discuss how researching one's own practice can lead to transformative practice changes and a renewed sense of agency. This expansive learning involves creating new professional knowledge through research–informed practices, leading to new insights and changes in their professional identities and practices. Through reflection on their own practice and engagement in self–study, teacher educators develop the capacity to examine their teaching practices critically, enhancing their teaching and research skills (Kelchtermans et al., 2018; Loughran, 2014).

Methods

To identify gains in mathematics teacher educators' professional learning, we adopted a quasi–experimental, mixed methods, pre–post design (Creswell, 2014). The sample comprised 28 mathematics teacher educators from 14 Chilean universities, 19 (67.9%) females and nine males (32.1%). The average age of the sample is 47 years, ranging from 33 to 75, and the number of years of professional experience in this group ranged between 1 and 50 years, with a mean of 11 years. Regarding professional and academic qualifications, 16 (57.1%) were mathematics secondary school teachers, 7 (25%) were primary school teachers, 5 (17.9%) had a bachelor's degree in mathematics, and 18 (64.3%) had a master's degree and 10 (35.7%) had a doctorate. Concerning their affiliation with a teacher education program, 13 (46.4%) taught math courses in primary programs, 12 (42.9%) taught math courses in secondary programs, and 3 (10.7%) taught math courses in both primary and secondary programs. Each participant was assigned an identification number (MTE1–MTE28), replacing their names. All participants signed a consent form that followed national ethical standards.

Participants completed an approximately 20–hour online self–instructional course. The course is divided into three modules. In the first module, titled "Why investigate your own practice?" participants explore the concept of teaching practice and the challenges that may arise within it through a case. Each participant must identify and describe a problem of practice based on their experiences educating future teachers. The second module, titled "Approaches to innovate or investigate one's own practice," continues the case discussion by presenting a dilemma: whether to follow an innovation or research approach to address an identified problem of practice. This module clarifies the definitions of researching and innovating in one's practice and analyzes how these

approaches can complement each other when tackling a problem. Each participant is also tasked with proposing an approach to address the problem of practice they identified in the first module. In the third module, "Generating an inquiry proposal," participants are introduced to key aspects of establishing a clear purpose and analyzing the feasibility of developing an inquiry project. By working on their identified problem of practice, participants create a proposal that includes the problem they wish to address, the purpose of their inquiry, the chosen approach, and an analysis of how feasible it is to implement their proposal. After completing the course, mathematics teacher educators participated in 6 synchronous workshops to strengthen different research skills. These workshops allowed participants to complement the knowledge and skills gained from the online course in a practical setting. Figure 1 summarizes the course and workshops in which mathematics teacher educators participated.

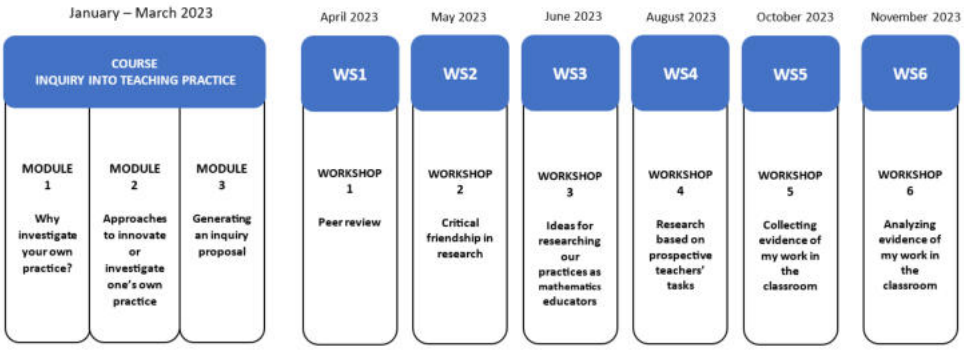

Figure 1: The course and workshops that mathematics teacher educators participated in

The research strategy used for collecting pre and post–test quantitative data was a questionnaire, whereas focus groups were used for collecting pre and post–test qualitative data. The questionnaire contained 30 items rated on a 5–point scale, from "I fully disagree" to "I fully agree". The items were adapted from the survey on teacher educators' professional learning developed by Ping et al. (2020) and the teacher educators' researcherly disposition scale developed by Tack and Vanderlinde (2016). The questionnaire has five scales: disposition to research (6 items), appraisal to research practice (5 items), appraisal to innovation practice (5 items), teaching for teacher education (8 items), and research for teacher education (6 items). The pre–test questionnaire data were collected at the beginning of the course in January 2023, and the post–test data a year later in January 2024. Descriptive statistics and paired t–tests were applied to analyze the data gathered.

The focus groups were organized to be conducted during two National Seminars of Mathematics Teacher Educators held by RedFID. Pre–test focus groups were conducted with participants who would take the course in December 2022 (n=31), and post–test focus groups were performed with participants who finished the course and actively participated in the different workshops in December 2023 (n=28). In pre–test and post–test focus groups, questions focused on how participants view professional learning and what they consider crucial topics and opportunities for strengthening mathematics teacher educators' professional development. A thematic analysis was done to identify recurring themes in the data (Clarke & Braun, 2017). While analyzing the data, two research team members cross–verified the coding of answers and jointly refined the different codes and categories

of analysis wherever necessary. That way, a high degree of consensus was achieved in the coding strategy, increasing the validity and trustworthiness of the data analysis (O'Connor & Joffe, 2020).

Findings

Quantitative results

The results of the questionnaire show relevant findings. First, as indicated in Table 1, the average scores in the post–test measurement increase in all the scales that measure aspects related to skills and interest in research. Second, only in the "Appraisal to research practice" scale the t–test was statistically significant ($t=2.372$; df 27; $p<0.05$). Third, we estimated the t–test of the pre–test and post–test scores of all the questionnaire items, finding statistically significant differences in only five items from three scales. From disposition to research scale item 5 "I am familiar with the results of recent research on teacher education" ($t=2.458$; df 27; $p=0.021$); from appraisal to research practice item 13 "I have experience in developing research on my teaching practice" ($t=3.400$; df 27; $p=0.002$), and item 14 "I have the methodological knowledge necessary to research my teaching practice" ($t=2.073$; df 27; $p=0.048$). And from research for teacher education scale item 11 "I have learned how to research my own practice" ($t=3.777$; df 27; $p=0.001$); and item 12 "I have learned the role of the mathematics teacher educator as a researcher" ($t=2.105$; df 27; $p=0.045$). These results evidence that participants in this professional learning experience perceived developing new research skills, especially related to researching their own practice.

Table 1: Results of the t–test on the different scales of the questionnaire

Scale	Pre–test score	Post–test score	t	df	*p* value
Disposition to research	3.77	3.88	0.837	27	0.410
Appraisal to research practice	**3.97**	**4.20**	**2.372**	**27**	**0.025**
Appraisal to innovation practice	4.13	4.23	0.699	27	0.491
Teaching for teacher education	3.60	3.42	-0.904	27	0.374
Research for teacher education	3.36	3. 58	1.027	27	0.314

Qualitative results

Mathematics teacher educators highlighted some key features of professional learning and some interesting changes in their approach to practice from the focus group analysis. Participants in the pre–test focus group mentioned two key issues regarding professional learning. On the one hand, mathematics teacher educators emphasise that professional learning allows the construction of different types of knowledge, such as disciplinary (mathematical), pedagogical, and socio emotional. However, it is noteworthy that the professional learning needs expressed by the mathematics teacher educators did not include those related to research and even less so to the research of their own practice: "Professional learning is not only disciplinary, but it has to do with competencies, skills, characteristics and everything that involves my job…" (MTE8, female, 22 years as a mathematics

teacher educator, pre–test FG3). Moreover, professional learning through research is associated with academic research and carried out by a privileged group of teacher educators who have the funds and protected time to conduct it: "With the privileged conditions of the assigned time, the teacher educator can devote himself to research. If these conditions do not exist in an institution, research should be forgotten" (MTE1, male, 40 years as a mathematics teacher educator, pre–test FG2).

On the other hand, since mathematics teacher educators have been involved in this professional learning instance, two main advances have been observed that we consider relevant to highlight. At the beginning (pre–test focus group), the mathematics teacher educators emphasised the need for constant reflection on their practice without necessarily specifying how this would be translated into concrete actions or a working methodology: "I think this is a very practical reflection, to look at oneself and questioning Wow, this year did not work so well for me, what happened? or What should I do?" (MTE21, female, 15 years as a mathematics teacher educator, pre–test FG4). In contrast, in the post–test focus group, participants emphasised not only the reflection of the practice but also that they had already acquired the necessary tools to engage in the process of inquiry into their own practice: "[RedFID] gave me skills, especially related to inquiry one's practice, knowing yourself, and the knowledge you have […] I really developed skills that I did not think I had" (MTE10, female, 4 years as a mathematics teacher educator, post–test FG3).

A second advance that is deemed significant pertains to the notion of research as mathematics teacher educators conceptualise it. In the beginning, in the pre–test focus group, several participants realized that research was something foreign to them, of an academic nature, or that it was not directly related to their teaching practice: "We are stuck with academic research... we do not do practitioner research that contributes more to teaching" (MTE11, male, 12 years as a mathematics teacher educator, pre–test FG3). Conversely, a year later, the participants considered research more broadly and recognised its value in fostering their academic careers: "I have broadened what I understood by research, what research was. It has changed my paradigms… Now, I can also investigate myself [...]. It has allowed me to understand that there are other ways of doing research." (MTE18, female, 15 years as a mathematics teacher educator, post–test FG2). In addition, researching one's own practice is seen as an option not only to improve teaching practices but also to impact student learning: "Another thing that I learned is that much evidence of our practice allows us to inquire about our own practice, and this is going to have implications in our way of teaching and, obviously, it has an impact on the outcomes of our prospective teachers" (MTE23, female, 4 years as a mathematics teacher educator, post–test FG4).

Conclusions

The present study aimed to investigate the professional learning of mathematics teacher educators who participated in the "Inquiry into teaching practice" course and six workshops as part of the RedFID's Professional Learning digital environment during a year. We adopted a quasi–experimental, mixed method, pre–post design, collecting quantitative and qualitative data. We found that participants scored significantly higher in their perceptions of gains related to research on teacher education and methodological knowledge and skills for researching their own practice. Furthermore, they expressed new insights about the research practice, emphasizing that researching their practice

as a teacher educator contributes to their own and prospective teachers' learning, evidencing participants expanded their knowledge about doing research and inquiry into one' practice.

These findings are in line with Willemse and Boei (2013), who state that research allows teacher educators to achieve professional development, improve classroom practices, and contribute to the knowledge base of the teacher profession. In addition, these results, despite being in line with the discussion about the research on one's practice as a means to improve the professional learning of teacher educators (Kelchtermans et al., 2018; Loughran, 2014; Murray et al., 2020; Ping et al., 2018), provide new insights of the challenges in doing this genre of research due to the necessity to acquire methodological knowledge and research skills to be able to do it. However, it is relevant to point out that, in general terms, the interest of investigating one's practice in participants has a greater focus on generic pedagogical issues rather than didactic or disciplinary issues associated with the teaching and learning of mathematics. It would be interesting to encourage research into one's own practice linked to disciplinary issues in teaching and learning mathematics to generate bodies of knowledge linked to the teaching of this discipline.

In sum, the present study provides new insights into professional learning in mathematics teacher educators through practice–based research and inquiry into one's practice. However, we must acknowledge the limitations and scope of the results obtained. For instance, the small number of participants in a specific context (Chile) limits the generalizability of the findings to a broader group of mathematics teacher educators. Moreover, this study relied solely on data gathered from questionnaires and focus groups. Incorporating additional qualitative data (such as in–depth interviews and reflective journals) could have offered a more comprehensive examination of the participants' learning experiences.

Despite these limitations, the findings of this study have the potential to contribute new knowledge and practical suggestions for the field of professional learning in teacher educators. We recommend continuing the study of the professional learning of mathematics teacher education through formal professional development programs situated in the workplace and focused on research and inquiry–based learning (Murray et al., 2020; Ping et al., 2018). It is essential to begin systematizing the results of initiatives and professional development programs for teacher educators, identifying good practices and relevant results that strengthen the professional learning of mathematics teacher educators.

Responding to emergent problems of practice in side-by-side coaching

Jen Munson[1], Mari Altshuler[2] and Erin E. Baldinger[3]

Side-by-side coaching, one form of practice-embedded PD, is designed to bridge the stubborn gap between professional development (PD) and classroom implementation. In this study, we investigate the problems of practice that emerge while teachers are participating in side-by-side coaching focused on ambitious mathematics instruction and their participation shifts from appropriation of practice to guided participation with the coach. We examine how the teacher and coach collaborate to respond to these problems of practice. Our analysis identified three emergent problems of practice, four pathways that the teacher and coach used for moving out of appropriation, and a suite of tools the teacher and coach used for responding. These findings have implications for designing practice-embedded PD that can support teacher learning of ambitious mathematics teaching practices.

Keywords: Teacher learning, Coaching, Problems of practice, Guided participation.

Prior Literature

For more than two decades, studies of effective professional development (PD) design have sought to address the enduring challenge of how to support teachers to take what they have learned in PD and implement it in their classrooms (e.g., Borko, 2004). Efforts to address the gap between PD and practice are evident in the proliferation of practice-embedded teacher learning, which situates PD closer to or within practice (Gibbons et al., 2021). Facilitators of practice-embedded teacher learning carry a variety of culturally bound titles, such as coach, mathematics leader, and numeracy coordinator (e.g., Gibbons & Cobb, 2017; Sexton & Downton, 2024). In this paper, we refer to the activities of supporting practice-embedded teacher learning as *coaching*, regardless of professional title. To understand how coaching can support teacher learning of ambitious mathematics practices, the field needs to decompose practice-embedded professional learning designs (Sztajn et al., 2020). In this paper, we examine side-by-side coaching, one form of practice-embedded teacher learning. In the context of side-by-side coaching, we specifically aim to understand what meaningful problems of practice emerge while teachers are enacting ambitious mathematics instruction and how those problems are addressed when a coach is positioned to support teacher learning in their classroom.

Decomposing Practice-Embedded Teacher Learning

Practice-embedded teacher learning designs create opportunities for in-service teachers to learn in, through, and from practice (Lampert, 2010) as teachers are able to enact and study practice in their classrooms (e.g., Gibbons et al., 2021). In these designs, the teacher educators (TEs) might be traditional university-based TEs, school-based professional developers, coaches, or any more knowledgeable other who engages in coaching. Practice-embedded PD typically involves cycles of

co-planning, teaching, and reflection, often with groups of teacher learners. Following sociocultural theory, these designs can create opportunities for learners to co-participate in practices as they learn to enact them (e.g., Wenger, 1998). Recent work has attempted to characterise the facilitation of practice-embedded PD to identify approaches that support teachers' learning (Gibbons et al., 2021).

In our study, we examine a one-on-one practice-embedded teacher learning design: side-by-side coaching. In side-by-side coaching, a coach is embedded in a single teacher's classroom, working side-by-side with the teacher to enact, problematize, and refine a focal pedagogical practice. Focal practices require in-the-moment responsiveness to student thinking, the improvisational work inherent to ambitious mathematics teaching. The coach and teacher interact with one another and with students, moving fluidly between forms of participation. To more precisely understand these interactions, we drew on Rogoff's (1995) constructs of *guided participation*, in which learners engage in shared activity with guidance to communicate and coordinate efforts, and *appropriation*, in which learners take up, transform, and enact practice, making these practices part of their repertoires. We used these two constructs to characterise structures of co-participation used during side-by-side coaching, thereby offering a detailed, empirical depiction of this practice-embedded teacher learning design (Munson et al., 2024). In doing so, we found seven patterns in the ways that the coach and teacher moved between forms of guided participation and appropriation. In three of these patterns, teachers shifted from appropriation of the focal practice to guided participation. We hypothesised that preceding these shifts, one or more problems of practice emerged that the teacher and coach attempted to address through guided participation, and it is these instances that we explore in this study.

Problems of Practice as Teacher Learning Opportunities

The pedagogical dilemmas teachers face are often referred to as *problems of practice* (Lampert, 1985). Problems of practice are not resolved by routine decisions with clearly established pathways. Rather, addressing these dilemmas requires adaptive expertise (Hatano & Inagaki, 1984), or professional judgement guided by the teacher's interpretation of data and understanding of the context. As such, problems of practice have been viewed as rich opportunities for inquiry, professional discourse, and learning (Horn & Little, 2010). One paradox of problems of practice is that they can be both perpetual, ongoing dilemmas, and immediate, singular challenges. For instance, one problem of practice in ambitious mathematics teaching is how to respond to student thinking so as to deepen students' mathematical inquiry without taking over (Munson, 2019). Teachers may experience this challenge as a daily tightrope; however, at any point the teacher must be ready to respond to a single student contribution. Problems of practice are not only theoretical; teachers have the "responsibility to act" (Lampert, 1985, p. 180). Decisions must be made and implemented in the midst of ongoing dilemmas for which there may be no singular, conclusive solution.

We agree with prior teacher education researchers that professional discourse about problems of practice can be fruitful for teacher learning (Horn & Little, 2010; Lefstein et al., 2020). In practice-embedded teacher learning designs, like the side-by-side coaching under investigation here, problems of practice can emerge from the act of teaching and can open opportunities for shared inquiry and decision making, which must be immediately tested by the responsibility of enactment. We

investigate the nature of these emergent problems of practice in side-by-side coaching to understand how they might be immediately addressed by the teacher and coach.

This analysis is situated in a larger study of side-by-side coaching in the classrooms of three primary mathematics teachers in the US. This analysis explores three linked research questions: (1) How often is a problem of practice present in the shift from appropriation to guided participation with students? (2) What problems of practice do the coach and teacher address in the transition from appropriation to guided participation with students? and (3) How do the coach and teacher address problems of practice in shifting from appropriation to guided participation with students?

Methods

Our study draws on a total of 21 side-by-side coaching sessions with three primary mathematics teachers (6-8 sessions per teacher) in the US in which the teachers aimed to develop their practice of conferring, or interacting with students during collaborative problem-solving to support sensemaking (Munson, 2019). Each coaching session occurred during a single mathematics lesson; the side-by-side coaching took place during the collaborative problem-solving portion of the lesson when teachers conferred with students. The three teachers who elected to participate in side-by-side coaching spanned different grades and career stages. Hope was a first grade (students aged 6-7 years) early-career teacher; Carmen was a second grade (students aged 7-8 years) veteran teacher seeking to make meaningful changes in her mathematics teaching practices; and Jane, a fourth grade (students aged 9-10 years) teacher, was selected by the school as a mathematics teacher leader. While all three shared the goal of supporting students to learn collaboratively through inquiry, they each had different teaching practices and motivations. As a second year teacher, Hope sought support to reflect on the decisions made during teaching. Carmen had no prior experience in inquiry-based mathematics instruction but was a confident literacy teacher. She aimed to make mathematics teaching and learning as nourishing as literacy. Jane felt she lacked access to a more knowledgeable other who could push her practice forward. She saw coaching as a way to connect with a like-minded practitioner. The first author served as the coach. Each session was video recorded, with a stationary camera located high in one corner of the classroom. Both the teacher and coach wore microphones. These records were professionally transcribed for analysis in qualitative video analysis software.

Because the focal pedagogical practice was conferring, we parsed the data into conferring interactions, which were operationalized as teacher interactions with students during collaborative problem solving, focused on students' mathematical thinking. There were a total of 50 of these conferring interactions; the teacher and coach were co-present and interacting with one another in all of them. We then segmented each conferring interaction into guided participation and appropriation. We operationalized guided participation as instances where the teacher and coach were working together on the focal pedagogy, sharing instructional leadership, or where the coach led and the teacher listened in. We identified five forms of guided participation during conferring interactions. Two of these forms—joint teaching and modelling—occurred while the teacher and coach were actively interacting with students. The other three forms—coordination of activity, pausing instruction to make sense or decisions, and reflection—occurred when the teacher and coach stepped

away from students and engaged with only each other. We operationalized appropriation as moments when the teacher took instructional leadership and the coach listened in.

After segmenting all conferring interactions, we mapped the sequences of these activities and looked for patterns in how each conferring interaction was structured. We found that when appropriation occurred, (n = 22 of 50), it was located at the beginning of conferring interactions and often (n = 17 of 22) was followed by one or more forms of guided participation with students: joint teaching or modelling. In the current analysis, we focused on these 17 conferring interactions, whose pattern of participation included a shift from appropriation to joint teaching or modelling. For each of these 17 interactions, memos were constructed which included four features: a description of what occurred during the teacher's appropriation of conferring, a description of what occurred immediately after the shift to guided participation, who initiated the shift (teacher or coach) and, where applicable, the problem of practice being addressed in that shift. We developed categories for the problems of practice and the ways the teacher or coach initiated the shift to guided participation. Where appropriate, problems of practice and responses were double-coded. We identified themes in the ways the teacher and coach responded to each problem of practice, which are reported in the findings.

Findings

In 15 of the 17 instances (88%) in which side-by-side coaching included a shift from appropriation to guided participation with students (joint teaching or modelling), the shift in participation addressed an emergent problem of practice. In the two other cases, an interruption from a student not involved in the conferring interaction precipitated the shift. In all other instances, the teacher and coach addressed an emergent problem of practice at the transition to guided participation. Our analyses focus on these 15 instances to illuminate the nature of these problems of practice, finding three distinct and related problems: (1) how to elicit, interpret, and respond to student thinking, (2) how to support students to make sense of the mathematical task or the mathematics within it, and (3) how to support students to develop models or strategies for the mathematical task at hand. In the following sections, we detail each of these problems, then turn to how the teacher and coach addressed them through side-by-side coaching.

Problems of Practice Addressed in the Shift from Appropriation to Guided Participation

In six instances, the shift to guided participation from appropriation occurred when teachers grappled with *how to elicit, interpret, and respond to student thinking*. When teachers approached students to confer, they were in the midst of problem solving, and their thinking was often still in formation or murky. Teachers began these interactions by attempting to elicit student thinking as they worked to orient themselves to what students understood, what strategies they were attempting, and where, if at all, they were struggling and why. In these six instances, teachers were variously challenged to elicit enough clear information about student thinking, make sense of the information they elicited, or develop an interpretation of the source of students' mathematical struggles, all of which are precursors to responding to and supporting student thinking. For instance, Carmen began a conferring interaction by eliciting students' thinking about the task: "Rosie had 67 flowers. Andre gave her some more flowers. Now Rosie has 90 flowers. How many flowers did Andre give her?" The pair of

students she spoke with gave contradictory and overlapping explanations of what they were trying, making it unclear what they understood and how they were working. Carmen turned to the coach and said simply, "I don't know." In that moment, the challenge was both how to glean enough information and how to form a justifiable interpretation such that a response could be developed.

In seven instances, the emergent problem of practice teachers faced was *how to support students to make sense of the mathematical task or the mathematics within it*. In these cases, teachers formed interpretations of student thinking that suggested that students were struggling to understand the mathematical task itself, interpret the context of the task, or struggling with the mathematical concepts that undergirded the task. Teachers then faced the dilemma of how to support student sensemaking without resorting to directives or prescribing procedures. For instance, Jane began an interaction with students who had been asked to determine if a specific situation involving filling up a vending machine with bottles, which came in six-packs packed into boxes, involved multiplication or division. The interaction came to a point of silence, and the teacher was not sure how to support the students to interpret the meaning of the task. Ultimately, this problem of practice involved deciding what to say that might move students to construct sustainable mathematical understanding in the moment.

In five instances, teachers confronted *how to support students to develop models or strategies* for the mathematical task at hand. In these cases, teachers saw that students needed to create models of the mathematical situation or develop a strategy for moving through the problem. In some cases, students expressed being stuck, and the teacher's dilemma was how to discursively create space for students to develop a pathway with some support while not dictating what pathway they should take. In other cases, students had selected a strategy or model but needed support to use it in ways that supported mathematical sensemaking. For instance, Hope posed a problem to four students: "I made 10 cookies and Ms. J ate 4 cookies. How many cookies are left?" When all students instantly declared the answer to be 6, Hope pressed them to construct models to provide proof. One student began to model the task with blocks by constructing a group of 10 and a second group of 4, then joining them. When Hope pressed the students to say why it did or did not make sense to make 4 more cookies in this context, one student said, "You take some out," and another added, "Because, if you make more cookies, then we [don't] have the number we need to make." But the student who constructed the joining model was not convinced. Hope faced the challenge of how to support the group to develop models and strategies that aligned to the task, their answer, and one another's understanding.

How the Coach and Teacher Addressed Problems of Practice

We explored how the teacher and coach moved between appropriation and guided participation by examining who initiated the shift out of appropriation and how they did so. In 12 of the 15 instances (80%) the coach initiated the shift, indicating that one role the coach played when the teacher was appropriating practice was to look for emergent problems of practice that could be elevated for inquiry or joint exploration. The teacher and coach used four pathways when moving out of appropriation: pausing for teacher-coach talk before shifting into joint teaching ($n = 5$) or modelling ($n = 3$), shifting directly into joint teaching ($n = 6$), or shifting directly into modelling ($n = 1$). Here, we focus on the most prevalent pathways: pauses leading to other forms of guided participation, and joint teaching.

The teacher and coach used pauses in three ways. First, the coach might initiate a pause to suggest an instructional move or line of questioning, with the intent that the teacher could implement those moves (n = 4). For instance, in the earlier example of Hope's interaction in which she encountered the problem of practice of how to support students to develop models or strategies for the cookie task, the coach initiated a pause to suggest that a productive next move might be to "tell the story with manipulatives." The teacher agreed; together the coach and teacher prompted students to prove their answers by retelling the story, modelling each part with the manipulatives available as they went. Second, the coach or teacher might initiate a pause to offer an interpretation of student thinking that the pair could discuss or debate (n = 4; note: one of these instances was double coded with the previous code). For instance, in the previous example of Jane's interaction, when she confronted the challenge of how to support students to make sense of the task, the coach initiated a pause in which she offered an interpretation that the students in the interaction were focused on defending their numerical answer of 10, while Jane was trying to focus them on the units involved; the coach posited that this communicative struggle was complicating their interaction. The teacher then invited the coach to model how to move through this challenge by saying, "Go ahead." Third, the teacher might initiate the pause to elicit the coach's interpretation of student thinking (n = 1). In each pathway involving a pause, the interaction during the pause precipitated the teacher and coach re-entering the conferring interaction with students in joint teaching, in which they collectively implemented something discussed, or modelling, in which the coach enacted the ideas generated at the teacher's request. These pathways allowed the teacher and coach to develop a hypothesis about student thinking, create a plan for how to respond, or both, which they then tested through implementation.

Alternatively, in more than one-third of instances (n = 6), the coach entered the conferring interaction directly, shifting the participation to joint teaching. In each case, the coach enacted an instructional move that addressed the problem of practice, such as posing an eliciting question, making a connection between what students said and their written work, or suggesting that constructing a model might be useful. Teachers picked up on these cues and co-participated in the interaction, and both adults shared responsibility for moving student thinking forward. For instance, in the previous example of Carmen's interaction in which she confronted the dilemma of how to elicit, interpret, and respond to student thinking, she turned to the coach and stated, "I don't know." The coach then entered the interaction with students, pointing out that their written representation was similar to their work on the 100-bead frame. The coach elicited student thinking about these models and the teacher joined in, ultimately supporting students to articulate a compensation strategy. Joint teaching was a key way to seamlessly address the emergent problem of practice, pointing the teacher down a potentially fruitful instructional pathway that the teacher and coach could traverse together.

Discussion

During side-by-side coaching, one prevalent pattern of participation was for the teacher to initiate instruction with students by appropriating the focal practice and then for the interaction to shift into guided participation. In most instances, this shift occurred after a problem of practice emerged. This study identified three problems of practice precipitating these shifts: (1) how to elicit, interpret, and respond to student thinking, (2) how to support students to make sense of the mathematical task or

the mathematics within it, and (3) how to support students to develop models or strategies for the mathematical task at hand. Through pauses, joint teaching, and modelling, the coach and teacher addressed these problems of practice using a suite of tools: suggesting or eliciting an interpretation of student thinking, suggesting a pedagogical move, and implementing pedagogical moves to advance the interaction with students. Taken together, these emergent problems of practice and ensuing responses paint a detailed picture of the dilemmas teachers face and how coaches might work with teachers to address them in the moment, simultaneously supporting teacher and student learning, extending earlier work (Gibbons et al., 2021; Munson et al., 2024).

The findings suggest appropriation can create opportunities to surface problems of practice that can then be addressed through guided participation. Appropriation was not an endpoint but a key part of the learning process, in line with Rogoff's (1995) argument that guided participation and appropriation are intertwined and mutually supportive. Further, problems of practice typically precipitated the transitions between appropriation and guided participation. Appropriation opened opportunities for problems of practice to emerge while the teacher was supported by an attentive coach, enabling the teacher and coach to respond to those problems of practice collaboratively. This suggests that the role of the coach during appropriation is to observe for problems of practice that can become opportunities for teacher learning through guided participation. Knowing the potential problems of practice that could arise when teachers are learning to enact a practice, such as a conferring, could support coaches in attending to teachers' appropriation such that they can recognize these dilemmas when they emerge. The coach then must select the right moment and tool for addressing that problem of practice. Given the challenges of responding to student thinking during instruction, these findings highlight the potential for side-by-side coaching to play an important role in teacher learning of ambitious mathematics instructional practices alongside other potentially productive coaching activities (Gibbons & Cobb, 2017).

These findings are bound by important limitations. The problems of practice we identified were directly linked to the focal practice: conferring with students during collaborative problem solving. We would expect other problems of practice to emerge during side-by-side coaching of a different focal practice, such as facilitating whole class discussions. Further, our sample was limited to 17 interactions across three classrooms with a single coach; a larger data set, with additional coaches, might reveal a wider suite of tools for responding to these problems of practice. We view these limitations as key opportunities for future research on practice-embedded teacher learning designs.

Empowering mathematics teacher specialist students as change agents: bridging theory and practice on professional development

Linda G. Opheim

University of Agder, Norway; linda.g.opheim@uia.no

This paper reports on a mathematics teacher educator (MTE) conducting action research with the aim of developing a course for teacher specialists that empowers them as change agents in the schools they work in, thus bridging theory and practice. Change agents can support both top-down and bottom-up changes, and the latter is the focus of this paper. Factors that can enable or inhibit teacher led change efforts are presented and discussed with respect to the phases of action research. Through the research, important factors are identified, and how these are dealt with collaboratively between the MTE and the students, securing results that leads to changes. Most notably, collectively we found ways to successfully get support by the principal or school leader to ensure bottom-up changes in school.

Keywords: Mathematics teacher educator, professional development, action research, change agents.

Introduction

Professional development programs can take on many forms and I will in this paper present some key ideas of designing and redesigning a professional development course in the Teacher Specialist program in Norway. Teacher Specialist was a government initiative with the aim of having dedicated teachers leading professional development with their colleagues in school.

I was involved in all phases of the process of giving a Teacher Specialist course in mathematics at my University; from participating in the working group who formulated the application to the tender from the Norwegian Directorate for Education and Training, to deciding the courses included in the program, writing one of the course descriptions, and finally lecturing this specific course. This provided me a unique opportunity to design a course built upon knowledge from research, and I will present the choices, development and learning in this paper using action research as a methodology.

Work culture in Norway has a noticeable flat organizational structure, where workers often have a great deal of autonomy; this is also so for teachers. While the curriculum specifies what the pupils should learn in mathematics, it is up to the teachers to choose the most appropriate methods to achieve this. Consequently, a professional development program called Teacher Specialist was not well received in the beginning because of the name (Hoem et al., 2017). In Norway, there is a skepticism to anyone claiming to 'be better' than others and it can therefore be challenging for these teachers to find their place as a leader in mathematics teaching at their school. An evaluation of the pilot for the Teacher Specialist education points to a need for improvement in the schools' involvement in the Teacher Specialist student's assignments. In addition, the Teacher Specialist students themselves ask for tools to initiate change processes at their own workplace and more awareness and training on colleague guidance (Seland et al., 2017). Considering these challenges Hoem et al. (2017) argue that we need to find ways to make these teacher specialist students change agents at their own workplace.

This is the background for designing a course in the Teacher Specialist program, and this led me to the following research question: How can I design a professional development course for Teacher Specialists in mathematics that will make them successful change agents at their workplace?

Change agents are here defined as "individuals who can successfully transform aspects of how organisations operate" (Brown et al., 2021, p. 1).

Theoretical perspectives

A goal of the Teacher Specialist program in Norway is to educate teachers who can act as educational change agents in mathematics at their school. So, this professional development program is not solely meant for individual learning, but to support teachers to successfully transform aspects of how their school operate. Being a change agent can be challenging, and most of the research literature generally conceptualize change agents as "those individuals who are best able to support the introduction of new top-down (as opposed to bottom-up) change" (Brown et al., 2021, p. 11). A top-down change is characterized by school leaders or policy-makers initiating change, and a factor for successful change in this perspective is distributive leadership (Brown et al., 2021). On the other hand, bottom-up change describes changes initiated by teachers trying to influence a school organization. The research on bottom-up change agents is limited, and so is research on the effectiveness of all types of change agents (Brown et al., 2021). However, Brown and colleagues (2021) identified in their literature review four main factors that may enable or inhibit teacher leaders' change efforts. These are:

> 1) principal or school leadership support; 2) buy-in to the role by practitioner colleagues; 3) access to training and professional development; and 4) perceived autonomy and teacher leaders' own positioning in the role. (Brown et al., 2021, p. 10)

These main factors that may enable or inhibit are also recognizable in the Norwegian Teacher Specialist initiative. Lorentzen (2020) has investigated Teacher Specialists and the boundaries they perceive to encounter in the Norwegian system. She has identified three types of boundaries:

> The knowledge boundary: Concerns perceived variations in the specialists' and the teacher staffs' perspectives of the specialists' performances. The specialists feel anxious about whether other teachers perceive their activities, especially their plenary presentations, as useful.
>
> The structural boundary: Concerns the specialists' perceptions of falling outside the schools' organisational structures, resulting in a mixture of positions and roles and the impression that teachers are forgetting about their role.
>
> The relational boundary: Concerns perceived variations in specialists' and the teacher staffs' perspectives of prominence. The specialists feel lonely and are anxious about being too pushy or outreaching to the other teachers. (Lorentzen, 2020, p. 683)

So, the research literature is clear about theoretical knowledge from universities is not enough to make teachers effective change agents in their workplace. Therefore, a course in the Teacher Specialist program should preferably include work that will empower the teacher specialists also in structural and relational areas which research literature point to regarding successful change agents.

Methods

I have conducted action research to answer my research question. According to Kemmis (2009), "action research aims at changing three things: practitioners' *practices*, their *understandings* of their practices, and the *conditions* in which they practise" (2009, p. 463). As previously stated, my research question is: How can I design a professional development course for teacher specialists in mathematics that will make them successful change agents at their workplace? In order to investigate this research question, I need to engage in a critical and self-critical process together with the Teacher Specialist students. There are various ways of describing action research, and Kemmis (2009) distinguishes between technical, practical and critical action research (pp. 469-471). These variations of action research are distinguished by the relationship between the participant-researcher and the others involved in or affected by the research. They vary from technical action research where the participant-researcher makes all the choices and decisions, to critical action research which is viewed as a collective effort where all voices have the same decisive power (Kemmis, 2009). I position this research as a practical action research, following the descriptions of Kemmis (2009) as a project that is self-directed, but in this case the others involved also have a voice (p. 470).

The context of this research is the course I am teaching to the Teacher Specialist students, and the aim of the research is to develop and adjust this course to provide support for the students to be successful change agents at their workplace. The number of students taking the course has been 16, 8 and 16, and they are required to be certified teachers and be employed as a teacher when they are taking the course. The teacher specialist professional development programme I taught was given as an opportunity from 2019–2021, and the Norwegian Directorate for Education and Training funded this by paying close to 40 % of the teachers' salary, thus freeing time to study. The teachers applied for the professional development through their principal, who had to actively agree to let teachers at their school take part in the teacher specialist study programme. The course I designed and taught was called 'selected professional-relevant methods and perspectives on learning'.

The data analyzed are extensive, and include the researcher's considerations when designing the course, course requirements, students' reactions and feedbacks and course outcomes. These are analyzed with respect to factors that may enable or inhibit teacher leaders' change efforts, and the results are structured according to the phases of actions research, which can be seen in Figure 1.

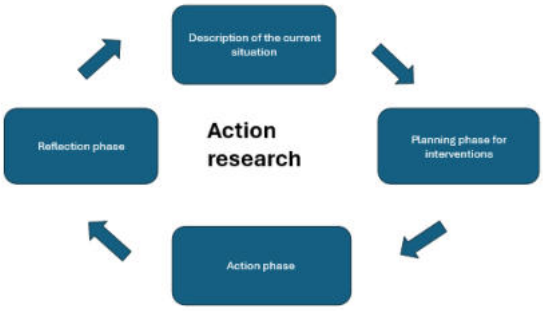

Figure 1: Phases of action research

First, I describe the current situation with respect to the research question I wish to address. This is followed by a planning phase of the interventions needed. The third and fourth phases are the action phase and the reflection phase. The findings and choices made in the phases of action research are discussed with respect to theory on change agents in the discussion part.

Results

Description of the current situation

Given that the model did not give the teachers extra money to study, but freed their time to develop their own teaching, I assumed that the students applying would mostly have an internal motivation to learn and improve their own teaching. Also, I assumed that while these teachers probably are highly motivated and with a high standard of work ethics, their workload is most likely not evenly distributed and there might be very intense periods teaching their classes. Therefore, the course needed some flexibility. One element I was unsure about was how they themselves thought of the term 'teacher specialist', their own role now and in the future, and also how their leader and colleagues looked upon this. We know from research that this can vary.

In 2020 a new curriculum was implemented in Norway, and there were some notable changes to mathematics in this curriculum. Previously, there were only learning goals in mathematics, but with the new curriculum, core elements were also introduced. These core elements are defined as the most important aspects of the subject that the pupils need to learn through school. In mathematics these core elements are: exploration and problem solving, modelling and applications, reasoning and argumentation, representation and communication, abstraction and generalisation, and mathematical fields of knowledge. While the curriculum was not implemented before 2020, the core elements where already known in 2019. The mathematical topics teachers were used to, like numbers and geometry, were now all part of the last core element, while the other core elements describe processes the pupils need to develop and master to be competent in mathematics. Also, these core elements should be an integrated part of teaching mathematics at all levels, from first grade until the pupils finish school.

While many teachers have taught mathematics and paid attention to these core elements before the new national curriculum was introduced, this is no longer optional. From 2020 all teachers are required to teach according to this curriculum. Teaching according to these core elements is challenging (Reinhardtsen et al., 2025), and I therefore assume many teachers would want support on how to develop such teaching. Consequently, the timing for teacher specialists to take on a leading role among colleagues is good.

Planning phase for intervention

Since I know how challenging it can be to be an effective change agent at your own school, I wanted to initiate some changes while the teacher specialist students had support both from me and their fellow students. Therefore, I designed a course where they not only learned about Lesson Study as a way of professional development, but they also had a compulsory task to lead colleagues in cycles of Lesson Study in mathematics at their workplace. While many courses in teacher education introduce Lesson Study as a professional development method and challenge their students to test it out

(Munthe et al., 2015), I have not heard of any other course challenging students to both learn about the method and lead their colleagues at the same time, before they have had any experience themselves with Lesson Study.

I knew that requiring the Teacher Specialist students to lead Lesson Study meant that I would have to be pragmatic on how it was done. At the university, the students learned about key aspects of Lesson Study and that the method is about systematizing teachers learning (Munthe et al., 2015). The first stage of Lesson Study is to do a GAP-analysis, that is to identify teachers need to improve their own teaching. This means it is a bottom-up method. The next stage is planning the intervention. This stage should take at least six hours to complete and I urged them to challenge their usual practice. The third stage is to conduct the intervention, and the teachers should draw about who teaches the lesson while all others have designated observation roles, observing the pupils not the teaching. The fourth stage is to discuss their observations up against their research question and how they can improve the lesson even further. The final stage, a crucial stage, is dissemination to colleagues at school.

The Teacher Specialist students are taking a course they get credits for, and the exam result is graded. I am therefore assuming they want to work for good grades, and thus need to design their assignment so they are willing to challenge their own practice and colleagues, without this resulting in a bad grade. Consequently, leading and reporting on how they conducted Lesson Study with their colleagues was a course requirement, but not relevant for their grade. In addition, I allowed them to deviate from any of the key aspects of Lesson Study, if they saw it as necessary to be able to do this with their colleagues. However, they would have to reflect upon possible benefits and losses by making such decisions.

While the written report was just a course requirement the Teacher Specialist Students received feedback on, the work they had put into it would still influence their exam grade. They had the first 5-10 minutes of their oral examination to present how they had led the Lesson Study process at their workplace, and to reflect upon the process and the choices they had made. This way, the students could use their theoretical insights and knowledge to reflect upon their own work as change agents in practice.

Action phase

Most of the Teacher Specialist students reacted positively when they learned about how they were expected to lead professional development at their own workplace, with a few exceptions. However, some of the students quickly made me aware that it might be challenging to get their school principal to set aside time for them and their colleagues to complete such a task. We therefore discussed how this best could be solved, and we agreed that I should formulate a letter to the principal. This letter was formulated in the 'Norwegian spirit', meaning that I did not demand the principal to give time for this. Instead I thanked them for allowing an employee and the school to commit to the Teacher Specialist education, expressed an understanding of tight schedules in schools, explained how Lesson Study could be beneficial to implementing the new curriculum, including references to The Norwegian Directorate for Education and Training emphasizing this method , and carefully reminded them that Teacher Specialist education would have course requirements that needed to be done in

schools. In Norway, it is mostly more efficient to let the principal feel they have a choice, but to argue so well and convincing that they see it as beneficial to support the Teacher Specialist student.

After I had written the letter, I sent it to the Teacher Specialist students so they could give feedback on it, and whether they believed it would be sufficient. For some of the students, I added text to address individual situations at their school. Whether the students used the letter was voluntarily, and not all students felt the need. However, all students now managed to get enough time and participating colleagues at their workplace to complete the required assignment on leading Lesson Study at their school.

Another notable thing in the action phase, was how much time we spent discussing the key aspects of lesson study. Because I allowed them to deviate from the method, they felt a need to understand why the requirements of Lesson Study were formulated the way they were, and this made the class discussions fruitful and closely connected to practice at the students' schools.

Reflection phase

It seems that allowing the Teacher Specialist students to deviate from key aspects of Lesson Study might have made them even more aware of why these requirements are there and the purpose. Several of them commented that they would not deviate from certain key aspects again, if they were to repeat the process. For instance, requiring that everyone in the group was present when working, spending more than six hours planning, and not deciding who would teach the lesson until after it was planned, were all key aspects it seemed like the students only fully saw the potential of after having omitted them.

The letter to the principal was something I had not thought of, but I think it was beneficial on more than one level. The most obvious was giving the students time to do the assignment, but it also provided the principal more insight into what Teacher Specialist student learns, and how this can be beneficial for the whole school, thus bridging the gap between the course and practice of the school.

Discussion

The research question guiding this action research was: How can I design a professional development course for Teacher Specialists in mathematics that will make them successful change agents at their workplace? I will in the following discuss my findings with respect to the theories on change agents.

There were four main factors identified in the literature by Brown et al. (2021) that may enable or inhibit teacher leaders' change efforts. The first of these was support by the principal or school leader. This factor also includes Lorentzen's (2020) structural boundary, where the Teacher Specialists can feel anxious about falling outside the school's structure. When I designed the Teacher Specialist course, I knew that the school principals had approved the study application by the Teacher Specialist student, and I assumed they had noticed and were aware that some of the course work would take place in this school. I assumed that the principal would be positive and support the teachers, while I was more unsure about the teacher colleagues. However, the Teacher Specialists made me aware that this was not necessarily the case, and we therefore wrote the letter to the principal. In hindsight, this was probably a good way of not only allowing the Teacher Specialists time for their assignment, but to ensure that school leaders were more aware of what they learned and how they could be a resource

for the school in the future. While we at the University can anticipate and make plans for how to facilitate our students school leadership support, I have learned that this is something that should be continuously discussed with the Teacher Specialist students. It can vary a lot, but it is also possible to find solutions, like the letter, with joint effort.

The second factor described by Brown et al. (2021), is the buy-in to the role by practitioner colleagues. I would say this factor includes Lorentzen's (2020) description of the relational boundary, but the relational boundary can also be part of the fourth factor discussed below. Finding a balance between giving teachers space and autonomy and giving them guidance and advice, is a difficulty for Teacher Specialist students, in all countries and especially in Norway with an egalitarian organisational structure. If the Teacher Specialist students are to be successful, they need to find this balance. I had chosen Lesson Study as a method for professional development with this in mind, because it is centred around the idea that it is the teachers that need to identify what they need to learn and further develop. Consequently, I am not asking the Teacher specialists to implement a top-down reform, but giving them a developmental frame they can use to support their colleagues in a bottom-up professional development at their school. This seemed to be a successful approach, given that several of the initiatives started with this Lesson Study continued in various ways. The Teacher Specialist students found colleagues to work with and got them interested, and this was reported both on the oral exams, but also further developed and researched through master projects.

The third factor Brown et al. (2021) draw attention to is access to training and professional development. This factor is also relatable to Lorentzen's (2020) knowledge boundary, although the Teacher Specialists are more worried about whether their colleagues view their knowledge as useful. Since the Teacher Specialist education is given as a professional development where the students simultaneously are working as teachers, this provides opportunities for access to training and professional development while they are acting as change agents. Experiences from this course also emphasise the importance of challenging the students to act as change agents while they are still doing the course, thus giving more opportunities to solve issues from practice with the support of fellow students and me as an educator.

Perceived autonomy and teacher leaders' own positioning in the role is the fourth factor Brown et al. (2021) point to. This factor is also relevant all of Lorentzen's (2020) boundaries. The system in Norway and the egalitarian organisational structure makes this factor even more important, because the Teacher Specialists need to take an active role in defining their position among colleagues. This was something we concurrently discussed throughout the course, and it was important to the Teacher Specialist students to both have these discussions, but also to have the autonomy to define this role back at their school.

Conclusion

When giving a professional development course where one of the aims is to empower the students to become effective change agents at their school, we need to address more than just the theoretical perspectives. We need to find ways of working that can provide support for the students with respect to all factors listed by Brown et al. (2021). While we as mathematics teacher educators can anticipate and make adjustments with respect to theories and research, we also need to include the students if

we want to be successful in finding ways where they can make sure they get support from their school leaders and colleagues. This is especially so if we want a self-preserving environment of bottom-up development in mathematics at schools. While this research demonstrates how all factors that might enable or inhibit teacher leaders' change efforts need to be addressed in such a course, most notably, collectively we found ways to successfully get support by the principal or school leader to ensure bottom-up changes in school.

Exploring mathematics teacher educators' pedagogical content knowledge: a case study

Andrés Pérez-Montilla[1], José María Cardeñoso[1] and Miguel Ángel Montes[2]

[1]University of Cádiz, Faculty of Education, Puerto Real, Spain; andres.perezmontilla@uca.es

[2]University of Huelva, Spain

This study is situated within the research line of Mathematics Teacher Educators (MTEs). Specifically, it aims to characterize aspects of the pedagogical content knowledge (PCK) used by an educator in their practice. To achieve this goal, the work begins with a literature review that presents various perspectives on the PCK required by an MTE. It then details the research design, which is characterized by adopting a qualitative-interpretative approach through a single case study, with the context being a pre-service teacher program for secondary school mathematics teachers. The results highlight three components of the MTE's knowledge that supported his practices. We hope that this paper contributes to a better understanding of the knowledge required by MTEs and their practices.

Keywords: Mathematics teacher educators, professional knowledge, teacher education, case studies.

Introduction

In recent decades, the research community has sought to understand the processes of teaching mathematics from a perspective focused on students' learning outcomes, with the teacher being a key actor. However, as noted by Krainer et al. (2021), attention has shifted towards the teacher, giving rise to a new research field: teacher education, in which teacher educators play an essential role. This paper is situated within the research line on teacher educators' knowledge and aims to characterize the pedagogical content knowledge (PCK) employed by a secondary mathematics teacher educator while delivering a pre-service teacher training course.

In this regard, research finds that the community of mathematics teacher educators (MTEs) is heterogeneous in terms of profiles, backgrounds, and training contexts (both pre-service and in-service). This diversity implies that there are multiple perspectives on what should be taught, the goals to be achieved, the resources used, and the challenges faced by MTEs (Li & Castro-Superfine, 2018). Consequently, there are various perspectives (Castro-Superfine et al., 2020; Peters-Dasdemir et al., 2023) attempting to characterize the knowledge required by an MTE, although there is a consensus that both the content knowledge for teacher education (MTECK) and the pedagogical content knowledge for teacher education (MTEPCK) are considered two relevant dimensions.

Thus, the research question we propose is: what knowledge does an MTE mobilize when teaching pre-service teachers? More specifically, and for the sake of brevity, we will focus on a specific dimension of PCK referred to as knowledge of the features of teachers' professional development (Escudero-Ávila et al., 2021).

Literature review

Research on the knowledge required by MTEs remains in its nascent stages, but there is a consensus that the knowledge necessary for teachers to effectively practice their profession constitutes a

foundational component or an essential dimension of a prospective framework or model for teacher educator knowledge (Chapman, 2021).

The role of a teacher educator is to provide support or guide to teachers within the context of adult education, which requires specific knowledge and competencies. In the case of MTEs, given that mathematics teaching involves highly specialized domain-specific knowledge, it is crucial to define the knowledge required by a MTE (Peters-Dasdemir et al., 2023). In this regard, Pérez-Montilla & Cardeñoso (2023) analyzed several frameworks related to MTE's knowledge, concluding the content they teach differs from that taught by mathematics teachers, and their audience is not schoolchildren, but teachers in training or in service. From this perspective, MTEs require a specific PCK that helps them "represent the subject in such a way as to make it accessible to their students" (Escudero-Ávila et al., 2021, p. 31). Therefore, and through a reinterpretation of Shulman's (1987) work considering the professional duties of MTEs, MTEPCK could be organized around three dimensions: knowledge of teaching teachers, knowledge of teachers' professional learning, and knowledge of the syllabus, with this study focusing on the second dimension (Escudero-Ávila et al., 2021). In this study we will focus on MTE'S knowledge of teachers' professional learning.

In their work, Escudero-Ávila et al. (2021) refer to knowledge of teachers' professional learning as *features of the professional development of mathematics teachers* (which we abbreviate as KFPD). This knowledge provides MTEs with insights into the evolving nature of teachers' learning processes and how these processes can be characterized. The authors also address the challenges teachers face during the specialization of their knowledge, the prior knowledge and preconceived notions they bring, and how these influence their learning. Similarly, scholars such as Prediger et al. (2022) use the term *knowledge of teachers' typical difficulties* to describe a facilitator's awareness of how teachers' preconceptions or prior knowledge may impede the attainment of professional development goals. On the other hand, Leikin et al. (2018) introduce another element of knowledge related to how MTEs (in their study, professional mathematicians) demonstrated *sensitivity* to mathematics teachers by addressing psychological aspects integrated into their courses, encompassing both cognitive and affective components. Additionally, *knowledge of teachers' typical content-specific learning pathways*, as introduced by Prediger et al. (2022), would provide MTEs with critical information regarding key aspects to focus on. This would also enable them to infer the stage at which teachers are in relation to a specific content area within a professional development program.

In any event, all the previously described approaches underscore the necessity for MTEs to possess a distinct type of knowledge compared to that of classroom teachers. This distinction arises from the unique characteristics of both the content being taught and the specific audience being targeted.

Design research

In this section, we describe the participant in our study, the context, the types of data collected, and the methodology of the analysis. This study is part of a larger ongoing investigation aimed at characterizing the professional knowledge of a mathematics teacher educator within the context of pre-service secondary teacher education.

Participant

Our participant, hereafter referred to as José, is an active secondary school teacher with over 20 years of experience and has been serving as a teacher educator for the past 5 years. He possesses extensive experience in delivering professional development courses to in-service teachers and has recently embarked on research in mathematics education. José was selected based on criteria of availability and intentionality, due to his significant professional background in teacher training and his dual role as both a teacher and educator.

Context

Our research was conducted during the first six sessions of a pre-service secondary teacher training program delivered (with 20 PSTs enrolled) at a Spanish university, due to resource constraints. The focus was specifically on the course *Learning and Teaching in the Mathematics Specialization* within the master's degree in Secondary Teacher Education—an essential qualification in Spain for becoming a certified teacher-. Each session lasted 4 hours, and the content of each session covered during the research is detailed in Table 1.

Table 1: Session schedule for the curriculum and learning analysis module

Session 1	Purposes of mathematics education	Session 4	Analysis of the Spanish curriculum III: specific mathematical competencies
Session 2	Analysis of the Spanish curriculum I: general overview	Session 5	Mathematical competencies: perspectives from PISA and Niss & Højgaard (2019) (design of a task analysis instrument)
Session 3	Analysis of the Spanish Curriculum II: general ideas on competencies	Session 6	Mathematical competencies: perspectives from PISA and Niss & Højgaard (2019) (design of tasks to develop competencies)

Information gathering

The sessions were recorded in both audio and video, and the audio recordings also captured the collective discussions that took place in small groups during these sessions. Additionally, a summary of the main learning objectives was provided by José to the researchers before each session. The data were segmented by selecting episodes whose content focused on the development of the PSTs' professional identity, their professional knowledge for teaching mathematics or effective teaching practices. This selection was based on the framework proposed by Escudero-Ávila et al. (2021), which identifies these three dimensions as essential components of the knowledge that an MTE should possess in relation to the content to be taught in a mathematics teacher education program.

Method

This study is conducted within an interpretive paradigm and adopts a qualitative approach through a single-case study design (Bassey, 2003), and the method for data analysis is of the top-down/bottom-up type (Grbich, 2003). The phenomenon to be studied is to characterize the PCK that informs an educator about how pre-service teachers learn during a PD program which we have denoted as KFPD.

We began the top-down process building on Prediger et al. (2022) components: knowledge about teachers' typical difficulties and knowledge of teachers' typical learning pathways considered as elements of KFPD and described previously. The bottom-up approach focused on systematically organizing and integrating emerging data into these predefined categories, with the goal of connecting the available information to the relevant theoretical concepts. At the end of the two processes, the initial category system was refined including a new component: knowledge about emotional and affective aspects of pre-service teachers' professional development. The credibility of the findings was ensured through member validation (Bryman, 2001). In the first stage, one member of the research group coded the information contained in the recordings. Subsequently, this coding was presented to the other members to gather their perspectives. Discrepancies were discussed, and consensus was reached by repeating the analysis, which is the one presented in this work.

Results

José's interventions have been coded as MTE_X-S, where X indicates the episode and S the order of the intervention, while the pre-service teachers (PTs) are identified as PT_X-M-S, with M representing a unique identifier for each PT.

Knowledge about teachers' typical difficulties

Episode 1 was selected from session 5 because it illustrates the role that knowledge about teachers' typical difficulties plays in the management of collective discussions, specifically in making sense of the interventions of the PTs. Segment MTE_1-2 shows a moment in which our participant counterposes PT's preconceptions revealed in PT_1-3-2 regarding the use of counterexamples in teaching, questioning and challenging to help them.

1	PT_1-3-1:	If I give the students $\sqrt{25}$ and then $\sqrt{9}+\sqrt{16}$, the result is clearly different. End of the problem, I mean, they'll understand that they can't do that anymore [add the radicands].
2	MTE_1-1:	So, you're trying to tell me that with the strength of your argument you're going to achieve… (smiles) I'm not sure how to say it…
3	PT_1-3-2:	What I'm trying to say is that counterexamples help to [see] that it's not a general rule. Therefore, if they're working abstractly or algebraically rather than numerically, they can't rely on those preconceived ideas.
4	MTE_1-2:	Keep in mind that the concept of a counterexample that a mathematician has, they don't [have it]… right? Well, okay, so the example you gave me doesn't work, but who's to say it's only that one? And you, as a teacher, know it. It's not that simple because the notion of a counterexample, like other mathematical proof techniques, has a certain level of sophistication, right? They don't necessarily have that. What's clear is that you need to suggest the correct answer; you can give an example or a counterexample. But that doesn't guarantee that the problem will be solved.

Episode 2, extracted from a later moment in session 5, illustrates how knowledge about teachers' typical difficulties enables our participant to anticipate the specific challenges that PTs face, which must be addressed. In this case, José highlights the difficulty of distinguishing which mathematical competency a student is drawing upon, due to the overlap of the skills involved and their supportive role.

5	MTE_2_1:	[…] Communicating with mathematics and about mathematics. Here, we understand that, on one hand, the pupil is able to establish communication

with mathematics. They need to understand texts in mathematical language, which can be visual or algebraic, right? For example, here we have two representations [points to the ppt] of the Pythagorean theorem, and they are two different ways of understanding the same concept. Being able to grasp that duality is crucial, and obviously, you can connect it with previous competencies, which often makes it difficult to draw the line between them, right? One competency influences another…

Knowledge of teachers' typical learning pathways

The third episode, selected from session 6, illustrates how José is aware of the different ways in which PTs reason, act, and react when selecting technological resources for the tasks they design. This knowledge enables to our educator to identify relevant focal points that can trigger moments of PD.

6	MTE_3-1:	But when you tell me that you've focused more on the IT aspect…
7	PT_3-4-1:	We're going to have a problem-solving session, and the next day [...] all those problems they did by hand the day before [...] (interrupted)
8	MTE_3-2:	Let me see if I understand you. You're supposed to have been working on... (interrupted)
9	PT_3-4:	The topic, the content...
10	MTE_3-3:	And now you're going to use a technological tool—what for?
11	PT_3-4:	To solve the problems and verify that the solution is correct. More than just checking, so they also learn how to use the computer to solve those same problems with different software.
12	MTE_3-4:	Okay. What's interesting, in my opinion, would be to say, alright, that seems like a good approach, […] How could the inclusion of that tool not only serve to tell me if the solution is correct or not, but also how could that tool help me pose questions that I wouldn't ask if I didn't have that tool [...]?

In episode 4 (extracted from session 1), José selects excerpts from the reports written by groups of PTs, around which he organizes whole-group discussions. Knowledge of teachers' typical learning pathways helps our participant to identify key areas that PTs need to explore and focus on.

13	MTE_4-1:	[…] You wrote down: incorporation of tools to assist with calculations. So, I understand from what you've said that you don't want to abandon calculations. Calculations must be present [in teaching], but somehow, they need to be supported.
14	PT_4-5-1:	A middle ground. I think it's also important to know how to do calculations by hand because otherwise, you don't fully understand... You don't completely grasp what's necessary for the computer to do in the background. That's what I believe.
15	MTE_4-2:	So, if one isn't knowing what the machine is doing, are we missing something?
16	PT_4-5-2:	It's not quite that, but I think it's important... I mean, if you're in a technology or engineering course and you need to apply mathematics and having a computer is great because otherwise it would be impossible, right? But for someone who is going to dedicate themselves to mathematics not to know how the computer works until they start working in the field is, I think, unfortunate. […]

Knowledge about emotional and affective aspects of teachers' professional development

During episode 5, which took place in session 6, José showed interest in a mathematical task developed by a small group of PTs. The task aimed to enhance mathematical competencies (Niss & Højgaard, 2019). This excerpt illustrates how knowledge of the emotional and affective aspects of

teachers' professional development was useful when providing feedback to PTs. It highlighted areas for improvement while also recognizing their efforts and strengths.

17 MTE_5-1: Okay, but let's not forget that what we want is for the students to become competent in some way. I'm not sure what specific competencies you're aiming to develop.

18 PT_5-2-1: It's because the activity we're considering involves us proposing real-life problems, like "If Juan and Pedro together have 5 euros, but the difference between them is 2 euros, how much money does each have?" We want them to model it. This way, we already have a competency.

19 MTE_5-2: […] But I think it's a good approach, understand me. However, you need to come up with something that has a bit more substance. I find the approach interesting, and I also think it's great point that you're using ICTs, even to critique them.

Finally, episode 6, extracted from session 1, places José in a group discussion. He shared a report with the whole group that had been prepared by a small group of PTs. This excerpt is illustrative because it shows how José draws on his knowledge of the emotional and affective aspects of teachers' professional development. During the public reading, he focused on the strengths of the report, drawing on them to introduce clarifications. His approach was accompanied by positive comments, which helped reinforce the PTs' confidence and encourage further development.

20 MTE_6-1: "Using mathematics to develop logic." Well, I find this interesting. The idea of having an exchange of ideas, right? For someone to develop their ability to think and critique, right? Very good.

Discussion

The aim of this study was to investigate the KFPD (Knowledge of the Features of Professional Development) mobilized by an educator in practice. Three elements of KFPD were identified. Firstly, José's knowledge of PTs' typical difficulties proved useful in managing collective discussions (episode 1). Specifically, it helped him understand PTs' preconceptions and how these can be an obstacle in their PD which led our participant to challenge PT-3's ideas about counterexamples. Therefore, we hypothesize that this knowledge would inform MTEs about when to introduce facilitation moves to sustain a focus on specific aspects of teaching related to students' thinking and reasoning (Gibbons & Nieman, 2024) and support productive discussions. In addition, our findings (see episode 2) suggest that this knowledge would have guided José in determining the most appropriate moments to introduce clarifying comments on aspects that could potentially be problematic, that is, it would support the practice of anticipating potential difficulties for teachers.

In another context, our findings regarding José's knowledge of PTs' typical learning pathways showed that our educator was aware of PTs' typical use of ICT resources in teaching in episode 3. In this respect, we hypothesize that José knew how PTs use teaching resources when designing a mathematical task, tailoring his feedback to challenge their preconceptions. As a result, we share with Prediger et al. (2022) the view that this knowledge is key to reacting in participant- and goal-oriented ways since it helps facilitators and educators prompt opportunities for PD.

Finally, José's awareness of the emotional and affective aspects of his pre-service teachers significantly supported his management of group discussions. He created comfortable environments that foster the exchange of ideas and practices, ultimately establishing a learning community (Ferreira

et al., 2024). Therefore, this element of knowledge could help MTEs in their practice by making it clear when it is appropriate to praise positive aspects of PTs' contributions, demonstrating their sensitivity to PTs' emotions. In line with Prediger et al. (2022), our results point out that this sensitivity is crucial, as it helps MTEs know when to prioritize atmospheric goals to maintain PTs' engagement.

Conclusions

Our empirical findings contributed to a deeper understanding of the knowledge required by an educator in practice. The findings presented suggest that an MTE's expertise requires multiple knowledge resources to navigate between different content goals, to notice what PTs can already bring in, and to build upon the fruitful starting points to advance their learning pathways (Prediger et al. 2022). However, several limitations must be highlighted. The analysed episodes present only very small extracts, which is why we consider it necessary to include other sources of information, such as semi-structured interviews, that capture the participant's reflections, allowing us to triangulate the descriptions made. Nevertheless, we hope this study will serve as a valuable contribution to the research community in understanding the complexity of MTEs' professional knowledge and practices.

Acknowledgment

This work has received support from the HUM-462, DESYM HUM-168, and the MTSK Network. It is also framed within the PID 2021-122180OB-100 and ProyExcel_00297 projects, funded by MICIU/AEI/10.13039/501100011033, FEDER, EU, and by the Junta de Andalucía, Spain, respectively.

Case Study on Mathematics Teacher Educator's Professional Roles During Teaching Practicum Course

Sanem Sarılıcan[1] and Fatma Aslan-Tutak[2]

[1,2]Bogazici University, Faculty of Education, Istanbul, Türkiye; sanemsarilican@gmail.com

While the role of teacher education is considered as a critical element for the education of prospective teachers, there is less known about teacher educators. Teacher educators are individuals who support the learning of both teachers and prospective teachers. The importance of teaching courses in the education of prospective teachers such as teaching practicum is well known. According to the literature on teacher educators, a person's classification as a teacher educator depends on the tasks and responsibilities that come with the profession and six professional roles for teacher educators were determined accordingly. Therefore, the study aimed to understand how these professional roles function in the context of teaching practicum by examining the professional roles of mathematics teacher educators. As a result, it was supported by the findings that the professional roles of teacher educators can be explained in accordance with the existing literature. However, findings showed that there are other aspects which need to be investigated in the context of teaching practicum.

Keywords: Teacher education, mathematics teacher educator, professional roles, teaching practicum.

Introduction

There is a growing, but still limited, amount of information regarding teacher educators as the role of teacher education is becoming more recognized as an important tool for the education of prospective teachers (Swennen et al., 2010). The European Commission (2013) defines teacher educators as anyone who constantly supports teachers and student teachers' formal learning. In Türkiye, teacher educators who hold a PhD in mathematics education or mathematics offer teaching courses at teaching departments. According to the comprehensive literature review conducted by Lunenberg et al. (2014) on the professional roles of teacher educators, the categorization of individuals as teacher educators is contingent upon the tasks and responsibilities inherent in this profession. One of teacher educators' responsibilities at institutions is offering teaching practicum courses, and it is well known that the teaching practicum plays a pivotal role in the education of pre-service teachers. Consequently, the way a teacher educator facilitates this course holds significance in shaping the learning experiences of future teachers. Therefore, understanding how teacher educators offer this course, focusing on the tasks and hence the roles they adopt may shed light on this essential part of teacher education. This qualitative study aims to investigate the professional roles of mathematics teacher educators' (MTE) in the context of teaching practicum. The study mainly describes MTE's professional roles who offers teaching practicum course in the field of mathematics teacher education in the lenses of six professional roles explained by Lunenberg et al. (2014) as: *teacher of teachers*, *researcher, coach, curriculum developer, gatekeeper* and *broker*. The study seeks to address the gap in understanding the context-specific professional roles of mathematics teacher educators, particularly within practicum courses. By focusing on how these roles manifest in practice, the

research aims to provide deeper insights into the interplay between professional roles of MTE's and teaching practicum course. Moreover, study aims to empirically investigate these professional roles that are theoretically given.

Teacher Educator

The occupational group of teacher educators are broad. Therefore, researchers claim that the definition of a teacher educator is uncertain to some extent (Hamilton et al., 2016; Livingston, 2014; Swennen et al., 2009). According to the European Commission (2013), teacher educators are "all those who actively facilitate the (formal) learning of student teachers and teacher educators" (p.8). Murray (2016) argues that teacher educators stand out by supporting students and assisting teachers in improving their practice. She also views them as second-order practitioners, responsible for teaching first-order practitioners. Therefore different from teachers, the role of teacher educators necessitates the acquisition of new and distinct forms of professional knowledge and understanding, as well as expanded and varied pedagogical abilities (Korthagen, Loughran & Lunenberg, 2005; Loughran, 2006). Lunenberg et al. (2014) defined the term teacher educator broadly and considered the ones that are instructing and guiding pre-service and in-service teachers in schools and in institutions of teacher education as per the definition of European Commission (2013). The term "teacher educator" has been defined in various ways, however, for the case of Türkiye, the current research focuses on university-based mathematics teacher educators specializing in mathematics education within the Faculty of Education.

Professional Roles of Teacher Educators

Lunenberg et al. (2014) identified six distinct professional roles undertaken by teacher educators in their analysis of 137 articles across diverse countries. The objective of their review study was to establish a comprehensive understanding of characteristics of professional roles of teacher educators and behaviours related to those roles and the teacher educators' professional development in relation to these roles and the behaviours that go along with them. They identified the professional roles as *teacher of teachers, researcher, coach, curriculum developer, broker, and gatekeeper*.

Majority of the research has focused on the role *Teacher of Teachers.* Murray and Male (2005) have made a widely recognized differentiation between *first-order teaching* and *second-order teaching*. A particular teacher education pedagogy is needed for second order teaching, and according to Loughran and Berry (2005) key components of this pedagogy are *modelling* in other words, practicing what is preached and explicating. To promote the development of prospective teachers, this entails teacher educators being able to reflect on and express their own actions and feeling. There is a notable increase in recognition of the teacher educator's role as a *researcher.* The consensus that teacher educators should be involved in research is becoming more widespread globally, extending beyond traditional research universities (Murray et al., 2011). However, teacher educators currently lack agreement on whether they should take on the role of a researcher, and if so, there is uncertainty about the specific responsibilities associated with this role in addition to the lack of consensus on the focus of such research (Lunenberg et al., 2014). The third role identified in the literature review is the role of *Coach.* This term is frequently employed interchangeably with other terms such as facilitator,

mentor, cooperating teacher, and school-based teacher educator. However, Lunenberg et al. (2014) pointed out that there is no universally agreed-upon definition for coaching. From the studies related to school practice in educational institutions, they have defined the main purpose of a coach as the individual who fosters the educational growth of the pre-service teacher. There is relatively less emphasis on the fourth professional role, *Curriculum Developer*, in the existing literature. The preliminary literature search of Lunenberg et al. (2014) shows that there is a considerable body of research dedicated to the development of teacher education curricula. However, according to these studies, researchers discovered that a small number of them specifically examine the teacher educator as the subject of study in their role as curriculum developers. *Gatekeeper* is the fifth professional role that researchers determined which relates to the duty of teacher educators in facilitating the transition of student teachers into the teaching profession. Teacher educator plays a crucial role in guiding and facilitating the entry of students into the teaching profession by providing them with the necessary knowledge, skills, and insights. The sixth professional role is the *Broker.* Lunenberg et al. (2014) mentioned that previously, the collaboration between a school and a teacher education institution typically involved interaction among an institution-based teacher educator, a mentor, and a pre-service teacher. The primary objective of this collaboration was primarily focused on the mentorship and guidance of the pre-service teacher throughout the teaching practicum course.

Methods

Design and the participant

This research is conducted as a case study which is a qualitative method where the researcher investigates a bounded system (referred to as a case) in real-life and contemporary settings (Yin, 2009). This can involve exploring a single bounded system or multiple such systems over an extended period. A university-based mathematics teacher educator was selected as a participant to examine how the professional roles of mathematics teacher educators occurred during teaching practicum. Participant of this study is Yasmin (pseudonym name) who has a PhD in mathematics education, and she has been offering the teaching practicum course for 14 years. A year before this study, I had been observing her classes for exploratory purposes. It was her classes that prompted my decision to concentrate on the professional roles of teacher educators.

Data collection

Data was collected through researcher's notes from classroom observations and an individual interview that was conducted with Yasmin. Firstly, I observed her teaching practicum classes and took field notes for one semester. Furthermore, I have joined Yasmin while observing the students' teaching at practicum schools including the feedback sessions after their teaching. Third, I conducted an individual interview via Zoom at the end of the semester to gain data on Yasmin's views on professional roles. The questions were drawn on the methodological framework offered by Lunenberg et al. (2014).

Data Analysis

The classroom observations of 11 lessons were analysed using an open coding strategy. Each information unit is labelled with a code that represents the essence of the data pieces. The open codes are compared to indicators from the Professional Role framework. The individual interview about the professional roles was also analysed through the framework, and interview data was interpreted in conjunction with classroom observations to familiarize both data sets for triangulation. In the analysis, for instance, the open code 'Developing the teacher education program' aligns with the indicator 'Curriculum development in practice' under the curriculum developer role. However, open codes such as 'Some pre-service teachers still struggle to explain mathematical big ideas' do not align directly with any predefined indicator, although they fit within the gatekeeper role. In such cases, new indicators were identified in accordance with the specific context of the practicum**.**

Findings

The analysis of classroom observations shows that Yasmin extensively exemplifies the professional role of a *teacher of teachers* in addition to the role of *coach*, *curriculum developer, gatekeeper and broker* as a mathematics teacher educator. However, the role of *researcher* could not be observed during the classroom observations. On the other hand, the analysis of interview questions shows that all roles including the *researcher* role can be observed in MTE's practices in teaching practicum course and interview data. Below, the findings for each role will be discussed separately by combining data from observations and interview.

Teacher of teachers

The role of teacher of teachers consisted of four main indicators: *(1) second order teaching; (2) promotion of active learning; (3) modelling;* and *(4) dealing with tensions and dilemmas.* The ability to work with adult learners in higher education and the ability to articulate tacit knowledge and underlying theory are features critical to second order teaching. Most of the open codes were associated with second order teaching. According to the open codes from the classroom observations such as "Asks questions to candidates" and "Forces them to think about definitions", it can be said that Yasmin was working effectively with adult learners and contributing to their reflection, development of conceptual understanding, and professional learning.

The data show that Yasmin concretizes articulating knowledge and underlying theory by explaining theoretical concepts such as cognitive demand of a mathematical task to students. In addition, statements such as "Big idea settled in the students' minds" and "Big idea is explained in the lesson plans" show that the teacher candidates develop the ability to include these theoretical concepts in their lesson plans. As a result, Yasmin contributes to the candidates' understanding and application of theory by expressing implicit knowledge explicitly. The open code "Yasmin gave time to prospective teachers to think" indicates that her directing prospective teachers to think and analyse their own strengths and weaknesses. This approach supports active learning and helps prospective teachers take responsibility for their learning. During the modelling process of the Yasmin, it is clearly seen that the advice she gave to the teacher candidates coincides with her own teaching style. For example, the codes "Have a plan B for teaching" and "The content is not the only important thing

in the lesson plan" reveal that the educator tried to instil in the candidates the flexibility and attention she showed in her own teaching. This shows that what she does and what she teaches are in harmony. Interview data was aligned with how the teacher educator lives the role of "teacher of teachers" and practices various aspects of this role. She determines herself as more of a teacher educator in teaching practicum course. In the interview, her statement, "Teacher educator research is my field" reflects her expertise in the field of research. These codes show that the educator takes a comprehensive approach to developing teacher candidates based on her own experiences.

Researcher

The researcher role included three main indicators: (1) Views of the role of the researcher; (2) the practical elaboration of the role of researcher; and (3) the focus of the research. The role of researcher could not be observed in classroom observations. This may be due to the structure of the teaching practicum course, since the course heavily includes practical orientations of teaching rather than theoretical knowledge. Moreover, it may be due to observer's inability to comprehend the underlying theory of Yasmin's decision-making processes. So, this was one of the reasons for having an interview with Yasmin. The interview showed that Yasmin emphasizes her research perspective with the phrases "My teaching and research" and "Teacher education is my research area." In addition, where she says "I also know from literature" how she integrates her existing knowledge.

Coach

The role of coach was explained under two main indicators: *(1) the task of workplace facilitators* and *(2) The task of institution-based coaches.* The identified behaviours of *the task of workplace facilitators* have been described with the behaviours as: offering local knowledge, practical orientation: giving advice about curriculum and classroom practice and promoting reflection aimed at transfer. Based on the frequency of these behaviours, it can be concluded that Yasmin's notable strengths in the role of a coach lie in offering local knowledge and promoting reflection aimed at transfer. For example, the codes "Provides students with detailed information about their school" and "Considers school culture" indicate that Yasmin guides teacher candidates by considering the socio-cultural characteristics of the school. This knowledge helps candidates better adapt to the school environment. Yasmin mentioning "How should prospective teachers dress" and "Classroom management" indicate that she provides concrete advice to student teachers about professional behaviour and classroom practices. "Preservice teachers shared their observations" and "Differences in how teachers conduct their lessons" indicate that preservice teachers observed different teaching approaches and discussed how they could transfer them to their own teaching practice. This type of reflection helps preservice teachers integrate practical knowledge with theoretical knowledge which supports "Promoting reflection aimed at transfer". The features of the behaviours related to the task of institution-based coaches are the caring therapist/belief and attitude therapist, which was observed in classroom observations, and fading boundaries: overlapping tasks, which unfortunately could not be observed. This behaviour refers to the role of providing support to teacher candidates and encouraging their professional development. The interview data revealed that coaching role means providing customized and professional support to teacher candidates to Yasmin. As she mentioned,

"I felt very close to coaching" and "The definition in the internship course may be different" indicate that the coaching process includes both academic and practical aspects to her.

Curriculum developer

The role of curriculum developer is investigated under one main category: *variety of approaches and practices.* Behaviours of the related role were determined as: societal discussions, principles guiding teacher education and curriculum development in practice. It can be asserted that societal discussion stands out as a prominent aspect within the role of the curriculum developer. Yasmin supports the development of teacher candidates by making comparisons on national and international curricula. Observations emphasize that teacher candidates should exhibit a skill-based approach in their lessons, and that technology integration, classroom management and the use of mathematical language are important for the development of these skills. While Yasmin provides guidance on the basic principles of the curriculum, she also attaches importance to reflective learning processes. The interview data shows that the role of a mathematics teacher educator as a curriculum developer involves various levels of experience and knowledge. Codes such as "being able to discuss IB-AP-MEB curriculum differences" and "figuring out the Big Ideas of learning objectives" reveal that the Yasmin develops a deep understanding by comparing international and local curricula. In addition, the expressions "developing the teacher education program" and "knowing the substructures of other courses" supports the “curriculum development in practice” behaviour, which was previously not observed during the classroom observations.

Gatekeeper

The variety of approaches and practices of the role of gatekeeper are: *standards and profiles, portfolios, and assessment of school practices.* As the assessment of school practices was observed, behaviours linked to standards, profiles, and portfolios were not observed in the classroom observations. The "gatekeeper" role of the teacher educator becomes particularly evident in the process of providing feedback on lesson plans and guiding teacher candidates in the right direction. Yasmin organized feedback meetings with the candidates, evaluated the candidates' lesson plans and focused on the big idea. For example, in one meeting, the candidate's relaxed attitude and mastery of the subject during the lesson were praised, while the points that needed to be developed were conveyed in a sweet manner. In this process, feedback on the candidates' mathematical content knowledge and pedagogical content knowledge played an important role. The gatekeeper role emerges more clearly and explicitly in the oral interview. Yasmin stated that the responsibility for measuring the candidates' competencies was her responsibility and she took care to be fair in the evaluation process. Making decisions about which schools the candidates could do their internships and the impact of this process on the candidates' future professional lives were emphasized as an important part of this role.

Broker

The broker, identified as the final professional role of teacher educators, was classified into two main categories: *(1) goals of cooperation and (2) competencies of the broker*. The goals of cooperation were further delineated into two behaviours: the student as the central focus and becoming a

collective. Consequently, it can be asserted that becoming a collective stands out prominently in the role of the broker. Observations reveal that the "Student as the central focus" behaviour emphasizes the importance of teacher candidates establishing effective communication with their mentors and receiving feedback on their lesson plans during the internship process. The student's collaboration with the mentor and developing joint projects increases the quality of their educational experiences. In addition, co-teaching practices and mentor-student interaction play a critical role in strengthening an approach where the student is kept at the centre. On the other hand, the "Becoming a collective" behaviour reveals the importance of cooperation and a sense of belonging between the university, teacher educator and the internship school. The close contact of mentors and teacher educators with students, acting in cooperation and encouraging a sense of belonging have been determined as factors that positively affect the development of interns The interview expands the scope of the "broker" role. Yasmin has close relationships with the internship schools and maintains these relationships with her personal efforts and existing connections. It is seen that she coordinates the student placement process by considering the different requests of the internship schools and offers solutions suitable for the specific demands of the school. These efforts reveal that the "broker" role is critical for optimizing the students' internship experiences. In addition, Yasmin constantly manages and tries to develop her relationships with these schools by paying attention to the requests of the internship schools. In this context, the importance of the coaching and broker role in the internship processes comes to the fore as a part of the educator identity.

Conclusion and Discussion

The findings of this study indicate that teacher educator's professional roles can be explained according to the extensive literature review by Lunenberg et al. (2014). For instance, *teacher of teachers* role was strongly observed through both the classroom setting and the interview, as being able to teach teachers which was mentioned as second-order teaching by Murray and Male (2005). These findings suggest that the role of researcher, which appeared less prominent, warrants further exploration to determine its significance in the preparation of teacher educators, and this will be a focus of my future research. The role of researcher on the other hand, became more prominent in the interview compared to classroom observations, where the MTE mentioned teacher education as her research area. This may be due to the practicum course's emphasis on practical teaching over theoretical knowledge. Therefore, a follow-up interview was conducted to gain further insights. Moreover, she highlighted that adopting teacher education research also feeds her knowledge about MTE practices. As it was mentioned to be the most important teacher educator role in the literature (Wold et al., 2011), the role of coach was strongly observed during the classroom observations and the interview as the MTE was providing; knowledge and experience about the local context of the school and concrete advice to prospective teachers about professional behaviour and classroom practices. Yasmin's role as a curriculum developer involves different levels of experience and knowledge as she informs her students about the national and international curricula. So, it can be said that she is aware of this role as it was mentioned in the study of Bouckaert and Kools (2018). However, curriculum development in practice behaviour was not seen clearly in the classroom observations which may be since the teacher educator, although taking an active role in curriculum

development, does not share these experiences in the classroom or does not see herself as an authority on this issue and prefers to only make general suggestions about what should happen. The gatekeeper role emerges more clearly in the oral conversation. Yasmin states that it is her responsibility to measure the competencies of the candidates and that she acts fairly in this process. Determining internship schools and the impact of this decision on the candidates' professional lives is an important part of this role. Lastly, the role of broker was outstanding where she oversees the student placement procedure by considering the many requests made by the internship schools and providing solutions that are appropriate for their needs, which are behaviours that are aligned with the broker definition of He An (2009). Besides, it is obvious that there are other aspects in addition to these roles, particularly in the context of teaching practicum and the case of Türkiye. These aspects will be further analysed through thematic analyses regarding the practicum and cultural differences.

Facilitators' noticing of teachers' responses to student thinking concerning a multiplicative thinking task

Victoria Shure[1], Rebekka Stahnke[2], Bettina Roesken-Winter[1] and Daniela Götze[3]

[1]University of Münster, Münster, Germany; vshure@uni-muenster.de

[2]IPN Leibniz Institute for Science and Mathematics Education, Berlin, Germany; [3]TU Dortmund, Dortmund, Germany

Professional development (PD) courses are crucial for the advancement of mathematics education and require facilitators to have specific expertise in navigating complex instructional scenarios. Through a situated examination, this study explores facilitators' (N = 148) noticing of a fictional PD situation concerning multiplication, particularly their use of knowledge elements. Overall, when perceiving student thinking in a fictional PD situation, facilitators demonstrated limited skills with regard to noticing the fictional PD situation. In terms of the interpretation of and decision-making related to teachers' responses to students' solutions, about half of the facilitators superficially interpreted a student's solution and focused on aspects not relevant to the situation. These findings provide insights for aligning future PD courses to better serve the distinct needs of facilitators.

Keywords: Facilitators, noticing, professional development.

Introduction

Continuing professional development (PD) for in-service teachers has been increasingly emphasised in recent years, with PD courses seen as crucial for the advancement of mathematics education, by enriching teachers' skills, and improving mathematics instruction overall (Prediger et al., 2022). Facilitators play a key role in this process, as they have a significant impact on teacher learning (e.g., Borko et al., 2011). At the same time, PD facilitation has been described as "ambitious and challenging work" (Jacobs et al., 2017, p. 3). The expertise of facilitators to engage in this work, and in particular their ability to notice during PD courses, is critical for facilitating teachers' learning. In line with van Es and Sherin's (2002) framework, noticing comprises the recognition of the significance of a situation, the establishment of connections between interactions and broader teaching principles, and using contextual knowledge to reason about interactions. Facilitator expertise in PD settings, essential for navigating complex instructional scenarios, with a focus on the mathematics involved, has been explored by Zaslavsky and Leikin (1999). Recent research, however, has often not regarded content-specific considerations, focusing instead on generic aspects that are relevant for different subjects (Prediger et al., 2022). Our study addresses this gap by focusing on content-related PD and, specifically, by investigating the knowledge elements facilitators use in their noticing of a PD situation, including their pedagogical content knowledge on the PD level (PCK-PD).

Theoretical background

The concept of teacher noticing (van Es & Sherin, 2002), underlining the identification of crucial aspects of instruction, establishing connections, and applying contextual knowledge for reasoning, is from our point of view transferable to facilitators and PD settings. This transferability is particularly

evident in the alignment of this framework with the PID model (perception, interpretation, and decision-making from Kaiser et al., 2015), which highlights situation-specific skills such as the ability to perceive events, interpret activities, and make decisions. In a PD setting, analogously to a classroom situation, perception, interpretation, and decision-making are key aspects of a diagnostic competence and capacity to skilfully facilitate and teach (Hoth et al., 2016).

As a means of considering the expertise that facilitators bring to PD settings, including of these aspects, frameworks for examining teachers' expertise (Prediger, 2019) have been lifted to the facilitator level (e.g., Karsenty et al., 2023). Prediger et al. (2022) applied a content-related framework for mathematics teacher expertise (Prediger, 2019) to the facilitator level. This framework encompasses tasks of facilitating as typical and complex situational demands associated with the facilitation of specific mathematics PD content. Facilitators handle these tasks with practices that are recurring patterns of facilitators' utterances and actions that are based on underlying knowledge elements, pedagogical tools, orientations, and situative goals. Facilitators' pedagogical content knowledge for teachers' professional development (PCK-PD) is one facet of their knowledge elements and thus underlies their noticing. Such PCK-PD consists of the knowledge the facilitators have in relation to teachers' learning. Jacobs et al. (2017) describe PCK-PD as "the ability to engage teachers in purposeful activities and conversations about those mathematical concepts and relationships and to help teachers gain a better understanding of how students are likely to approach related tasks" (p. 3). Thereby, the PCK-PD that facilitators bring is important to consider in relation to facilitators' noticing to better understand their role in initiating teachers' learning. Furthermore, in understanding facilitators' use of PCK-PD, facilitator qualification programs can be better tailored to meet the needs of facilitators and better prepare them for such complex situational demands.

Against this background and, in particular, the underpinning aspects concerning noticing and facilitator expertise, we investigate the expertise and needs of the facilitators in a mathematics PD and qualification program, and specifically, facilitators' use of PCK-PD when they notice. We thereby pursue the following research questions: *RQ1a) How do facilitators perceive a fictional PD situation involving multiplicative thinking? RQ1b) How do facilitators interpret a fictional PD situation involving multiplicative thinking? RQ1c) How do facilitators make decisions concerning a fictional PD situation involving multiplicative thinking?*

Methods

Participants, data collection and analysis

In total, 148 facilitators participated in this study. The facilitators were primary mathematics teachers involved in the *QuaMath* (Developing *Qua*lity in *Math*ematics Classrooms and Teacher PD) facilitator PD (FPD) qualification and teacher PD (TPD) program (for program details, see Prediger & Selter, 2024). At the time of the survey, the facilitators were about to begin the FPD program that encompasses the first year of the ten-year program for the qualification and professional development of mathematics facilitators and teachers. After this first year, the facilitators' PD will continue. At the same time, they start to lead the TPD of the program themselves using the materials provided. In the last three years, sixty-eight of the facilitators had experience leading 10 or more mathematics PD courses, 36 of the facilitators had experience facilitating fewer than 10 PD courses and 44 facilitators

did not provide any PD. The facilitators' teaching experience ranged from one to 39 years (M=15.7) and their facilitation experience ranged from no experience to 23 years (M=3.9).

The facilitators were provided with a situated multi-part instrument (Figure 1) prior to the beginning of the FPD program. They were first asked to consider a classroom-level task addressing multiplicative thinking: "Draw a picture that fits the task. Why does your picture fit the task?" Then they were asked to describe a typical solution that they would expect from a) a student who had understood multiplication and b) a student who had not understood multiplication (Figure 1, Part 1), thereby showing their perception of student thinking that is essential for leading PD. This first part requires the use of necessary PCK-PD for the explanations of student (mis)understanding of the multiplication task with an explicit description of this (mis)understanding with language relating to, e.g., units, equal groups, and the differentiation between multiplier and multiplicand, and by referring to students' explanations of these concepts and their ability or challenges to connect these concepts in different representations (e.g., verbal, symbolic, pictorial) for the multiplicative thinking task.

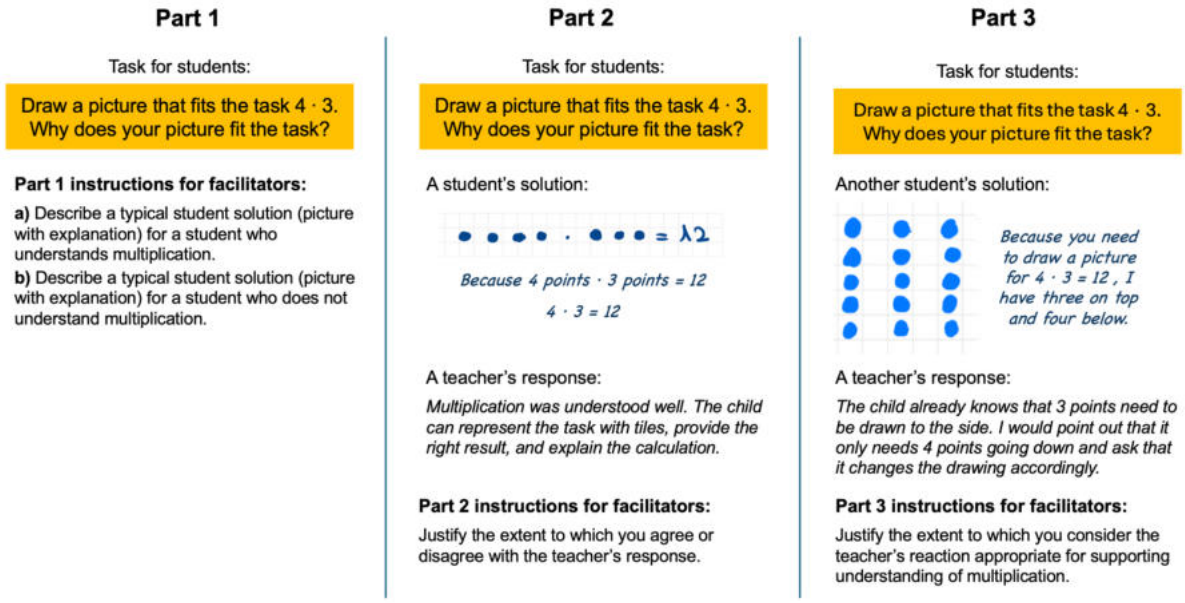

Figure 1: Situated instrument provided to facilitators for investigating their perception, interpretation, and decision-making

In the second part of the instrument (Figure 1, Part 2), the facilitators were provided with an incorrect student solution to the multiplicative thinking task in addition to a teacher's response to the student's thinking. The facilitators were asked to justify the extent to which they agree or disagree with the teacher's response to the student's solution. This part enabled the examination of the facilitators' diagnostic/interpretive knowledge elements concerning the teacher's response to the student's thinking and the facilitators' ability to interpret the student's challenges as relating to conceptual understanding, and specifically the idea of unitising, with connecting representations and with an overemphasis on procedural, automatised handling of multiplication.

For the third part of the instrument (Figure 1, Part 3), a further incorrect student solution to the task was provided along with a teacher's reaction. The facilitators were asked to justify the extent to which

they consider the teacher's reaction appropriate for supporting multiplicative thinking. This third part allowed for investigating the facilitators' decision-making regarding teachers' ideas about student learning, requiring recognition that the teacher's reaction is not constructive for learning, does not allow the student to understand why the representation is incorrect, that the teacher's response emphasises procedural knowledge and does not examine conceptual understanding.

The analysis to answer the research questions was based on the knowledge elements used for noticing from the facilitator expertise framework (Prediger et al., 2022) to reveal how the facilitators perceived, interpreted, and made decisions concerning the three parts of the situated instrument. A coding system, incorporating the main PCK-PD knowledge elements, was developed and a sum score of 22 points possible was obtained for the situated instrument, with between 0 and 12 points based on the extent to which the facilitators addressed the knowledge elements in their perception of student thinking (Part 1), 0 and 6 points for interpreting the teacher's response (Part 2), and 0 and 4 points for decision-making concerning the teacher's reaction to the student solution (Part 3). For example, a response for Part 1 with "a) understood ♦♦♦♦ · ♦♦♦♦ · ♦♦♦♦ b) ♦♦♦♦ · ♦♦♦" would score 1 point (only for Part 1b), as only a fitting solution in that part was provided. For Part 2, a response like "no understanding of 'thinking in groups', which is the basis of multiplication - the result is probably memorised - the justification does not really fit the presentation," would score 1 point for noting memorisation, 1 point for mentioning not connecting representations, and 2 points for PCK-PD detail concerning the lack of conceptual understanding. In Part 3, a response that finds the teacher's reaction unsuitable and highlights finding out why the student drew that representation and whether he or she has deeper understanding would score 3 points (1 point for each aspect). Twenty percent of the facilitators' completed instruments were coded by two members of the research team to ensure inter-rater-reliability ($\kappa = 0.88$).

Results

Considering how the facilitators noticed a PD situation addressing students' multiplicative thinking (RQ1), the mean scores for Part 1 (Perception: $M = 2.61$ ($SD = 1.27$)), Part 2 (Interpretation: $M = 1.60$ ($SD = 1.02$)) and Part 3 (Decision-making: $M = 1.48$ ($SD = 0.91$)) as well as the overall mean sum score of 5.27 ($SD = 2.26$) (out of 22 total) displayed the facilitators' need for support in perceiving and interpreting the situation as well as in making decisions while utilising the relevant knowledge elements that were embedded in the fictional PD situation.

Facilitators' perception of student thinking (RQ1a)

In terms of the facilitators' perception concerning student thinking in the fictional PD situation (Part 1), the facilitators often provided a general description of a pictorial representation of the task, did not include an explanation of the reasoning behind the representation and did not refer to a student's explanation or ability to connect different representations that fit the task. The following example that scored a total of 2 points for Part 1 demonstrates this frequently provided description of student thinking when multiplication is understood and not understood: "a) The child draws four times three flowers. b) The child draws four flowers once and three flowers next to it" (Fac._1). This type of description of a task that did not include an explanation of why the pictorial representation fits the task, was provided by 114 facilitators for Part 1a and 134 facilitators for Part 1b.

In contrast, a small number of the facilitators identified the significance that understanding multiplication encapsulates an explanation in addition to a drawing of the task and, aside from providing a description of a correct drawing of the task, referred to students' explanations of the concept (10 facilitators) or their abilities to use/connect different representations (4 facilitators). The following example demonstrates the use of the appropriate knowledge elements:

> Child who has developed multiplicative thinking: - understands 4 times 3 as four 3s - he/she could, for example, draw 4 groups of 3 dots or choose the arrangement as a rectangular field of dots with 4 rows of 3 dots each […] and is therefore flexible in the way they are presented (e.g., contextual relationships). The description would make it clear that the child gets the equal group idea with the respective power (four 3s) and can explain the tasks using different representations. b) Child who has not developed multiplicative thinking: - it draws 4 dots and next to it 3 further dots - in the explanation it would explain that with the 4 dots you find the 4 from the multiplication task and with the 3 dots you find the 3 from the multiplication task - it is therefore stuck on the purely symbolic level and only represents the single number with dots - but doesn't have a conceptualisation about the meaning of the multiplication task. (Fac._2)

For Part 1a, the above example scored 2 points for the solution, 1 point for the explanation, 1 point for connecting representations; and for Part 1 b, 1 point for the solution, 1 point for the explanation, 1 point for connecting representations. In sum, most facilitators focused on a general description of solutions to the task. A small number of facilitators provided accompanying explanations along with their descriptions of the solutions and emphasised the importance of connecting different representations while using concepts such as unitising or equal groups, as seen above.

Facilitators' interpretation of a teacher's response to student thinking (RQ1b)

Concerning the interpretation of the teacher's response to the student's thinking, the majority of the facilitators disagreed with the teacher's positive assessment of the student's solution showing four dots with a multiplication symbol and three dots as being equal to twelve. In terms of the level of detail of the facilitators' interpretations of the teacher's response, approximately half of the facilitators focused on the student's solution and interpreted superficially as reflecting a memorised solution/overemphasis on procedures. The following highlights this common interpretation, scoring 1 point: "I do not agree. The solution is not clear from the drawing. The task is not shown with tiles. It could simply have been memorised. The result is correct, but the calculation is not explained" (Fac._3). Similarly, the facilitators often went into limited detail concerning the interpretation of the student's challenges as being related to conceptual understanding (71 facilitators) or with connecting/going between different representations (53 facilitators), as exemplified by the following example that received 1 point for noting the lack of conceptual understanding: "I disagree because the drawing shows that the child has not understood multiplication. It should always draw 3 dots 4 times, only then can you read the result from the diagram" (Fac._4).

Furthermore, a large portion of the facilitators (n = 91) did not apply PCK-PD in their interpretation of the teacher's response. In contrast, a small group provided an interpretation using knowledge elements explaining the student's difficulties as being related to conceptual understanding, and

specifically difficulties with unitising (Lamon, 1994) or with multipliers/multiplicands, and with connecting representations, as displayed in the following response:

> I cannot agree with this statement. The child has not yet understood multiplication as thinking in units. There is a mixture of material and symbol here. (Multiplier 4 shown as four tiles, multiplicand 3 as 3 tiles and the drawing symbol placed in between but not as a multiplicative idea – in units.) The explanation could go in the right direction, if not misunderstood – but does not fit the picture drawn. (Fac. P_5)

In comparison to the facilitators' interpretation responses that superficially addressed or did not address PCK-PD aspects, the above response shows the facilitator's focus on the student's difficulty as being tied to not understanding the concept of unitising (2 points). The facilitator also explains the mixed use of symbolic notation and pictorial representation as being connected to the student's lack of understanding (1 point). Such interpretations were seen infrequently, in less than 10% of responses.

Facilitators' decision-making concerning a teacher's response to student thinking (RQ1c)

In making decisions concerning the teacher's response to student thinking in the third part of the situated instrument, the facilitators overwhelmingly agreed that the teacher's response was not conducive for promoting student learning. In total, only 25 of the facilitators provided a positive or neutral assessment of the teacher's response. In regard to providing reasons for their decision-making about the teacher's response, overall, almost half of the facilitators (48%) did not identify the embedded PCK-PD knowledge elements and instead focused on aspects that were not relevant to the situation, visible in the following example that scored 0 points: "This is not a representation of multiplication for me but only a drawing of dots!!!" (Fac._6). When the facilitators were able to reason using PCK-PD, the most frequently applied knowledge element emphasised letting the student be active in the learning process, (n = 44), as seen in a response that received 1 point for this knowledge element:

> To promote understanding, the child should become active and not be presented with the solution. More suitable would be: Count how many points you have. Is it 12? How many more are there? Think about how this came about? What do you have to do to get it right? What would you pay attention to next time? (Fac._7)

In addition to responses to the teacher's reaction underscoring the importance of letting the student be active in correcting the mistake, some facilitators emphasised that the student's incorrect pictorial representation was not explored by the teacher in the fictional situation (n = 29). Furthermore, some facilitators highlighted that the teacher did not investigate if the student possessed conceptual knowledge in addition to procedural knowledge as their rationale for finding the teacher's response unsuitable (n = 23). The following example scored 3 points for the application of these two knowledge elements and the correct assessment that the teacher's reaction was unsuitable:

> I think the teacher's continuation is unsuitable. Instead of just pointing out how the picture should be changed, it would be more effective to enter into a dialogue with the child. I would have the dot picture drawn again and have the child observe or explain to me what they are doing and why […] In any case, it can be said that the child's explanation is too imprecise and needs to be

reworked (together with the teacher). In my opinion, the rather weak explanation also indicates that the principle of the two-dimensional representation of multiplication was insufficiently understood. (Fac._8)

Overall, the analysis of the facilitators' decision-making highlighted the facilitators' recognition of the teacher's response not being conducive for supporting learning progress and especially emphasised their focus on enabling the student to take a more active role in the learning process and in constructing a viable conceptualisation of multiplication.

Discussion and conclusions

In summary, the facilitators were able to successfully provide general descriptions of correct pictorial representations of the multiplication task in Part 1, thereby demonstrating their perception of student thinking. A perception of the situation that used knowledge elements to connect understanding to being able to explain the task and connect/switch between different representations was not identifiable in the responses from most facilitators. While the facilitators overwhelmingly correctly interpreted the teacher's response in the second part of the situated instrument as not constructive, they tended to provide superficial details in their interpretation of the student's challenges. Finally, almost all facilitators were able to correctly assess the teacher's response in Part 3. More than half of the facilitators did not draw on PCK-PD knowledge elements in their decision-making with respect to the fictional PD situation. Instead, they focused on aspects that were not relevant to the situation or mainly focused on pushing the teacher to let the student self-correct the representation as the key reason that the teacher's response was not appropriate for supporting multiplicative thinking.

These findings highlight the needs of the participating facilitators in relation to the necessary PCK-PD knowledge elements for the teaching and learning of multiplication. Thereby, more targeted activities in the FPD program can address these needs to better prepare the facilitators for the complex endeavour of leading TPD. In utilising a situated approach to assess the facilitators' approximated noticing, this study was able to gain insights into facilitators' situation-specific skills. While only one fictional situation was presented, future research will consider the facilitators' noticing in further situations. This study did, however, offer insights into facilitators' use of knowledge elements in their noticing of a fictional situation at the beginning of the FPD course, thus contributing relevant information for the future design of FPD courses as based on the facilitators' abilities and needs. Meanwhile, facilitators took part in a one-year qualification course, and we investigated their noticing of teachers' responses to student thinking concerning the multiplicative thinking task again. So far, these results indicate a development towards highly relevant PCK-PD knowledge elements. In our ongoing research we will continue to unpack facilitators' learning.

Acknowledgement

The *QuaMath* program has been funded in Phase 1 (2023–2028) with 17 million € from the Standing Conference of State Educational Departments, and additional staff support from the federal states for facilitators and state coordinators has been provided (about 20 million €).

Teaching quality in mathematics lessons from the perspective of facilitators and how they perceive the teachers' perspective

Maya Zastrow[1], Bianca Fink[1], Florian Schacht[2], Leander Kempen[3], Bärbel Barzel[2] and Lars Holzäpfel[1]

What does quality in mathematics teaching mean to you? This question was given to facilitators in the nationwide QuaMath (Developing Quality of Mathematics Classrooms and Teacher PD) program in Germany (N = 243). The facilitators were also asked what answers they would expect from those teachers who will participate in their PD courses. The data analysis was carried out using qualitative content analysis, inductive categories were formed and compared with the five principles for high-quality mathematics teaching (Prediger et al., 2022). Analyses indicate differences between facilitators own understanding of quality and their view on how teachers would answer in this question.

Keywords: Professional development, facilitators, teaching quality, professional learning, mathematics.

Theoretical background

Quality of teaching in mathematics

One aim of professional development (PD) programs in mathematics is to improve the quality of teaching. Teaching quality has been the focus of both general and subject-specific empirical educational research for several years (Praetorius et al., 2018). In recent years, a distinction between surface and deep structures of teaching has become increasingly popular for describing and analysing teaching (Decristan et al., 2020). Surface structures of teaching are therefore easily identifiable features that are diverse and interchangeable: methodological and organisational design features, social forms and easily observable teacher and student behaviour (Pauli, 2020). In contrast, deep structures of teaching focus more on the content-related engagement with the learning content and the interactions which is indirectly observable and play a crucial role in student learning (Decristan et al., 2020). These deep structures provide answers to the question of how the content and methods should be implemented (ibid.). In the context of mathematics the German Centre for Teacher Education in Mathematics (DZLM) developed 'five principles for high-quality mathematics teaching' (Prediger et al., 2022), that can be assigned to the deep structures of learning. These principles are based on a combination of normative, epistemological, empirical and practical perspectives and relate to the subject of mathematics. The five principles are as follows: Conceptual Focus, Cognitive Demand, Student Focus and Adaptivity, Longitudinal Coherence, and Enhanced Communication (ibid.).

Facilitators' views of the quality of teaching in mathematics

In order to improve the quality of teaching, it is necessary to approach various levels: the classroom level, the teacher PD level, and the qualification of facilitators who carry out the PD for the teachers: the facilitator PD level (Figure 1). Our study is part of QuaMath, a nationwide 10-year implementation program in Germany aimed at enhancing the quality of mathematics classrooms and teacher PD. The program first focuses on qualifying facilitators in alignment with the five principles for high-quality mathematics teaching (see above) (facilitator PD level). Subsequently, the facilitators work directly with teachers, delivering PD sessions grounded in the QuaMath program (teacher PD level). In our study we refer to the facilitator PD level. Effective PD for facilitators of mathematics teachers requires a clear understanding of the competencies they need to support and inspire teachers in improving instructional quality. To address this, we draw on the framework by Peters-Dasdemir et al. (2023) (Figure 2), which outlines key dimensions of facilitators' competencies. This framework provides a systematic approach to examining how facilitators are prepared to guide teachers in developing high-quality mathematics instruction and how their professionalization can be supported effectively.

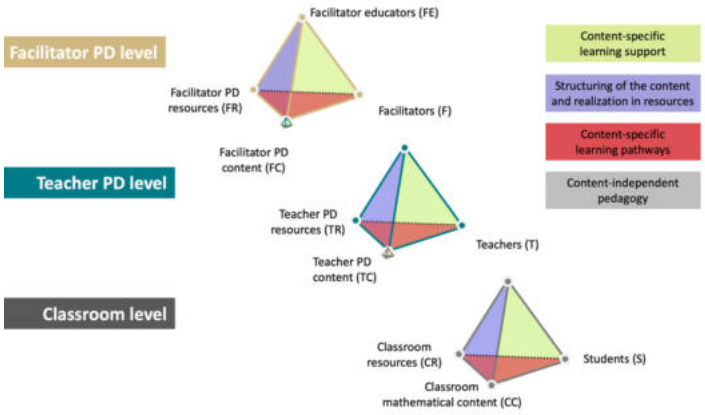

Figure 1: Three-Tetrahedron Model (Prediger et al., 2019, pp. 410)

Figure 2: Competency framework of facilitators in mathematics education (Peters-Dasdemir et al., 2023, pp. 329)

In the following, we focus on two dimensions of the framework. (1) Research shows that generic or content-related beliefs, along with pedagogical attitudes, implicitly or explicitly shape facilitators' practices (Prediger et al., 2021) (dimension: **professional beliefs**). Since QuaMath facilitators are responsible for conveying QuaMath content in their PD sessions, it is crucial that their understanding aligns closely with the core principles of QuaMath. This raises an important question: What do facilitators actually think about quality mathematics teaching? Specifically, is there already a shared understanding of quality mathematics teaching among all participants involved in QuaMath? While there is substantial research on teachers' beliefs and orientations in general, little attention has been paid to what teachers, teacher educators, or facilitators specifically think about effective teaching practices (Wisniewski & Siegel, 2020). This aspect can also be viewed through the lens of participant-orientation: understanding the knowledge, experiences, and ideas that facilitators bring to the

QuaMath program is crucial for us. Participant-orientation focuses on tailoring PD to the unique needs, beliefs, and prior knowledge of the participants. Adopting this participant-centred approach has been shown to significantly enhance the effectiveness and impact of PD programs (Barzel & Selter, 2015). (2) On the other hand, we are interested in how the facilitators see their future participants: what answers do they expect teachers to give to the question: what is good mathematics teaching? This question not only allows us to assess the facilitators' competence in the field of participant-orientation, but also provides insight into the dimension **role identity**: As facilitators often hold multiple professional roles, such as being both classroom teachers and PD facilitators, they must navigate between these roles, which can be particularly challenging for novice facilitators (Perry & Boylan, 2018). A key question for us is how facilitators transition into their (new) facilitator role. Comparing facilitators' own perceptions of good mathematics teaching with their understanding of teachers' expectations provides insights into the dynamics of this role shift. Their self-perceptions, in contrast to teachers' expectations, reflect both their understanding of the profession and the progression of their expertise development.

Research questions

The above considerations lead to the following research questions:

Research question 1: What do facilitators think of good mathematics teaching? To what extent do the characteristics mentioned by the facilitators correspond to the QuaMath principles (five principles for high-quality mathematics teaching) and what kind of understanding of teaching do their answers indicate?

Research question 2: How do the facilitators anticipate the teachers' answers in comparison? To what extent do these anticipated characteristics correspond to the five QuaMath principles and what kind of understanding of teaching do the anticipated answers suggest?

Methods

The data was collected during the kick-off workshop of the facilitator PD in the QuaMath program. The facilitators were asked the following open-ended questions, which they answered freely, without predetermined options:

1. What do you think constitutes quality mathematics teaching? Write down three characteristics of quality.
2. Consider potential teachers' responses to the question: What do you think constitutes quality mathematics teaching?

$N = 333$ facilitators were questioned, 155 from primary schools (46.5%) and 178 from secondary schools (53.5%). Of these, 300 have studied a university teaching program, 18 had not, and 15 did not specify. Teaching experience ranged from 1 to 40 years, with a median of 14 years. The median experience as a facilitator is two years and varies from 0 to a maximum of 34 years.

This study uses a mixed-methods approach, integrating both qualitative and quantitative data to offer a comprehensive analysis of the research question. Initially, the data were analyzed through qualitative content analysis (Kuckartz & Rädiker, 2023). To identify the key characteristics of

effective mathematics teaching as perceived by the facilitators, an inductive category system was developed. This system, consisting of 30 categories, was informed by a literature review on (mathematics) teaching quality.

To evaluate the understanding of teaching reflected in the facilitators' responses, the data were analyzed a second time according to two categories: (1) *aspects related to surface structures of teaching,* where the facilitators' descriptions of effective mathematics teaching align with an understanding focused on surface-level elements, such as teaching methods, and (2) *aspects related to deep structures of teaching,* where the facilitators' references to quality characteristics indicate a more profound understanding of learning and teaching, such as cognitive demand.

The answers of each facilitator were then summarized and rated on a scale between 1 – 4 (1 = all answers pertain to surface structures of teaching, 2 = the majority of answers relate to surface structures of teaching, 3 = most answers refer to deep structures of teaching, 4 = all answers reflect deep structures of teaching). Table 1 presents two sample responses and their corresponding rating.

Table 1: Examples of the rating

	Named characteristics	Does the characteristics refer to surface or deep structures of teaching?	Rating
Facilitator 1	Cognitive activation	refers to deep structures of teaching (cognitive demand)	4 (all answers refer to deep structures of teaching)
	Promotion of communication	refers to deep structures of teaching	
	Orientation towards understanding	refers to deep structures of teaching	
Facilitator 2	Silence	refers to surface structures of teaching	2 (the majority of answers refer to surface structures of teaching)
	Group work	refers to surface structures of teaching (method)	
	Different levels	refers to deep structures of teaching (adaptivity)	
	Learning videos	refers to surface structures of teaching (media & learning materials)	

25% of the data was independently coded by two researchers with Cohen's kappa values ranging from .70 to .77 for the different analyses, indicating substantial agreement (Landis & Koch, 1977). To examine differences between facilitators' own perceptions of good mathematics teaching with their understanding of teachers' expectations, a paired t-test was conducted.

Results

RQ1: What are the facilitators' ideas of effective mathematics teaching? Figure 3 presents the categories, ranked by their frequency of mention by the facilitators (N = 243). The top five categories—adaptivity, conceptual focus, learning atmosphere, structure/clarity, and cognitive demand—are highlighted, with adaptivity being by far the most frequently mentioned, appearing in 96 responses. Notably, the categories corresponding to the five QuaMath principles for high-quality mathematics teaching (highlighted) are among the top seven most frequently cited. A total of 39% of the responses align with these QuaMath principles.

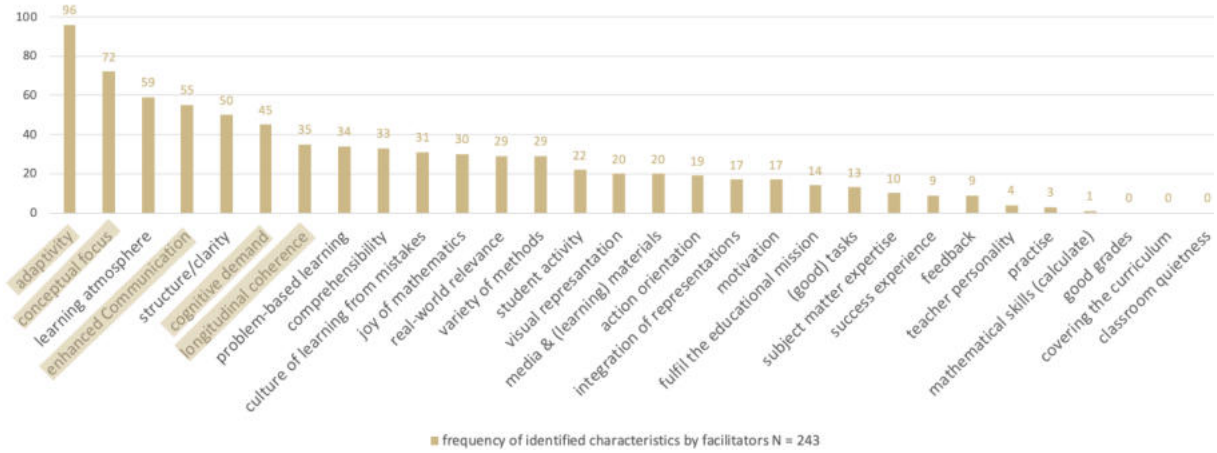

Figure 3: The facilitators' own understanding of mathematic teaching quality

When the facilitators' responses are rated on the scale between 1 (all answers refer to surface structures of teaching) and 4 (all answers correspond to deep structures of teaching) the average rating is $M = 3.37$ ($SD = 0.795$). This suggests that the facilitators' perceptions of effective mathematical teaching are more strongly aligned with an understanding that emphasizes deep structures of teaching.

RQ2: How do facilitators anticipate the teachers' responses in comparison to their own perspectives? Figure 4 illustrates the differences between the two perspectives: that of the facilitators' own views and their expectations of the teachers' responses. The data reveals an unequal distribution across the categories. From the facilitators' perspective ($N = 243$), the three most frequently mentioned categories are adaptivity, comprehension orientation, and learning atmosphere. In contrast, facilitators expect that the teachers ($N = 209$) would most often mention adaptivity, good grades, and media & materials. Notably, only 16% of the anticipated responses align with the QuaMath principles for high-quality mathematics teaching, compared to 39% for the facilitators' own beliefs.

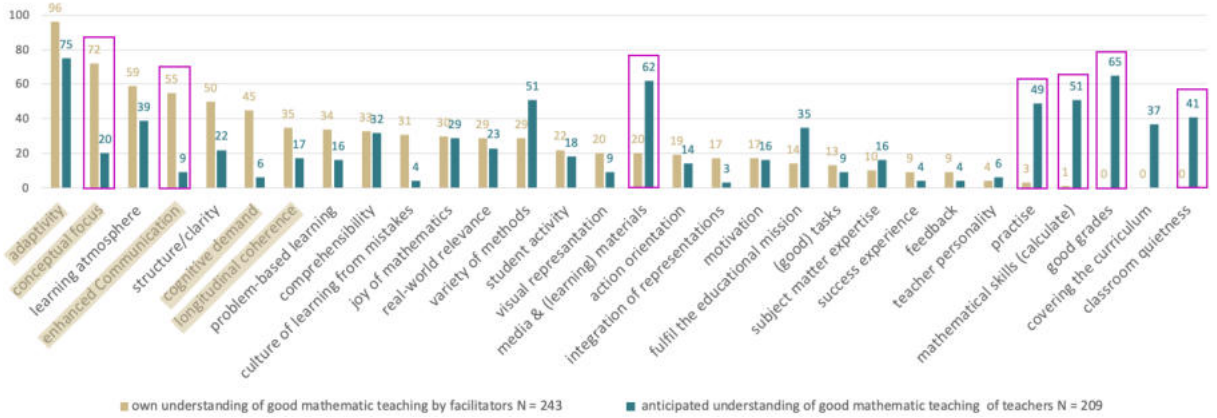

Figure 4: Comparison of facilitators' own ideas and facilitators' expectations of teachers' responses

The main disparities between the two perspectives are highlighted in the following categories: Conceptual focus, enhanced communication, media & material, practice, mathematical skills, good grades and classroom quietness.

The expected responses were rated based on their alignment with surface (1) or deep (4) structures of teaching. The average rating for the anticipated responses was $M = 2.03$ ($SD = 0.82$), indicating that the facilitators tend to attribute a more surface-level understanding of teaching to the teachers.

The comparison of the two perspectives reveals a distinct contrast (Figure 5): While facilitators' own ideas of good mathematic teaching are more aligned with deep structures, their anticipated responses from teachers tend to reflect surface-level structures. This distinction was also confirmed statistically ($t(171) = 14.78$, $p < .001$) with a strong effect size ($d = 1.27$).

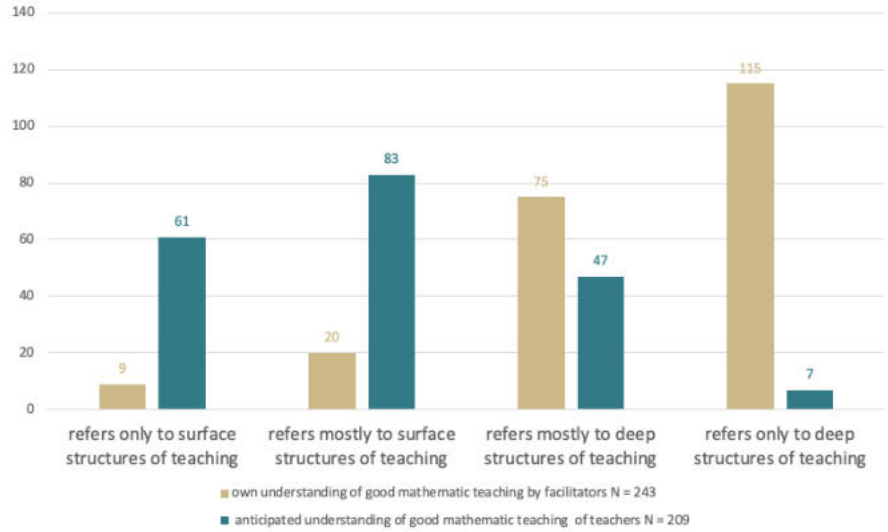

Figure 5: Comparison of perspectives regarding surface and deep structures of learning

Discussion

The findings reveal that a significant portion of the facilitators' responses align with the five QuaMath principles for high-quality mathematics teaching. This alignment indicates that facilitators possess professional beliefs and orientations that closely reflect the program's core principles, a critical factor given their role in promoting these ideas during PD sessions. Such a shared understanding among facilitators is essential for the success of a large-scale program like QuaMath, as it fosters coherence across their practices. Coherence, in turn, is a key driver of the effectiveness and impact of PD initiatives (Prediger & Selter, 2024). The finding that facilitators predominantly associated quality aspects of teaching with deep structures highlights a strong alignment between their professional beliefs and key insights from empirical teaching research, which emphasize the critical role of deep structures in improving student learning outcomes. This reflects the potential of QuaMath to bridge research and practice, ensuring that its facilitators are positioned to enact research-based instructional approaches in their PD sessions.

When examining facilitators' perceptions of their future participants, a distinct pattern emerges: facilitators tend to assume that teachers focus primarily on surface structures of teaching, such as lesson materials, while deeper structures, such as cognitive demand, are less frequently anticipated. This perception may stem from facilitators' prior PD experiences, where teachers often expressed needs tied to practical, surface-level aspects, and reflects facilitators positioning themselves as

advocates for an understanding of learning that refers to the deep structures of teaching. The divergence between facilitators' views of good teaching and their perceptions of teachers' priorities highlights an emerging professional identity. Notably, these findings, collected at the start of the QuaMath program, suggest that facilitators are already beginning to distinguish their new role from that of the teachers they aim to support.

The question of whether teachers primarily assess teaching quality based on surface characteristics cannot be answered from this survey. However, we anticipate gathering relevant data in the coming months as facilitators conduct their PD courses, focusing on the topic of high-quality mathematics teaching and the five principles. Additionally, it will be of interest to examine how facilitators' perspectives evolve over the course of the QuaMath program, with further data to be collected at its conclusion.

One limitation of our study is that facilitators' responses were provided as keywords, leaving some ambiguity about their precise meanings. Additionally, the five principles were introduced during the opening of the QuaMath program, and facilitators may have recalled them when completing the questionnaire. However, our analysis of their responses revealed that only a small portion (15%) directly referenced the exact wording of the QuaMath principles. These mentions primarily related to the concept of cognitive demand, a widely recognized aspect of teaching quality that extends beyond the specific principles of the QuaMath program.

The aim of QuaMath is to convey the underlying aspects of teaching quality of mathematics to teachers and to anchor them in teaching practice in the long term. The results show that this understanding has already been initiated in the facilitators and we can assume that they strive to strengthen and communicate these aspects of deep quality of mathematic teaching in their future PD courses.

Acknowledgment

We would like to thank all our colleagues who held the QuaMath workshop 'pedagogical content knowledge on PD' in Berlin, where the data for this study was collected.

The QuaMath program has been funded in Phase 1 (2023–2028) with 17 million € from the Standing Conference of State Educational Departments in Germany, and additional staff support from the federal states for facilitators and state coordinators has been provided (about 20 million €).

A Study of Mathematics Teacher Educators' Knowledge from the Perspective of In-Service Teachers

Pablo Giadas[1], Maria Chiara Cibien[2], Laura Muñiz-Rodríguez[1], Federica Ferretti[2] and Luis J. Rodríguez-Muñiz[1]

[1]University of Oviedo, Spain; giadaspablo@uniovi.es; [2]University of Ferrara, Italy

Keywords: Mathematics teacher, Mathematics teacher educator, Knowledge.

Introduction

In recent decades Mathematics Teacher Educators (MTEs) have been the subject of study due to their role in the preparation of future mathematics teachers (Beswick & Goos, 2018). International researchers in mathematics education have studied MTEs' knowledge with the aim of constructing a theoretical model. In this regard, Even (2008) noted that these studies are mostly carried out by MTEs themselves through self-study techniques. This, along with the idea highlighted by Beswick and Goos (2018) that there is no clear answer as to which professionals should investigate MTEs' knowledge, suggests that the right questions may not be being asked to explore MTEs' knowledge. Following the approach in Giadas et al. (2023), this research is top-down conducted, based on In-Service Mathematics Teachers (ISMTs) trained by MTEs. The aim of the research is to analyse the perceptions that ISMTs have regarding MTEs' knowledge. Specifically, this study seeks to answer the following research question: What are ISMTs' perceptions of MTEs' knowledge? By addressing this question, existing MTEs' knowledge models will be deepened. This research considers the term MTEs in a broad sense, including terms used in TWG27 such as educators or facilitators.

Theoretical background

MTEs' knowledge has been explored through various methodological techniques due to the variety in MTEs' profiles (Giadas et al., 2024). The literature seems to lack clarity on MTEs' training background and experiences. This fact hardens the task of reaching a definition of MTE and establishing a theoretical model that characterises their knowledge. Additionally, this situation is influenced by the fact that different profiles of MTEs exist, such as facilitators or mentors (Karsenty et al., 2020), each associated with different knowledge depending on the professionals they train and their research activities (Martignone et al., 2022). In this sense, some of the aspects used to characterise the MTEs' knowledge are the standards expected of MTEs' work, the presumed MTEs' knowledge, the practices carried out by MTEs, and the existing knowledge models for mathematics teachers (Karsenty, 2020). In this study, the Mathematics Teacher Educators Specialised Knowledge (MTESK) model proposed by Martignone et al. (2022) is used because it takes into account multiple MTEs profiles. This model considers the MTEs' knowledge divided into Mathematical Knowledge (MK), Pedagogical Content Knowledge (PCK) and beliefs related to both types of knowledge.

Methods

This research presents the results of an exploratory study conducted with eleven ISMTs from different Italian regions, all teaching in lower-secondary schools (grades 8 to 10). The used instrument was an anonymous open-ended questionnaire, distributed via Google Forms and designed by the authors to

understand and explore the participants' perceptions on the MTEs' knowledge. The questionnaire comprised three questions related to the general aspect about MTEs' characteristics and knowledge. The questions were: (Q1) What are the most important characteristics you think a 'good' MTE should have? (Q2) What are the most important knowledge you think a 'good' MTE should have? (Q3) Is it necessary for a 'good' MTE to be familiar with the main research results in mathematics education? If so, which ones? This instrument allowed us to collect data in the same way Martignone et al. (2022) did in their research and to explore whether ISMTs consider necessary for MTEs to possess knowledge of research in mathematics education. The participants' responses (units of analysis) were collected in a spreadsheet, and they were analysed using deductive analysis (Patton, 2014). In this regard, the division proposed by Martignone et al. (2022) was used. The different units of analysis were classified in two phases: firstly, into MK and PCK domains, and then in more detail into the different subdomains of the MTESK model.

From the idea to the implementation: Ensuring coherence and vision transfer in the development of teacher professional development

Lars Holzäpfel[1], Maya Zastrow[1], Bianca Fink[1] and Daniela Götze[2]

[1]Pädagogische Hochschule Freiburg, Institute for Mathematical Education, Germany; lars.holzaepfel@ph-freiburg.de; [2]TU Dortmund University, Germany

Keywords: Professional development program, coherence, teacher educators.

How do you design an effective, coherent professional development (PD) program? Empirical research in recent years has shown that certain quality characteristics significantly influence the effectiveness of PD (a.o. Borko et al., 2004; Darling-Hammond et al, 2017; Desimone, 2009). Based on this extensive research, the German Centre for Mathematics Teacher Education (DZLM) has developed six design principles for effective PD for mathematics teaching (Barzel & Biehler, 2020). The principles include competence orientation, participant-orientation, teaching-learning diversity, case reference, promotion of cooperation and promotion of reflection (ibid.). Since then the principals are used in the design, implementation and research of PD concepts and PD materials in different projects.

On of them is the 10-year national implementation program QuaMath (Developing Quality of Mathematics Classrooms and Teacher PD) in Germany, which aims to develop the quality of mathematics education and teacher PD. In QuaMath the six design principles for effective PD serve (among other aspects) as the basis for the design of the QuaMath PD modules, with an additional principle added to the six characteristics: Coherence. As early as 2001, Newman et al. found that training program were often fragmented, that different objectives prevailed and that participants found it difficult to connect the content. A coherent vision of good teaching is often lacking, training topics are not linked to a larger context and there are no references to each other. Accordingly, coherence has been identified in several studies as a quality feature for effective PD (a.o. Darling-Hammond et al., 2017; Desimone, 2009). Coherence often refers to the consistency between PD content and teachers' school contexts (with curricula, school goals and education system reforms). In addition, Borko et al. (2004), for example, argue that training programs that offer thematically related modules and a coherent sequence of activities increase the likelihood that teachers will integrate what they have learned into their teaching. Hill et al. (2013) and Cobb et al. (2013) also show in their studies that coherent PD programs based on a clear, overarching vision are more effective than programs consisting of loose, disjointed modules and materials.

Prediger & Selter (2024) already described the PD concept of QuaMath, its vision, goals and coherent core elements. As the project is quite large, involving mathematics education experts from 12 different universities across Germany and the development of 26 PD modules, the question arises, how the development of a coherent PD program can be implemented. In our poster we present elements that contribute to the development of coherence. We also examine the extent to which the visions (goals, core elements) are already anchored in the minds of the teacher educators involved - a prerequisite for the creation of coherence.

The research questions include:

- Which elements contribute to the coherence of the training program?
- What challenges and difficulties can be observed in the creation of coherence among the participants?
- What frameworks, guidelines and support can help to create coherence and at the same time take into account the ideas of the participants?

Reflecting on action research cycles to enhance my teaching of jump strategy to pre-service teachers

Tarryn Lovemore[1]

[1] Rhodes University, South African Numeracy Chair, South Africa; Tarryn.Lovemore@ru.ac.za

Keywords: Reflective practice, Mathematics teacher educator, Empty number line, Action Research.

Introduction

In this poster presentation, I share my experience as a mathematics teacher educator (MTE) reflecting on an intervention programme, and action research study, with pre-service teachers (PSTs). The intervention trialled the jump strategy to support mental computation. I modelled using and teaching the jump strategy with the empty number line (ENL) and facilitated PSTs in creating micro-teaching videos of implementing the strategy. Analysis from Cycle 1 of the intervention lead me to consider how I could enhance my practice in Cycle 2. Hence, the research question is, 'In what ways did I enhance my teaching of the jump strategy through reflection in action research cycles?'.

Literature review and theoretical framing

The mathematical knowledge and number sense of PSTs is of concern in South Africa and internationally (Bowie et al., 2019). Hence, there is a need for MTEs to reflect on ways in which they can enhance their teaching of mathematics didactics to support PSTs. Garcīa et al. (2006) use reflection-on-action to simultaneously engage in teaching and research for enhancing learning as both MTEs and researchers. I too was guided by Schön's (1983), reflection-in-action and reflection-on-action. After Cycle 1 of implementation, I reflected *on* the success of the intervention, which lead me to consider ways in which I might enhance my own teaching of the strategy. In Cycle 2 of the intervention, the findings from Cycle 1 guided my reflection-*in*-action.

Methods

In this action research study, I trialled the jump strategy as an intervention during a mathematics didactics course with 120 primary school PSTs. Cycle 1 took place over 6 lecture sessions in Term 4 of 2023. From this cycle, I analysed PSTs' micro-teaching videos with an adherence checklist (Smith et al., 2019), based on four identified key elements (ENL, jumps, key phrases, gestures). PSTs were mostly able to implement the strategy with some level of fidelity. However, I noticed ways in which I could adapt my own teaching of the strategy. Therefore, in Cycle 2, in Term 4 of 2024, also with first year PSTs, I kept a reflective journal to guide me in exploring and enhancing my practice (see Figure 1). I thematically analysed the reflective journal and one video-recorded demonstration using codes based on the adherence checklist of the four key elements as well as coding themes that emerged from the data.

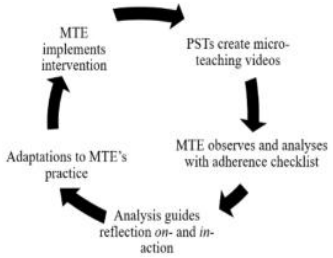

Figure 1: Action research

Findings

Three themes emerged in relation to how I enhanced my teaching in Cycle 2: making key elements explicit; creating opportunities to practise through micro-teaching; and guiding reflection.

Based on analysis from Cycle 1, as the MTE, I became aware of aspects in each of the four key elements that I could make more explicit when teaching the jump strategy on the ENL. During Cycle 2, I kept these in mind during my teaching and reflection (on- and in- action). After lecture 4, I noticed that I still needed to make the key elements explicit for the PSTs. I reflected, "I did a recap with the four key elements. I did not name them or label them as such before, maybe I should use a checklist for the PSTs to check their own examples" (RJ24-10-03). This initiated a plan to use the analytical tool (adherence checklist), from Cycle 1, to support PSTs in Cycle 2, by labelling each key element and guiding the PSTs to reflect on their own examples.

I also noticed the need for PSTs to have more opportunities to practise teaching the strategy, as evidenced in my reflection referring to PSTs demonstrating to the class: "I think that this is a useful strategy to get the PSTs to practise in class and to reflect on each other's examples early on in the intervention" (RJ24-08-20). Reflecting on this, I realised that I should not be the only one demonstrating the strategy during class. I used micro-teaching more frequently for PSTs to get more opportunities to practise teaching the strategy and I used this to initiate discussions around the pedagogical value of the key elements of jump strategy. I noted in my reflective journal that PSTs tried to reflect on and compare their strategies, and that "…it was good that students were questioning the strategy while working in pairs" (RJ24-09-17). Intentionally planning for reflective opportunities was important. I encouraged further reflective feedback amongst PSTs by guiding them to use the adherence checklist to evaluate and reflect on each other's micro-teaching examples.

Conclusion

The findings from Cycle 1 indicated areas where I could improve my teaching of the jump strategy. My reflections on and in Cycle 2 showed the need for MTEs to focus on making key elements of a strategy explicit in their teaching, to create opportunities for PSTs to practise through micro-teaching and to intentionally guide reflection based on PSTs' micro-teaching. This example of using action research to enhance the MTE's practice could guide other MTE-researchers in their research, reflection, and practice of implementing similar interventions.

Mathematics teacher educators' noticing in a problem posing task

Sara Rodríguez-Segarra[1], Luis Carlos Contreras[1] and Nuria Climent[1]

[1]Universidad de Huelva, Faculty of Education, Huelva, Spain; sara.rodriguez@ddi.uhu.es

Keywords: Noticing, mathematics teacher educator, problem posing, fractions.

Background

Noticing is an essential teaching skill which can be developed by an individual depending largely on their knowledge and experience. Van Es and Sherin (2021) revised their original framework for learning to notice, identifying three stages: *attending*, which consists in identifying noteworthy features of classroom interactions and disregarding selected features of classroom interactions; *interpreting,* i.e. using one's knowledge and experience to make sense of what is observed and adopting a stance of inquiry; and finally the stage of *shaping*, where the aim is to construct interactions and contexts which provide access to additional information.

In the context of the implementation of a problem posing task using fractions with pre-service primary teachers (PPTs), a comparative study was carried out into the noticing of two teacher educators. The aim of this study is to identify potential similarities and differences in the noticing of two of the MTEs from varying academic backgrounds through the knowledge they bring into play in a specific episode.

Noticing in a specific episode: methodological aspects

The focus of this paper is on two MTE's noticing of one PPT solution for a training task, in which the PPTs had to devise a problem with fractions, structured into two additive stages involving an addition and a subtraction. In addition to the problem itself, the PPTs were required to provide a solution with an accompanying illustration, and to explain what the fractions meant and predict the possible difficulties the pupils might face. The implementation was recorded and the focal point is an episode where a PPT was asked for reading and explaining his problem writing on the blackboard in order to invite other PPTs to discuss and offer solutions. (Figure 1).

PPT: There are ten balls. After a match, half of them have been lost. Out of ten. And a fifth of those remaining have been punctured. To rectify this, half of the remaining balls have been bought. How many balls are left?

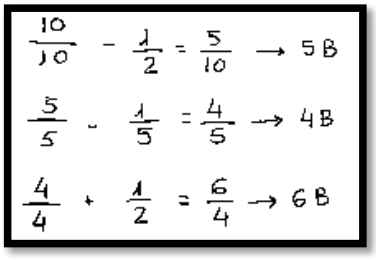

Figure 1: PPT's solution to his fractions problem

The clip containing the PPT solution was then separately played to two MTEs, of differing backgrounds, who had designed and implemented the task in another moment. After the two had watched the video, they were given a semi-structured interview designed to draw out their considered reflections on the three stages of noticing. A transcript of the video recording was then provided for

further comment. Following this analysis, an interview was conducted in order to triangulate interpretations and a consensus was achieved.

Regarding informants' backgrounds, the first (MTE 1), with 13 years' experience as primary educator and researcher, had studied a first degree (5 years) in mathematics, followed by a master's degree in secondary level mathematics teaching and a doctorate in mathematics education. MTE 2, with 11 years as primary educator and researcher, had originally studied (general) primary education (4 years), and after a master's degree and doctorate in mathematics education.

Results

Results are organised according to the stages of noticing. Although the MTEs' commentaries in the first stage (*attending)* are along similar lines, drawing on their mathematical knowledge (MK) of fractions, the aspects they focus on differ and amount of time spent considering them. Thus, whilst MTE 1 shows a deeper substantive knowledge of the topic (types of arithmetic problems, the meaning of fractions, definitions of fractions, phenomena associated with fractions as operator, and so on), MTE 2 demonstrates a pedagogically oriented perspective firmly rooted in the primary classroom.

In their interpretation of the video recording, both MTEs link their knowledge of how PPTs tend to understand mathematical content to their experience as researchers and trainers. They account for the episode in terms of the generally held part-whole conceptualisation of fractions that intuitively attracts students and tends to prevail in school mathematics. Nevertheless, while MTE 1 relates the use of part-whole to a difficulty in identifying operator, MTE 2 identifies as the main obstacle what is meant by unit at any given moment. Moreover, both take into account pedagogical aspects. While MTE 1 foregrounds knowing how to formulate a problem for pedagogical purposes, while MTE 2 regards the formulation as a means of evaluating the PPT's content knowledge:

In *shaping* stage, both MTEs orient their responses towards constructing the PPT's mathematical content knowledge. Although both would manage their responses in broadly similar ways, MTE 1 describes a sequence of interventions to encourage reflection on the aspects identified and interpreted in the previous stages of noticing. For his part, MTE 2 does not explicitly state their intention to encourage the PPTs to consider potential misunderstandings around the different meanings fractions can take, but rather focuses his response on a solution in keeping with the context of the set problem.

There are similarities between the informants, largely with respect to the interpreting stage, although differences were found in the attending and shaping stages, as well as in terms of the deployment of examples and the use of mathematical vocabulary. Hence, this study foregrounds potential differences in the profiles of teacher educators. More in-depth studies might uncover different possibilities connected with particular profiles that promote more effective work among teams of teachers. In addition, this study could be approached from other theoretical perspectives.

TWG 28: Collaborative Settings in Mathematics Teacher Education

An introduction to TWG 28: Collaborative settings in mathematics teacher education

Geoff Wake[1], Stéphane Clivaz[2] , Paula Gomes[3], Pernilla Mårtensson[4] and Aoibhinn Ní Shúilleabháin[5]

[1]University of Nottingham, Nottingham, United Kingdom; geoffrey.wake1@nottingham.ac.uk

[4]University of Gothenburg, Gothenburg, Sweden

[5]Dublin City University, Dublin, Ireland

The second convening of TWG 28 at CERME 14 was stimulated by seventeen papers and one poster documenting research from eleven countries. Discussions were framed around four interrelated themes: the role and preparation of facilitators, collaborative early-career and pre-service teacher education, discourse and socio-cultural dimensions of collaborative research, and didactical theory and knowledge development. Contributors highlighted the complex competencies required of facilitators, spanning from orchestrating reflective questioning to nurturing collegial trust. A range of theoretical framings of different contributions including consideration of paradidactic systems and the ATD underscored the global relevance of collaborative inquiry, and pointed to how deep analyses of textbooks and student work can surface tacit pedagogical knowledge. Learning studies that focused on variation theory and lesson studies in the Japanese tradition were prevalent in the work reported.

Keywords: Teacher education, collaborative settings, professional development, lesson study

Introduction

This was the second meeting of TWG 28, which was established at CERME 13. The group builds on the work of an informal network of European mathematics education researchers that has developed around studies of collaborative settings in which teachers and researchers, together with educators, more widely explore mathematics teaching and learning. The work of the TWG at CERME 14 involved in the majority those who attended CERME 13 whilst also welcoming colleagues for whom this was their first involvement. In this way the group built on their previous work whilst also expanding in new directions. The group was focused around seventeen papers and one poster presentation. The contributions came from eleven European countries with a good distribution between North and South, and East and West confirming the continuing interest, particularly in lesson and learning studies in mathematics education, internationally.

The contributions to our discussions collectively portrayed research in collaborative settings in teacher education as a multifaceted field of inquiry for advancing mathematics teacher education, revealing both the promise and the complexities inherent in collaborative professional learning. The programme for the conference was organised around four main areas of study: that of facilitating collaborative work including the role and work of those who do this; collaborative teacher education of those in early stages of their career, including the pre-service phase; talk and discourse in

collaborative settings, including consideration of socio-cultural issues; and didactical theory and didactical knowledge.

In the remainder of our overview, we provide a brief insight into the flavour of the contributions to the group and our discussions which in addition to brief presentation of each paper encouraged questioning around context, findings and conclusions that might be drawn as well as thematic exploration providing opportunities for synthesis and considering directions for future research.

Facilitating collaboration

Issues facing those who facilitate collaborative research was a major part of the discussion of the group in the previous meeting of CERME, and this focus was continued in 2025. The competencies demanded of study facilitators, especially in lesson and learning studies were identified and considered as major areas of concern. Discussions were assisted by the overviews provided by Quaresma and colleagues, and Kanbolat and Arslan.

Beyond organisational acumen and logistical coordination, facilitators must also cultivate a truly collaborative climate, especially through developing considerable expertise in using reflective questioning strategies, backed up by robust mathematical, pedagogical, and didactical knowledge. Our reflections underscored that effective facilitation of collaborative research focused on close-to-practice activity, that is often in classrooms and entails more than managing schedules or materials. Our conversations outlined that effective facilitation requires fostering open dialogue, guiding inquiry, and sustaining collegial trust, while also navigating shifting personal and professional pressures and institutional constraints. It was recognised that without administrative backing and management support, together with finding sufficient time to work adaptations that are sensitive to socio-cultural contexts, facilitators may struggle to maintain momentum or to engage all teachers meaningfully in the process.

There was agreement that, for research in collaborative settings researchers must attend to the cultivation of skilled facilitators capable of guiding the intricate cycle of lesson planning, enactment, and reflection (see, for example, the paper of Gomes and colleagues). While existing work has identified the core competencies of facilitation, ranging from orchestrating collaborative talk to structuring post-lesson debrief, the processes by which novices acquire and refine these capabilities remain opaque. It was considered that directions for future research could include longitudinal studies that might examine how targeted training programs shape facilitators' use of probing questions during reflection meetings and how these questions, in turn, scaffold teachers' professional growth as indicated by Bahn and colleagues. By mapping intended lines of inquiry against practitioners' actual reflective trajectories, scholars could illuminate the mechanisms that undergird robust Lesson Study implementations and thereby design more effective preparatory experiences. In relation to this the study of Békési and colleagues points to how collaboration is something that needs to be learned by participants in ways that are productive for those participating.

Collaborative talk

Related to facilitation is the critical role of discourse in collaborative lesson and learning study settings. This was addressed by contributions from Clivaz and colleagues, and Faria and colleagues. Analyses of post-lesson reflection meetings and teacher talk reveal that the quality of facilitator questioning can bridge the gap between teaching practice and broader professional development, deepening participants' practical and theoretical understanding. Discourse analysis distinguishes cumulative, disputational, and exploratory talk, designating exploratory talk, marked by critical yet constructive engagement, as particularly potent for collective knowledge construction. As pre-service and in-service educators negotiate the evolving micro-didactical contract within classrooms (that is, the implicit agreements governing teaching and learning interactions) they shift from traditional, instructor-centered paradigms toward participatory, teacher-led inquiry. This transition demands time and mutual adjustment but paves the way for richer, more collaborative professional learning. Roorda and de Vries, in their poster presentation, explored classroom discussion in the context of Japanese Problem Solving lessons. The contribution of da Ponte and colleagues illustrates the issues inherent in developing from pre-service teacher to become more experienced in leading whole-class discussions.

Included in our discussions in this theme was the research of collaborative talk focused on knowledge for teaching by Leakey. Linked to analysis of talk of this nature, issues of deep-seated socio-cultural practices at both societal and educational professional levels and interactions with translation of different source languages were raised in the contribution of Wake and Lander. This discussed issues around how we, as researchers, are interpreting each other's work.

Early stages of, including pre-service, teacher education

Research in initial teacher education (for example, see the contributions of Presutti, and Andriano and Robuti) shows that the micro-didactical contracts that become established in classrooms, influenced by general patterns of teaching that emerge in our different countries, and in response to teacher beliefs, classroom relationships and their interactions with students, are important in collaborative settings. These are particularly important to our understanding of how early career teachers transition from traditional university training to a more teacher-led, collective activity with a focus on ongoing professional learning. This evolution requires time for pre-service teachers, educators, and more well-established teachers to adjust to the characteristics of collaborative professional learning such as those focused on lesson and learning studies (see the work here of Békési and colleagues).

Some variants of Lesson Study (including bi-institutional models that connect university and school settings, as well as Learning Study approaches that emphasize problem analysis and iterative refinement of teaching material) demonstrate how the group are using adaptable lesson studies across contexts and content areas, as well as in supporting the development of early career teachers. Detailed studies in this area, for example, see the research on algebra instruction by Cosan reveals that collaboration across institutions can catalyse a shift from mere procedural proficiency to deeper technological and theoretical reasoning, prompting students themselves to articulate and justify their

solution strategies. Yet these structured collaborations can also provoke discomfort among teachers when sequences become overly regimented, suggesting a delicate balance must be struck between fidelity to collective planning and the autonomy needed for teachers to tailor implementation (for example, the contribution of Antoine).

Didactical theory and knowledge

Another strand of our discussions focussed on how collaborative activity can function as 'paradidactic' systems, wherein pre-service and early career as well as more experienced teachers and teacher-educators can form inquiry communities whose collaborative planning and reflection in ways that can sharpen their Mathematical Knowledge for Teaching. De Haan and colleagues, Østergaard, and Mårtensson and colleagues shared their work using learning studies and variation theory to explore these issues. By analysing student work, leveraging planning templates, and interrogating textbook content through the process known in Japan as kyozai kenkyu, participants make tacit pedagogical knowledge visible and can extend their knowledge for teaching including their horizon content knowledge. Comparative studies of textbooks from diverse cultural contexts further illustrate how critical engagement with instructional materials can inform new modes of support. For example, our engagement with consideration of such activity underscores the global relevance of the methodologies of our work we employ in collaborative research of this nature and the theoretical framings we use in exploring and extending our thinking in relation to teacher knowledge. The work of Garcia and colleagues, Østergaard, Bahn and Cosan,in particular drew on the Anthropological Theory of Didactics to frame their thinking.

Conclusion

In conclusion, the second meeting of TWG 28 reaffirmed the vibrancy and complexity of collaborative inquiry in mathematics teacher education and provided promising avenues for future enquiry. Participants illuminated the multifaceted roles of facilitators, the nuanced dynamics of teacher discourse, and the evolving didactical contracts that shape pre-service and in-service learning alike. Our discussions underscored the imperative of cultivating facilitation expertise through longitudinal, context-sensitive training; of deepening our theoretical grasp of paradidactic systems and variation theory; and of attending rigorously to socio-cultural dimensions of our work across different contexts. Future comparative and longitudinal research that considers both university-based teacher preparation and school-embedded practice appears potentially very attractive. By sustaining our dialogue across borders and career stages, TWG 28 can continue to refine collaborative frameworks that can help advance mathematical knowledge for teaching and how this might be best facilitated.

Disciplinary and meta-disciplinary noticing of prospective teachers in a lesson study experiment

Valeria Andriano[1,2] and Ornella Robutti[2]

[1]Liceo Scientifico Galileo Ferraris, Turin, Italy; valeria.andriano@unito.it

[2]University of Turin, Italy

Abstract *This study involves secondary school prospective teachers in an Italian master's degree in mathematics, when they are involved in a course of mathematics education, while doing an experiment of lesson study. A group of four prospective teachers are observed, while engaged in the planning phase of a lesson study, in which they have chosen to work on the introduction to functions in grade 11. The study aims to analyse prospective teachers' discussions, focusing on their noticing as a theoretical lens to qualitatively describe teachers' reflections. The results suggest that the transition between disciplinary and meta-disciplinary ways of noticing during the discussion improves teachers' awareness and enables them to make decisions about the lesson plan.*

Keywords: Lesson study, prospective teacher education, noticing, disciplinary, meta-disciplinary.

Introduction and literature review

Several studies suggest that Prospective Teachers Education (PTE) programs should include activities that engage teachers in researching their practice (Potari & Ponte, 2017). According to Mason (2021), the concept of *noticing* in mathematics teaching serves as a valuable tool for encouraging teacher reflection and enhancing professional expertise, as the way teachers observe and reflect on their practice can significantly impact the quality of their instruction (Jacobs et al., 2010; Sherin et al., 2011). This is enhanced when prospective teachers have the opportunity to work in professional communities. Several studies point out Lesson Study (LS) as a professional development process where prospective teachers develop their knowledge through collaboration in a reflective setting (Ponte, 2017; Chen & Zhang, 2019; Gomes et al., 2022; Minisola et al., 2024). Ponte (2017) pointed out that given the nature of national policy on PTE, it could be problematic to implement LS in PTE, and the process should be adapted.

In the last decades there has been an increasing attention on teacher noticing (Konig et al., 2022). Some studies testify a growing interest in applying the concept of noticing to LS (Lee & Choy, 2017; Choy et al., 2017; Ylmaz & Yetkin Ozdemir 2023; Andriano et al., 2023). Among them, only a few studies apply noticing in LS in PTE (Bakker et al., 2022; Ylmaz & Yetkin Ozdemir 2023), and secondary school mathematics teachers noticing in LS in PTE is underexplored.

The aim of this study is to explore noticing skills in prospective secondary school teachers during lesson study. We focus our attention on the planning phase to understand which elements of noticing are fundamental in planning the lesson.

Theoretical framework

The theoretical background is based on the practice of *noticing* (Mason, 2021). According to Mason, being a teacher requires sensitivity to learners, and this is possible because of awareness-in-discipline. As Mason sustains, awareness is educable and can be improved by the *discipline of noticing*, i.e. "a

systematic method for conducting research into one's own practice" (Mason 2021, p. 231). There are different conceptualizations of noticing: some authors define noticing as that to which teachers attend (Mason, 2021), for others noticing involve two processes, attending, and making sense. Moreover, making sense for some researchers is solely interpreting (Sherin et al., 2011), whereas for others it involves interpreting and deciding how to respond (Jacobs et al., 2010). Among the growing number of research studies on teachers noticing, many of these studies explore noticing skills when reviewing teaching videos (Rosaen et al., 2008; Sherin & van Es, 2009) and only a few in the context of lesson study (Choy et al., 2017; Ylmaz & Yetkin Ozdemir, 2023). Choy (2017) extended the notion of teacher noticing to examine what and how teachers notice during the planning of lessons. However, much of the discussion is about specific attributes, such as student thinking, student production, teacher-student interaction. When teachers plan a lesson in the context of LS, they must take into consideration multiple aspects: the mathematical content, the curriculum and other institutional constraints, such as textbooks, resources, classroom setting, the choice of pedagogical approaches, the task, student thinking. In this research we use the notion of teacher *noticing* to examine what and how teachers notice in the planning phase of a LS related to mathematical content.

When noticing regards mathematics as a discipline, there is a spectrum in which one could distinguish, among others, two different levels: disciplinary and meta-disciplinary (Williams & Roth, 2019). According to Williams and Roth, the disciplinary regards the knowledge of mathematics seen from the inside, with all the rules, definitions, practices and the corresponding terminology and linguistic forms. The meta-disciplinary regards mathematics seen from the outside and involves awareness of the nature of the discipline. It is the level at which the epistemic quality of the discipline becomes clearer, and a conscious theoretical control becomes possible. It is the meta-knowledge level that emerges from the reflection on the knowledge inside the discipline.

To frame our analysis of teacher noticing about mathematics, we consider two dimensions related to how teachers use noticing. The first is related to what teachers notice at the disciplinary level, the second to what teachers notice at the meta-disciplinary level. Moreover, we are interested to investigate how the used noticing helps them in making the corresponding choices in the lesson plan. Therefore, our research questions are:

RQ1: How do prospective teachers use noticing when planning a lesson during LS?

RQ2: How does this noticing enable them to make decisions about the lesson plan?

Context

This research is a case study developed in Italy in the academic year 2023-24. The prospective teachers were attending the first year of the 2-year master's degree in mathematics in a public University. All of them already have a degree in Mathematics and none of them have teaching experience. LS was introduced in three 2-hour lessons, as part of a course in Mathematics Education (the second author is the professor of the course). 20 teachers were involved in the LS, split in five groups of four. All the participants were contacted in advance and indicated their willingness to participate in the study. The first lesson was devoted to a general introduction to LS.

The LS had the following structure:

1. two planning meetings (one in person and one on-line)
2. one research lesson
3. one debriefing meeting

After the general introduction to LS every group chose one among four given topics related to a research problem (Table 1).

Table 1: Topics proposed to the groups

Research problem	Topic	Observation focus
Distinguish functions among other mathematical relations	Introduction to function	Strategies and different semiotic register used by students
Combinatorial thinking	Introduction to combinatorics	Students' combinatorial thinking
Calculate the area of a region bounded by curves	Applications of the integral	Students' geometrical thinking and use of signs
Give meaning to the equation of the plane in analytical geometry	Plane equation in 3D geometry	How students move from geometric concept to the equation

Therefore, the groups have not been engaged in the first step of a LS cycle, i.e. selecting a topic and defining the goal. The reasons are two: for time constraints and because the participants had no teaching experience and therefore the research problem would not have come from a concrete teaching problem. The lesson planning phase had two sessions, one in person and one online. Then, each group taught the lesson to the class of prospective teachers: one component of the group performed the lesson whereas the other components observed the lesson, and the other prospective teachers acted as if they were the students. Then, each group had one post-lesson discussion in person, in which they shared what they noticed and how they could improve the lesson, and a second session online in which they wrote a second version of the lesson plan. Finally, there was a whole class discussion to share some final considerations. Since there was one teacher educator and one facilitator in the room at the time, the groups worked autonomously, and the facilitator went around the groups to supervise the work.

In this study we analyse the video recordings of only one of the four groups. The topic chosen by the group was: introduction to functions. The participants were four prospective teachers, henceforth referred to as Teacher A, B, C, D.

Introducing LS in prospective teacher education needs adaptation of LS, and these adaptations raise some issues (Ponte, 2017). In our adaptation there are some advantages, because participants are engaged in a truly collaborative relationship, they are at the same level and there is not an expert so there is a balanced relationship among participants. Moreover, it has been performed with 20

participants and two teachers' educators, so it proved to be scaling. On the other hand, a limitation is that the research lesson was not performed with secondary students, due to the institutional constraints of prospective teacher education at university level in Italy.

Method

The aim of this research is to analyse prospective teachers' noticing during the planning phase of a lesson study. Therefore, our data is the videorecording of all LS meetings and lessons along with teachers' observation notes and lesson plans collected and saved during the meetings. The research follows a qualitative approach. To carry out the analysis the authors viewed many times the recorded video, first individually and then together, looking for episodes of noticing. With an episode of noticing we mean an episode in the discussion where we could find three distinct parts: attending, reflecting, and acting (Andriano et al., 2023). We looked for moments of attending, then we keep track of this attending: do they start a critical reflection within the group? And does this reflection enable the group to act, or make decisions? When we find attending, reflecting, and acting, we call it an episode of noticing. Then we transcribed these episodes. Having identified an episode of noticing, we analyse what teachers notice in the episode. If the noticing regards mathematics knowledge, namely a disciplinary aspect, we analyse also if teachers' noticing is at a disciplinary level, i.e. regarding mathematics from the inside (rules, definitions, etc…), or at a meta-disciplinary level, i.e. regarding mathematics from the outside (meta-knowledge). In the analysis of video recordings of the first group's planning meetings we identified 11 episodes of noticing. Among them, 9 regards mathematics knowledge. In this study we carry out the analysis of one moment of teachers' noticing regarding mathematics knowledge.

Data analysis

In this study we analyse one episode of noticing taken from the first meeting. The lesson is about the distinction between functions and relations that are not functions. Teachers are discussing and drawing graphs of functions (e.g., parabola) and graphs of curves that are not functions (e.g., circles). We will present one episode of noticing regarding mathematics knowledge in relation to one specific epistemological node, the concept of function, which is discussed by the prospective teachers.

Attending

Teacher D: The thing that would interest me is to understand what the focus is. That is, what is the element that makes us say that a function suits us in one way and doesn't suit us in the other.

Teacher D started attending a new thing. The graph she drew (Figure 1) shows that she knows how to recognise a function from the graph, so she knows the concept at the disciplinary level. The point is at the meta-disciplinary level as she will explain in the following.

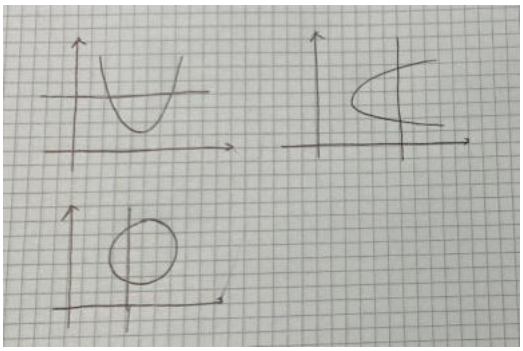

Figure 1: Teacher D drawings

Reflecting

From now on starts the critical reflection within the group:

Teacher D: Mathematically why is it a problem that the vertical axis encounters twice, and it is not a problem that the horizontal one does?
Teacher A: Because that's how it is from the definition of function
Teacher B: Yes, right.
Teacher A: You understand this from the function definition.
Teacher B: That the domain is on this here axis and the codomain is on the y axis.
Teacher A: And we associate with each element of the domain one and only one element of the codomain. [together with B from "to each element..."]
Teacher D: No, I agree that this is the definition, but I'm wondering why, and I've never asked myself that, so it's good that we're doing it, I'm just wondering why the definition is put like this, because we're really interested in those facts in this way.

In the last sentence teacher D explains clearly that she is attending to other things, she says “why the definition is put like this”. She wants to understand why the definition of function is important in mathematics, why it is given in that way. Her noticing is at a meta level: it is meta-disciplinary. This is further reinforced by the next sentence: “and I never asked myself, so it’s good that we are doing it”. She had a shift of attention, and she seems aware of the fact that she is thinking about function from a new point of view. On the other hand, the other two teachers’ reflections are at a disciplinary level. They know the definition and, repeating the same words together, they know it by heart. They know how to recognise a function, but their sentences are within the disciplinary level. They know the concept from the inside of the discipline, with all the rules, the definitions, the techniques. There is an asymmetry between teacher D and the other two: they are reflecting at different levels. Then the critical reflection of the group of teachers goes on by continuing to move between the two levels, but this asymmetry makes the other teachers gradually get the point of teacher D, until all teachers of the group move at the meta-disciplinary level:

Teacher A: I think she wants to find a motivational aspect.
Teacher D: Why will this thing function well and this one not? I don't know if I can explain myself, so as not to just learn mechanically.
Teacher B: I don't know why they invented this concept.

Teacher C: Maybe that's the problem. If we have thought of the function to describe one thing as a function of another, the problem lies in the moment in which... that is, if I have to study one thing that depends on another.

Teacher B: Ah, wait, I have an idea. If you think that with this function, we are representing the movement, the various positions, then you really cannot be in two positions at the same time, that is, if you indicate time here and space here then you cannot necessarily be in two positions at the same time.

Teacher D: Exactly. So, we have an independent variable that moves and then the rest that depends on this independent variable and can only have one value.

During the discussion teacher D explains her point of view and in the first sentence teacher A gets the point and passes at a meta-disciplinary level. In the third sentence also teacher B moves to the meta-disciplinary level "I don't know why they invented this concept". And then all the teachers start reasoning at a meta-disciplinary level. Reasoning at a meta-disciplinary level opens new perspectives to teachers. This enables for example teacher B to find a different point of view on function that gives an answer to teacher D's first question. The group of teachers, through the discussion at a meta-disciplinary level improves their awareness on the nature of the discipline.

Acting

The very rich dialectics between disciplinary and meta-disciplinary levels of noticing brings a new awareness to teachers, which enables them to be in action, namely, to consequently decide the kind of task and how to design it.

Teacher B: We could start from the space-time graph, precisely, time below and space above
Teacher A: Yes, I like that.
Teacher C: Yes.
Teacher D: We could start with a physical example of a space-time graph.
Teacher B: Let's start with a physical example, a person who moves.
Teacher D: And so, let's say that the ordinate tells us about the distance from the starting point.

The group discussion on a meta-disciplinary level improves teachers' awareness and opens new perspectives on the discipline. This enables teachers to act, to make the decision of designing a task starting from a space-time diagram.

Discussion

The aim of this study is to analyse the reflections of prospective secondary school teachers during the planning phase of lesson study. To carry out the analysis we used noticing as a theoretical lens. We have identified episodes of noticing characterised by three steps: attending, reflecting, acting. In this study we analysed one episode of noticing regarding mathematical knowledge. We analysed the critical reflection with respect to two categories: disciplinary and meta-disciplinary (Williams & Roth, 2019). The first research question is: how do prospective teachers use noticing when planning a lesson during LS? We found that teachers' noticing regards mathematical knowledge at a disciplinary and meta-disciplinary level. The episode of noticing starts with one teacher attending to mathematical knowledge at a meta-disciplinary level. The teacher had a shift of attention from disciplinary to meta-disciplinary. At the beginning of the critical reflection the other teachers'

sentences are at a disciplinary level. At this moment there is an asymmetry in the group between reasoning at two different levels. During the discussion there is a continuous shift between the disciplinary and the meta-disciplinary level until all teachers' reasoning is meta-disciplinary.

Regarding the second research question: How does this noticing enable them to make decisions about the lesson plan? We found that the collective reasoning at the meta-disciplinary level changes teachers' point of view and opens new perspectives. It is a way to see the discipline from another point of view. During the discussion teachers become more aware of the nature of the concept of function. This new awareness enables them to act, and they decide to design the lesson starting from a space/time diagram. Moreover, the choice to start from a space/time diagram shows that teachers have a broader perspective that includes another discipline, physics. Therefore, this study suggests that the dialectic between disciplinary and meta-disciplinary could improve teachers' awareness on mathematics and could offer new perspectives towards other disciplines. This could be particularly significant in the design of interdisciplinary lessons as in the case of STEM or STEAM activities.

In this paper only one episode has been analysed. We need to expand the analysis to other episodes where the disciplinary/meta-disciplinary dialectic emerges. Moreover, further research is needed to analyse which are the characteristics of the applied design and the facilitator's moves that could emphasise this dialectic between disciplinary and meta-disciplinary.

“I’ve really seen myself as a robot”: professional development and perception of teachers involved in a collaborative setting after a second implementation loop

Camille Antoine[1]

[1]LIRDEF, Univ. Montpellier and Univ. Paul Valery Montpellier 3, Montpellier, France;
camille.antoine@umontpellier.fr

This PhD research investigates the professional development of schoolteachers involved in a collaborative research with science and mathematics education researchers. For two years, this group has coconstructed a complete sequence of lessons on the attribute mass for pupils from 4 to 7 years old, based on a children’s book. This paper presents the first results of this study. It appears that all the teachers have increased their abilities to identify the difficulties of their pupils and clarify their didactical objectives and issues. Nevertheless, as the sequence became more structured, they felt a sort of a discomfort in their teaching practices and found their pupils less motivated by the lesson than the first years. This observation leads us to discuss the balance between the collective development of a structured, detailed common scenario and the latitude left to the teachers in their implementation.

Attribute and measurement, collaborative research, teachers’ professional development, elementary school, concept of mass.

Context

At the interface between mathematics and physics, “attributes and measurement” is an essential domain in sciences. In the French curricula for elementary school, “attributes and measurement” is one of the four main themes of mathematics teaching. These two concepts also appear in the kindergarten’s curricula in the area entitled “Exploring shapes, magnitudes and organized sequences”. A progression is recommended to enhance the attribute’s conceptualization: the discovery of a specific attribute begins with direct perception, followed by activities involving direct and indirect comparisons. Its measurement is then introduced, initially with arbitrary units and then with the usual units. In the line of Piaget studies, many research point out the relevance of this progression for the cognitive development of children (e.g. Sarama et al., 2011).

However, many schoolteachers face difficulties to follow this progression (Munier & Passelaigue, 2012). When they follow it, they often do so only for the length and very little for other attributes (mass, volume, duration, angle, etc.), which may be explained by the difficulties they have in distinguishing attributes from measurement (Passelaigue & Munier, 2015). One question seems essential: how to enhance the schoolteacher’s knowledge and practices concerning the teaching of attributes and measurement and foster their professional development on this specific domain? Various studies show that collaborative settings can enhance the improvement of didactical knowledge of teachers (e.g. Chanudet & Favier, 2023) and, more generally, the professional development of teachers (e.g. Bednarz, 2013). Moreover, our previous research (Antoine et al., 2023) shows that it is possible to foster pupils’ learning thanks to children's books in which attribute

is central to the story. In particular, they favour working on attribute apart from its measurement and also encourage pupils' language activities. Consequently, our hypothesis is that the use of children's books in a collaborative research setting involving schoolteachers and sciences education researchers could be a lever for teachers' professional development on the attribute and measurement teaching process.

Theoretical framework: a collaborative research setting on mass teaching with a children's book

In the line of *collaborative research* which works "with" the teachers rather than "on" them (Bednarz, 2013), our collaborative setting is based on the four principles identified by Allard & al. (2022): collective construction of a common problematic; support on teaching contexts and practices; iterative loop of conception and implementation of the resources; sharing responsibilities and tasks among the different participants. As Abboud, Robert and Rogalski (2022) suggest, we rely on the usual practices of the teachers involved in order to remain in their *Zone of Proximal Development of Practices* (ZPDP). We focus on the *didactical* professional development that we define as enhancing teacher's knowledge and practice on a specific teaching subject: mass teaching and more generally attributes and measurement teaching. In the line of many research which study knowledge needed to teach, we consider both subject matter knowledge (SMK) and pedagogical content knowledge (PCK). We rely on Magnusson's model to categorize the PCK into five different components: orientation to teaching science, knowledge of science curricula, knowledge of students's understanding of science, knowledge of instructional strategies and knowledge of assessment of scientific literacy (Magnusson et al., 1999).

The group is composed of five schoolteachers (Célia, Coralie, Déborah, Victoire and Yaëlle, having pupils from 4 to 7 years old, and facing various socio-cultural context, as three of them teach in "educational priority zones") and three science and mathematics education researchers (including the author) and meets once a month. At the beginning of the setting, researchers brought several children's books. The schoolteachers decided to work on the attribute mass and chose the book *Just a little bit* (text by Ann Tompert, illustrations by Lynn Munsinger). *Just a little bit* tells the story of an elephant and a mouse who want to play on a seesaw despite their weigh difference. Various animals come and sit on the mouse's side to help them until finally the board tips over when a beetle arrives. So, in this book, the concept of mass is essential to understand the story. Various aspects of this concept can be worked: mass additivity, distinction mass-quantity, balance and unbalance states of the seesaw, language formulations to express a comparison ("A is heavier than B"), schematisation of a seesaw thanks to the book's illustrations, etc.

During the first year of work, the group designed and implemented lessons in their five classes. These experiments were recorded, and the group then analysed what happened from the point of view of the pupils' mathematical learning. Thus, real-time feedback enabled adjustments to be made to the sequence. The teachers' objectives have become refined (Antoine, 2023) as they improved their skills to identify pupils' difficulties and the didactical issues, which led the group to work on a more detailed lesson plan for the second iteration loop, on the teachers' demand.

Problematic and method

Based on these observations, our research question are the following: what does the restructuring of this sequence between the first and the second year reveal on the professional development of the five schoolteachers? What impact has it had on their practices? And how did the teachers experience the second iteration loop?

All the group's meetings were recorded and transcribed. In the verbatim, we analyse each moment of the discussions by identifying the mathematical topic questioned and what we call a *look* on this topic. These looks are inspired and adapted from the PCK model in order to categorize the different ways of questioning a specific mathematical topic. We characterized each *look* with one of the Magnusson's categories, and added the "SMK *look*" and a "*look* on pupils' procedures". Sentences were coded (using the software Transana) according to two dimensions: the specific mathematical topic discussed (the list of all the topics was determined from our didactical analysis), and the *look* on this topic. Four examples of this code are given in the figure 1.

Topic / "Look"	Binary formulations of comparison	Schematisation: coding from observation
Pupils' difficulties	"I don't think he could use that formulation, so he said 'because the lion is heavy and the giraffe is light'. But you see, it's a way of saying which is heavier."	"The drawing contradicts the physical reality. So it's not just a question of vocabulary, it's that they actually draw it up there."
Teaching strategies	"We worked on the formulations 'heavier than', 'lighter than', 'less heavy than', 'as much as', and what I wanted to do was get each pupil to make a sentence choosing two animals."	"I'll tell them 'we're going to take two animals'. We anticipate, discuss, pose, check and then I'll ask 'face the scale, draw what you see'. So first I make sure that the drawing is consistent with what's there."

Figure 1: Examples of quotations coded with both a 'look' and a topic

We now present the evolution of the lesson plan between the first and second implementations in order to identify traces of the teachers' professional development in the restructuring process. Then, we will question the origins of a "discomfort" expressed by the teachers during the second iteration loop, which leads us to reflect on the teachers' professional development process and the effects of the collaboration on their practices.

Evolution of lesson plan between the first and the second year

During the first year, the work of the group was exploratory: the different lessons based on the children's book were designed and implemented progressively in the class. As there were three different levels of class and in order to remain in the teachers' ZPDP, the group elaborated a plan of the lesson, called "episodes". Whereas the instructions and the precise scenario of the episodes were not detailed, the group discussed and decided their contents and their articulation to facilitate each teacher's appropriation of those episodes. The plan was structured in four phases: the discovery of the book and its vocabulary, the reproduction of the story thanks to a small seesaw built by the group, the introduction of a Roberval scale as another instrument to reproduce the story and compare masses and, finally, the introduction of mass measurement procedures for the older pupils.

At the beginning of the collaborative work, the teachers felt unable to distinguish an attribute from its measurement, and did not identify precise didactical objectives on this topic. Progressively, in the teachers' speeches, the objectives of the global sequence have become more and more specific

and focused on the particularities of the mass teaching, thanks to their analysis of the children's book (figure 2). This analysis, combined with classroom experiments, enabled the teachers to better understand and spot pupils' difficulties, establish remedial strategies and "unfold" all the didactic issues involved in teaching mass. In particular, the teachers expressed the need to "elementarise" objectives which could serve as prerequisites for certain lessons in the sequence, to facilitate the progression of pupils' learning. This demand led the group to rework on the plan of the lessons during the second year.

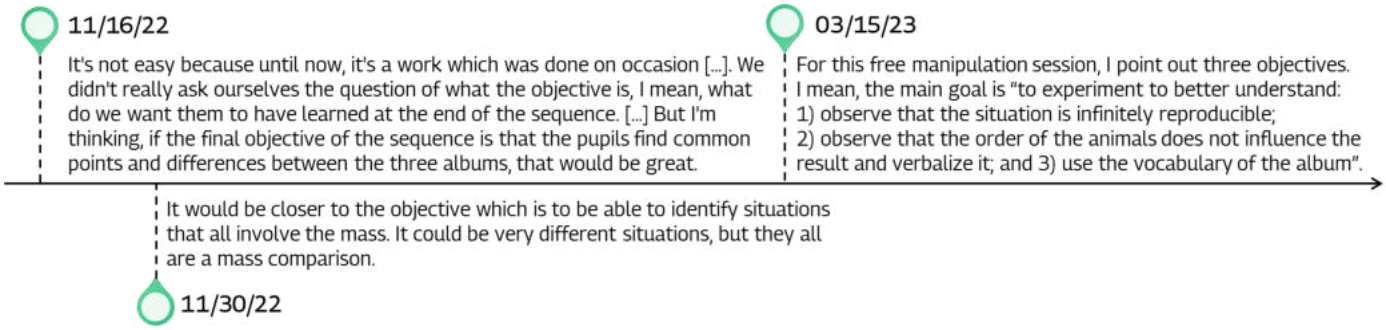

Figure 2: Evolution of Yaëlle's speech about the objectives during year one (Antoine, 2023)

The different phases of the sequence and their order did not change in the second year. Yet, three major themes have been identified to structure the learning objectives: conceptualization of mass, language issues and schematisation issues. For each of these themes, an overall progression was worked out, in conjunction with the other two, and specific activities were reorganized and placed to fulfil those new objectives. Specific attention was paid to the articulation of the objectives, and in particular to the identification of certain 'must-haves' that became prerequisites for other objectives. For example, in the language issues theme, the group identified several steps in the learning process of the pupils: understanding of the book's vocabulary; reuse of this vocabulary to describe the seesaw's state of unbalance; using of "heavy" or "light" instead of "big" or "little", etc. The group also noted that the French expression "*la planche bascule*" [the board rocks] could be confusing for the pupils. Indeed, it can convoy the idea of movement but can also be used in "*la planche bascule* du côté du plus lourd" [the board tilts on the side of the heaviest object], which refers to a static state of the seesaw. Moreover, the French word "*bascule*" can also refer to the seesaw itself! To avoid this confusion, they decided to use this expression only to designate a movement, a change in the state of the seesaw, and to use another expression to designate a static tilted state of the seesaw.

Quickly in the restructuring of the plan, a key moment was identified: the moment when pupils must leave the story to reinvest their learning outside any fictional context, right before the introduction of the Roberval balance. Therefore, on several meetings, the group focused on the elaboration of a common intermediate assessment. Three tasks were designed to verify the good mastering of certain skills for all pupils, based on the articulation of the three themes of the plan.

The details brought to the common plan around the three major themes and the elaboration of an intermediate assessment point out an improvement of the teacher's PCK in at least three of the five components identified by Magnusson. By refining the sequence objectives, they show a better understanding of the concepts of attribute, measurement and mass (SMK). They can also anticipate

the difficulties their pupils could encounter (PCK – student's understanding of science) and they develop several strategies to deal with them (PCK – strategies) and to assess their pupils' learning (PCK – assessment), mainly by identifying a progression of the learning and prerequisites to some specific activities and by using more precise vocabulary and instructions.

The second experiments loop: analyse of a "discomfort" felt by the teachers

Expression of a "discomfort" feeling. The teachers experimented the lessons for the second time in their classes with a more detailed and complete lesson plan. But, at the end of the sixth meeting of the second year, in February 2024, they expressed a feeling that the experiments were not going as well as the previous year. From their perspective, their pupils felt less free to experiment with the material and less motivated by the different lessons, whereas it was the same book and similar activities than the first year. We transcribe a part of the group's discussion below:

Célia	I have the impression that my way of doing things is less interesting than last year. I have the feeling that I over-frame them [her pupils]. I have the feeling that last year I was able to create research situations, and less this year. I don't know why.
Victoire	What I'm doing is a lot more polished on my side. And while last year we were all about enthusiasm and self-discovery, this year I feel it's more step-by-step, and we're losing a bit of the magic, but ... […]
Yaëlle	I wonder if we haven't locked certain things up too tightly. In particular, this precision of language that we've imposed on ourselves this year, hasn't that made us lose a bit of...
Victoire	Spontaneity?
Yaëlle	Of spontaneity and enthusiasm. This year, I've really seen myself as a ***robot***, being very careful… One do not say "rock"… […] We pay attention and, inevitably, we're less…
Victoire	Emotional. So maybe that's what the pupils are missing.
Yaëlle	Maybe they're thinking… they act like us. […] "We're careful, we can't do anything stupid, we have to say the right things". […] It's a bit like those classroom situations where, when you haven't planned exactly what you're going to do, sometimes you do some brilliant stuff. And when you come up with something, and you're really into it, you know, you're an expert in it and you've read all the literature on it, and in fact you just flop.
Coralie	I think that there's a balance. We need to keep a common thread because it was also a request from us to have a guide. But how do we build this guide to keep the spontaneity of the children, the research activity of the children, and also to be able to bounce off what's daily done in our classes, because we have children who are all different. And I think that's perhaps why we need a third year now, a third experiment to find just the right balance.

They particularly pointed out one moment when the pupils did not act with the same commitment: when the seesaw is introduced to reproduce the story. On their demand, during the next meeting, the group watched videos of this phase from the first and second year to compare the instructions given. This viewing enabled them to identify a lack of problematisation when introducing the seesaw during the second year, and led them to adjust their instructions and their focus for the following lessons. This may appear paradoxical: the second iteration loop was more structured overall but this specific lesson was not, as it had happened "naturally" during the first experiment.

The teachers' perception. At the end of the year, in individual interviews, when asked about this particular moment when they felt discomfort, they agreed (at different levels) that, after all, the

second version of the sequence enhanced their pupil's understanding, but some of them still kept the feeling that their pupils were less motivated.

Déborah — This year, I've got to grips with the sequence. I've reinvested it. […] And so I got to the bottom of things, in fact. […] I think that almost all my students understood. They went where we wanted them to go. Because they were more focused. Because I was clearer about my objectives. […] It's true that there were times when we said to ourselves, they're less curious, they say fewer things. But in fact, afterwards, I say to myself that maybe they say fewer things, but maybe they also say things of better quality.

Yaëlle — Was it really because I was […] more in control in relation to the fact that the sequence had to be like that, that we'd all set ourselves objectives, that we'd said to ourselves the next time we see each other, we've got to be there, there and there. So, I might have been the one who was less opened. And yes, the children are less involved and less enthusiastic. […] Still, I have the impression that, in terms of vocabulary, things have been much more successful this year.

Coralie — Last year, I felt I'd been a bit... Yes, I felt I'd been a bit messy. This time it was clearer. And therefore certainly clearer for my students too.

Our hypotheses. The discussion above shows that the teachers, and Yaëlle in particular, question the restructuring of the sequence, considering that it may have restricted their practices and reduced their latitude in responding to the pupils' suggestions, successes or difficulties. The use of the noun "robot" to refer to herself is strong: it is as if Yaëlle felt trapped within the plan and had lost a part of her didactical and pedagogical freedom. It appeared very paradoxical to all of them: they felt more confident and "expert" about the mass teaching process but also felt like they failed to implement it in their classes. The lesson of the introduction of the seesaw is a great example of this paradox. We can formulate four hypotheses to explain this phenomena:

"*First-time magic effect*": as this was no longer the first time, they were able to compare their classes and their pupils' achievements, even though they were different. They also might have "idealised" the first experiment as it was new and exploratory and as they had no specific expectations.

"A*cademical research effect*": my own PhD study might have been a hindrance to teachers. During informal discussions, some of them expressed their worry that deviating from the planned sequence would influence my research results in a negative way. This matter was then clarified with them.

"*Resource design effect*": at the beginning of the second year, the group began to discuss the possibility of disseminating the sequence to other teachers. Consequently, the teachers might have thought that they needed to test and verify the relevance of the sequence. The research focus changed: the first year was very exploratory while the second year was intended to confirm and adjust some of the group's hypotheses about the pupils' learning process with the children's book.

"*High standards effect*": on the base of the first-year experiments, the teachers got a broader view of all the didactical issues involved in the mass teaching and learning processes. They might even have felt overwhelmed by such an extent, that they did not perceive before, as some of those issues are so "naturalised" for adults that they have become very difficult to spot. As we mentioned it, they wanted to work on the learning progression with more precise, almost "elementary", objectives in

order to clarify and articulate those issues. They also wanted to make sure they would go deep enough into the mass topic. For them, the plan was supposed to be reassuring and helping to propose the different lessons in the "right" order. Their knowledge contributed to improve but also disturb their practices, and they therefore wanted to follow a more precise plan for fear of "failing".

It seems that the collaborative setting and the experiments interfered with the teacher's preexisting knowledge and practices about this specific teaching process. To our point of view, the discomfort they felt illustrates that the didactical professional development is a complex process, in which improvement of the didactical knowledge and changes on the practices are closely related. We can even assume that those moments of discomfort or disruption may be necessary to a professional development as they can push the teachers to question their practices, and are inherent, in fact, to the development of new knowledge. This reflexive attitude also reveals a professional development.

Discussion

The analysis of the evolution of the sequence and of teacher's interactions and speeches shows that the teachers involved in this collaborative research have improved their knowledge on the teaching process of attributes and measurement. They have a better understanding of the concepts of attribute and measurement, have developed teaching and assessment strategies relating to mass and can more easily spot and remedy their pupils' difficulties. Nevertheless, this improvement in their knowledge led to a feeling of discomfort in their practices, which was generally shared by the teachers. To our opinion, this disruption was necessary, as it enhanced them to adopt a reflexive posture on their practices and then, to adjust their instructions and their activities to facilitate pupils' learning, and shows a real professional development. For the third year, the group wants to explore another attribute with another book, but it is likely that the teachers will also implement the sequence on the mass in their classes. At this point, they plan to follow the structured sequence they designed in the second experiment, while allowing themselves to get out of the sequence, if this seems more relevant to them, according to their pupils' activities and their classes' situations.

Our results raise major open questions for this TWG. What level of detail is needed, and what specific types of details are necessary in the construction of teaching sequences to ensure global didactical coherence? How to balance the structuration of these sequences in order to disseminate them within the educational community and the need for teachers of flexibility in their classrooms? What implications might this expressed feeling of "discomfort" with overly structured resources have on teachers' professional development programs? What visions of the teacher implicitly underpin the different collaborative settings which aim to construct such sequences?

Potential roles of facilitators' questioning during post-lesson reflection

We wish to explore the role of the facilitator's questioning during post-lesson reflection meetings and how this can further or delimit the growth of the participating teachers' professional knowledge. We analyse the dialogue from a reflection meeting, which took place after a grade 8 geometry lesson, held by a group of teachers working with lesson study for years. We draw on the Anthropological Theory of the Didactic to map potential questioning and knowledge emerging from lesson plan and lesson observation to compare with the question and answers actually raised during the reflection meeting. From this we see crucial differences, and the need for further research regarding the role of facilitators' questioning being somewhere between the didactic system, in which teaching takes place, and the paradidactic system, in which professional development such as lesson study takes place.

Keywords: Lesson Study, practice knowledge, facilitator role, study and research paths.

Introduction

Our contribution is about the roles of facilitators' questioning during reflection meetings in lesson study (LS) and deals with different foci in TWG28, especially organizational contexts in collaborative settings in mathematics teacher education (CSMTE), and the roles of different participants in CSMTE. We are interested in how the questioning as part of the facilitator's practice can support the development of practice knowledge among the teachers participating in LS as an example of CSMTE. However, we hypothesise that this requires explicit knowledge about the role as facilitator of others' learning in the specific context. In CERME 13, several studies in TWG28 provided insight into the facilitators' roles in LS conducted outside Japan. Masselin & Artigue (2023) presented a French case of long-term professional development for facilitators and future facilitators of LS regarding the process of their work with so-called *situation seeds* which are formulations of open problems adapted to the context of each teaching situation of the teachers in LS. Gomes, et al. (2023) reported from Portugal the importance of the facilitator's *balanced leading* actions of LS sessions, within the preparations of resources, task design and planning the research lesson. Finding a good balance between their guiding roles as project leaders and orientating teachers towards the thinking of others and exploring their thinking are crucial for the professional development (PD) of teachers' collaborative work in LS. Asami-Johansson et al. (2023) modelled teachers' collaborative learning in PD, specifically on *board work* in a case of a Facebook group in Japan. At the Facebook forum, teachers who post and lead the discussions on the forum play a role of facilitator of the study group. The more passive participants *study* how the experienced group members deal with different aspects on the posted board work and carry out their didactic discussions in a constructive manner. We wish to understand the functioning of the facilitators'

questioning better, and propose more explicit uses of notions from the Anthropological Theory of the Didactic (ATD, Chevallard, 2019) to a priori map this for a specific lesson. We consider the questioning having the function of situation seeds and as supporting the facilitators balanced leading of actions in LS, helping teachers to study and learn from their own and others' work related to the specific lesson.

When we use the term "facilitator" in the context of CSMTE, it may include slightly different levels and functions of their roles, depending on the PD system for in-service teachers, and the specific situations their studies or projects are realised in. In Japan, the role of facilitators in their PD systems spans multiple layers from national, municipal and local school levels, as well as degrees of collaboration (Miyakawa & Winsløw, 2019). Indeed, the roles and functions of facilitators are complex, and it can be challenging to foresee specific phenomena to observe in the processes of PD, and which questioning from the facilitator will develop practice knowledge among the participating teachers. Within ATD, researchers have tried to model this complex structure of organizational contexts and roles of different participants within LS as PD (e.g. Winsløw et al, 2018; Miyakawa & Winsløw, 2019; Otaki et al, 2020). In this contribution, we propose to link this with the concept of *study and research paths* (SRP) for the analysis of the questioning as situation seeds and supporting the balanced leading of the process mirroring the relation between didactic and paradidactic systems. Below we elaborate on these notions.

Theoretical background of the Anthropological Theory of the Didactic

Studying the nature and functioning of LS, Winsløw (2012) proposes the notions of paradidactic system and infrastructure to analyse and compare teacher collaboration regarding realisations of specific didactic systems. A didactic system (colloquially known as lesson) consists of a group of learners (potentially guided by a teacher or facilitator), addressing a problem or question to be studied e.g. finding the area of a geometric shape not earlier addressed by students. During the process learners and teachers may draw on relevant resources. This holds true for students learning mathematics, or teachers developing their practice knowledge (Winsløw, 2012; Miyakawa & Winsløw, 2019). The paradidactic system consists of the pre-didactic system, where teachers study for and plan the study lesson, the didactic observation system, where teachers observe the study lesson, and the post-didactic system where the realisation of the didactic system is evaluated and potentially revised (Winsløw, 2012). The work conditions, available resources, and traditions, habits and policies linked to the teachers' work naturally affects the study and learning processes of the teachers, when participating in the PD. Thus, Winsløw "defines the paradidactic infrastructure […] as everything which conditions and constraints the [paradidactic system] in its different phases […]" (Winsløw, 2012, p. 293). Though the nature of how Japanese teachers learn from and realise LS may be rather different from how LS is interpreted outside of Japan (Miyakawa & Winsløw, 2019), Winsløw and colleagues (2018) argue that detailed analyses of knowledge developed through the interaction between didactic and paradidactic systems are key to understand the potentials of exploring and exposing LS outside Japan. They propose to understand the functioning and dynamic of didactic and paradidactic systems by analysing the type of tasks or questions which are pursued and what answers are developed. Developing (practice) knowledge through question-answer dialectics is considered learning within ATD, and therefore in this paper we will focus on

question-answer dynamics when proposing the need for a priori mapping of facilitators questioning. In ATD, this mapping is linked to Study and Research Paths (SRP). Considering LS a SRP, the study processes means to pursue a teaching question (with the aim of developing students' learning) by drawing on existing knowledge, study new knowledge from resources (e.g. textbooks, web-pages, teacher journals, lesson plans, etc.). The knowledge is combined in the research process, when developing the teaching activity and presenting it in the lesson plan. This is the result of the work within the predidactic system. It represents a hypothetical answer materialised in the lesson plan, which is then realised (didactic system), observed (didactic observation system) and reflected upon (postdidactic system). All the systems will give rise to questions of both mathematical and didactic nature, some addressing students learning of the specific mathematical content. Other questions will emerge from the paradidactic system and aim at teachers' development of their practice knowledge. Thus, learning is developed when learners are engaged in the dialectics between question and answers, between study and research, meaning the dialectic of decomposition and reconstruction of knowledge (Winsløw, Matheron & Mercier, 2013; Jessen, 2017).

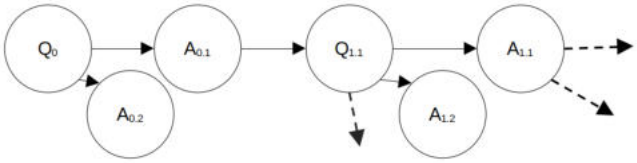

Figure 1: Illustration of a question-answer map (QA-map) to support teachers in SRP

An SRP is initiated, often by the teacher/facilitator, posing a generating question, $Q_{0,}$ in LS a teaching question. This is an open question which the learner understands, but it requires the learner to engage in study and research processes if the learner is to develop an answer, A, to the question. By means of its answers, the generating question will lead to derived questions, e.g. $Q_{1,1}$, addressing parts of the initial question. Therefore, an answer to a derived question, e.g. $A_{1.1}$ will be a partial answer to the initial question, Q_0. When working with SRP we use QA-maps (see Figure 1) to show both a priori the learning potential of posing Q_0 to certain learners, and a posteriori to map the knowledge addressed and developed during the SRP. We hypothesise that SRP can be a strong tool for analysing SRP, in particular for capturing the role of facilitators' orchestration of the learning of participating teachers. In Japan, expert teachers or researchers take the role as facilitators in different settings of LS (Miyakawa & Winsløw, 2019) and they have been part of this practice for years in what we consider apprenticeship. When initiating LS as PD outside of Japan, we lack this apprenticeship, and to further the *balanced leading* of *study* (and research) activities and productive uses of *situation seeds,* we consider it relevant to map facilitators' questioning

This leads to the research question of this paper: What is the impact of facilitators' questioning during the post lesson reflection meeting when analysed as a study and research path compared to a similar a priori analysis?

Context of the study

Our data stems from a research lesson at an ordinary public school in greater Copenhagen, where the mathematics teachers have worked with lesson study in various forms for more than nine years

(see Bahn et al., 2022). For the first four years, an external facilitator, $F_{ext,}$ supervised the activities. During the next three years, two supervising teachers were trained by the F_{ext}, and since 2022, they have been acting as facilitators. This paper, is based on one of these *internal facilitators*', F_{int}, work. Since 2020, it has been mandatory for all teachers from their school to participate in LS.

The LS-activities at this school started as empirical studies for the first author's Ph.D.-studies (Bahn, 2018), but were expanded and developed into a systematic programme for PD. Despite the LS efforts running for 9 years, we still consider the PD immature compared to Japanese LS e.g. with respect to facilitation. Concurrently three types of practices are being developed: teachers' practices of teaching (linked to the didactic system), teachers' practices of developing teaching (intertwining the didactic and the paradidactic system) and facilitators' practices of supporting teachers' development of teaching (linked to the paradidactic system). Recognising that new practices are hard to develop from scratch or from vague descriptions, it has been part of the LS-activities to invite Japanese expert teachers and teacher educators to demonstrate their principles and practices of teaching and facilitation once or twice a year. Researchers of didactics have been involved in the activities and final comments to the LS several times.

As there is no education to become a LS-facilitator, the Japanese system of apprenticeship has been adopted including learning from the Japanese visits. Thus, the training of F_{int} has been based on the accumulated knowledge and experiences from the 9 years running. Prior to facilitating LS, the F_{int} has worked as a mathematics teacher for more than 30 years, and more than 10 of those as a trained supervisor for other teachers. Furthermore, F_{int} has participated in international LS activities (Japan and UK) and numerous professional discussions with facilitators.

The data comprise the lesson plan (generated in the predidactic system), and F_{ext}'s notes from and video recordings of the study lesson (didactic observation system) and the post-lesson reflection meeting (postdidactic system). F_{ext} was not involved before the study lesson and the post-lesson reflection. In both he was solely present as an observer until the very end, where he give some final comments. The lesson plan was send to F_{ext} a few days in advance. Based on these data we can map examples of F_{ext}'s (tentative) a priori questioning and F_{int}'s a posteriori questioning during the realised facilitation and compare those referring to knowledge linked to the didactic and paradidactic systems.

During the post lesson reflection, in the transition from sharing observations to reflecting on specific elements, F_{int} proposed: "[…] From our reflections I have marked these 'Can we do something to get the conversations going?' […] and [...] 'Could we do something to make the goal clearer to the students?' or?". We consider these first derived questions in our a posteriori analyses, stemming from the overarching "Q_0: How to decide on what to discuss further?".

The lesson – intentions, realisations and reflections

In the lesson plan, the learning goals are stated as "an understanding of information needed to draw identical right-angled triangles" and "an emerging understanding of cosine without mentioning the word in this lesson. The larger the angle, the shorter the adjacent side". During the lesson, students were working with three tasks (t_1-t_3) on identical right angled triangles and one task (t_4) on the

connection between the angle and the adjacent side: t_1 Draw a triangle with a 10 cm hypotenuse, t_2 Draw a triangle with a 10 cm hypotenuse and a 5 cm side, t_3 Draw a triangle with a 10 cm hypotenuse and an angle of 60°, and t_4 Draw a triangle with a 10 cm hypotenuse and an angle of 45° in a diagram with two right angled triangles drawn, one with an angle of 30° and one with an angle of 60° all sharing the same origin (0,0). The teachers anticipated that based on the three first tasks, the students would realise the connection between the size of the angle (at 0,0) and the length of the (adjacent) side in t_4. This was intended to form basis for later learning about cosine.

Method

Following Jessen (2017) we draw on existing methodology for using SRP when we compare an a posteriori analysis of the questioning from the post-lesson reflection and an a priori analysis based on the lesson plan and observations. We see a potential in facilitators gradually developing the mapping of questions and answers derived from Q_0: How to teach students cosine in lower secondary mathematics? The lesson plan represents a preliminary answer to Q_0, which the group of teachers implement and test in a classroom. When receiving the lesson plan, key elements to be observed can be noted, but also it gives rise to specific questions linked to choices made.

Based on reading and analysing the lesson plan, F_{ext} starts mapping possible questions and answers. During observation of the study lesson, the QA-map is revised as written notes due to observations. Adjustments are made from analysing teachers' observations and comments. Final adjustments are made 'on the fly' based on teachers' dialogues. In this case, we have furthermore been able to consider other adjustments, as we have been analysing the data set a posteriori of the whole lesson study. Through the discourse analysis (cf. Jessen, 2017) we identify questions raised explicitly or implicitly and potential answers developed by the group. For this paper we present one branch of the QA-map to show how the analysis can shed light on the importance of the paradidactic system and knowledge surrounding a PD like lesson study.

Results

Below we present our analyses of expected and realised QA dialectics during the reflection meeting. We paraphrase the transcribed dialogue and Figure 1 show the mapping of the reflection.

A priori analysis – expected facilitator questioning

From reading the lesson plan F_{ext} expected some challenges for the teacher and the students stemming from an unclear connection between the two learning goals as well as between the tasks and the learning goals. For instance, while right angled triangles are fundamental to the function of cosine, the two learning goals are unconnected.

Some of the expected challenges indeed did arise in the lesson. Based on notes from observing the lesson and the sharing of observations, F_{ext} would have wanted the teachers to consider the connection between the (final) learning goal and how the teaching supports or hinders the students in achieving that goal. The didactical idea (Winsløw et al., 2018) of the lesson seemed to be (based on the assumption) that if the students see and hear a series of illustrative cases (in $t_{1\text{-}3}$) they will deduce the relevant knowledge about the relation between angle and length (in t_4), in the triangles. This clearly did not happen, according to shared observations. When starting the reflections, F_{ext}

would have wanted to help teachers realise the weak or missing connection between the tasks and the learnings goals, and that these two learning goals are unrelated. In fact, each of them could be better achieved individually.

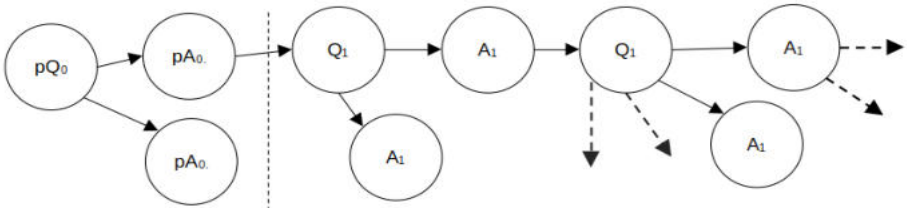

Figure *2*: Illustration of the QA-map of F_{ext}'s a priori analysis. The dotted line indicates a shift from paradidactic QAs to didactic QAs

After sharing observation data in the post-lesson reflection, the fundamental question of *how to decide on what to discuss* for the remaining.

g time arises. One approach to answering this fundamental and generative question, pQ_0, , is for F_{ext} to identify if there is an "overlap between teachers' observations and F_{ext}'s learning goal for the teachers" ($pA_{0.1}$). Since this was the case, F_{ext} could ask questions which would lead teachers to realise the missing connection. For instance, such questions as "how many students did actually realise the connection between angle and length by themselves?" as Q_1 and the mathematical question of "what *is* the connection?" as $Q_{1.1}$. Such questions should guide the teachers to formulate how such connections could (or could not) be established (first mathematically, then didactically). In this sense, F_{ext}'s questioning for others' learning bears a clear intention and critical concurrent analyses of the potential and realised situations, anchored in F_{ext}'s paradidactic knowledge.

A posteriori analysis – realised questioning

After the sharing of observations (in reality blended with autonomous reflections and evaluations), F_{int} sought to narrow down the reflections. In order to "decide on what to discuss" (pQ_0), F_{int} posed some suggestions which he had emphasised by himself from the pool of shared observations. Accordingly, F_{int} proposed "Can we do something to get students' conversations going?", as Q_1, "Could we do something to make the goals clearer to the students?" as Q_2, and (indirectly) "something else?" as Q_3. As has been validated in a following conversation between F_{int} and F_{ext}, F_{int} did not have a specific intention for these proposals other than they seemed representative of what had been shared and somewhat considered relevant. The following response by a participant, which seems to answer the question about getting students' conversation going (Q_1), was that "during the relatively short time, too much content was being worked with, which then again does not encourage students' reflections" (A_1). Underpinning the lack of paradidactic intention from F_{int}, he – as a teacher – responded in the affirmative, that the balance between the content at stake and time allocated is difficult to strike ($A_{1.2}$). The question of how to get students conversations going was not touched upon again, and not related to the mathematical content knowledge of the lesson.

Discussion and concluding remarks

So, what is the impact of facilitators' questioning during the post lesson reflection meeting when analysed as a study and research path compared to a similar a priori analysis? From the very brief

analysis presented above, we see at the reflection meeting, questions and answers shared among the participants, were linked to didactic knowledge and more practical aspects of the lesson as time management. The initial question regarding decision on what to discuss, was chosen based on F_{int}'s paradidactic knowledge and the functioning of the infrastructures build around the specific lesson study activities. But what comes after, is all based on specific observations from the lesson, and participants draw on their prior didactic knowledge and experience as teachers. The following conversation between F_{ext} and F_{int} even indicate unclear definition of the role as facilitator.

From the a priori analysis we see the potential of developing knowledge regarding the nature and function of intended learning outcomes, and how this relates more deeply to mathematical knowledge concerning geometry. Therefore, our preliminary conclusion is that the lack of explicit uses of paradidactic knowledge (how to develop the LS participants' didactic knowledge), together with the facilitator's mathematical knowledge to form questions, we see missed learning potentials for the participating teachers. Of course, this is only a pilot of the full analysis of the questioning during a post-lesson reflection meeting and more data needs to be analysed, as well as similar studies conducted. However, we see a potential of elaborating research on the role of facilitator's questioning during the reflection meeting in LS as an example of CSMTE. By considering the nature of facilitators' questioning as didactic, paradidactic or mathematical in nature, we may be able to explain why some questions function well as *situation seeds*, or *balanced leading* of LS.

Observing lesson study in Japan, much knowledge regarding facilitators' role and questioning appear as tacit knowledge developed through different forms of apprenticeship (cf. Asami-Johansson, et al., 2023). This is possible because LS is integral (though in various forms) to teachers' practice, and have been developed over decades, with vast amounts of documentation form former LS to get inspired form. When LS is initiated outside Japan, we lack the infrastructures, we lack the documentation, we lack the resources to be studied and the existence of a rich milieu where questions and answers can develop. Therefore, we might need to be much more explicit about the role of the facilitator and the knowledge needed to be taken into consideration, when learning the role of facilitator. In Denmark, teachers have a mixed background mainly consisting of (generic) didactic knowledge, little mathematical knowledge, and no paradidactic knowledge (Jessen & Rasmussen, 2020). We consider this a constraint for implementing LS and educate Danish teachers to become facilitators creating productive reasoning. More research into ways of mapping potential reasoning and reflection and compare with actual reflections made, we may be able to build stronger implementations of LS in Denmark and other countries.

Whole-class discussions are a significant challenge for teachers. Lesson study is recognised as a process of professional development that may contribute to gradual changes in teacher practice and which values whole-class discussions. This study aims to know how a teacher's understanding regarding whole-class discussion develops when participating in three lesson studies. This case study is interpretative, qualitative and uses discourse analysis. The participant is an in-service teacher of grades 5-6 with 20 years of experience. Data collection included audio recording of an initial interview, as well as of the lesson planning and reflection over the lesson studies. The results show that: i) after leading the first discussion, the teacher already considered important activities collaboratively done while planning; and ii) over the lesson studies, her discourse anchored on previous lesson study experiences by noticing changes in her practice and on students and suggesting new actions.

Keywords: Mathematics teaching, whole-class discussion, planning, reflection, lesson study.

Introduction

Research contributions to understanding whole-class discussions in mathematics teaching and learning are significant. According to Mosvold (2024), research has paid attention to aspects that support those discussions, such as frameworks, simulations prior to the discussion, and to leading discussions, focusing on teachers and students' actions. The author indicates that it is necessary to "lay the foundation for developing a professional practice that acknowledges the skills and knowing that are involved in leading mathematical discussions" (p. 487), because nowadays traditional patterns of communication are still widely observed in mathematical teaching and learning. Therefore, it is necessary to support teachers in preparing and leading whole-class discussions, namely through professional development such as lesson study. Lesson study has been identified as a process that gradually but significantly fosters teachers' practice and students' learning (Fujii, 2018). In this process whole-class discussions are considered the heart of the lesson (Takahashi, 2021). However, even though the development of teacher knowledge when participating lesson study is the most reported aspect in research, it "is unclear whether there is a long-term impact on teaching and learning" (Ding et al., 2023, p. 95). Thus, we seek to know how a teacher's understanding regarding whole-class discussion develops when participating in three lesson studies, by answering the following question: what changes occur in a teacher's discourse about whole-class discussions when preparing or reflecting about this lesson moment?

Whole-class discussion in mathematics

Currently, the curriculum in Portugal states the importance of promoting a dialogical learning environment, particularly in mathematics (Canavarro et al., 2021). In the curriculum, whole-class discussion is suggested as a way of working, a possible moment of assessment, a strategic teaching action and an opportunity to develop students' mathematical capacity. In fact, whole-class discussion

may promote these dimensions, but it requires teacher engagement to plan and lead a discussion and even to reframe their understanding of whole-class discussion, if necessary.

Students develop their mathematical communication capacity if this also emerges in the dialogue with the teacher. Therefore, recognizing the importance of the language that students use to describe and reason is not enough and teachers must create opportunities for students to participate in the mathematical discourse (Planas et al., 2023). Also from a social constructive perspective, Kooloos (2022) considers that discourse-based teaching, which means "teaching through whole-class discourse that builds on students' various ways of thinking" (p. 15), helps to develop students' mathematical thinking. In his study, Kooloos (2022) also considers the distinction between a whole-class discourse and a whole-class discussion: the first concerns the dialogue about students' different ideas, while the second occurs when students actively engage with their colleagues' mathematical ideas. So, regardless of the structure (Takahashi, 2021), a productive whole-class discussion is necessarily based in a discursive practice that engages students. For that to happen, interactions students-students and teacher-students must occur. Thus, we characterize a whole-class discussion in mathematics as a dynamic and collaborative discussion, facilitated by the teacher and based on the students' solutions. It is a process that seeks to support the exploration and negotiation of mathematical concepts and procedures, enhancing the development of students' learning.

Research supports the idea that it is important to promote discussions to support students' mathematical thinking (Kooloos, 2022; Mosvold, 2024), and establishes this dialogue as a tool for teaching-learning (Planas et al., 2023). However, traditional communication patterns, like recitation and lecture, are still dominant (Mosvold, 2024). Contributing to the prevalence of a traditional pattern of communication may be the challenges experienced by teachers about whole-class discussion, such as promoting students' active participation, managing time, unpredictability and diversity, and maintaining an appropriate cognitive challenge (Faria et al., 2023). These challenges, in turn, are anchored in practices that are in tension with whole-class discussions: restrict the time for interpretation, solution and discussion; questions the students mostly to clarify answers and correct errors; and registers on the board with no planning and no monitoring (Faria et al., 2023).

Lesson study and whole-class discussion

Lesson study is a teacher professional development process that is practice-based, teacher-oriented, student-focused and collaborative (Ding et al., 2024). Participant teachers collaborate in a reflective and dialogical environment with a common goal of improving their students' learning, that can be composed with five phases: goal setting, lesson planning, research lesson enacting and observation, post-lesson discussion, and reflection (Fujii, 2018). Considering teaching as a social practice, we note that teachers' discourse during all the phases of lesson study is more than speech, it is a way of (re)building meanings, professional identities and social relationships. This understanding is inspired by Fairclough (1992) definition of discourse. Therefore, although collaboration can also be challenging (Ding et al., 2024), the exchange of ideas, questions or noticing aspects is significant for teachers, since in various studies it is mentioned by the participants as a relevant part of the process.

The planned lesson in a lesson study should have a structure and flow that allow access to students' mathematical thinking (Fujii, 2018; Takahashi, 2021). For this to happen, it is important to foresee

how to promote students' interventions, namely by planning whole-class discussions as part of teaching practice. During the planning phase, participant teachers work collaboratively with various mathematical tasks to carefully choose one with a clear learning focus and that will promote important mathematical ideas to emerge in the discussion (Fujii, 2018). In this professional development process, even the board is a dimension that needs to be planned "in order to best compare and contrast students' solutions" and "to organise both thought processes and results" (Fujii, 2018, p. 7). In addition, according to Takahashi (2021), it is also important that these lesson plans have flexibility and openness, so that questions and answers arise from students' interventions, going beyond show and tell. Planning the whole-class discussion in a lesson study process goes beyond the written lesson plan. In fact, while the students are working autonomously on the task, teachers must monitor their mathematical activity so that they "can use the information they gather during this time to plan who they want to call on during the whole-class discussion, and in what sequence" (Takahashi, 2021, p. 26).

Methods

This study follows an interpretative and qualitative approach, with participant observation design. We analyse the case of Marta, who has been teaching mathematics at grades 5 and 6 (10-12 years old), for around 20 years. She was interviewed before participating in the first lesson study, carried out with a group of 9 teachers (2021/22), and participated in two more lesson studies (2022/23), the second one with three teachers and the third with two. The first author was the facilitator and lead the interview. All the authors participated in data analysis and manuscript' writing.

The data were collected i) in Marta's initial individual interview (2021-2022); and ii) in the planning and reflection phases of her first, second and third participation on lesson study (2021-2023). The interview had the purpose of getting to know several aspects of Marta' practice, with a particular focus on whole-class discussions. Data are analysed through Fairclough's (1992) critical discourse analysis, which considers discourse to be understood as a mode of action, even if only intended. The concept of intertextuality states that all discourses are anchored in previous ones. Thus, the change of each individual discourse can provide evidence of an intended change in teaching practice. Studying this intertextuality means identifying discursive changes arising from a new combination of different discourses or noticing the absence of new elements in the discourse (Fairclough, 1992). Therefore, after the transcription of the sessions, we selected excerpts associated with the preparation of the whole-class discussion and the reflection on discussions. After, we selected Marta's interventions in which it was possible to identify changes in her discourse regarding whole-class discussions.

Results

Initial interview

When asked about students' communication during discussions, in her interview, Marta replied:

> Marta: Communication, how so? To solve an activity, sometimes they even speak in a large group because I launch an activity and they have the opportunity to explain, right?... I think they talk. I try to work on it, but sometimes it's not easy. They struggle to communicate.

There is a strong association of student communication with talking or explaining strategies. Even though Marta considers that students speak, she identifies that this is a skill that presents challenges for students. About this struggle, she considers:

> Marta: I think it's more a question of language and mathematical concepts… Then I say: "But you have to know how you thought. Explain, how did you think?".... And then, sometimes, I also make corrections and ask again for them to explain.

Thus, Marta links with the students' struggle to communicate to their lack of conceptual understanding. In her intervention, it is not clear how she supports students to develop this skill, particularly during the discussion, since she gives them the responsibility of knowing how they thought and verbalizing this thought. Regarding students communicating with each other in situations of disagreement, Marta stated:

> Marta: Sometimes it's even better than having to explain it ourselves. We can't always do this… We ask those students who finished first or who already have a more formed idea to help others. They accept this help.

In these excerpts from the initial interview, Marta considers that students struggle to communicate their mathematical ideas, particularly during discussions. In this regard, she corrects students or asks them to repeat the explanation and, although she considers positive that students communicate with each other in situations of disagreement, this is understood has a moment of accepting help.

First lesson study

The teachers began a dialogue about how to act when questions arise about the task. Regarding the work on Geometry and Measurement, the topic selected for the research lesson, Marta says:

> Marta: My tendency is when I see them measuring, if is not necessary, for example, I say 'Well, that's not for measuring!', and then I don't let them continue the task alone.

By not letting her students work on the task by themselves, Marta may be lacking to promote their mathematical activity and authorship, important aspects to enrich a whole-class discussion. On this first lesson study, when reflecting on the lesson led, Marta focused a lot on the whole-class discussion, specifically on how planning and leading it felt like an innovation to her practice:

> Marta: When I facilitated the lesson, the whole-class discussion was what most deserved my commitment and attention as it were, perhaps, the most innovative factor in my teaching practice. Leading students in whole-class discussions in order to highlight and connect their contribution to the aim of the lesson is to leave my comfort zone because, in this way, there will always be aspects that I cannot anticipate, but that I will have to know how to attend in order to guide a productive whole-class discussion.

When reflecting, Marta gave special attention also to the tasks used:

> Marta: Tasks should have a more exploratory character to be more interesting and challenging, as this will encourage greater student participation… In the sessions we analysed several student responses to a given task. This analysis allowed us to see those different ways of communicating. The student must be able to explain their reasoning and be valued for it.

Instead of speaking about not letting students do the task alone if questions arise, Marta reflects on the need to have exploratory tasks and how this is connected to students participating and communicating in a discussion.

Second lesson study

In response to a question from the facilitator, Marta began to analyse a diagnostic task, but she turned into a broader reflection, by focusing on students' difficulty in explaining and recording their mathematical ideas so that they could later be mobilized in the whole-class discussion:

> Marta: They're already beginning to ask each other questions and I think this is good. But I'm also a bit more alert, because of the last year's lesson study and research lesson... We're more aware of certain things. Now, I move around, look at different strategies and ask them to go to the board. When they go to the board, I ask them to explain to their classmates.

Marta went on to specify some aspects associated with the students' activity during the discussion. She identified changes in the interaction between the students during the discussion, which she seems to associate with changes in her practice, influenced by her first participation in lesson study:

> Marta: A difficulty they have is putting ideas down on paper and organising them in writing, because they can convey ideas orally or sometimes some of them just stay in their heads... We have to encourage that what they talk about in their small group is actually what is discussed afterwards and that it is explained as well as possible.

Marta pointed out that, in relation to the whole-class discussion, the students tend to verbalize other aspects or only the initial part of what they explored during the autonomous small group work. This struggle to communicate during the whole-class discussion was already mentioned by her during the interview. However, during this planning phase Marta was linking the teacher' actions during autonomous work and the students' communication during the discussion.

Third lesson study

Marta schematized how the board could be organised during the whole-class discussion (Figure 1). In the previous lesson studies, although the board organisation was considered, Marta and the other teachers participating in the lesson study never made a drawing or a scheme.

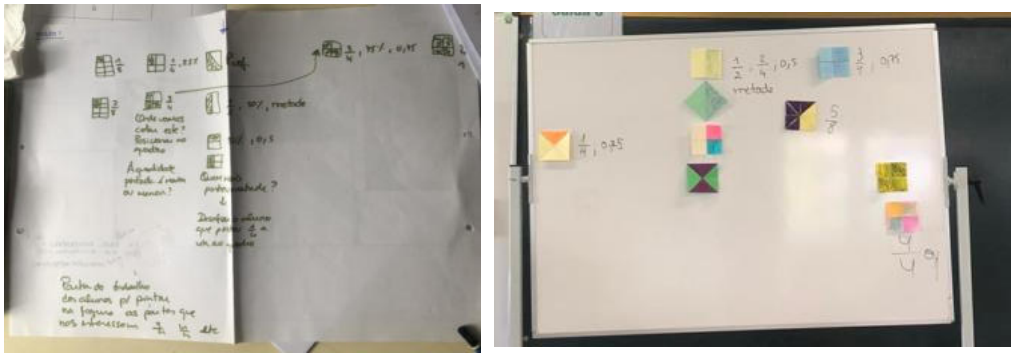

Figure 1: Board scheme and board in the actual lesson

When reflecting on the lesson, Marta focused on the board organisation as a main aspect of the whole-class discussion preparation and as support for students learning.

Marta: That's right, that was one of the things I had also noted down. And it was quite curious, because Filipa always focused a lot of the sessions on organising the board and here I really had the feeling that having thought about and organised the board, what it would look like when we stuck things on the board, was very important because the fact that we had already done it and thought about it, helped. It made a difference because maybe I was going to stick things up randomly and the organisation of ideas for the students wouldn't be so good. So, the fact that we had already rehearsed and thought about it was good, because I stuck mine in the middle and then asked the students where they should stick it. The way I called students out was also even more intentional.

Besides the research lesson that was observed by all participants, Marta had the chance to lead the lesson to another class, before our post-lesson discussion two days after, where she shared:

Marta: Well, I was just remembering that too. I was already remembering that from 1/4, when I said it was 0.25... Because if it's the whole square, and then we divide, and half of 100 is 50, and half of that is 25... I was also thinking that it could have been explored a bit and that didn't happen. And it already came up today, so there are already differences from a [discussion] leading to the next.

From one lesson to another, she adjusted her interventions during the whole-class discussion in order to prompt the connection between different representations. Besides reflecting on the particular whole-class discussion that was observed, she extended her reflection to the possibility of improving her leading of this moment in other lessons.

Discussion

Our aim was to know how a teacher's understanding regarding whole-class discussion develops when participating in three lesson studies, by identifying what changes occur in her discourse about whole-class discussions when preparing and reflecting about this lesson moment. Her discourse does indeed show changes over time, supporting the idea that discourses are dynamic and are not neutral, carrying ideologies that can be shaped through social relations (Fairclough, 1992), as it happens in highly collaborative professional development contexts like lesson study.

In the initial interview, Marta associated communication during the whole-class discussion with students speaking or explaining. She considered that students struggle with communication in discussions because they have conceptual difficulties. Alongside this difficulty, she stated in the interview that she corrects the students when this happens, reinforces the request for an explanation and gives the student the responsibility of knowing how they thought and knowing how to explain it during the discussion. Regarding mathematical disagreements in a whole-class discussion, Marta said that those students who have finished or who have clearer mathematical ideas can help the others, considering that their colleagues are mostly willing to accept help. Thus, this does not necessarily mean that a negotiation of mathematical ideas is being prompted. Therefore, we may consider that Marta's initial understanding of whole-class discussion was more aligned with a whole-class discourse that with a whole-class discussion (Kooloos, 2022).

Throughout the planning and reflection that took place in the *first lesson study*, Marta's discourse continued to associate the teacher's interventions with helping the students, i.e., if there is a misunderstand of the task, they solve it together with the teacher. This practice may run counter to promoting the students' mathematical authorship and impoverishes the discussion, since it restricts

students' solution and discussion time (Faria et al., 2023). In addition, during the reflection after the first research lesson and the whole-class discussion that followed, Marta's discourse began to consider important elements of lesson study such as anticipating strategies, selecting challenging tasks, managing unforeseen events and leading productive whole-class discussions, encouraging student participation and valuing different ways of communicating (Fujii, 2018; Takahashi, 2021).

In the *second lesson study*, Marta stated, while preparing the whole-class discussion, that the students were starting to pose questions, which is something that when considered and managed by the teacher can enrich the discussion (Kooloos, 2022; Planas et al. 2023; Takahashi, 2021). Students' questioning is an aspect brought into the planning by Marta, an action that she did not associate to the students until this moment. As for her practice, she considered herself more alert to whole-class discussion, sharing that now she circulates during autonomous work, identifies different strategies, selects them and asks the students to explain (Takahashi, 2021). Also, in this second lesson study in which Marta participated, she understood more broadly the students' difficulty in communicating, going beyond difficulties in conceptual understanding. By then, when planning the whole-class discussion, she provided suggestions for her action and the actions of her colleagues, such as encouraging that the ideas discussed in the small group were brought to the discussion by the students and explained as well as possible. This new discourse illustrates an intention to develop her practice, which is shaped by lesson study as Marta clearly illustrates (Fairclough, 1992).

When taking part in the *third lesson study* Marta planned the board for the whole-class discussion with more detail that ever before (Figure 1). When reflecting on this aspect and its impact on the discussion, Marta related the teacher's aim regarding the board organisation and the sequence of students' interventions to the quality of the students' mathematical understanding (Takahashi, 2021). Marta also added to her reflection how teachers' interventions during the whole-class discussion may support or not the achievement of the lessons' aim, namely the establishment of connections, which is something that she considers to be able to improve from a class to another.

Marta's discourse also illustrates aspects that seems to have contributed to these changes, such as a) exploring tasks and anticipating students' solutions and challenges; b) the presence of a facilitator who supports the exploration of aspects like the board organisation; c) participation in more than one lesson study enriching her reflections. Overall, throughout the sessions of the lesson studies, it is possible to identify that Marta's discourse about whole-class discussion changes. By the moment she begins to reflect about the whole-class discussion that she led on the first lesson study, she begins to anchor her discourse to particular moments and activities that are important in lesson study. Over the next two lesson studies, her discourse when preparing and reflecting about the whole-class discussion is anchored also in her previous experience within the context of lesson study.

Conclusion

The results illustrate two main aspects: i) after leading the first discussion, Marta's discourse begun already to consider activities collaboratively done during the lesson study planning phase, like selecting tasks; and ii) while planning and reflecting over time, Marta's discourse was anchored on her previous lesson study experiences. This aspect becomes apparent when Marta notices change in students such as posing questions and changes also on her practice, like monitoring students'

mathematical activity. Continuous participation in lesson study has allowed Marta to gradually plan and reflect on different aspects related to whole-class discussions: the tasks, the students' solutions and encouraging their participation and, finally, the organisation of the board and it connection to the quality of the students' learning, an aspect so highly highlighted by the literature on lesson study. Therefore, even though the contribution of lesson study may be traceable during the teacher first participation, sustained involvement in this process is important. Due to limited space, we focused on how Marta's understanding of whole-class discussions developed over time. The triangulation of her understanding, planning and leading, considering lesson study features such as collaboration, will be object of further work to better understand the contribution of lesson study to whole-class discussions.

Research has shown that collaborative settings and activities positively impact motivation and learning in both teacher education and schools. Collaborative skills are also considered essential 21st-century skills. However, there is limited research on the necessity of teaching these skills and effective methods for doing so. It is often assumed that pre-service and in-service teachers, as well as students, are inherently capable of collaboration. We hypothesise that collaboration requires practice, as it is not an innate skill. Further, how pre-service teachers perceive collaboration, and its use seems to impact their readiness to collaborate and to implement collaborative tasks. We will also discuss activities we designed to enhance collaboration.

Keywords: collaboration, perceived usefulness, perceived ease of use, pre-service teachers

Introduction

Education and its focus are evolving, and in the last few decades competencies and 21st-century skills have gained prominence. Schools now focus not only on knowledge transfer but also on preparing students for their adult life. Collaboration and cooperation are crucial in both educational and work settings. As Robutti and colleagues (2016) emphasise in their study, these terms are similar but differ in meaning. Both collaboration and cooperation involve working together, but they differ in their approach, much like multidisciplinary and transdisciplinary settings. Cooperation aligns with multidisciplinary settings where all participants contribute towards the same goal. In contrast, collaboration aligns with transdisciplinary settings, requiring negotiation among participants. This implies that collaboration is more complex, demanding negotiation, communication, networking and finding consensus. The growing societal demand for collaboration may explain why collaborative settings had an extra working group, TWG28, at the 13th CERME conference and the growing research interest in collaborative settings (Robutti et al., 2016). As noted in the introduction to TWG28 in the proceedings of CERME13 (Wake et al., 2023), the group was split into two sub-groups to facilitate discussion of the numerous papers and posters, many of which focused on Lesson Study (LS). LS, a method of teachers' professional development originating from Japan going back to 1872, has become a key area of educational research (Robutti et al., 2016). This suggests that the main interest is teachers' professional development, and the studies build on pre-service and in-service teachers' ability and willingness to collaborate. We aim to study if this willingness and ability, the prerequisites of collaboration, are there or need to be developed and enhanced and how this can be achieved. While young children in many countries must attend kindergarten to socialise before

entering school, during school time, teachers' methods decide if a student is exposed to collaborative activities; however, nobody questions the necessity of learning collaboration. Consequently, not all students are exposed to collaborative activities. This raises the question of whether pre-service teachers can collaborate. Research indicates that childhood experiences influence teachers' teaching methods (Castro, 2010) and that the underlying beliefs about teaching and learning are stable (Liljedahl et al., 2012). To examine this, we will conduct research involving students, pre-service and in-service teachers. First, we will review the literature to define collaboration, then establish a theoretical framework, describe data collection and analysis, and finally, discuss our findings.

Literature review

While research exists on preparing teachers to collaborate (Santagata & Guarino, 2012), it often focuses on discussion skills and lesson study. However, collaboration has numerous forms requiring more active participation. In educational settings, teachers can collaborate by co-teaching a class or collaborating across disciplines. Regardless of the form, collaboration involves negotiation, agreeing on goals, working together and sharing responsibilities (Barfield, 2016). Collaborative tasks, such as project-based and STEAM (Science, Technology, Engineering, Art and Mathematics) activities enhance learning (Houghton et al., 2024). Project-based learning, defined as students engaged in a science-related topic over a longer time working in groups (Krajcik & Blumenfeld, 2005), inherently requires collaboration. These transdisciplinary activities necessitate networking among teachers, schools and even beyond. This challenges the traditional classroom setting and requires teachers to practise boundary crossing (Akkerman & Bakker, 2011). In this context, boundary crossing means that teachers step outside their areas of expertise and collaborate with colleagues from unfamiliar disciplines to find solutions through negotiation. Akkerman and Bakker (2011) carried out a literature review and studied what boundary crossing in different research areas means. They identified four basic mechanisms: (1) Identification: noticing differences and similarities; (2) Coordination: developing strategies; (3) Reflection: examining perspectives; (4) Transformation: changing one's perspectives. In all cases, boundary crossing also involves a potential learning opportunity (Akkerman & Bakker, 2011). Although collaborative teaching practices and boundary-crossing have been researched, there seems to be a research gap in understanding how collaboration skills are acquired. A suitable theoretical framework is needed to explore this, one particularly focusing on the social aspect of knowledge creation and teachers' beliefs, as these influence their teaching methods (Schoenfeld, 2011). We understand beliefs as Goldin and colleagues, i.e., finding something true or false depending on knowledge, social or mental state and affective status (Goldin et al., op. 2009).

Theoretical framework

Many studies on collaborative settings rely on Activity Theory, which stems from Vygotsky's work in the 1920s. This theory claims that learning occurs through interaction with tools, culture and experts who provide scaffolding (Hashim & Jones, 2014). Noticing that learning requires sociocultural and historical contexts, this theory has been recently referred to as Cultural Historical Activity Theory (CHAT) emphasising the connection between thoughts and actions (Nussbaumer, 2012). CHAT views a whole activity as a unit comprising a subject (involved person), an object (the

task) and tools (mediating device) (Hashim & Jones, 2014). In educational settings, CHAT often frames studies on Lesson Study (LS) (Wake et al., 2023; Robutti et al., 2016). However, this already requires collaborative skills, and we aim to investigate how these skills are acquired. As boundary crossing requires negotiation, we employ the expanded version of CHAT, Engeström's Theory of Expansive Learning (TEL) (Engeström, 2014). TEL calls for a multi-dimensional approach and a community of learners who act collectively to construct new knowledge crossing boundaries. This aligns with Social Constructivism, which views knowledge creation as a social process (Amineh & Asl, 2015). To understand teachers' beliefs, we adapt Davis's Technological Acceptance Model (TAM) (Davis, 1985) into the Innovation Acceptance Model (IAM) (Békési et al., in progress). Davis studied user acceptance of technology focusing on perceived usefulness and ease of use to predict future implementation. The same variables apply to teachers and students in an educational context. Innovation, in this sense, encompasses anything new, including collaborative settings. Once teachers are convinced of the usefulness and ease of use of an activity or a teaching method, they are more likely to implement it. TEL and Social Constructivism guide our study on collaboration, while TAM and IAM inform our understanding of teachers' beliefs. This theoretical network guides our study to address the following questions:

RQ1: How do pre-service teachers' school experiences impact their attitudes towards collaboration?

RQ2: How can teacher training enhance pre-service teachers' beliefs about collaborative settings?

RQ3: How can we support students, pre-service, and in-service teachers in collaborative activities?

Methods and data collection

We studied three different groups: students, pre-service teachers, and in-service teachers, using different approaches and methods. Over two school years (2022-2024), we conducted collaborative STEAM projects with three lower secondary school classes. The two or four-month-long projects involved more subject teachers and required collaboration among students, teachers, and between students and teachers, and occasionally even beyond. These project-based collaborative STEAM activities explored topics such as settling down on MARS, renewable energy, the power of water and designing a house. These activities were carried out by a teacher team teaching English, German, Biology, Geography, Physics and Mathematics, the Mathematics teacher, also a researcher in the team, initiated the projects. The teacher team evolved after the success of the first project in 2022. Four teachers were involved in the first cycle and six more joined the team in the second cycle with varying levels of participation. TEL's four mechanisms guided the teacher team's work: identification, coordination, reflection, and transformation. We identified shared goals and coordinated our approaches in regular meetings. We reflected on each other's views and adapted ours to find an agreement. Collaboration between students and teachers followed a cyclical pattern (Lewis et al., 2019): (1) study: establishing a team and selecting a topic; (2) plan: identifying teaching/learning goals; (3) teaching/carrying out the activity; (4) reflection: evaluating the activity.

As for pre-service teachers, the researcher, who is also a teacher trainer, designed and conducted a course focusing on innovative teaching methods involving collaborative teaching methods, technology implementation and STEAM activities. This course aimed to familiarise pre-service

teachers with these methods and influence their beliefs about their usefulness and ease of use. The course provided examples, practice opportunities and had a collaborative learning environment during the whole course. Pre-service teachers worked in groups, which were regularly rearranged, and the groups also shared their views on Padlet, a collaborative platform. Pre-service teachers' work also followed the same cyclical pattern but in a slightly different way. As the course participants didn't know each other, the researcher created the teams, defined the topics and took an active part in the reflection to make pre-service teachers aware of possible changes in their beliefs.

To answer the first two research questions, data were collected from students, teachers, and pre-service teachers through Likert-scale questionnaires and open-ended questions. All stakeholders, even external contributors, completed questionnaires during and after completing each project or the course. Pre-service teachers were also questioned after their first implementations. To answer RQ1 and RQ3, we conducted semi-structured interviews with a smaller group of students, including one who was particularly involved in the projects, as well as two teachers and four pre-service teachers.

Data analysis and findings

The questionnaires included general questions about participants' likes and dislikes, as well as their expected or experienced learning effects across all groups. Some questions were more specific depending on the group. In this section, we present only the data relevant to our research questions. Figure 1 and Figure 2 display some general questions and the responses from all stakeholders. Note that the pre-service teachers answered these questions after the course but before implementing the activities.

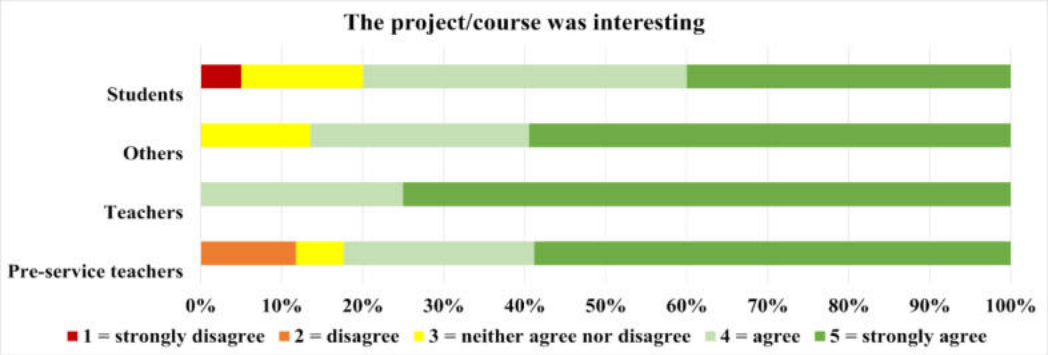

Figure 1: Stakeholders' interest in the project or the course

Comparing the results, the stakeholders seem to differ in their beliefs. Students found the project interesting but were unsure about the learning impact. Others, mainly parents attending the presentation day, found the project both interesting and beneficial for learning. While all teachers found the project interesting, they were unsure about the causes for the learning impact if it was due to the project or another variable.

Pre-service teachers found the course focusing on these projects just as interesting as students found the projects themselves; however, pre-service teachers were not fully convinced about the projects' positive learning impact. Figure 3 depicts pre-service teachers' responses collected after their first implementation of the activities in their teaching.

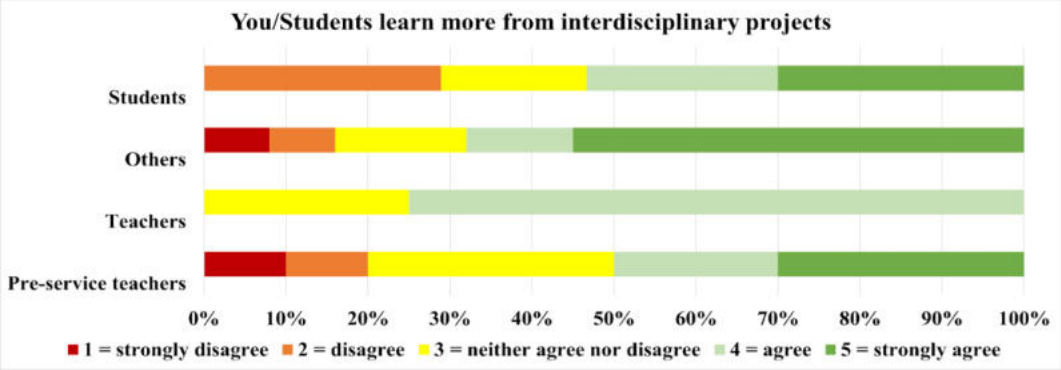

Figure 2: Stakeholders' beliefs about usefulness

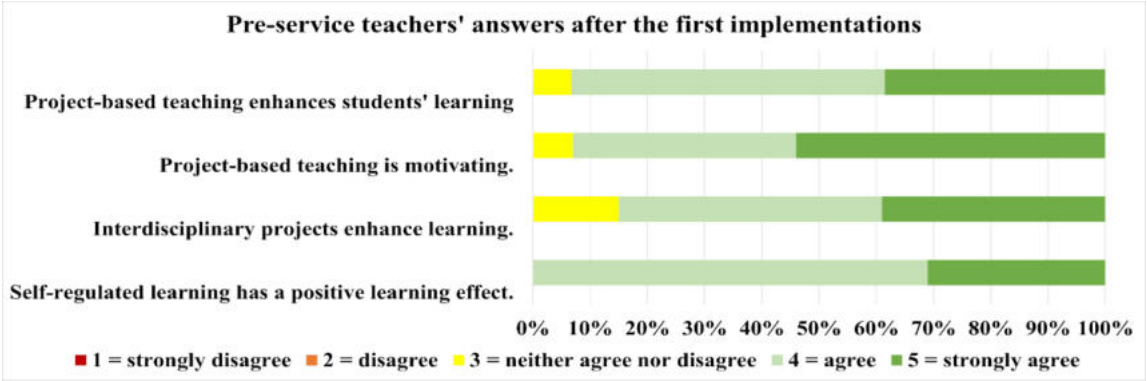

Figure 3: pre-service teachers' beliefs after the first implementations

A comparison between Figure 2 and Figure 3 reveals a clear shift in pre-service teachers' beliefs about interdisciplinary projects. Negative beliefs disappeared, and approximately 90% of teachers had positive or very positive beliefs after implementing the activities. To investigate this shift further, teachers and pre-service teachers also received questions regarding their school experience and whether they participated in interdisciplinary projects as students or at the university. Only two teachers in the team are under 35, and only one of them participated in a project still at elementary school as she mentioned in her interview, otherwise the teacher team had no prior experience with project-based collaborative teaching. Pre-service teachers' answers showed a similar trend. During the 4 cycles starting in 2021, we questioned 54 pre-service teachers, and only two in the latest cycle in 2024 said that they participated in an interdisciplinary school project.

To further explore the influence of prior experience with collaborative settings, we conducted interviews. The two youngest members of the teacher team seemed most likely to have experienced collaborative settings during their studies, so we interviewed them. They have similar backgrounds: both are in their early thirties; both are head teachers of a class and teach more subjects. We will refer to them with the fictitious names Anne and Kathy. One significant difference is that Anne participated in a project as a primary school student, but Kathy didn't as we discovered during the interview. Then, both had a traditional secondary school and university education. As for their participation in

the project, Anne joined the teacher team in the first project already, participated in teacher team discussions and contributed actively to the project. We interviewed her to understand her motivation.

Researcher: Why did you agree to join the project? What was your motivation?
Anne: Why did I agree to it? Well, first of all, because I believe the students benefit tremendously from it. It's something completely new for them, and it helps foster cohesion and cooperation within the class. I also think it's beneficial for the teaching team to have more points of contact and to encourage more communication among us. I believe that parents also view it very positively, as it creates a good impression, showing what we are doing at the school, and the parents can see that as well.

In contrast, Kathy started a separate project in her class and followed a different structure. She worked independently and joined forces with the teacher team just for the sake of a presentation. Although Anne and Kathy had different approaches, they both considered project-based interdisciplinary teaching as beneficial. Kathy emphasised in her interview that the greatest gain is the social development experienced in her class during the project.

Researcher: What do you think the students learned during the project?
Kathy: Well, just working independently, working in a team. And simply planning so that it has to be finished by Friday and presented, and within the production just coordinating who does what and how we do it. So, it has a lot of— I mean, I find it has a lot of social advantages. They learn to work independently. It's really about the social aspect and not about any specific expertise.

Kathy's actions seem contradictory. While she finds the social aspects of her project the most important for her students, she is reluctant to engage in collaboration with her colleagues.

Researcher: Could you imagine collaborating with other colleagues and working together?
Kathy: It always depends on who is involved. Well, I must admit that I am a bit of a perfectionist, and I always like to have a certain structure. That's a small problem where I need to let go a bit, I have to say. When several people are involved, we have to do it completely differently. You can't do it the way we did it now.

Kathy gave a detailed description of her school experiences referring to a lack of options, sitting all the time and experiencing just frontal teaching, which illuminates her attitude. Kathy's case proves that school experience impacts future teaching practices. Even though Kathy recognises the potential benefits of collaboration for her students, she cannot cross the boundary between individual work and collaborative engagement within a community.

Regarding RQ1, the answers to the questionnaires (Figure 1, 2 and 3) along with the interview data suggest that early experiences impact both pre-service and in-service teachers' beliefs. However, recognising the value and usefulness of collaboration can motivate teachers to implement collaborative activities, and this addresses RQ2. Experiencing collaboration's positive effects both in learning and teaching facilitates a shift in beliefs.

We also questioned the students about their likes and dislikes regarding the projects. This was presented in detail at the MEDA4 conference in Bari (Békési et al., 2024). Here we highlight just our findings: students valued the social aspects: they praised working in groups in the first place and the freedom to select a topic and to create in the second.

The data reveals the acceptance of the use of collaborative activities by all stakeholders, but it varies if one considers the positive learning impact, the social aspects or the increased motivation. Students who participated in multiple projects learned to collaborate through direct experience (learning by doing) and appreciated its benefits. Pre-service teachers and teachers belong to a generation that has no such an experience from their school life and crossing the boundary to start collaboration seems an obstacle to overcome. Interviews and questionnaire responses suggest that early school experiences significantly impact teachers' beliefs and practices. However, pre-service teachers became more open to collaboration after experiencing its benefits during the course resulting in a belief shift demonstrated by the questionnaire administered after the first implementations. This finding addressing RQ3 implies that collaboration needs to be practised and through practice, you can learn to collaborate.

Discussion and conclusion

Our findings indicate that a lack of experience with collaborative settings during their own schooling significantly impacts teachers' practices as they have doubts about the use of innovation and the ease of use as described by the IAM model. This aligns with existing research emphasising the crucial role of teachers' beliefs, which are strongly shaped by their own school experiences, and determine their instructional choices (Castro, 2010; Liljedahl et al., 2012). However, we found that providing practice opportunities can foster a shift in beliefs regarding the use of collaboration. This finding is consistent with Santagata and Guarino (2012), who argue that pre-service teachers need preparation for collaborative settings, and with Engeström's (2014) TEL theory suggesting that scaffolding is necessary for teachers to cross boundaries. Additionally, our research supports the idea that collaboration is valuable not only among students but also between pre-service and in-service teachers, as demonstrated in previous studies (Houghton et al., 2024; Akkerman & Bakker, 2011). Overall, our findings confirm that both experience and structured support are essential for fostering a collaborative mindset among educators.

Since practice shapes beliefs, it is essential to design projects and courses that offer practice opportunities for collaborative engagement. We intend to study students' artefacts and their interviews to triangulate our data. Future research should also explore the long-term effects of collaborative practices on both students' learning and teachers' instructional practices.

Acknowledgement

We would like to say thank you to all students, teachers and pre-service teachers participating in our projects. Especially, the Erasmus+ Programme, STEAM Connect with project number 021-1-LU01-KA220-SCH-000034433 for supporting our projects.

Types of talk and mathematical knowledge for teaching problem-solving: Dialogic analysis of a lesson study

Stéphane Clivaz[1], Valérie Batteau, Luc-Olivier Bünzli, Audrey Daina, Sara Presutti[2] and Jean-Philippe Pellet[1]

[1]Lausanne University of Teacher Education, Switzerland; stephane.clivaz@hepl.ch

[2]HEP Valais

This study investigates mathematical knowledge for teaching problem-solving in lesson study among primary school teachers. Eight meetings were analysed, revealing mainly three types of talk, cumulative, disputational, and exploratory, evolving across the lesson study cycle. Knowledge levels differed among the types of talk, offering insights into teacher knowledge development.

Keywords: Type of talk, lesson study, mathematical knowledge for teaching problem-solving.

Introduction

This research aims to analyse the type of mathematics problem-solving knowledge for teaching used when primary school teachers work collaboratively in a lesson study process and examine how dialogic interactions contribute to knowledge construction.

Two papers and one conference paper have already been published about the first part of the study. The first paper outlines the theoretical and methodological aspects (Clivaz, Daina, et al., 2023), while the second presents the results of the analysis of the first part of the LS cycle (covering five out of eight meetings, Clivaz, Batteau, et al., 2023). Following the CERME13 conference paper (Clivaz, Presutti, et al., 2023), this contribution links the micro-level utterances' dialogic features to types of speech at the meso-level of longer episodes during LS meetings. These results have not been published yet.

Theoretical framework

This article lacks the necessary length to comprehensively expound upon the associated research's theoretical framework. Consequently, we direct the reader to our previously published works elucidating the concepts of Lesson Study (Clivaz, Batteau, et al., 2023, p. 2); knowledge levels (Clivaz, Batteau, et al., 2023, pp. 2–4); as well as Lesson Study Dialogic Analysis (LSDA, Clivaz, Daina, et al., 2023, pp. 24–28; 37). We present briefly here the Mathematical Knowledge for Teaching Problem-Solving, the Lesson Study Dialogic Analysis, and its link to the types of talk.

Mathematical Knowledge for Teaching Problem-Solving (MKTPS)

Research on problem-solving (PS) has mainly focused on students' perspective. However, some studies have explored teachers' understanding of problem-solving and their mathematical knowledge for teaching (Ball et al., 2008). Based on a literature review of studies from 1922 to 2013, Chapman (2015) identified six categories of problem-solving knowledge for teaching, including problem-solving content knowledge and pedagogical problem-solving knowledge. These categories are influenced by teachers' problem-solving proficiency, affective factors, and beliefs. Adopting Chapman's findings, we propose a graphical representation of this categorisation (Figure 1) to bridge

the categories of mathematics problem-solving knowledge for teaching and mathematical knowledge for teaching.

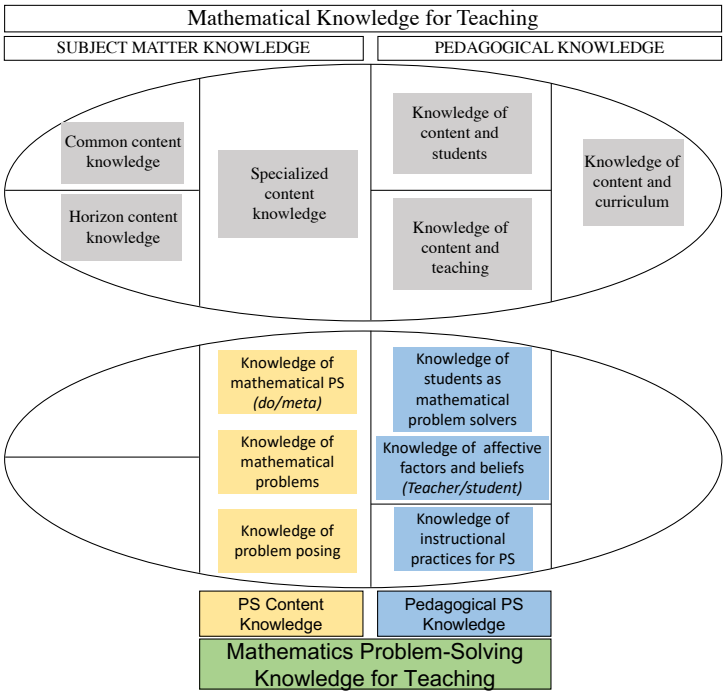

Figure 1: Mathematical Knowledge for Teaching Problem-Solving (MKTPS). Mathematical knowledge for teaching (the upper grey part of the figure) is taken from Ball et al. (2008); mathematics problem-solving knowledge for teaching (coloured categories) is from Chapman (2015). For the description of the categories, refer to (Clivaz, Daina, et al., 2023).

We then needed to determine knowledge levels (Table 1) to identify the participants' knowledge evolution throughout the meetings or differences related to the roles (teacher, facilitator). These levels do not constitute a hierarchy: contextualised knowledge or questioning is as valuable as generalised knowledge. The knowledge levels are labelled from 1 to 5.

Table 1: Knowledge levels (Clivaz, Daina, et al., 2023)

Knowledge levels	
1	Inaccurate knowledge, lack of knowledge, self-assumed ignorance, and/or debatable personal representation
2	Unexplained knowledge. Observation, testimony
3	Incomplete knowledge, knowledge with a low degree of certainty. Explicit questioning
4	Contextualised explicit knowledge. Speaker knows or appears to know the rationale
5	Generalised, decontextualised knowledge (decontextualisation process, possibly not fully completed). Generic example

Types of talk

Our analysis of the utterances and types of talk is based on the work of the Cambridge Educational Dialogue Research (CEDiR) team who developed a Scheme for Educational Dialogue Analysis particularly the SEDA group (SEDA, Hennessy et al., 2016). We adapted their micro-level utterance

analysis to our context (Clivaz, Daina, et al., 2023). Following the SEDA method, we linked this micro-level analysis at the utterance level to the meso-level, defined by a series of speaking turns in which the topic remains constant. At this level, we adopted the three types of speech characterised by Mercer and colleagues (Littleton & Mercer, 2013, pp. 15-16; Wegerif, 2020, pp. 28–29):

> Cumulative talk: Characterised by speakers building positively but uncritically on what the others have said. Everyone expresses their knowledge in the conversation, but there is no critical position or evaluation. Cumulative discourse is characterised by repetitions, confirmations and elaborations.
>
> Disputational /qualificatory talk: Characterised by disagreements between discussants and a competitive atmosphere in which each person makes their own decisions. There is little sharing of resources or constructive criticism, and interactions are often about taking short positions without justification.
>
> Exploratory talk: Characterised by everyone engaging critically but constructively in the conversation. Everyone brings information they consider relevant; this is questioned and argued, and group members seek to reach agreement before moving on to another stage. It is possible for an outside observer to follow the line of reasoning.

These types of talk have been determined by our LSDA indicators (Clivaz, Daina, et al., 2023, p. 37). In order to move from the classroom to the LS context, the members of the CEDiR group made some adjustments to these types of talk (Dudley, 2013). We also added the qualifier *qualificatory* to disputational and considered two more types of talk: Structuring conversation and managing understanding. These two types were less prevalent in our results, and we don't discuss them in this paper.

These types of discourse can be seen as different ways of thinking together. The exploratory talk is considered the most 'educationally effective' (Littleton & Mercer, 2013, p. 16).

Data, method and research question

Context, data collection and method

A LS group of ten teachers and facilitators from the Lausanne region was formed for this study. The facilitators, one math educator (the first author of this paper) and one teacher, aimed to focus on problem-solving in the classroom, without necessarily focusing on a particular mathematical topic. After discussing difficulties in teaching problem-solving, the group concentrated on helping students understand the problem representation. During the next meeting, they selected a problem from a state test that students struggled with in the past. The group then discussed representation, student approaches, and mathematics involved before planning a research lesson. After teaching and observing the lesson, the group discussed their observations of student performance and the importance of manipulatives, whole-class discussions, mathematics, and support for struggling students. Based on this discussion, they planned a second lesson in a second class, observed and discussed it. The last meeting allowed a discussion about the two lessons, the finalisation of the lesson plan, the assessment of the cycle and the desire for the next cycle.

The eight meetings were video recorded, transcribed and coded with the help of qualitative data analysis software. The coding of the data and the method are described in detail in Clivaz, Daina, et al. (2023). The three levels of analysis are nested, and provide a systematic structure for the analysis of the data. Systematic coding is carried out at micro-level. Then, the aim is to characterise the communicative events in such a way as to highlight the "interaction function" in the sense of Dudley (2013). Therefore, each communicative event can be characterised as a type of talk (arrow 2 in Figure 2). This type of discourse allows analysing the LS phases (arrow 3 in Figure 2).

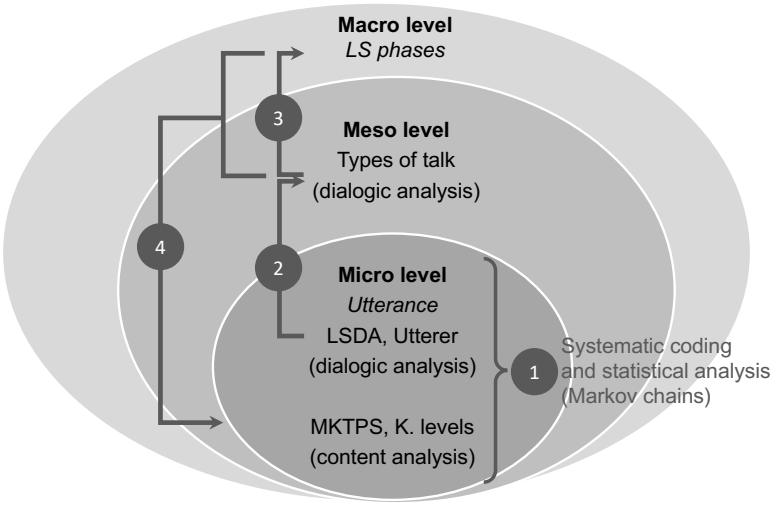

Figure 2: Nesting of analysis levels

Research question

Our main research question is: In what way is MKTPS built collectively during the LS process? For this article, we will focus on the sub-question: "What are the types of talk? Are they evolving? Is the MKTPS building related to the type of talk (arrow 4 in Figure 2)?"

Results

Types of talk during the LS meetings

The various types of talk can be associated with specific phases within the LS cycle, the types of MKTPS, and the knowledge levels. Our initial hypothesis posited that the specific MKPTS category would not correlate significantly with the types of talk, and our analysis validated this assertion. We also anticipated that the types of talk would undergo evolutionary changes during the course of meetings, contingent upon the specific nature and focus of each meeting. Furthermore, we expected that certain levels of knowledge would manifest more prominently within specific types of talk. The ensuing sections present the findings about these two dimensions.

Figure 3 illustrates the predominant discourse modalities observed during the meetings: exploratory talk (53%), cumulative talk (23%), and disputational talk (10%). A closer examination of individual meetings reveals distinctive characteristics. For example, Meeting 1 (M1), a general discussion about problem-solving teaching, is distinguished by the prevalence of cumulative talk (58%). In this meeting, participants expressed their ideas and questions independently, with limited cross-

referencing or interdependence in their utterances. This contrasts significantly with M8, a discussion about the two lessons, lesson plan, cycle assessment, and considerations for the next cycle. In M8, participants exhibited a marked reduction in cumulative talk and a notable surge in exploratory talk (70%) and disputational/qualificatory talk (24%, both highest incidence within the LS cycle). During this meeting, participants actively engaged in building upon each other's ideas and occasionally expressed disagreements with other participants. This escalation in exploratory discourse is also conspicuous when comparing meetings with similar themes. M2 and M3, (study of the curriculum material) witnessed an increase in exploratory discourse during the latter meeting, transitioning from 37% to 62%. Similarly, the planning of the second research lesson (M6) was characterised by a predominant presence of exploratory talk (76%) compared to the planning of the first research lesson (M4), with a lower incidence at 50%. The contrast is even more pronounced when comparing the post-lesson discussion following the first research lesson (M5) with the one following the second research lesson (M6). In the first discussion, each teacher successively reported their observations, which were predominantly cumulative (48%). In contrast, during the second discussion, almost every observation was related to those of colleagues, comparing or contrasting the observations in an exploratory way (65%), or sometimes disagreeing in a disputational/qualificatory way (14%).

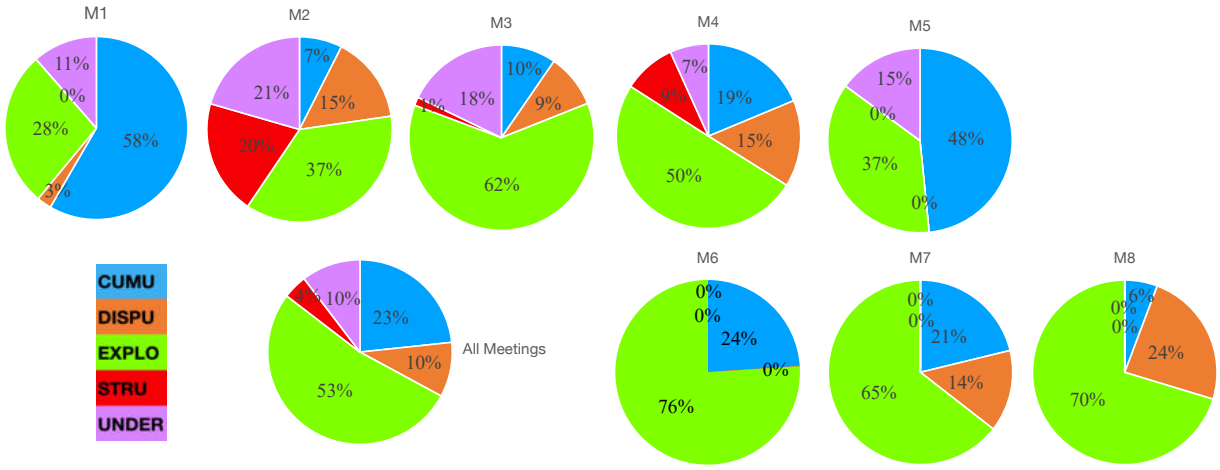

Figure 3: Type of talk for each meeting and for all the meetings

Levels of knowledge present in the types of talk

Upon examining the knowledge level in the three primary types of talk, a distinction emerges between cumulative talk and exploratory talk (see Figure 4). Specifically, there is a higher prevalence of level 4 (Contextualised explicit knowledge. Speaker knows or appears to know the rationale) in exploratory talk (29% compared to 19%). In contrast, level 2 (Unexplained knowledge. Observation, testimony) is relatively less prominent. This difference can be attributed to the definitions of type of talk and knowledge levels. But it can also be rationalised by the observation that during phases of a meeting characterised by exploratory discourse (at the meso level), knowledge tends to be more comprehensively justified (at the micro level). The observation that disputation talk is close to exploratory talk in terms of levels of knowledge is more unexpected. However, a closer examination of the transcripts reveals that, despite taking “short positions without justification” in response to

previous utterances, participants in disputation talk often demonstrate that they know the rationale of this knowledge, with a reduced occurrence of unexplained knowledge compared to cumulative talk.

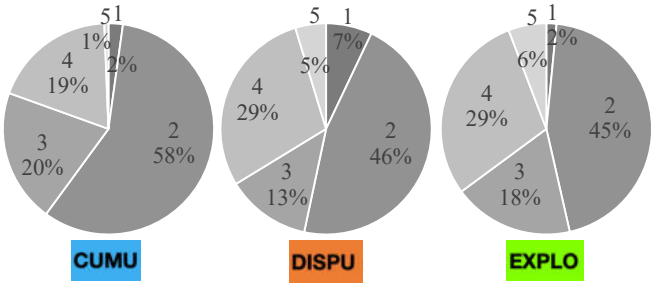

Figure 4: Knowledge levels for the three main types of talk

We refined our analyses by studying the transitions between levels of knowledge and this by type of talk (Figure 5).

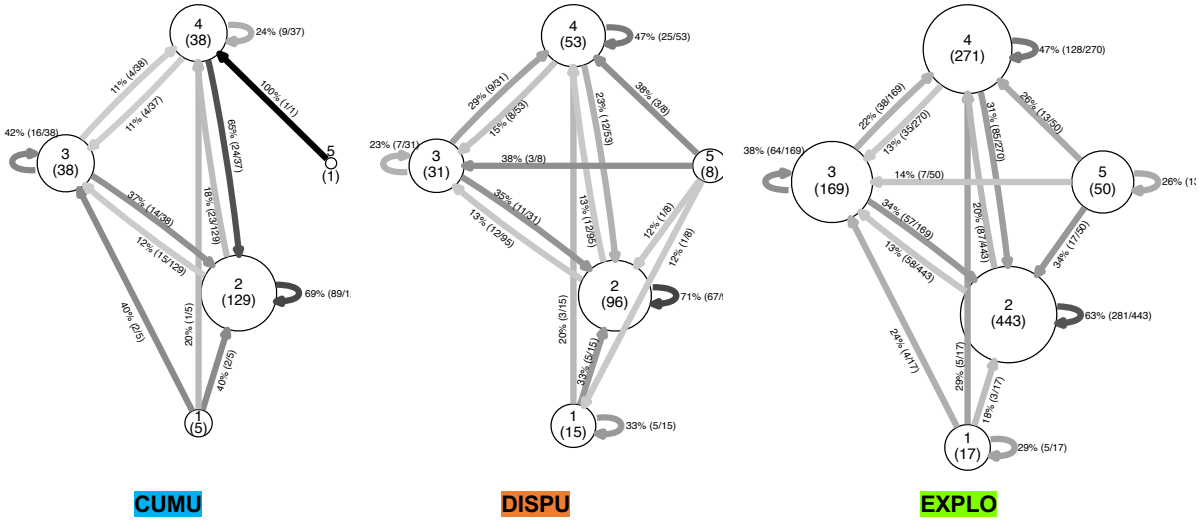

Figure 5. Markov chains for the levels of knowledge by type of talk

These Markov chains show that the exploratory and cumulative talk differ on the transitions from level 3 to level 4, going from 22% for the exploratory talk to 11% for the cumulative. This result can be interpreted as follows: when one speaker expresses incomplete knowledge or a question, the next speaker will express explicit contextualised knowledge. Similarly, the transition from level 4 to level 2 (unexplained knowledge, of the order of observation or testimony) is much more significant in the cumulative type of talk (65%) than in the exploratory type (31%).

These results from analyses of transitions between levels of knowledge illustrate how knowledge is constructed in exploratory talk in contrast to cumulative talk. These results confirm our research hypothesis based on the work of Littleton and Mercer (2013, p. 16) according to which the exploratory talk was judged to be the most "educationally effective". These results also allow us to analyse the dynamics in the construction of knowledge, through transitions between levels of knowledge.

In addition, there is no level 5 generalised, decontextualised knowledge in the cumulative talk, unlike the exploratory and disputational one. The transitions from levels 2, 3 and 4 to level 5 knowledge are all below 10% for the three types of talk. There is therefore no significant transition to level 5 of decontextualised knowledge, which we might have expected in the exploratory talk. On the other hand, there were transitions from level 5 to level 2 for the exploratory (34%) and disputational (12%) talk. Similarly, there were transitions from level 5 to level 3 for the exploratory (14%) and disputational (38%) talk, and to level 4 for the exploratory (26%) and disputational (38%) talk. As the number of occurrences is low, we can emphasise that in the exploratory and disputational talk, the decontextualised knowledge mobilised in one round is reexamined or recontextualised to classroom situations in the next round. These results illustrate the dynamics between decontextualised knowledge and knowledge of the order of questioning or classroom observation.

Level 2 knowledge is most present in the cumulative talk, in contrast to the other two. In a cumulative talk, participants express their knowledge without taking a critical or evaluative stance, and this knowledge is mainly level 2. In this type of talk, the participants talk about what they observed during the research lessons or refer to their classroom practices without considering the previous interaction.

The types of cumulative and exploratory talk are similar in the transition from level 2 to level 4, at 18% and 20%, respectively. Following a classroom observation, the turn to speak carries contextualised knowledge. This can be explained by the search for consensus in these two types of talk (Littleton & Mercer, 2013).

The transitions from levels 2 to 3 (12 to 13%) and 3 to 2 (34 to 37%) are similar for the three types of talk. This means that the type of talk do not differ with regard to the transition of knowledge linked to a class observation that is followed or preceded by a question or incomplete knowledge. Similarly, the transitions from level 4 to level 3 (between 11% and 15%) are similar for the three types of talk. These results may be explained by the very nature of the level 3 knowledge code, which involves either questioning, which may be conducive to knowledge building, or incomplete knowledge, which may be less conducive to knowledge building if it is not followed by level 4 or 5 knowledge.

Conclusions and perspectives

The development of teachers' mathematical knowledge about the teaching of problem-solving in a collaborative setting is a complex process. The findings of this case study are specific to the group under examination, and individual factors have impacted the results. Nevertheless, the mixed-method approach provides a comprehensive and interactive perspective on the collective construction of MKTPS. The unique characteristics of LS and MKTPS stressed in our results reinforce the idea that LS and PS teaching are interdependent and demonstrate how teachers' professional knowledge is shaped through dialogic engagement during LS. This supports the notion that LS and PS teaching are "two wheels of a cart" (Fujii, 2018) and highlights the significance of a dialogic process in developing teachers' professional knowledge.

Bi-institutional lesson study on algebra: what is it and what can lower secondary school teachers learn?

Derya Diana Cosan

University of Copenhagen, Department of Science Education, Denmark; ddc@ind.ku.dk

Abstract

This study explores the use of bi-institutional lesson study to address transition issues between two institutions, and the case of algebra in Danish lower and upper secondary schools. This new variant of lesson study is presented based on our theoretical framework, the anthropological theory of the didactic. It is investigated what teachers can learn by engaging in this approach and what challenges may arise. Preliminary results indicate that this approach may enhance teachers' awareness of students' relationship with a specific content area and further the participating institutions' alignment of expectations.

Keywords: Lesson study, bi-institutional lesson study, algebra, institutional transition problem.

Introduction

Transition problems from Danish lower secondary to upper secondary school are experienced as more acute in mathematics than in subjects like English or Danish, where more students experience more continuity between the disciplines as taught in these two schools (Ebbensgaard et al., 2014). Transition problems can be due to organizational, social or developmental reasons (Cantley et al., 2021). The cited difference motivated us (Cosan, 2024) to focus on more specific, subject-related or academic differences. Cosan (2024) presents a model for school algebra as consisting of the following three aspects: 1) setting up an algebraic model, 2) substituting in an algebraic model and 3) rewriting or operating on an algebraic model. According to Cosan (2024), the transition problem in algebra between Danish lower secondary and upper secondary school is predominantly related to the theory and practice of rewriting or operating on an algebraic model.

Whenever transition problems exist between two consecutively attended school institutions, this may encourage teachers from the institutions to collaborate, aiming to understand and ease the transition by establishing a shared knowledge of the requirements and expectations at each level.

In this context, considering the potential of lesson study is relevant. Lesson study began in Japan and is a collaborative professional development approach that centers on students and is designed to develop and support teachers' practices. Research shows that the implementation of lesson study impacts teaching practices, teacher learning, student learning, and the development of professional learning communities (Ding et al., 2024). Lesson study is a widely recognized teacher professional development format that is utilized in both lower and upper secondary schools even beyond Japan; however, in many countries including Japan, it is somehow different and less common in upper secondary school (Nishimura et al., 2018).

This paper introduces a new form of lesson study - *bi-institutional lesson study* - involving two connected (consecutive or neighboring) institutions, which was tested in Danish lower secondary and

upper secondary school, to aid students' transition, focusing on algebra (which, for reasons not developed in this paper, appears to be particularly central to the overall transition). The hypothesis is that teacher professional knowledge can be developed through collaborative lesson study with the aim to facilitate a specific transition occurring between the institutions.

Background: Lesson Study

Lesson study, or *Jugyo Kenkyu*, is a form of collaborative professional development widely used in Japan and other East Asian countries to improve teaching and learning. It involves teachers working collaboratively to plan, observe, and reflect on a lesson. The lesson study process consists of following a cycle known as the lesson study cycle in the following manner: A team of teachers identifies a learning goal and collaboratively plans a detailed research lesson. One member of the team of teachers teaches while the others observe and collect data. They then analyse, reflect on, revise, and report the lesson (Lewis, 2002).

As pointed out in Miyakawa & Winsløw (2019), lesson study can facilitate both the development and use of didactic knowledge and help it to become shared across a larger community of teachers. In a Western context, teachers are used to work in relative isolation, having individual responsibility for their teaching. Implementing lesson study in their practice allows them to work more collaborative and as pointed out by Lewis et al. (2009), the use of lesson study "makes various types of knowledge more visible, such as colleagues' ideas about pedagogy and students' mathematical thinking, thereby enabling teachers to encounter new or different ideas, and to refine their knowledge" (p. 286). Thus, lesson study as a professional development allows the teachers to develop and strengthen shared didactic theory.

Ding et al. (2024) review a large body of studies that show how lesson study contributes to teachers' professional knowledge, and how this has resulted in improvements in their teaching methods and also their common knowledge of mathematics. They cite research papers demonstrating how lesson study has led to changes in teaching methods, including better focus on students' work and interaction during the lessons. At the same time, this review also highlights that studies have shown how lesson study has improved students' mastery of mathematical content, such as both theoretical and practical aspects of fractions. The authors also stress that lesson study is often limited to teachers within a single school and that it is more frequently utilized by teachers in elementary and middle schools, and to a lesser extent in secondary schools.

Theoretical framework

In this paper, the work is situated within the theoretical framework: the Anthropological Theory of the Didactic (hereafter ATD) introduced by Yves Chevallard (2019). ATD suggests that the notion of praxeologies can be used to model human knowledge and activity. A praxeology consists of two parts, praxis and logos. The praxis refers to practical knowledge while the logos refers to explicit knowledge about the praxis. Concretely, a praxis consists of types of tasks T and techniques τ utilized to solve these tasks whereas the logos consists of a technology θ, which refers to the discourse used to explain, justify, and describe the techniques, and a theory Θ which refers to the more formal justification of the technology (Miyakawa & Winsløw, 2019). While a mathematical praxeology is

related to the praxis and logos about mathematical tasks and techniques, a didactical praxeology refers to the praxis and logos about the teaching of a mathematical praxeology. According to ATD, teaching mathematics involves developing and sharing a mathematical praxeology, and teaching itself constitutes didactic praxeologies. The mathematics teachers' knowledge is fundamentally rooted in and developed through engaging in didactical praxeologies. However, these didactical praxeologies are always based on mathematical praxeologies, so these two kinds of praxeology are inseparable (Miyakawa & Winsløw, 2019). A key concept in ATD is *didactic infrastructure* which encompasses the conditions and constraints influencing and shaping teachers' classroom activities (Miyakawa & Winsløw, 2019). Praxis which is related to teaching but occurs outside the classroom for instance the preparation of a lesson or participation in professional development, is called *paradidactic praxis* and the *paradidactic infrastructure* then relates to the conditions and constraints under which the paradidactic praxis takes place. So, how teachers participate in paradidactic practices is influenced by and shaped by this paradidactic infrastructure (Miyakawa & Winsløw, 2019).

Lesson study is focused on didactic praxis, the research lesson. Planning the lesson, observing it, and reflecting on it are three key tasks within lesson study and these tasks are according to ATD not didactic but paradidactic tasks (Winsløw et al., 2018). Lesson study itself therefore is a possible element of paradidactic infrastructure according to ATD (Miyakawa & Winsløw, 2019).

Bi-institutional lesson study

In a *bi-institutional lesson study*, teachers from two consecutively attended institutions, referred to as I_1 and I_2, collaborate to plan, observe, and review a research lesson in I_1, to facilitate the transition between these two institutions and to develop the participating teachers' common didactic knowledge. Bi-institutional lesson study can be used to address specific problems that arise when students transition between two educational institutions such as lower secondary and upper secondary school. This approach enables teachers from I_1 and I_2 to collaboratively reflect and improve on their teaching practices, focusing on developing a shared knowledge of students' thinking and learning in challenging mathematical praxeologies during these transitions. Like a regular lesson study, carried out within one institution, a bi-institutional lesson study follows a lesson study cycle and provides the opportunity to develop didactic and mathematical knowledge about teachers' own practice. However, the bi-institutional lesson study also affords the opportunity to build didactic and mathematical knowledge about practices in the neighboring institution.

Research question

This paper will address the following question:

Can lower secondary school teachers' didactical and mathematical praxeologies be developed by engaging in a bi-institutional lesson study focused on algebra? If so, which praxeologies and what challenges can appear?

With this question, the focus is specifically on investigating whether Danish lower secondary and upper secondary school teachers develop new didactical and mathematical knowledge related to their own and each other's practices after participating in bi-institutional lesson studies.

Context and Methods

In the 2023/2024 school year, six lower secondary school teachers and two upper secondary school teachers participated in bi-institutional lesson studies. To ensure that all teachers had the opportunity to participate in the planning of the lesson, the teachers were divided into two smaller groups, each consisting of three lower secondary school teachers and one upper secondary school teacher. These teachers work at a lower secondary school and an upper secondary school in the same municipality, where most of the students who choose upper secondary school actually end up in the one participating in this study. The upper secondary school teachers had previously been involved in the Erasmus+ TIME (Teachers' Inquiry in Mathematics Education) project, which aimed to explore how upper secondary school teachers can collaboratively develop their practice through lesson studies (Jessen, Bos, Doorman & Winsløw, 2023). Therefore, the two participating upper secondary school teachers in this project already had some experience with lesson study.

Throughout the school year, each group planned and conducted three lesson studies, resulting in a total of six lesson studies. Each lesson study was planned and carried out over a period of 4-5 weeks and followed the lesson study cycle. The two groups also participated in observation and reflection related to each other's research lessons. Each lesson study included a first try and a research lesson. The first try could be taught by all the lower secondary school teachers while the research lesson was always taught by the lower secondary school teacher who normally taught the class.

In the first bi-institutional lesson study, I, as the author, facilitated the planning meetings, helping teachers set goals, choosing a task, defining learning objectives, filling out the lesson plan, and identifying observation points for the research lessons. As the teachers gained experience, my role shifted to becoming more of an observer. For the research lesson, another facilitator and a knowledgeable other from the university and university college were always present.

In the following section, the method for data analysis will briefly be presented. After the implementation and observation of the lesson studies, the teachers were interviewed. Two lower secondary school teachers did not participate in the interviews due to illness and a change of workplace. Notice that this paper is a part of a larger project, where we are interested in the data from all six semi-structured interviews with two upper secondary and four lower secondary school teachers. However, the data for this paper consists of an interview with one of the lower secondary teachers, who was also the one teaching the research lesson, due to space constraints. A more comprehensive analysis will be presented elsewhere, based on interviews with all the teachers to provide broader answers to the research question.

All the teachers involved in the project were experienced teachers with many years of teaching practice. The interview questions were designed to gain knowledge about teachers' experiences from participating in the bi-institutional lesson studies. The questions were divided into two parts: first, the teachers' individual experiences were explored, focusing on both the benefits they gained and the challenges they encountered. Then, their experience with the collaboration was examined, both within their institutions and across institutions.

After transcribing the interview data, the content was reviewed multiple times to gain an overview of the data material. This process, which is still ongoing, helped to identify key statements and observations from the teachers that could contribute to answering the research question.

A thematic approach, drawing on ATD, was applied to analyze the teacher's experiences and the development of their didactical and mathematical praxeologies through participation in bi-institutional lesson studies. Central statements from the transcriptions were identified to highlight both the benefits and challenges faced by the teacher, as well as how these challenges were connected to the development of both mathematical and didactical praxeologies. These statements were then organized into two main themes: 1. *Increased professional awareness and facilitation of student involvement*, and 2. *alignment of expectations between institutions*. The framework ATD was applied here to interpret these themes in terms of how the teacher's didactical and mathematical praxeologies evolved through the bi-institutional collaboration. Specific quotes from the analysis were used to support the identified themes and to illustrate the teacher's experiences and learning in relation to both the practical and theoretical aspects of their teaching.

Analysis and results

Generic lesson study outcomes: professional awareness

The teacher points out that her participation in the project has impacted her teaching by making her more aware of the importance of actively incorporating students' knowledge into the lessons:

"It is more important for the students to get involved rather than for me to be in the spotlight during the lessons—both in terms of them actively solving tasks and also being verbally active."

This illustrates how participation in the bi-institutional lesson studies has helped her recognize the value of shifting focus from teacher-led instruction, which is more or less her usual practice, to a more facilitative role where students explore and solve problems together.

In this context, she expresses that "there is often something that is right and wrong [referring to the result of a math problem], but there are many ways to approach solving things, such as methods or, what you might call, procedures". So, the teachers' view of mathematical praxeologies developed. The teacher refers to the fact that there can be different techniques for solving the same task and similarly, during validation (in the sense of Brousseau, 1997, p. 15), she argues that one must consider different technologies and more theoretical aspects, including how to justify the various technologies. Based on the bi-institutional lesson study, it can be observed that the teacher experiences a shift from a more technical level to a more technological/theoretical level, and a demand for students to explain their techniques and methods. In open lessons, the teacher then has to address a greater variety of solutions, and reasoning of a more theoretical nature. This is a mathematical praxeology, but it requires a didactic praxeology to generate and manage this mathematical praxeology, which is what is discussed during the planning meetings. Especially during lesson planning, the paradidactic infrastructure facilitates the interaction and development of the teachers' mathematical and didactic praxeologies, from two different institutions.

So, she acknowledges that the identification and validation of different approaches students use to find a solution for a mathematical task are just as important as the final answer. This indicates a development in the teacher's professional awareness, extending a focus on mathematically correct results to include students' methods and thinking. She now recognizes the value of recognizing and exploring the many different ways by which students can solve a task in mathematics.

A central focus of the bi-institutional lesson studies has been how the teacher can facilitate a teaching approach that increasingly involves students. In the interview, the teacher expresses that the bi-institutional lesson study has allowed her to reflect on how she should balance control and freedom in the classroom:

"It is a challenge to let go of the control and see where it leads... how can you keep it controlled while still allowing the students to actually contribute knowledge and participate in the lesson."

This reflection highlights one of the major challenges in teaching, according to the teacher, namely finding the right balance between guiding students and giving them the space to develop their own understanding of algebra. Indeed, this could be a general outcome of a first lesson study experience even within one school, but was here accentuated by the participation of teachers from another school who had both previous experience with lesson study, and helped focusing on topics (like algebraic techniques) which are of particular importance in the future of students.

Specifically bi-institutional outcomes: alignment of expectations between institutions

Collaboration with upper secondary school teachers has also made the teacher aware of differing expectations between the two institutions. The teacher frequently mentions this:

"It has been rewarding to gain insight into my expectations and their expectations, which were not exactly the same. My expectations for what I send my students out of school with, and their expectations for what they receive in terms of what the students' are capable of. It was like, 'Wow.'"

A concrete example of this difference in expectations concerns students' knowledge related to linear equations: "Their expectations of what the students can do... at the upper secondary school, they expected the students to know more... they had higher expectations than I do." This example shows how the two institutions can have different perceptions of students' academic levels, which may create a need for discussion.

Another important realization for the lower secondary school teacher was how comprehensive algebra is: "Even something like linear equations, what they expect the students to be able to do and what I expect my students to manage when they leave school. There was a difference." This difference became particularly evident in the way linear equations were approached, reflecting distinct mathematical praxeologies. This gap in understanding can only be fully grasped by considering the broader institutional conditions that affect each institution. While the lower secondary school teacher focused on the technique of solving equations by guessing, upper secondary school teachers emphasized the theoretical dimension of setting up and solving equations, expecting students to handle more complicated tasks, at least according to the lower secondary school teacher.

During the planning meetings, the participation of upper secondary school teachers highlighted a critical gap between practices across the two institutional levels. The conversations between the teachers helped lower secondary teachers prepare their students better for future challenges. These conversations emphasized the different meanings, value, and importance assigned to algebra in the two institutions, highlighting its extensive scope and its varying importance in each institutional context. The reflection prompted a broader conversation on how to bridge these praxeological differences and align teaching practices more effectively.

The mere extent of the subject algebra is emphasized by the teacher: "It may have dawned on me how extensive it actually is compared to how little time is actually given to it in lower secondary school." Thus, through the bi-institutional lesson studies, the teacher has become aware that school algebra is more complex and extensive than she previously assumed. This contributed to a deeper understanding of what is required to prepare students for the transition from lower to upper secondary school.

The collaboration with upper secondary school teachers in lesson studies has helped lower secondary school teachers become more aware of specific algebraic skills that students need later. If the lower secondary school teacher had not previously seen algebra as such an extensive subject area, it could indicate a general lack of communication between lower secondary and upper secondary school institutions, regarding what is required and expected of students in algebra. This could strengthen the argument for why bi-institutional lesson study is effective, as it forms a "practice near" infrastructure for teachers to share their views and knowledge of the academic content across institutions.

Based on the interview, it can be seen that the bi-institutional lesson studies have provided the teacher with new and valuable knowledge. She has gained new academic awareness, recognized the importance of aligning expectations between institutions, reflected on how to best involve students in teaching, and acknowledged the extent of algebra. At the same time, she has faced challenges, particularly in balancing control with student involvement in the classroom.

Conclusion

This study examined the use of a bi-institutional lesson study to address the transition problem between Danish lower and upper secondary schools, focusing on algebra. Motivated by the difficulties in algebra during this transition, the study works within the Anthropological Theory of the Didactic (ATD) to understand the interaction between mathematical and didactical practices across institutions. The analysis of a lower secondary school teacher's experiences highlighted several key findings. The teacher gained knowledge about the nature and extent of algebra, and the corresponding expectations of teachers in upper secondary education. This collaborative process also facilitated a better understanding of how different teaching practices impact student learning. The teacher faced challenges in balancing classroom management with encouraging student contributions. However, overall, the bi-institutional lesson study approach appears to have promising potential for improving the alignment of teaching practices and otherwise addressing transition problems.

Preparing and leading a whole-class discussion in a lesson study in initial teacher education

João Pedro da Ponte[1], Nicole Duarte[2], and Filipa Faria[1]

[1]Instituto de Educação, Universidade de Lisboa, Portugal; jpponte@ie.ulisboa.pt

[2]Instituto Politécnico de Leiria, Portugal

Based on the analysis of a lesson study carried out during an initial teacher education program, we seek to understand how this teacher education process can promote opportunities for a prospective teacher to develop her practice about preparing and leading whole-class discussions in the classroom. We follow a qualitative approach, and the data was collected through observation and recording of the lesson study sessions. The analysis of data is made based on a comprehensive model for preparing and leading whole-class discussions. The results show that the lesson study seems to have contributed to the development of the prospective teacher's practice of how to prepare and lead whole-class discussions. She managed to promote an interesting whole-class dynamic but she found it difficult to get most pupils to participate in the whole-class discussion.

Keywords: Whole-class discussion, lesson study, mathematics teaching, initial teacher education.

Introduction

Whole-class discussions assume great relevance in pupils' learning, enabling the exploration of mathematical ideas, anchored in the pupils' solutions and of the tasks proposed by the teacher. The role of the teacher is central, encouraging pupils to present and justify their ideas, requiring that the teacher prepares well the enactment of a whole-class discussion (Fujii, 2018; Stein et al., 2008). However, leading these discussions has been identified by research as a challenge for teachers and, especially, for prospective teachers, since it requires a broad knowledge in content, didactics and pupils and the way they learn (Fujii, 2018; Stein et al., 2008). In addition, leading whole-class discussions also requires "solid expectations for what is likely to happen, [and] novices are regularly surprised by what pupils say and do, and therefore often do not know how to respond to pupils in the midst of a discussion" (Stein et al., 2008, p. 321). According to Fujii (2018), one way to deal with the challenges of leading whole-class discussions is to anticipate possible strategies for dealing with pupils' difficulties, preparing how to act in the different moments of the lesson and the teacher interventions to do.

Lesson study is recognized as a formative process with potential to promote the development of knowledge of prospective teachers, namely on leading whole-class discussions (Ni Shuilleabhain & Bjuland, 2019). Focused on pupil learning, lesson study provides opportunities for prospective teachers to prepare lessons in detail, anticipating pupil work and teacher actions. This teacher education process allows not only prospective teachers to prepare the lesson, but also to lead it and reflect on the pupils' work and learning (Bjuland & Mosvold, 2015). In this study, we seek to answer the following research question: What practices a prospective teacher enacts in the preparation and leading of a whole-class discussion in a research lesson?

Preparing and leading the whole-class discussion through lesson study

The quality of a whole-class discussion is strongly influenced by the teacher's preparation for the lesson (Fujii, 2018; Takahashi, 2008). This preparation begins when the teacher identifies the

mathematical content to be addressed and defines the learning goal to be developed with the pupils in the lesson (Boerst et al., 2011). From there, the teacher needs to select tasks for which the pupils do not have an immediate solution method, which creates opportunities to build or deepen their understanding of mathematical concepts, procedures, representations and ideas. After that, the teacher needs to anticipate various solutions and difficulties that pupils may present. To do this, the teacher should consider the diversity of strategies and how they may relate and establish connections between them and with the learning goal to develop in that lesson. Also, it is important to identify possible difficulties the pupils may have in interpreting the task, analyse articles with suggestions on pupils' usual responses and difficulties with similar tasks and analyse the curriculum documents (Stein et al., 2008). This study also allows the teacher to realise what pupils' strategies and answers are most likely to emerge and what errors or misconceptions they may have (Boerst et al., 2011). It is also important for the teacher to prepare the questioning and interventions when leading the whole-class discussion. Such questions should contain a certain degree of challenge, promoting disagreements and allowing the teacher to understand the pupils' difficulties.

Then, the teacher should think about how to begin the discussion of the strategies used by the pupils, already selected and sequenced in the preparation phase (Boerst et al., 2011). The teacher leads the whole-class discussion with special attention to i) the pupils' work; ii) mathematical ideas; and iii) classroom interactions. By analysing the pupils' work, the teacher is able to obtain, understand and make connections between the different ideas, solutions and strategies used by the pupils. When the pupils explain how they solved the task, the teacher may ask questions to support them in expressing their reasoning, particularly to highlight important mathematical ideas related to the task and the lesson. And with regard to interactions, the teacher's interventions may also encourage pupils to participate in the discussion, encouraging them to listen, analyse and respond to their peers' reasoning (Boerst et al., 2011). Since a whole-class discussion, in order to be productive, results from pupils sharing their thoughts, the teacher may reformulate the ideas they present in an incomplete or erroneous way. Sharing incorrect or incomplete ideas can lead to disagreements between pupils, which is a great opportunity to argue, criticise and explore errors (Stein et al., 2008). The whole-class discussion ends with a final synthesis that may be enriched with the collaboration of the pupils. This moment aims to highlight and summarise the main mathematical ideas explored throughout the lesson and point connections between the established goal and other ideas previously known by the pupils (Duarte et al., 2024).

The model of Stein et al. (2008) says very little about how to lead a whole-class discussion. There are other models about this classroom moment (e.g., Boerst et al., 2011; Kooloos et al., 2023), but they tend to emphasize particular aspects. This indicates the need of a comprehensive model to account for all the main aspects of this lesson activity. To this end, we developed a model that serves as a basis for data analysis that we present in the next section.

Research methodology

This research follows the qualitative approach and the interpretive paradigm (Bogdan & Biklen, 2007) and considers as its data source the sessions of a lesson study carried out at a higher education institution in Portugal in the initial teacher education of primary teachers. The lesson study was carried out in the 2023/2024 academic year and involved two prospective teachers who were attending the first semester of the first year of their master's degree program in teaching (Júlia and Alda, pseudonyms). There was a total of eleven sessions (S*n*), held weekly and lasting approximately two hours each, organised as

follows: goal setting – S1, S2; lesson planning – S3, S4, S5, S6; research lesson – S7; post-lesson discussion – S8; reflection – S9; and preparing to disseminate the results – S10, S11. The lesson study was an integral part of the internship programme, which was being carried out in a grade 2 class with pupils that were between the age of six and seven. The prospective teachers were supervised and guided by a teacher from the higher education institution, who took on the role of researcher, preparing and conducting the lesson study sessions. After analysing the medium-term planning provided by the school where the prospective teachers were doing their internship, the participants decided that the research lesson would focus on the theme of numbers and the topic of multiplication. The lesson's learning goal would be to solve problems with rectangular arrangements that fostered an understanding of the relationship between multiplication and successive addition of equal numbers. All the work carried out for the research lesson considered the exploratory approach, namely in the selection of the task, which is shown in Figure 1. There was much reflection about which task to choose (as indicated by Fujii, 2018) and in anticipating students' responses (as indicated by Stein et al., 2008).

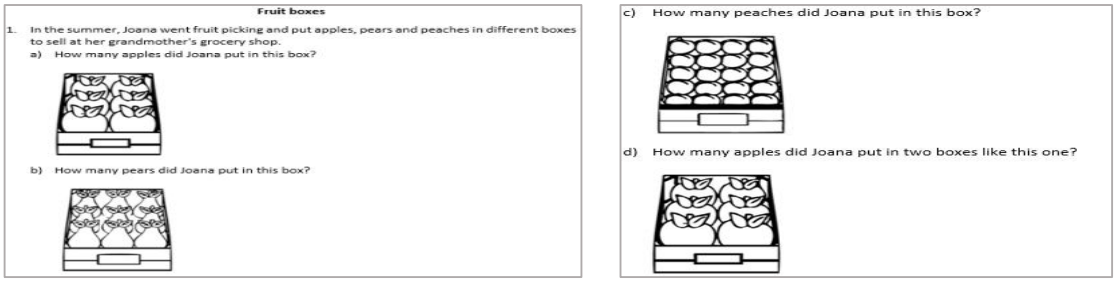

Figure 1 - Task proposed to the pupils in the research lesson (adapted from Rocha & Menino, 2009)

To promote the final synthesis, the prospective teachers decided to explore with the pupils a table, which systematises some of the strategies that may be used to solve the task and includes a space to fill in with the pupils' suggestions.

We analyse how Júlia prepared, conducted and reflected on the research lesson. Although she conducted exploratory lessons before in pursuit of her degree, valuing their contribution to pupil learning, her participation throughout the lesson study showed a pronounced development of self-reflection on her own practice. The data was collected through observation of the planning sessions and the carrying out of the research lesson. The lesson study sessions were recorded and relevant excerpts for this study were transcribed. The data was analysed using a deductive method, considering the model presented in Table 1, which organises the teacher practices to be considered when preparing and leading a whole-class discussion, final synthesis. In this model, the preparation of the discussion includes aspects that have long been recognised in the teacher education literature (e.g., Fujii, 2018; Stein et al., 2008). With regard to leading the whole-class discussion, the model proposes the identification of three practices that need to be conducted simultaneously: initiating discussion and intervention according to the situation and goal, analysing pupils' work with a focus on mathematical ideas, and promoting pupil participation. As for the final synthesis, we have added the action of summarising and highlighting the main mathematical ideas or procedures explored to the establishment of connections previously indicated by Stein et al. (2008). In our analysis, we identify significant episodes from the preparation and leading of the research lesson conducted by Júlia, through which we sought to understand how the prospective teacher led the whole-class discussion during her

participation in the lesson study. In addition, we analyse how the prospective teacher led the whole-class discussion and seek to understand how the lesson study contributed to the development of her knowledge about leading whole-class discussions. (Pupils' names are pseudonyms).

Table 1 - Practices to consider when preparing and leading the whole-class discussion and final synthesis (adapted from Duarte et al., 2024)

To prepare the whole-class discussion		To lead the whole-class discussion	To conclude the whole-class discussion with a final synthesis
Before class	**During class**		
Initial preparation Choosing the task Solving the task Preparing to carry out the task in class	Presenting the task Monitoring the pupils' work Selecting pupils' answers Sequencing	Initiate the whole-class discussion and intervene according to the situation and the goal Analyse pupils' work with a focus on mathematical ideas Promote pupil participation	Conclude, with the collaboration of the pupils

Results

Preparing the whole-class discussion

After selecting and adapting the task to propose to the pupils in the research lesson, the participants anticipated possible strategies that the pupils could use. As such, they solved the task in several ways, regardless of the degree of correctness or sophistication of each solution strategy:

Júlia: I, sincerely, think that on b) they [pupils] may use…
Alda: Counting one by one.
Júlia: [Counting] by rows and by columns: 3+3+3 and 3+3+3. Here is the same. To say 3 columns of 3 or 3 rows of 3 or 3 horizontally, and 3 vertically… And whereas in the previous question the factors changed, replacing their position, but the result was the same, here [question b)], no. The factors are equal, does not matter to replace position. In question c), in addition to these, there are two products: 4×5 or 5×4 and the position of the factors matters again. (S3)

Faced with the diversity of possible strategies for solving the task, the participants discussed how they could select and sequence the pupils' answers for the whole-class discussion, namely considering the wrong or incomplete strategies, which "should be presented first, if we want disagreements to arise" (Júlia, S4) and, therefore, lead the pupils to explain and justify their solutions. In addition to beginning the discussion with wrong or incomplete strategies, the group also chose to sequence the pupils' answers according to an increasing degree of complexity and sophistication:

Alda: Counting one by one is simpler, I think it makes sense to begin by that one.
Júlia: And it must be the more used, at least in this [first] question. The multiplication should be the most difficult for the pupils and it is also where we want to get, so it makes sense to be the last one. And if we want that they connect addition and multiplication, I think that is the order. From additions to multiplications.
Supervisor: And in b)?
Júlia: I would do the same. However, I would not select counting one by one, because that was talked before… The aim of the lesson is not counting one by one… Therefore, I would not select it. (S4)

Júlia also suggested giving priority to strategies that made it possible to explore the aim defined for the lesson, choosing not to value strategies such as counting one by one from the first question of the task. Depending on the different solution strategies that the participants anticipated, they also prepared questions and teacher interventions to use during the whole-class discussion to promote

pupil learning (Duarte et al., 2024; Stein et al., 2008). Júlia considered important to intervene not too much, allowing pupils to take a central role in explaining their reasoning, nor to validate or induce the answers, and often challenge other pupils to participate in the discussion:

Supervisor:	And these interventions [support and challenge] are directed towards a group, a pupil, the whole class?
Júlia:	To the groups, I think. The class must be provoked to always participate. Moreover, they must listen with attention what a group says to be able to criticize. To say: "Are there other ways to count, group x? That group counted in another way. Explain how you thought" or, for question b), "the group A added 3 with 3 and group B did 2 times 3. However, the result is 6 in the two solutions… Is this right? Why? Group C, explain why it yields the same result". (S4)

Leading the whole-class discussion

In the research lesson that she led, Júlia begun the discussion with an invitation to the group that she selected to be the first to present a solving strategy: "the group of Carolina, how did you do it? Explain to your colleagues" (S7). This invitation action led the pupils to share their solutions and explain them, as it occurred with the discussion of question a):

Júlia:	Ricardo did 2+2+2. Is there another way to say this?
Ricardo:	2×2.
Júlia:	2×2? So, let us pick here in this operation that Ricardo told us.
Hugo:	2×2 is 4!
Júlia:	2×2 is 4. Very well. However, you know how we call the operation that has this signal [point towards ×]?
Ricardo:	Is "times"!
Júlia:	Is "times". And how do we call the operation?
Fabiana:	Is "x".
Júlia:	But it has a name… the "x" is called "times", not "x". But what is the name of the operation? This here is an addition [points towards +], and this one uses "times", how we call it? You do not know? Say, Hugo?
Hugo:	Mult…?!
Júlia:	Multiplication! When we use "times", we are doing a multiplication. Let us go back to your responses. Hugo, it is your turn, say it.
Hugo:	It can be 2×3.
Júlia:	Very well. So, it is 2×3 and not 2×2. What does it yield?
Hugo:	6.
Júlia:	6. But look at one thing. Do we have two times three or three times two?
Pupils:	Three times two!
Júlia:	Then, the correct operation is 3×2. (S7)

In this episode, Júlia also analysed the pupils' work with a focus on mathematical ideas, interpreting Ricardo's reasoning and actions of initiating and intervening when she invited him to think of another answer that would allow making connections between the addition of equal numbers and multiplication. At Júlia's invitation, and although he gave a wrong answer, Ricardo made the connection with multiplication. Hugo said that the product of 2×2 is 4 and mentioned the name of the operation at sake. Apparently, these two pupils already knew multiplication, possibly because they had private mathematics lessons. As this was the first moment of the lesson in which the operation appeared, Júlia chose not to immediately highlight the error, but took advantage of Ricardo's intervention to explore multiplication with the pupils. Then, she resumed to the answer 2×2, again with intervention actions, now challenging the pupils to validate this response, with Hugo correcting the operation enunciated by Ricardo. In this episode of the discussion, Júlia also interrupted the pupils' interventions, again through interventions in order to support/guide them, encouraging pupils

to clarify their explanation, but also to promote the continuation of their involvement in the discussion, seeking to promote their participation (Duarte et al., 2024; Kooloos et al., 2023). The prospective teacher also used intervening actions, highlighting important mathematical ideas, introducing information and validating pupils' answers, and analysing pupils' work when she promoted connections between the pupils' answers 2×3 and 3×2.

Another episode, referring to the discussion of question c), highlights how Júlia promoted the participation of the pupils, when faced with a situation of disagreement in which Francisco, when explaining his reasoning to his colleagues, had a question about the position of the factors:

Francisco:	First, we counted, 1, 2, 3, 4, 5 [a column. After 1, 2, 3, 4 [a row]. And we understood that it could be 5×4, I mean 4×5.
Júlia:	And why it could not be 5×4?
Igor:	It would yield I don't know.
Júlia:	Francisco said that you thought that way [by columns] 4 times, and in this way [by rows] 5 times. And it could not be also 5×4?
Igor:	It would not be. It would yield other number. I need to do the computation.
Júlia:	Children, what do you think?
Maria:	Would be another thing.
Júlia:	They thought 5, 5, 5, 5, four times [columns]. And would not yield 5×4?
Rui:	It would be 20. So, that would be another thing.
Júlia:	It would be? How that would be?
Rui:	I think it is in both ways.
Júlia:	Why?
Rui:	I don't know.
Júlia:	Let's all discuss. Ricardo, say it?
Ricardo:	Because there are there 5 rows with 4 up front [rows] and 4 rows with 5 downwards [columns].
Júlia:	Do you want to come here [to the board] explain?
Ricardo:	Here [points the board] there is 4+4+4+4+4 [points to the columns], equal 20. [Points to the rows] 5+5+5+5 equals 20.
Júlia:	So, we can do 5×4 if we think as Francisco and we can do 4×5 if we think as Ricardo. How is it? Explain once more.
Ricardo:	4+4+4+4+4 [points, at the board, to the columns downwards] and 5+5+5+5 [points at the board, left to right]. (S7)

Faced with the difficulty of Francisco, Júlia, analysing the pupil's work, sought to promote connections between the mathematical aspects of his strategy with the aim of the lesson and (Duarte et al., 2024), to this end, made an intervention, challenging and insisting with the pupils to explain why "it could not be 5×4". When she realized that the pupils were not so involved and participative in the discussion, she made an intervention, inviting them to share their opinion about what their colleagues said (Boerst et al., 2011). Júlia also made actions related to the analysis of the pupils' work, apparent in her mathematical activity during the discussion and, in the connections, she promoted between the pupils' strategies and the aim of the lesson. Such actions, often in the form of challenges, presented pupils with mathematical questions and situations in which they were called upon to justify their explanations (Stein et al., 2008). The prospective teacher also showed that she analysed the pupils' work, trying to understand their reasoning, choosing to respond to them in a more explicit way, informing/suggesting by highlighting information. The situation of disagreement, motivated by the difficulty of some pupils in understanding that the position of the factors does not change the product, was solved through the explanation of a pupil, Ricardo. The prospective teacher, although she made several interventions, allowed the pupils to justify their reasoning and reach a consensus.

Concluding with a final synthesis

The whole-class discussion ended with a final synthesis, promoted through the exploration of the previously prepared board organization, which also led to the discussion of some of the pupils' ideas:

Júlia:	This first part is correct? 2+2+2 is equal to 3×2?
Some pupils:	No!
Júlia:	No? Why not? What is wrong here?
João:	It is the same.
Júlia:	Is it the same? You all agree?
Pupils:	Yes.
Júlia:	Why so? I want to know why you agree that 2+2+2 is equal to 3×2. Why that is correct?
Tomás:	Because it is 3 times 2.
Júlia:	We have 3×2. We are adding 3 times 2. So, now 3+3 is equal to what?
Tomás:	To 2×3.
Júlia:	Mariana?
Mariana:	6.
Júlia:	Yes, is 6. However, I do not want to know the result. I want to know 3+3 is equal to what in a multiplication?
Sofia:	6.
Júlia:	Sofia, I just said to Mariana that I don't want to know the result. Carolina, how is 3+3?
Carolina:	It is 2×3.
Júlia:	All agree?
Pupils:	Yes.
Júlia:	Because we are adding three twice. So, now, 3+3+3. How is it in multiplication?
Francisco:	3×3. (S7)

In this segment of the final synthesis, Júlia encouraged the involvement of the pupils, who explained their reasoning and expressed themselves in relation to the explanation of their colleagues, validating the answers presented. In this way, the final synthesis was promoted through the collaboration of the pupils in filling out the table where they summarized and highlighted the main ideas explored in the lesson (Duarte et al., 2024) and evidenced connections between successive addition and multiplication, namely between the pupils' answers 2+2+2 and 3×2.

Conclusion

The preparation of a whole-class discussion is the object of attention in many studies, and there is a broad consensus around the usefulness of the model of Stein et al. (2008). However, it seems necessary to better clarify everything that has to do with the first phase of the preparation of the lesson, namely the choice and solving of the task, which we seek to do in this study. Regarding leading the lesson, we suggest that three practices intertwine, initiating the discussion and intervening according to the situation and the aim, analysing the pupils' work with a focus on mathematical ideas, and promoting pupil participation. Several of these aspects are mentioned in previous studies, with emphasis on a dimension or another, and often under other terms (e.g., Fujii, 2018; Kooloos et al., 2023; Stein et al., 2018). The model we present also highlights the importance of concluding the whole-class discussion through a final synthesis, led with the collaboration of the pupils, where we highlight two important aspects, the summary of the essential ideas of the lesson and the connections of these ideas with other mathematical ideas already known by pupils.

In this study it was possible to verify that a prospective teacher of the first years, already with some previous experience in leading whole-class discussions within the framework of an exploratory approach,

managed to achieve an interesting dynamic of discussion, inviting pupils to participate and intervene according to the situation and the aim and analysing the pupils' work with a focus on mathematical ideas. However, she did not always make the most appropriate interventions and, above all, she manifested difficulty in promoting a broad participation of most pupils. The contribution of the lesson study to the development of her knowledge about leading whole-class discussions seems to have been mainly in the organization of the preparatory work to do for the enactment of the discussion. Thus, in future lesson studies to carry out with other prospective teachers, we will strive to pay more attention to ways to promote a broader pupil participation.

Applying variation theory: a challenging case in pre-service teacher education

Dédé de Haan[1,2], Siebrich de Vries[2,3], Gerrit Roorda[2,3] and Paul Drijvers[1]

[3]University of Groningen, the Netherlands

Although research has shown that conducting a learning study – a lesson study using variation theory – can enhance mathematical knowledge for teaching, the specific role of variation theory in this process remains unclear. The aim of this study was to get more insight in the relation between the use of variation theory and the development of participants' mathematical knowledge for teaching. A team of three pre-service teachers carried out a learning study, as part of a last-year module within mathematics teacher education. Pre-tests, student work and lesson plans were analyzed on how variation theory was applied and how this related to the participants' mathematical knowledge for teaching. Findings suggest that applying key elements of variation theory contributes to aspects of this knowledge, particularly during the first phase of the learning study. However, implementing variation theory in lesson design remains challenging, indicating a need to strengthen the support provided within the learning study module in pre-service teacher education.

Keywords: Learning study, preservice teacher education, mathematical knowledge for teaching, variation theory.

Introduction

Several studies have shown that conducting a learning study, a lesson study in which variation theory is used as a learning theory, can lead to a deepening of knowledge for teaching (e.g., Cheng, 2014; Lai & Lo-Fu, 2013; Mårtensson, 2023). Variation theory fundamentally addresses how concepts, or phenomena, should be understood, by focusing on its critical aspects and by structuring teaching to ensure that these critical aspects can be discerned by the learner. However, the relation between the use of variation theory and fostering mathematical knowledge for teaching remains unclear. Royea and Nicol (2019) found that it helped pre-service teachers (PSTs) in mathematics education in understanding mathematics, and in teaching mathematics in different ways, but they also found that PSTs perceived applying variation theory as difficult. Based on these findings, we designed a learning study module for pre-service teachers in their last year of pre-service mathematics education for lower secondary. We examined experiences of one team of three PSTs who participated in this module. The aim of this study is to shed more light on the way variation theory is used by the PSTs in each phase of the learning study, and on the relation with the development of their mathematical knowledge for teaching. Our research question is: In what way is applying variation theory in a learning study related to fostering pre-service teachers' mathematical knowledge for teaching?

Theoretical framework

Mathematical knowledge for teaching

The model of Mathematical Knowledge for Teaching (Ball et al., 2008) describes what kind of knowledge and skills teachers need when teaching mathematics. The knowledge and skills are divided into several domains. The central domains Specialized Content Knowledge (SCK), Knowledge of Content and Students (KCS) and Knowledge of Content and Teaching (KCT) are the domains most connected to the actual teaching in classroom: SCK is the deep knowledge of a topic within mathematics (relational understanding, according to Skemp (1976)), in order to be able to explain the topic; KCS is the knowledge of how students think about a topic, how they understand the topic, and KCT is the knowledge of the organization of the lesson, the way tasks are designed, in order for students to understand the topic. In 2017, Ball elaborates further on what teachers need to be able to do when teaching mathematics and identifies this as the *mathematical work of teaching* (Ball, 2017). A central aspect of the work of teaching is "being aware of and oriented to learning about and coordinating with others' perspectives" (Ball, 2017, p. 17). All students are different, everyone is shaped by their background, which causes different ways of thinking, of reacting on questions, on combining information. This perspective on teaching and learning is in line with the perspective on teaching and learning provided by variation theory.

Variation theory and its central concepts in a learning study

Variation theory presumes that individuals understand phenomena from their own perspective and that learning takes place when the way of understanding a phenomenon, or a so-called Object of Learning, has changed (Lo, 2012). For this learning to occur, some aspects of the Object of Learning must vary while other aspects remain constant (Marton, 2015). If a learner understands an Object of Learning in terms of its critical aspects, a learner has gained relational understanding of the Object of Learning (Marton, 2015). To make this more concrete, the following three elements of variation theory are critical in a learning study (Lai & Lo-Fu, 2013; Lo, 2012; Marton, 2015):

First, learning is always directed at something: the Object of Learning (OL). Unlike a learning objective, an OL not only tells what to learn, but also how to get there. This is therefore the key distinction between an OL and a learning objective: the OL includes the aspects that need to be considered, to create the possibility for learners to identify what is important (or: critical) and what is not, depending on their existing knowledge.

Second: investigate your students' (mis)conceptions, as these play a key role in determining the final OL and the critical aspects to address. For instance, if a student believes that in equation $y = ax + b$ the slope is equal to a, and in $y = d + cx$ the slope is equal to d, this suggests a misconception: the student likely assumes that the first term of the formula always represents the slope. However, in linear equations, the order of terms is not critical for identifying the slope; what *is* critical, is the coefficient of the independent variable.

Third: use patterns of variation in teaching, based on critical aspects derived from the misconceptions of students. For instance, related to the example above, by varying the order of terms and leaving all

other aspects of the equation invariant, students can discern themselves what is critical and what is not, in connecting the slope to the numbers in the equation.

Methods

The PSTs that participated in the learning study course were in their fourth and last year of pre-service mathematics teacher education for lower secondary at NHLStenden Hogeschool, University of Applied Sciences, in the Netherlands. Two teacher educators (TEs) taught the course, one of them in a dual role as TE and first author of this paper. Twelve PSTs participated in the course (four groups of each three PSTs). All meetings were class meetings, until the implementation of the research lesson - from that moment on, the TE met with each group seperately (each TE supervised two groups). The course lasted from September 2022 – May 2023. The course meetings took place every two or three weeks, during one morning, and lasted two to three hours. During the rest of the week, the PSTs were in their school-based practicum, in which they conducted the research lessons as part of the learning study course.

In this study, we gathered data from one group of PSTs (ages 21-24).They all taught in Grade 7 (first grade of Pre-vocational Secondary Education). The PSTs had no experience in applying variation theory, nor with doing research. The implementation of the course is presented in Figure 1.

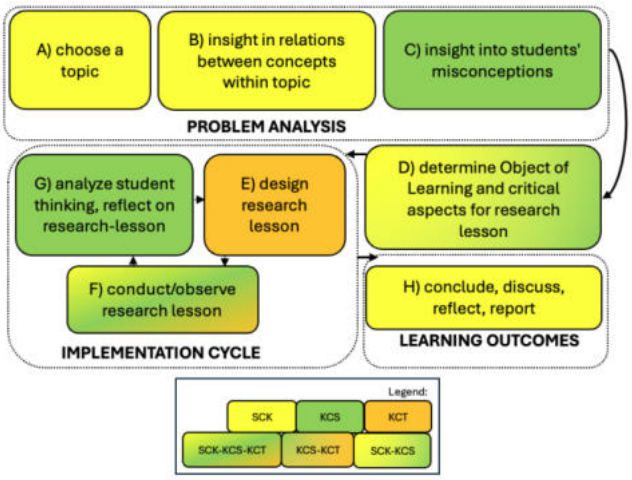

Figure 1: Implementation of the learning study course, September 2022 – May 2023

Figure 1 outlines the different phases of the learning study course and illustrates how the associated activities are connected to the knowledge domains identified by Ball et al. (2008), represented by different colours. The phase of the Problem Analysis takes seven meetings, from September to January. During this phase, PSTs choose a topic and design a concept map, with critical aspects, connections, structures, using the notions of relational and instrumental understanding (to get from A to B, in Figure 1). Then they design a pre-test. For each pre-test task, the guiding question is: "What do you know about students' understanding of the Object of Learning when completing the task?" Pre-tests are iteratively revised, based on feedback from peers and TEs, to address this question. Once approved by the TEs, PSTs administer the final pre-test during their teaching practice and subsequently analyze the results (from B to C, in Figure 1).

The instructional strategies employed were mainly presenting examples and non-examples (of concept-maps, of pre-test questions, of research lessons). This way the PSTs could identify the criteria of a good concept map, pre-test question, or research lesson. For instance, the NON-EXAMPLE of a pre-test question in Figure 2 does not give information on possible misconceptions: a right answer for a) does not give enough information on the learners' conceptions of negative numbers, and a right answer for b) does not give information on why a student thinks -5 is smaller than 6. However, the EXAMPLE does give a lot of information on misconceptions, which also incorporates decimal numbers and well chosen whole numbers.

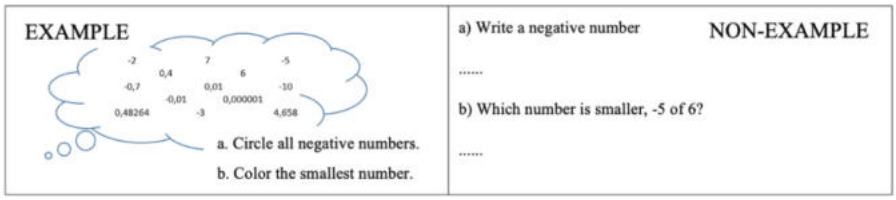

Figure 2: Example and non-example of a pre-test question

During the implementation phase, which takes six meetings from February - May, PSTs design a research lesson, focusing on OL and critical aspects, with use of targeted variation. They reflect on teaching and observing with the TE after each cycle of implementation. The TE provides resources to enhance the research lesson if necessary; each PST conducts the research lesson.

We gathered PSTs' written material during the learning study process: (revised) pre-tests (with justifications), analysis of results of implemented pre-tests, choice of OL with critical aspects, (revised) lesson plans (with justifications), their final report. In our analysis, we focused on the development of the pre-test and the research lesson. From the perspective of variation theory, we examined the extent to which the OL and critical aspects were addressed. Following Kullberg et al. (2024), we examined which (critical) aspects of the OL were made possible for students to discern (and which were not), and we connected this to the respective domains of mathematical knowledge for teaching. For instance, if PSTs designed a pre-test task to identify a specific misconception, but in the analysis, they found a different misconception they had not predicted - yet they understood its origin - their KCS improved.

Results

We present a few examples from the pre-test and the research lesson.

Choice and development of Object of Learning and pre-test by the PSTs

The pupils just got acquainted with representations of linear relationships, during the first weeks of Grade 7, without a focus on 'translation skills' from one representation (situation, formula, graph or table) to another. Therefore, the PSTs chose *linear relationships* as their temporary OL, and focused on translation skills, by tasks like the one from the first version of the pre-test in figure 3.

1. To the formula $m = 3n + 5$, Klaas makes the table below:

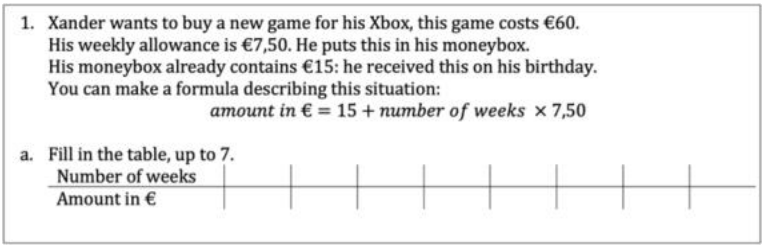
m	0	1	2	3	4	5
n	0	8	13	18	23	28

a) Mention two things that are not right about Klaas' table.

Figure 3: Task from pre-test version 1

PSTs' justification of this task was that they were curious whether students would see that m and n were interchanged, in the table; that 5 and 3 were interchanged, and that $(0,0)$ was incorrect. They did not justify why they wanted students to mention two incorrect things.

Peers and supervisor provided feedback, such as that too many answers were possible (for instance, $(0,0)$ and $(2,13)$ are not right), but that all these answers do not give enough information on whether the students would make the kind of mistakes the PSTs were looking for. Based on feedback, the team changed their pre-test-task; see figure 4.



1. Xander wants to buy a new game for his Xbox, this game costs €60.
His weekly allowance is €7,50. He puts this in his moneybox.
His moneybox already contains €15: he received this on his birthday.
You can make a formula describing this situation:

$$amount\ in\ € = 15 + number\ of\ weeks \times 7{,}50$$

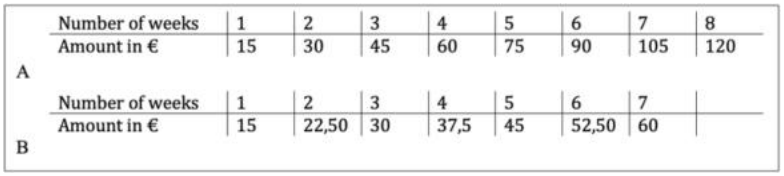
a. Fill in the table, up to 7.

Number of weeks							
Amount in €							

Figure 4: Task from final pre-test

PSTs justified these changes by explaining they wanted to see what kind of mistakes students make themselves, instead of having students guess what kind of mistakes are made by someone else, as in Figure 3.

The PSTs implemented the pre-test in their classes. Although some students gave a correct answer, there were also mistakes. In Figure 5, two types of mistakes are presented:



A

Number of weeks	1	2	3	4	5	6	7	8
Amount in €	15	30	45	60	75	90	105	120

B

Number of weeks	1	2	3	4	5	6	7	
Amount in €	15	22,50	30	37,5	45	52,50	60	

Figure 5: Two different student-answers to the task of Figure 3

In their analysis, the PSTs noted that they had not anticipated students starting the table with week 1 rather than week 0. In retrospect, however, they considered this choice understandable - after all, why begin with zero weeks? They also observed that these responses began with an initial amount of €15. While this value is difficult to justify when applying the formula correctly, it appears more reasonable when considering the context, particularly in the case of Answer B. The PSTs came to realize that presenting both the context and the formula simultaneously made it more difficult to interpret students' reasoning. In the case of Answer A, they were unable to determine how the students arrived at their solution; they only observed that €15 was added for each week, and that €7.50 played no role in the table. They concluded: "Students do not yet have a sufficient understanding of the concepts of slope and y-intercept."

Their final OL was *the translation from formula to table*, with critical aspects that students should be able to recognize the dependent and the independent variable in both formula and table and recognize the slope and the y-intercept in both formula and table.

Analysis of the development of Object of Learning and pre-test

Looking at Figure 3, we see a task with the assignment "find the mistakes" in a table to a given formula. The task is focusing on "translation from formula to table", and the critical aspects addressed are to recognize the dependent and the independent variable in both formula and table, and to recognize that the number of the slope in the formula is used as the increase in the table. However, both aspects are simultaneously varied in the same task: the top-row in the table is labelled with the independent variable, and the bottom-row is labelled with the dependent variable; the increase of the numbers of the bottom-row of the table is related to the the y-intercept instead of the slope. Since both aspects are varied in the same task, it is hard to determine how students think, from analyzing their answers; furthermore, yet another mistake ($(0,0)$ is incorrect) is included, without an explanation how this reflects a critical aspect.

In Figure 4, the final pre-test task, some aspects are changed:

- a context and a formula are presented, instead of just a formula;
- the labels of the rows are kept invariant, instead of interchanged;
- students have to fill in the values in the table themselves, instead of deciding about the way someone else thought: no focus on a critical aspect here, but still a possibility to show how you think.

Based on the answers as presented in Figure 5, the PSTs could detect whether students choose the right number for the increase of money per week - and they detected that students start a table with 1, and not with 0 - which made them think about whether writing 0 in a table is critical, or not. This reflection can be identified as SCK. The analysis of their students' thinking shows an increase of KCS, and from the arguments for re-designing the pre-test task, we identify KCT.

Research lesson task developed by the PSTs

In the opening of the research lesson, the PST put a task on the board, as presented in Figure 6. The class was divided in teams of four students each, and they had to answer the question: *Which table belongs to the formula of the taxi costs?*

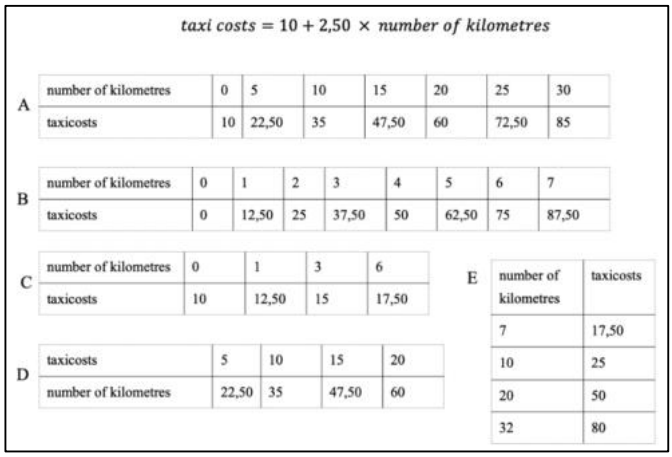


Figure 6: Opening task from research lesson

Based on the observations in the classroom, the PSTs noticed that students did not examine the remaining tables once they had identified the correct one. As a result, they failed to recognize the errors in the other tables. When prompted, students thought table E was incorrect, solely because it was vertically oriented. To address this issue, the assignment *"Find the misconception in the other tables"* was added in the subsequent lessons.

Analysis of the research lesson task

As mentioned before: the OL was "the translation from formula to table", with critical aspects: 1) students should be able to recognize the dependent and the independent variable in both formula and table, and 2) students should be able to recognize the slope and the y-intercept in both formula and table.

In this task, several aspects of the OL are varied simultaneously: the labelling of the rows (table D), the attention to the step-size (tables A,C and E), the value of slope and of y-intercept (tables B and E). The orientation of the table was also varied. The critical aspects were addressed in different ways - at the same time numerous other aspects were dealt with, both critical and non-critical.

By incorporating various possible misconceptions into the task, and by making incremental adjustments to the task during successive implementations of the research lesson - with the aim of encouraging students to reflect on these misconceptions - PSTs demonstrated both KCS and KCT.

Discussion and conclusion

We presented results of the written materials of one team of PSTs. From this, we see some development in mathematical knowledge for teaching in the problem analysis phase of the learning study course, and during the implementation phase. This is in line with the findings of Lai and Lo-Fu (2013), who found that the phases of the learning study in which student thinking is central, are successful in fostering mathematical knowledge for teaching. However, the design of task in the research lesson is not tightly aligned with OL and critical aspects chosen. Is this due to a lack of experience in applying variation theory ("It takes time to come to understand the aspects of variation theory and how those aspects are related" (Royea & Nicol, 2019, p. 14)), or to the inherent complexity of variation theory itself, or to the structure of the learning study course? This study does not provide enough information to answer the questions stated above, since it has significant limitations: the analysis is based solely on written materials from just one group. Incorporating qualitative data, such as interviews with the PSTs, could have offered a richer understanding of their learning experiences. Analyzing similar data from other groups in the course could also have provided a deeper understanding of the learning outcomes. Although this study is therefore limited in scope, we aim to answer the research question based on the data available to us: In what way is applying variation theory in a learning study related to fostering pre-service teachers' mathematical knowledge for teaching? We can conclude that applying the first two elements of variation theory (determining the OL, and finding misconceptions to decide on critical aspects of the OL) is related to fostering mathematical knowledge for teaching in analyzing student answers (KCS), reflecting on student answers (SCK) and reflecting on the design of the task (KCT). The third element of variation theory (using targeted variation in the research lesson, focused on the OL and its critical aspects) is partly

related to the KCS that was fostered as a result of analyzing student answers. To provide explanations for this, we require additional data and a more in-depth study.

Reconsidering textbooks as representations of current didactic paradigms in lesson study

Textbooks are important resources for mathematics education in many educational institutions. They also play a crucial role in LS in the kyozai kenkyu phase. We introduce the notion of the current didactic paradigm to analyze how textbooks represent the prevailing modes of study in institutions. We particularize this analysis in the case of the introduction of multiplication in Primary Education in Japan and Spain. We discuss how textbooks propose different approaches based on distinct epistemological models, pursuing different didactic aims, and based on diverse didactic means. We conclude by hypothesizing how LS transformative potential might be enhanced by the incorporation of textbooks that represent alternative paradigms in the kyozai kenkyu phase.

Keywords: lesson study, kyozai kenkyu, textbooks, didactic paradigms.

Introduction

Twenty-five years after the publication of Stigler & Hiebert's (1999) book, there is a vast body of research that shows how teacher educators and researchers have promoted LS in many countries around the world, together with several attempts to theorise it. This resulted in a complex scenario in which different LS models coexist. To clarify the situation, Seleznyov (2018) summarised what are the seven critical components of LS when it is more closely connected to the Japanese tradition, with *kyozai kenkyu* as one of them. *Kyozai kenkyu* is understood as the "planning" part of LS (Kim et al., 2021). However, it is much more than just the planning of the lesson. In *kyozai kenkyu, the* teachers "investigate all aspects of the content and instructional materials in the context of how students think about and understand the concepts they are going to learn" (Takahashi et al., 2005, p. 101). The process "involves examining teaching materials and tasks from mathematical and educational points of view as well as from the students' point of view" (Fujii, 2015, p. 278).

The importance of *kyozai kenkyu*, as a deep-rooted collaborative practice of the teaching profession (Shinno & Mizoguchi, 2021), is not always recognised beyond Japan (Choy & Lee, 2020; Fujii, 2015). Existing research does not always document it accurately (Seleznyov, 2018).

Although the teaching materials considered in *kyozai kenkyu* are not restricted to textbooks, they play a prominent role as primary resources for teaching in Japan (Shinno & Mizoguchi, 2021; Watanabe et al., 2008). These textbooks, which are carefully designed, represent an interpretation of the current curriculum: presenting tasks and problems for studying content using different instructional tools, suggesting paces across different contents, emphasising how the current topic relates to what came before and will come later, and giving a rationale for the selection of a particular material or tool (Watanabe et al., 2008).

Textbooks may be an advantageous gateway to understanding and comparing different cultures. In turn, they may contribute to a deeper understanding of *kyozai kenkyu* and to better support teachers

outside Japan, considering their cultural context. In addition, an enhanced understanding of textbooks might inform new ways of supporting teachers during *kyozai kenkyu* by incorporating and comparing Japanese textbooks with those in their local context.

In view of the above, the first aim of this paper is to introduce some theoretical tools from the Anthropological Theory of the Didactics (ATD), arguing how these could be helpful to uncover "cultural specificities". Then, to narrow the scope, we focused on a particular topic (multiplication of whole numbers in Primary School) and on Spanish and Japanese textbooks. By analyzing how this topic is introduced in each textbook, we aim to uncover some essential features of the existing culture in each country. We will end by briefly discussing how *kyozai kenkyu* mediated by these textbooks might be different in each country. Thus, we aim to contribute to discussions on knowledge creation in collaborative settings and how research informs the analysis of such settings, in coherence with domains 3 and 9 of the TWG28.

Theoretical framework and methods

Let us consider a school institution I and an ill-defined field $\mathcal{F}$ of mathematics to be taught in I. The notion of the *current didactic paradigm* in I related to $\mathcal{F}$ ($CDP_I(\mathcal{F})$) was proposed by Gascón and Nicolás (2022) as a model of how mathematics education around $\mathcal{F}$ is interpreted in I. A didactic paradigm is taken as a functional unit composed of four components: (1) a current epistemological model of $\mathcal{F}$, (2) the didactic ends pursued by I about the learning of $\mathcal{F}$, (3) the didactic means considered in I to achieve these ends, and (4) the didactic phenomena that the epistemological model unravels and to which the paradigm, globally considered, offers an alternative answer.

To perform the didactic analysis of the $CDP_I(\mathcal{F})$, it is assumed, as a fundamental hypothesis, that the researcher must adopt an explicit "point of view". This is embodied in the notion of *the reference didactic paradigm* (RDP), which expands the former notion of the reference epistemological model (Gascón, 2014). It is a fundamental instrument for researchers' emancipation from institutional dynamics that can be taken for granted, hindering the identification of didactic phenomena. Following the above-mentioned structure, a $RDP_I(\mathcal{F})$ should always be interpreted as a scientific hypothesis (Gascón & Nicolás, 2022). It is a tool for researchers to uncover undesired didactic phenomena linked to the current didactic paradigm in I, conjecturing that a study process ruled by the $RDP_I(\mathcal{F})$ might reduce or even avoid them.

Methodologically, to analyse the $CDP_I(\mathcal{F})$, the first step is the construction of a hypothetical $RDP_I(\mathcal{F})$, adopting thus an explicit position about a possible way of studying $\mathcal{F}$ in I. Then, the researchers take into consideration different sources that might give them access to relevant features of the $CDP_I(\mathcal{F})$, interpreted always from the perspective of the $RDP_I(\mathcal{F})$. Textbooks, as mediators between the intended and the implemented curriculum, offer a privileged entry to the analysis of the $CDP_I(\mathcal{F})$.

To narrow the scope of this paper, we focus on how multiplication is presented to pupils in Spanish and Japanese textbooks. First, we will outline the key features of a possible reference didactic paradigm to be used. Then, we will consider excerpts from two textbooks and conduct a qualitative analysis based on the basic components of a didactic paradigm, seeking to identify distinctive features of the current didactic paradigm in each country. Finally, we discuss how this might critically affect *kyozai kenkyu* in each country and LS as a whole. By doing this, we attempt to address the question: how cultural assumptions embodied in textbooks affect *kyozai kenkyu* in LS?

Components of a reference didactic paradigm of multiplication in Primary Education

In this section, we outline some fundamental features of a possible RDP that includes the multiplication of natural numbers in the Primary Education (PE) institution. Methodologically, we considered different sources for constructing a RDP (Gascón & Nicolás, 2022), which we also describe. Provisionally, we interpret multiplication within a broader field that includes what is commonly known as "arithmetic" in PE. We use the symbol $\mathcal{Q}$ to denote this blurry conglomerate of praxeological components, which we assume is not clearly determined in advance. From the perspective we adopt here, arithmetic is not limited to the study of numbers, operations, and their properties, but it should be integrated within the study of discrete and continuous magnitudes and measurements (Chambris, 2022; Chevallard & Bosch, 2001). Besides, the RDP needs to be compatible with a global disciplinary paradigm about the study of mathematics assumed by the researchers. In conjunction with the position of the ATD, we globally assume the mathematical modelling paradigm (Gascón, 2014), which postulates that any mathematical activity can be interpreted as the construction of mathematical models of intra- or extra-mathematical systems.

Thus, the reference didactic model $RDP_{PE}(\mathcal{Q})$ proposes that the genesis of school arithmetic is embedded in the universe of magnitudes and measures. School arithmetic is initially based on the study of extra mathematical systems of physical objects with measurable qualities (like quantity, length, area, volume, mass, etc.). This does not mean that school arithmetic is necessarily restricted to the study of these systems. The recursive nature of the system-model relationship postulated by the ATD would lead to a progressive distancing from them, to consider intermediate systems of more formal objects (like systems made of symbols that evoke the physical objects) and even the study of pure arithmetic systems (such as the system of prime numbers, or of the divisors of a number). The main didactic end promoted by the $RDP_{EP}(\mathcal{Q})$ is precisely to engage students in authentic modelling processes. This way, the genesis of arithmetic objects in schools will be linked to questions that arise from the study of these systems, like how to compare objects in terms of a certain measurable quantity, how to communicate to others about measurable qualities in objects, how to make this communication effective, and how to express measurable qualities of objects that are created from a certain combination of others.

In terms of didactic phenomena, our $RDP_{EP}(\mathcal{Q})$ emerges as a reaction to didactic phenomena in current educational systems already described in research, like the progressive degeneration of mathematical practices around magnitudes and measures, which isolates arithmetic from magnitudes, forgetting the role of magnitudes in the construction of arithmetical objects and weakening their rationale (Chambris, 2022). According to Chevallard & Bosch (2001), in school arithmetic, the study of magnitudes and measurement processes tend to fade away. The mathematical work prioritises the study of arithmetical objects on their own, at the risk of compromising their meaning.

The introduction of multiplication in Spanish and Japanese textbooks

In Spain, we will consider a grade 2 (7-8 years old) textbook[1] (other textbooks and grades have also been revised). As shown in Figure 1, multiplication is introduced in the context of the measurement

[1] Fraile, J., & Pineda, A. (2023). *Matemáticas 2 Primaria* [Mathematics 2 Primary]. *Proyecto abanico*. Vicens Vives.

(quantification) of collections of objects arranged in equal size subgroups. The underlying problem is how to determine and express the measure of the whole. Multiplication is presented as a model of the sum of equal addends, as shown in Figure 1. Thus, it is linked to the additive meaning of the composition of measures (Vergnaud, 1982).

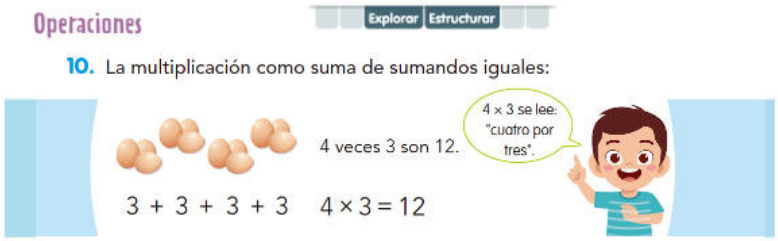

Figure 1. Introduction to multiplication in a Spanish grade 2 textbook (p. 214)

This meaning is reinforced later (Figure 2) through different exercises in which collections similar to the one in Figure 1 are displayed, chains of sums are presented, and pupils are asked to express this situation using the "new" operation. Multiplication appears as a new operation useful for representing (model) already known situations. In fact, it is nothing else but a new expression of an old meaning.

Figure 2. Introduction to multiplication in a Spanish grade 2 textbook (p. 214)

In Japan, the introduction of multiplication is widely described in the literature (Hino & Kato, 2019; Isoda & Olfos, 2021). At first sight, the Japanese grade 2 book we are considering[2] resembles the Spanish one. The introduction of multiplication is also based on the measurement of collections structured in subcollections of equal size (Figure 3). However, now, pupils are asked to explore these systems without any reference to addition. In fact, the focus is on the structure of the system, giving rise to verbal models that express such structure (Figure 3, right-hand side). In the absence of new techniques, pupils are expected to obtain the total measure of the given collections by counting.

Multiplication is presented as a new operation that models new situations: the total measure of a discrete system formed by groups of equal size (Figure 4, left-hand side and middle). Discursive models, called "math sentences", are introduced, and the students' activities are focused on the writing of sentences following this model (Figure 4).

[2] Fujii, T., & Majima, H. (2020). *New Mathematics 2B for Elementary School*. Tokyo Shoseki.

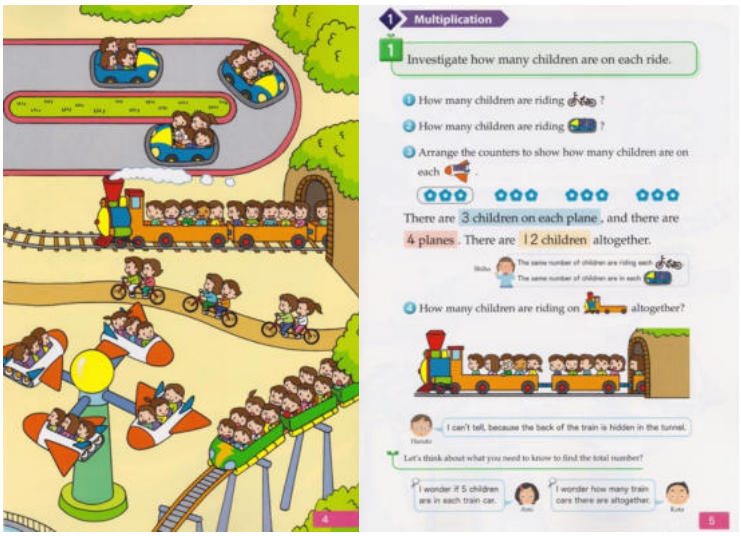

Figure 3. Introduction to multiplication in a Japanese grade 2 textbook (p. 4-5)

From a mathematical perspective, pupils are faced with the measurement of collections considering different kinds of units (for instance, pupils and planes), considering the relation that exist between them (3 children on each plane). As Hino & Kato (2019, p. 129) explain: "the meaning of multiplication of whole numbers, decimals, and fractions is represented as B × P = A, where B is the base quantity, P is the relative value, and A is the corresponding quantity that has the specified relative size with respect to B".

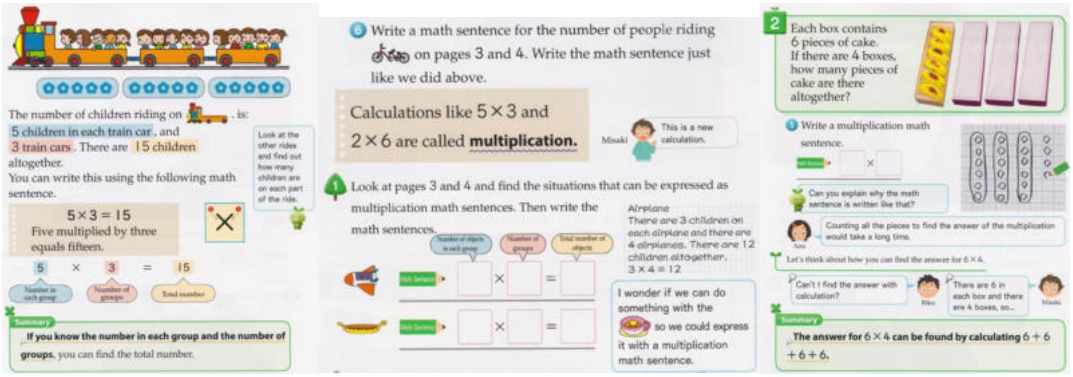

Figure 4. Multiplication in a Japanese grade 2 textbook (Fujii & Majima, 2020, p. 7, 8 and 10)

Only when this meaning has been established do the pupils think of strategies other than counting to determine the total measure of the collections, considering that counting would take a long time. Thus, addition appears as a more effective strategy to obtain the measure of the given collections but never as the meaning of multiplication (Figure 4, right-hand side).

Analysis and discussion

The Spanish and Japanese textbooks introduce multiplication in the context of systems of discrete collections of objects, arranged in subcollections of equal size, and the problem of how to find their measure. From this, each textbook follows a very different path, which we interpret here considering the components of two essentially different current didactic paradigms: $CDP_{SP}(\mathcal{A})$ and $CDP_{JP}(\mathcal{A})$.

From the perspective of the underlying epistemological model, in the $CDP_{SP}(\mathfrak{Q})$ multiplication is reduced to addition in the sense of the composition of measures (Vergnaud, 1982). Presented as a new operation, it is nothing but a new expression for "old" situations. In contrast, in the $CDP_{JP}(\mathfrak{Q})$ multiplication is introduced in the sense of isomorphism of measures (Vergnaud, 1983), as a new meaning that cannot be reduced to previous meanings. In both cases, discrete magnitudes (collections) are presented. However, in the Spanish case, these mainly play a decorative role. Multiplication, as repeated addition, could be introduced without any reference to them and, in fact, it is more than likely that the collections play a marginal role in classroom work, deepening the separation between numbers and magnitudes (Chambris, 2022). In the Japanese case, using collections is crucial. Numbers do not represent only measures, but also the function operator (e.g., in Figure 4, "5" means, at the same time, "5 children" and "5 children in each train car"). This new meaning needs to be introduced and understood. It is modelled discursively by the math sentence "number of objects in each group".

The previous relates to the didactic ends of each paradigm. In the $CDP_{SP}(\mathfrak{Q})$, we interpret that the end is to keep children very close to their previous knowledge of addition, avoiding an epistemological break. Thus, the focus is on the translation between new expressions of the form $a \times b$ and old expressions such as $b + \cdots + b$. Thus, it is not surprising that a short and direct introduction, followed by examples, is sufficient. On the contrary, the $CDP_{JP}(\mathfrak{Q})$ pursues students' entry into a new world, which implies thinking differently about quantities and, in particular, considering relations between them. Although the situations presented in the textbook resemble old ones, the mathematical activities around them are new. This explains, at least to some extent, why textbook authors need 6 pages to familiarize pupils with multiplication, as well as the emphasis placed on the "math sentences" as intermediate models. In terms of further aims, in the Spanish case, multiplication as repeated addition is a direct and cost-effective way of introducing it. However, in the middle term, this will provoke epistemological issues when continuous magnitudes and proportionality are introduced. In contrast, the Japanese approach is more demanding but better suited to further developments, in line with the "extension and integration" principle (Isoda & Olfos, 2021).

A full analysis of the didactic means within each didactic paradigm is not possible here. However, we see how, in the $CDP_{SP}(\mathfrak{Q})$, the direct introduction of multiplication through an example plus similar exercises seems to be sufficient. We interpret this in the context of a disciplinary current didactic paradigm strongly based on "show and tell" methodologies. In Japan, we identify features of the *structured problem-solving* paradigm (Stigler & Hiebert, 1999). The book proposes different situations that resemble open-closed ones. It is expected that they will use their previous knowledge (like counting, addition or whatever) and engage in collective discussion and evaluation of their strategies before a final strategy is declared (Figure 4, right-hand side). Nonetheless, what the book proposes needs to be reconsidered from the perspective of "using the textbook to teach" instead of "teaching the textbook" (Shinno & Mizoguchi, 2021). The latter is more common in countries like Spain, whereas the former directly connects with LS practices in Japan.

Conclusions

Our analysis, although brief, points out essential differences in the $CDP_{SP}(\mathfrak{Q})$ and $CDP_{JP}(\mathfrak{Q})$ from the perspective of the $RDP_{PE}(\mathfrak{Q})$. Will this impact LS processes?

In the case of Japan, Isoda & Olfos (2021) described two LS experiences regarding multiplication carried out under the conditions of the $CDP_{JP}(\mathcal{Q})$. In both cases, the research lessons were created around the idea of working directly with collections (sweets in a box and dots, respectively), finding equal-sized groups, and expressing the total amount of objects in terms of those groups. The students were asked to think about different ways of grouping objects, how to express these groupings, and how to obtain the total amount. Different approaches were used to achieve understanding through discussion. In short, we consider that the essential features of the $CDP_{JP}(\mathcal{Q})$ followed by the textbook have been maintained through the *kyozai kenkyu* process, which has led to the design of these lessons.

What could happen if a group of Spanish teachers engage in *kyozai kenkyu* from the perspective of a Spanish textbook? We do not know for sure, but it is more than likely that the fundamental features of the $CDP_{SP}(\mathcal{Q})$ are barely questioned, thus limiting the transformative power of LS. That is, LS will reinforce or, at most, refine the relation between teachers and $CDP_{SP}(\mathcal{Q})$. This phenomenon may not be unique to the Spanish case. In the Japanese case, we wonder if LS also leads to an improved relationship between teachers and the $CDP_{JP}(\mathcal{Q})$, but it does not really challenge it.

On the other hand, what could have happened if in *kyozai kenkyu* the teachers engaged in a deep analysis of materials (textbooks, in particular) that followed didactic paradigms that offered alternative perspectives? We hypothesise that it would enhance the transformative power of LS, making it possible to question how mathematics education (around the topic under consideration) is organised within their institution. We plan in exploring this line of research in future work.

In this paper, we aim to understand how an experienced teacher, Vanda, who had already participated in two LS, has an initial experience as a lesson study facilitator. She was challenged to facilitate LS by a more experienced facilitator, who was alongside with her all the LS sessions. The two facilitators worked collaboratively to prepare the LS. Data collection included participant observation, with audio recordings of the preparation and LS sessions, and audio recordings of semi-structured interviews before and after the LS and included document collection. The results show how the dimensions of resources, orientations, goals and identity (ROGI framework) interplay in framing Vanda's concerns and practices as a novice facilitator.

Keywords: Novice facilitator, lesson study, professional development.

Introduction

Lesson study (LS) is a collaborative professional development (PD) process aimed at enhancing student learning through planning, teaching, observing, and reflecting on a research lesson. In Japan, a 'knowledgeable other' is invited as an external expert to provide extensive feedback especially at the end of research lessons (Hourigan & Leavy, 2021). In contrast, in Western LS there is often a facilitator who organizes and leads the process (Hourigan & Leavy, 2021), balancing expertise, teaching, and guidance, while allowing teachers to express their questions and collaboratively build knowledge (Mynott & Michel, 2022). The fact that "teachers drive the agenda and co-design the learning opportunities in real time" (Lewis, 2016, p. 538) means that many aspects of the LS sessions cannot be script in advance by the facilitator. So, preparing and facilitating the LS sessions is complex (Lewis, 2016; Mynott & Michel, 2022). It requires facilitators to understand the many facets of school life and teaching, to have knowledge about LS, content and pedagogy for collaborative and sustained teacher learning (Akiba et al., 2019; Hourigan & Leavy, 2021; Lewis, 2016). Thus, it is very important to know how such facilitators can be prepared.

Framework

Facilitators of PD for mathematics teachers play a pivotal role in strengthening teachers' professional expertise and in bringing educational innovations into schools (Karsenty et al., 2023). They are responsible for managing PD activities, setting norms, promoting teacher collaboration, and guiding discussions. To be effective, facilitators require adequate preparation and ongoing support, as their effectiveness improves with experience (Karsenty et al., 2023; Lewis, 2016). Considering that it is important to focus on enhancing the facilitator' decision-making abilities, which develop over time, Karsenty et al. (2023) developed the ROGI framework with four components: resources (R) involves intellectual, material, contextual, and social tools available to facilitators, highlighting the

significance of content knowledge and pedagogical content knowledge for effective facilitation; orientations (O) refers to the facilitators' beliefs and values about teaching and learning; goals (G) includes both explicit and implicit purposes for PD, such as content, process, and environment goals; and identities (I) defined as how facilitators perceive their roles within a given context.

In LS, as a collaborative PD process where teachers work together to plan, teach, observe, and reflect on lessons, the facilitator's role is even more complex. LS facilitators are expected to navigate the dynamic and often unpredictable nature of LS sessions, support teachers in real-time co-design of learning experiences, and foster a collaborative environment where teachers feel comfortable sharing ideas and reflecting (Akiba et al., 2019; Lewis, 2016). Mynott and Michel (2022) highlight the often "invisible" nature of LS facilitation, pointing the importance of the facilitator being able to subtly guide the process without dominating it. This requires facilitators to have not only content and pedagogical knowledge but also the ability to manage group dynamics, support reflective practice, and adapt to the emergent needs of the group and to the often-unpredictable nature of LS sessions (Lewis, 2016; Mynott & Michel, 2022). Additionally, novice facilitators must model effective teaching practices while simultaneously learning from the process (Hourigan & Leavy, 2021).

Akiba et al. (2019) and Clivaz et al. (2023) emphasize the importance of facilitators to engage in continuous learning and reflection to improve their practice. Mynott and Michel (2022) argue that the "invisible" work of facilitation requires ongoing learning and support, particularly for those new to the role. This aligns with the idea that facilitators often develop their expertise through a combination of formal training or collaboration with more experienced facilitators, and on-the-job experience, where they can experiment with different facilitation strategies and learn from their experiences (Clivaz et al., 2023; Hourigan & Leavy, 2021; Lewis, 2016). Therefore, understanding how facilitators develop the skills and knowledge to effectively lead LS and focusing on the evolving practice and learning of novice facilitators is essential. So, our research question is: How does an experienced teacher navigate her initial experience as a lesson study facilitator?

Methods

This research is qualitative and interpretive, with a case study design of a novice LS facilitator, Vanda (pseudonym) who had already participated in two LS. She was challenged to facilitate LS by a more experienced facilitator (Paula), who was alongside with Vanda all the LS sessions. Preparing the LS sessions involved collaborative work of the two facilitators, both teachers with several years of mathematics teaching experience (grades 7-12), who had already planned lessons together. Vanda had previously participated in two LS facilitated by Paula. In the LS facilitated by Vanda, after the first session, preparation always started with Vanda reflecting on the previous session. Eight mathematics teachers volunteered to participate in the LS. All had more than twenty years of teaching experience, except for one first-time teacher, and all but two teachers had previously participated in same LS as Vanda. The teachers decided to plan lessons on the topic "functions", to grade 10 students.

Data collection included participant observation (in preparing for and during LS sessions), with audio recordings of the preparation sessions (PS1, PS2, …), and of the semi-structured interviews before (II) and after the LS (FI). We focus on Vanda's concerns because they shaped her actions and reflections during LS preparation and interviews, particularly in clarifying the LS process, leading

whole-class discussions, and her transition from an experienced teacher to a novice facilitator.

Table 1: Categories and subcategories considered in data analysis

Category	Subcategory	Indicators
Resources	Knowledge about and for the LS process	Refers to previous LS; uses Paula as a support to consolidate/validate a particular issue/idea
	Knowledge about the teaching approach	Refers to the different kinds of tasks; the structure of the lesson; the whole-class discussion; the dynamics of the lesson
	Material resources	Proposes training tasks; shares tasks for the classroom
	Social resources	Acknowledges the support and sharing among participants (collaboration) as fundamental to their learning
Orientations	Facilitator orientation for teacher learning	Promotes situations that she considers as important for teachers' learning; identifies/remembers episodes of practice that contribute to teachers' PD; makes decisions about the content from previous teachers' interventions
	Teacher orientation for student learning	Proposes orientations/resources/dynamics/examples that contribute to students' learning; values a particular teaching approach
Goals	Content goals	Identifies important aspects for teacher learning
	LS process goals	Makes decisions to support teachers learning about the LS process
Identity	The way she sees herself	Recognises/positions herself as a teacher or/and as a facilitator
	How others see him/her	She is recognised as a teacher or/and as a facilitator

Based on Vanda's concerns, and as we focused on her role as LS facilitator, to analyse her processes of decision-making we adjusted the components of ROGI framework (Karsenty et al., 2023) using a deductive and inductive coding process (Table 1): to resources we added knowledge mobilized regarding and for LS as well as knowledge mobilized about the exploratory teaching approach; in orientations we considered the facilitator's guidance for teacher learning, which encompasses ideas/conceptions about how teachers learn (the interplay with practice, discussions/reflections with the construction of ideas, "teachers learn by engaging in practice"), along with the teacher's orientations for student learning; in goals, we considered the goals for the LS process, namely the facilitator's decisions for teachers to learn about the LS process; and in identities we considered the data referring to how the facilitator perceives herself, both as a teacher and a LS facilitator.

Results

Clarifying the LS process

In the initial interview, Vanda spoke about her experience as a LS participant and expressed her concern in clarifying what work would be done at each stage of the LS so that all participants got a clear idea of the process (goals).

> Vanda: I think we must present the concept of LS, don't we? And for everyone to reflect on what they think... Either those who have already been [in LS] or those who are new to it (II).

To address this concern, Paula asked her about what resources they could use, when preparing session 1, immediately after the interview. Vanda suggested using a form that the teachers could fill in with questions about LS, based on their previous experience as LS participants. Paula questioned whether, before this form, it would be important for the teachers to read a policy brief which she shared with Vanda before the LS. After some discussion, Vanda suggested using the form as a resource for participants to record their ideas about LS after the session. To "present the concept of LS" (PS_1), she suggested asking the participants to read the document before the session and to adapt presentation (ppt) they used to share their work on another LS (material resources).

> Vanda: To share this [policy brief] for them to read before the session... In the LS session, presenting the [LS] diagram... We can give some examples, or don't you think so? Maybe not, because we are going give them answers, aren't we?... [We could] ask people who have experienced LS… What they would do differently or what they would do the same? … In our planning, we write "steps on the diagram… To be completed collectively", that's it. This way we can understand if everyone, at least, identifies the LS stages correctly... (PS_1)

Vanda facilitated the session as planned. Although not all participants did the suggested reading, they all shared their ideas, mainly those who had participated in LS before, or asked questions, particularly the first-time teachers. Reflecting on how she facilitated session 1, Vanda acknowledged the collaboration among the participants as key to their learning (social resources), and emphasised their active role in the LS sessions, drawing an analogy with the work she does with her students (teacher orientation to student learning).

> Vanda: [As] there were people who had already been [to LS] who shared their ideas, those who had not, may have got a much better idea than the one shared by a facilitator... As with our students... They are much better at sharing with each other than we are, sometimes… It was in line with what I'd hoped would happen. (PS2)

Thus, drawing on her knowledge of LS and participants, and on the discussions with Paula (resources), Vanda selected different resources (material and social resources) and made several decisions about how to facilitate the session, aiming to clarifying the LS process for all participants. Emerging from her concern to clarify the goals for each session, Vanda suggested using a PowerPoint presentation with the LS stages to be completed in the session, based on participants' ideas, rather than presenting a pre-filled slide. In doing so, Vanda created situations she believed would be more valuable for participants' learning (facilitator's orientation for teacher learning).

To lead productive whole-class discussions

Referring to her teaching practice (the way she sees herself as a teacher), Vanda emphasised her

increased attention to students' solving strategies and representations, as well as to whole-class discussions, because of participating in LS:

> Vanda: The way I begun to see the kids' answers and allow them to share... My teaching practice changed a lot... I used to focus on a particular answer, and it would go on the board. Last year, I found myself wanting them to do it, to show it in a different way, and I began to see things that I had never really thought about... I think that the more we work in this format, so to speak, the more we can innovate... It is only by doing it that the teacher realizes whether it works or not. (II)

Reflecting on her previous LS experience, Vanda noted that the task they designed was too extensive and did not lead to much discussion, prompting participants to suggested that in future LS more attention should be paid to leading whole-class discussions. In the initial interview, Vanda emphasised that in the planning should be important consider time for the students' autonomous work while leaving time for them to "explain their reasoning, and I think this is also important... We want them to expose themselves and... Discuss the results in the lesson" (II).

Considering this, when preparing session 1, Paula shared with Vanda a video in which a teacher led a whole-class discussion, starting from a task that the students solved using different strategies. Vanda stressed the importance of recording in the session plan and discussing with the teachers "how do we... record and choose questions [solving strategies] for the discussion... 'How to select strategies for the whole-class discussion?'" (PS_1). In session 1, the teachers solved the proposed task, but they struggled to align the task with the curriculum, which limited the time for whole-class discussion. Reflecting in this session, Vanda stressed the importance of active student participation in lessons and leading the whole-class discussion: "One of the things that I think has to be a concern, really, is that in the lesson we are going to observe, the students must play an active role, and we have to see them debating ideas" (PS_2). From this concern, her teaching practice, and the way she sees herself as a teacher, Vanda, "very keen on 'seeing is believing, experiencing is knowing'", as she stated in the initial interview, suggested having the teachers play the role of students:

> Vanda: Getting them to work on the task and run the simulation... 'Kids [colleagues], we have a task for you. We present the task, ... 'You have *x* time to complete it.' We collect the answers, show them if needed for them to explain their ideas, and then we explain that this is what we are aiming for [in the research lesson]. (PS2)

In session 2, Vanda monitored the teacher's work on a task she proposed, and encouraged them to share their ideas, but she ended up explaining teacher's answers. Reflecting on this session, she identified the preparation to leading the whole-class discussion as a less successful aspect. She pointed to leading this moment of the lesson among peers and managing time as challenges:

> Vanda: What went wrong? Time management, on my part, as the 'leader'... We had so much planned... And we didn't do half of it... Perhaps there should have been more time for the colleagues to clearly explain how and why they did what they did... It's very difficult to simulate a teacher explaining to a teacher... When I look at my colleague's solving strategy, I'm following it, right? (PS3).

From this reflection, when planning session 3, Paula and Vanda discussed how to plan the whole-class discussion, based on the task they planned to propose. Initially, Vanda suggested a short discussion, similar to session 2, making more detailed planning for the research lesson. However, as leading whole-class discussions was a challenge pointed by Vanda and these participants in previous LS, Paula questioned whether preparing such discussion could be part of the planning process "Is it very different to do it with this task or another ...?" (PS3). She then suggested adding students' answers for teachers to analyse, select and sequence as a starting point for planning the whole-class

discussion. Vanda agreed that it was important for teachers to plan the whole-class discussion more thoroughly, analysing possible students' answers. She also emphasized the importance of teachers anticipating students' strategies and difficulties and using them to prepare the whole-class discussion. When facilitating session 3, Vanda monitored teachers' work, photographed their answers and displayed those that she considered interesting, giving teachers the opportunity to explain them, to ask questions about their colleagues' answers and to reflect on their teaching practice. There was also time for her to show on the board the students' answers, previously selected on PS3, prompting further discussions about selecting and sequencing students' answers and leading whole-class discussions.

Thus, Vanda identified leading whole-class discussion as a key aspect for teachers' learning (content goals), based on teachers' feedback from a prior LS (facilitator's orientation for teacher learning), and valuing it in her lessons (identity). She suggested leading whole-class discussions based on the teacher' work in tasks she proposed, as she values teacher learning through practice (orientations). Although she faced challenges in leading the discussion with the participants without dominating the discourse, Vanda drew on her pedagogical knowledge and discussions with Paula (resources), to lead discussions and create a safe environment for participants to share ideas, ask questions, and reflect on their teaching practice.

Becoming a LS facilitator being an experienced teacher

Referring to her view of herself as a facilitator (identity), in the initial interview, Vanda stated that during the teacher education process she led, the aim was to "teach [the teachers] how to use a specific software". She added that facilitating LS would be quite different, as it requires "being able to tailor what you are going to work on in each session to meet the participants' needs" (goals), emphasizing this as both a challenge for the facilitator and a valuable aspect of LS: "I don't think I have this... getting people to think, to go along with what you need, while also considering their needs... I don't have this role of facilitator." (II)

In her view, it would be important to collaboratively plan the sessions with Paula and to develop her knowledge about LS by reading articles (resources):

> Vanda: The one thing I know I'm really going to have to do is to be constantly... Working with you. Because I can't get there on my own. Will I have to read a lot? Yes... I'm going to have to read a lot about this. Maybe the reading that I didn't do initially [as a participant], I will have to do carefully. Because I think it's important, right? To share knowledge, one must be knowledgeable. (II)

Afterwards, Vanda read an article about LS carried out in Portugal. She also had other articles from a LS in which she participated. However, referring to herself as a facilitator (identity) in the first LS sessions, Vanda kept saying "I know how to teach kids, I don't know how to teach colleagues" (PS_3).

In the final interview, Vanda stated that she felt more like a colleague than a facilitator, pointing to planning and making the global organisation of the LS as challenging: "I feel like a colleague. Facilitator ... OK, I know how to hold a conversation, in quotes, with colleagues... Doing this work myself [e.g., planning the session] that you do so well, I don't feel I can do it."

Vanda emphasised the collaborative work with Paula as essential for preparing sessions (resources):

> Vanda: Our discussions before the sessions were essential, weren't they? I think that if they hadn't existed, it would have been very different... And it was thinking and finding

> strategies for getting round issues, problems, in other words, challenges, that the benefit lies... For me it was very rich... It wasn't just one person thinking about the session, was it? We were sharing ideas. (FI)

Although Vanda felt she could not prepare a LS session independently, she became comfortable drawing session plans in later sessions, emphasizing the collaborative work with Paula and having her available during the sessions (resources). She added that, even though she still had a lot to learn as a facilitator, working collaboratively on session preparation enhanced her learning as a LS facilitator:

> Vanda: [It was] very easy to do [facilitator's role] because you're always there… It went far beyond my expectations... I think I have a lot to learn, but I learnt a lot... I didn't even feel like a facilitator at first, did I? Clearly, the preparation we did in the last sessions had much more input from me than the earlier ones. (FI)

Vanda pointed out that LS facilitators "have to deal with too many unpredictable things" (final interview) and need to have in-depth knowledge about LS. She emphasized the importance of facilitators having prior experience as LS participants "to then be able to be on the other side" (final interview), and of learning from practice:

> Vanda: Training [facilitators] would maybe involve doing it [facilitating LS], wouldn't it? … Or having training, or someone working with the facilitator... I like 'doing it'... You have the training, and you get a working group at school, and you, at school, play this role... Planning, doing, planning, doing. I think it would be important, yes, for anyone who wants to become a LS facilitator. (FI)

In Vanda's perspective, facilitators learn through practice, either with teacher educators or other LS facilitators. She highlighted the importance of the "plan, do, plan, do" cycle, similar to the work carried out in the LS mentioned in this paper.

Thus, Vanda reflected on the preparations of the LS sessions and her identity as facilitator, noting the challenge of tailoring the sessions to participants' needs and emphasising the importance of collaborative planning and discussing with Paula (knowledge about and for the LS process). Initially she considered herself unprepared for planning sessions and for her role as facilitator, and by the final interview, she felt more prepared to handle the complexities of facilitating LS (identity), recognizing that each session's preparation offered an opportunity for her growth and learning as LS facilitator (knowledge about the LS process). She emphasized that LS facilitators need to have extensive knowledge of LS, prior experience as LS participants, and learn through practice.

Conclusion

The analysis of Vanda's initial experience as a LS facilitator illustrates the intricate balance of identity, orientation, goals, and resources in her journey from a novice to a more confident facilitator. Navigating the complexities of facilitating LS, she continuously sought to refine her practice, drawing on her experiences, and relying on both material and social resources, such as collaborative planning with Paula, that she pointed as essential in shaping her facilitation practice, and relevant literature. Although initially Vanda expressed uncertainty about facilitating the learning of colleagues, in contrast to her confidence in teaching students, her orientations, particularly her belief in teacher learning through practice and collaborative work, informed her decision to simulate classroom scenarios and encourage collaborative learning among teachers (as in Clivaz et al. (2023) and Akiba et al. (2019)). Key goals for Vanda were clarifying the LS process and enhance participants' knowledge, particularly in leading whole-class discussions. As she gained experience as a facilitator, she provided more time for teachers sharing their ideas and reflecting on their teaching practice. This reflects the complexities of assuming

the 'teacher of teachers' role (Hourigan & Leavy, 2021) and highlights the importance of aligning session goals with participants needs. Despite her initial uncertainties about her role as a facilitator and her ability to lead colleagues, through continuous reflection, collaborative planning with Paula, and practical experience, Vanda's identity as a facilitator evolved, shaped by her initial concerns and experiences and later by her growing confidence in leading LS sessions. By the final interview, she felt more confident in her ability to tailor LS sessions to participants' needs and acknowledged the importance of "doing" as central to her learning and growth as LS facilitator, as in Lewis (2016) and Hourigan and Leavy (2021). Vanda underscored the importance of extensive knowledge of LS, prior LS experience as a participant and the importance of continuous practice, reinforcing the "plan, do, plan, do" cycle as essential for growth as LS facilitator.

Vanda's reflection further enhanced her belief in learning through practice, the value of reflective practice and collaboration in professional learning. Her experiences highlight the dynamic nature of the LS process, where facilitators not only guide others but also engage in continuous learning themselves, adapting to the needs of participants and the demands of each session. By the end of the LS, Vanda acknowledged that while she still had much to learn, she had stepped up from being a hesitant facilitator to a more confident one, feeling more prepared to handle the complexities of facilitating LS.

The Roles of Knowledgeable Others in a Mathematics Lesson Study

Oben Kanbolat[1] and Selahattin Arslan[2]

[1]Erzincan Binali Yildirim University, Faculty of Education, Erzincan, Türkiye Republic; okanbolat@erzincan.edu.tr

[2]Trabzon University, Faculty of Education, Trabzon, Türkiye Republic

This study investigates the roles of knowledgeable others (KO) in a lesson study (LS) model. The research involved an academician, a teacher, and three pre-service mathematics teachers over a six-weeks period. Data were collected through video recordings of meetings, field notes, semi-structured interviews, focus group interviews, and reflective reports. The obtained data were analyzed with the help of the qualitative data analysis program NVivo and taking into account the LS sharing contents stated by Kanbolat (2015). As a result, it was determined that KOs predominantly assume roles as informants, critics, and, less frequently, learners. The study also highlights the differing contributions of the academician and the teacher as KOs, examined through the lens of their sharing contents.

Keywords: Knowledgeable others, lesson study, sharing contents, teacher education.

Introduction

LS, originating in Japan, has rapidly gained prominence as a model for teacher education and professional development worldwide (Fernandez & Yoshida, 2004). A distinguishing feature of LS, is its structural process, which involves planning, implementing the plan, observing, and evaluating the implementation. This collaborative approach fosters professional growth, as teachers engage with a diverse group of participants, including colleagues, administrators, and other stakeholders in education (Kanbolat & Arslan, 2022).

Another appealing aspect of LS attractive is its flexibility in participant profiles. LS group members may include teachers, pre-service teachers, students, administrators, academics, parents, educational policy makers, in short, everyone involved in the learning-teaching process (Kanbolat & Arslan, 2022). This diversity not only enhances the impact and functionality of LS but also allows for the integration of varied perspectives and expertise.

Among the participants, knowledgeable others (KO) play a pivotal role by contributing their expertise in subject matter, pedagogy, or LS methodology. Their involvement enriches the exchange of ideas and experiences, enabling deeper insights into teaching practices. While the roles of KO are well-defined in some contexts where LS is widely practiced, in others, these roles remain ambiguous (Clivaz & Takahashi, 2018).

This study addresses this gap by exploring the roles of KO in LS processes and aims to reply to the following question : What are the roles of KO in the mathematics-focused LS?

On knowledgeable others

KO play a crucial role in the LS model, enhancing the quality of discussions (Wood and Sithamparam, 2014) and contributing to its effective execution (Bjuland & Mosvold, 2015; Kanbolat, 2015; Takahashi, 2013). In Japan, where LS is widely practiced, KO are integral to LS groups, offereing

expertise in subject content, teaching and LS process (Hourigan & Leavy, 2021). Depending on the context, KO may serve as experts, teacher trainers or members of the LS group (Jacques, 2023), leveraging their strong content and pedagogical knowledge, and LS experience (Fernandez, 2002; Seino & Foster, 2021; Takahashi & McDougal, 2016).

KO contribute significantly to discussions by addressing curriculum-related issues, students' mathematical thinking, and other aspects of teaching knowledge (Amador & Weiland, 2015). They effectively bridge theory and practice, a core principle of LS. In cases, KO also provide participants with access to theoretical insights or recent research developments. (Fernandez, 2002), helping teachers shape and deepen their learning outcomes during the LS process (Clivaz & Georgy, 2020; Hourigan & Leavy, 2021). Moreover, KOs encourage group members to engage in meaningful dialogue, stimulate critical discussions, and question established practices within the LS environment (Jacques, 2023).

The LS Research Group at Teachers College, Columbia University, identified three key reasons for KOs to provide feedback during research lessons: (1) offering a fresh perspective on the group's LS process; (2) contributing subject-specific insights, new ideas, or reforms discussions, and (3) sharing experiences from other lesson study groups. (Fernandez, Yoshida, Chokshi & Cannon, 2001). These components also help define KO roles. In addition, Clivaz and Clerc-Georgy (2020) defined four roles for KO: meeting organizer, teacher trainer, researcher and group member.

Understanding KO roles is essential both for those undertaking this role and for refining their definitions in the literature. Unlike previous studies, this provides a detailed analysis of KO roles through categories such as classroom management, students recognition, feedback, mathematical knowledge, unexpected situations, problem-solving instruction, material usage, contextual knowledge, learning outcomes, assessment process, and group/individual teaching (Kanbolat, 2015). Furthermore, the distinct contributions, as a KO, of the teacher and the academician offer valuable insights by examining their roles both throughout the LS process and within the context of sharing contents. This dual perspective highlights how KO can benefit from the LS environment and from each other's expertise.

Method

The study involved an academician and a mathematics teacher serving as KO, along with three pre-service teachers who were assigned with pseudonyms: Esma, Erkan and Hakan. The academician, a graduate from the primary school mathematics teaching program, had one year of teaching experience, completed a master's and doctoral degree, and has been teaching mathematics education at a public university for five years. His research focuses on training mathematics teachers, and he teaches courses such as General Mathematics and Linear Algebra.

The participating teacher had three years of teaching experience and was working on a master's thesis in mathematics education. The teacher also served as KO during the pilot study and was the only participant with prior lesson study experience. The researcher facilitated the LS process by preparing the environment but did not intervene as a KO.

The LS process was conducted over 6 weeks as part of a teaching practice course. Three cycles of LS were carried out in the study, with each cycle comprising planning, implementation, reflection, re-planning, re-implementation, re-reflection and plan finalization (Fernandez et al., 2001; Lewis, 2000). Each cycle focused on instructional plan, resulting in six classroom practices, each lasting two hours, for a total of 12 hours. Each pre-service teacher conducted two classroom practices.

Data collection involved video recordings of LS meetings, researcher field notes, semi-structured interviews, focus group discussions, and reflective reports. The data were analyzed through content analysis, focusing on the research question, what roles do KOs play in these sharing environments? Using NVivo qualitative analysis software, the researcher coded meeting recordings, informed by initial role codes derived from field notes. Three primary roles of KOs emerged from the analysis:

Informant: Providing information, explanations, or answering questions related to the content.

Critic: Offering constructive criticism of statements or practices related to the content;

Learner: Asking questions to deepen understanding or exchange ideas about the content.

The researchers revisited the video segments to the coding of Kos roles, incorporating the LS sharing content categories identified by Kanbolat (2015). These categories included classroom management, students recognition, feedback, mathematical knowledge, unexpected situations, problem-solving instruction, material usage, context information, learning outcomes, assessment process, and group/individual teaching.

The analysis revealed the specific roles KOs assumed within these sharing environments and the frequency of their contributions. Figures were createdto illustrate the roles of KOs and the dynamics of their participation in LS environments.

Findings

When analyzing Figure 1, which was created by considering the sharing contents and the roles of KO and using of the meeting records, it is evident that the KOs predominantly play the role of *informant* and rarely taht of *learner*. Specifically, KOs mainly assumed the role of *informant* in conversations about *student recognition*, the role of *critic* in discussions on *giving feedback*, and the role of *learner* in dialogues concerning *student recognition* and *material usage*.

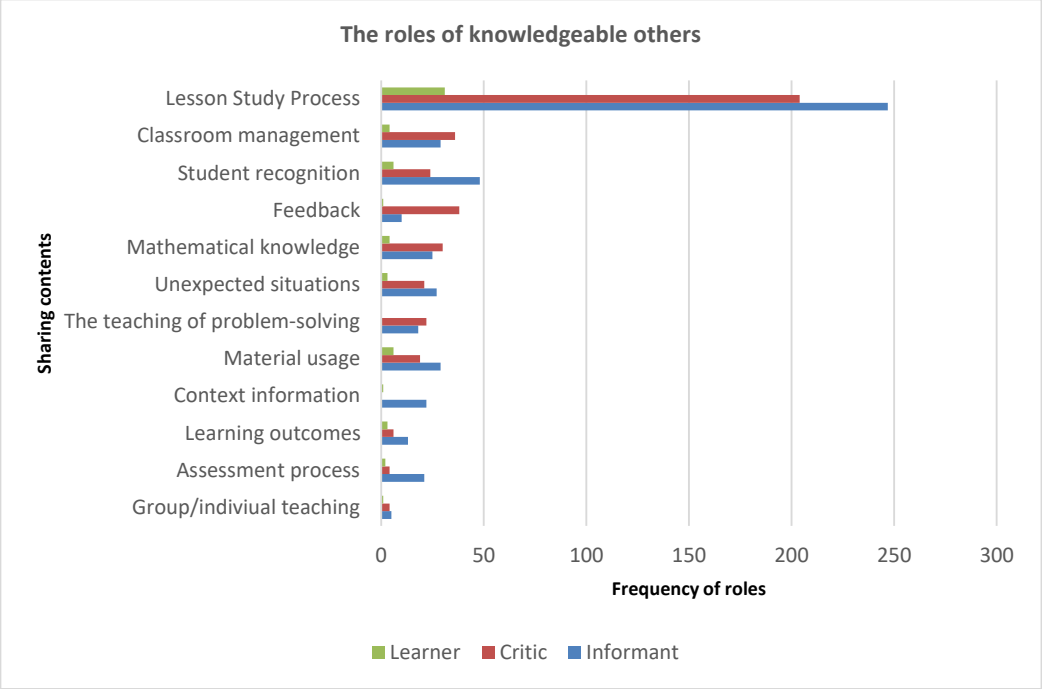

Figure 1: The roles of knowledgeable others

Figure 2, which separates the roles of the academician and the teacher as KOs, indicates that the teacher exhibited the roles of *informant*, *critic* and *learner* more frequently than the academician throughoutthe LS process. In addition, when the content of the sharing is examined, it is noteworthy that both of KOs displayed the role of *critic* equally in contexts related to *mathematical knowledge*, *assessment process* and *learning outcomes*. However, neither exhibited the role of *critic* in relation to *context information* and nor the role of *learner* in the context of *teaching of problem solving*.

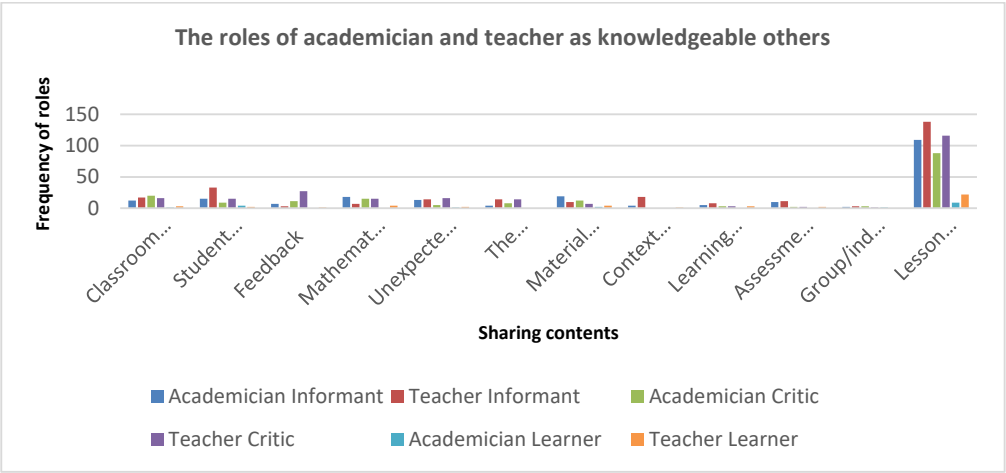

Figure 2: The roles of academician and teacher as knowledgeable others

Analyzing Figure 2 in terms of the academician's role in the LS process reveals that the academician is more informative than the teacher in discussions about giving *feedback*, *mathematical knowledge*

and *material usage*. The teacher's statements during the focus group interview support the finding that the academician acts as an *informant* in the context of *mathematical knowledge*:

> Different opinions, especially the views of our academician, were very valuable for me. In our usual practice, we often focus on achieving specific outcomes—if this is the case, then that must be true, and so on. However, I was exposed to a range of new viewpoints. For example, concepts like length, distance concepts... were not only approached from an educational standpoint, but also explored as pure definitions. Is a square? To me, a square is defined as a shape with four equal sides. Yet, I learned that a square can also be considered a type of trapezoid... or a rectangle. If I were working on this alone, I would not have ventured into such a discussion.

In terms of the critic role, Figure 2 shows that the academician assumes this role more frequently than the teacher in discussions about *classroom management, material usage, and group/individual teaching techniques.* The reflection report from Erkan, one of the pre-service teachers, provides an example of the academician's *critical* stance *in classroom management*:

> Our academician also suggested that it would have sufficed to include 5–6 tables instead of printing the entire table. Additionally, he mentioned, I wish you had solved all 3 questions in time measurement because you moved to the field with 10 minutes remaining... (Excerpt from Erkan's 2nd cycle reflection report)

Additionally, Figure 2 indicates that the academician exhibited the role of *learner* by asking more questions than the teacher in contexts related to student recognition and group/individual teaching techniques in the LS process. An example of the academician's *learner* role is evident in the following question directed to the teacher:

> Teacher, you know better, but it is not the sixth grade, right? Algebraic expressions?...

Figure 2 demonstrates that the teacher took on the role of *informant* more than the academician in the discussions about *classroom management, student recognition, unexpected situations, teaching problem solving, context information*, *learning outcomes*, *assessment* and *group/individual teaching.* The academician's statements about the teacher's role as an *informant* in *student recognition* are particularly noteworthy:

> In that environment, the classroom teacher anticipated potential questions from students, misconceptions or mistakes that could arise or evolve in the future... While discussing the foundational aspects of the subject and the elements that would form the basis, we relied entirely on the teacher's guidance. We must acknowledge this, as it became clear that we could not adequately predict students' prior knowledge and potential issues when approaching the topic.

Furthermore, Figure 2 shows that the teacher assumes the *critic* role more often than the academician in terms of *student recognition*, *feedback, unexpected situations* and *teaching problem solving*. The teacher's field note about the classroom practice supports this *critic* role of the teacher regarding the *teaching of problem solving:*

> We introduced problem-solving tasks without solving any problems beforehand. Students were not fully motivated to engage in setting up problems. (Excerpt from the teacher's field note of 2I2C).

Lastly, Figure 2 illustrates that the teacher exhibited the *learner* role by asking more questions than the academician in contexts related to *classroom management, feedback, mathematical knowledge, unexpected situations, material usage, context information, learning outcomes* and *assessment process*. The teacher's query to the academician — *If there is a difference between a rectangle and a square, and they are called by different names, how can they be the same? I still find this contradictory* — exemplifies the teacher's role as a learner within the context of mathematical knowledge.

Discussion and conclusion

The research identified that the KO in the LS process assumed the roles of *informant, critic* and *learner*. These findings highlight that KOs contribute not only as experts but also as group members who actively learn and benefit from the LS environment. Notably, the academician and the teacher primarily served as *informants* with their roles as *learners* being less frequent.

The findings further reveal that the KOs most often assumed the role of *informant* in discussions related to *student recognition*, the role of *critic* in during *feedback-related* conversations, and the role of *learner* in discussions concerning *student recognition* and *material usage*. The relative experience of pre-service teachers in *student recognition* and providing feedback, which develops as a result of one-to-one communication and interaction with the student, may have caused the KO to assume the roles of *informant* and *critic*.

The academician consistently displayed the role of informant across all sharing environments, particularly in discussions about *feedback, mathematical knowledge and material usage*. This dominance may stem from the academician's university-level teaching responsibilities and expertise in pure mathematics and related courses. The literature similarly emphasizes that KOs in LS groups often provide insights into *mathematical knowledge* and innovative ideas (Fernandez et all., 2001; Lewis & Hurd, 2011; Watanable, 2005).

In addition, the academician demonstrated the *critic* role across most contexts, particularly in discussions about *classroom management*, *material usage* and *group/individual teaching techniques*. However, the academician displayed the role of *learner* by asking more frequently than the teacher in discussions about *student recognition* and *group/individual teaching technique*, as evidenced by their inquiries aimed at deepening understanding.

Conversely, the teacher exhibited the role of *informant* in every sharing environment and more frequently than the academician in discussions about *classroom management*, *student recognition, unexpected situations, teaching problem solving, context information, learning outcomes, assessment process and group/individual teaching technique.* It is noteworthy that the sharing contents in which the teacher is more active informant have the characteristic of being nourished and developed by in-class experiences. This is because the teacher interacts directly with the classes in which the application is performed and with the relevant age group. For example, the teacher has more input to offer in explaining and limiting the achievements in conversations because he is an individual practitioner (Cheach, 2010).

The teacher can also contribute more about the class atmosphere, the students' pre-learning experiences and readiness levels, and some special students, because the classes in which the discussed practices will be applied are, in fact, the teacher's classes. As a matter of fact, in the LS

environment, the teacher is expected to guide other group members on how students learn the relevant content by making use of their experiences (Watanable, 2005). In the process, in addition to the role of *informant*, the teacher assumed the role of *critic* in all sharing contents except context information. Especially in the discussions about *student recognition, giving feedback, unexpected situations and teaching of problem solving*, in which he exhibited the *informant* role more than the academician, he also assumed the *critic* role more than the academician. In addition to all these, the teacher exhibited the *learner* role more than the academician with the questions she asked in the environments related to *classroom management, feedback, unexpected situations, context information, learning outcomes and assessment process.* In particular, the presence of an academic conducting courses on pure mathematics and material use at the university may have paved the way for the teacher to exhibit the *learner* role more than the academic in environments related to *mathematical knowledge* and *material usage*.

Collaborative planning in lesson study: The role of mathematical knowledge for teaching

Sarah Leakey

University of Nottingham, United Kingdom; sarah.leakey@nottingham.ac.uk

This qualitative analysis of recorded teacher meetings during a lesson study cycle on fractions identifies the mathematical knowledge for teaching used and developed by a group of primary school teachers. The analysis aims to understand how mathematical knowledge for teaching and collaborative planning influence one another. The results show that throughout the cycle teacher participants draw upon and build all elements of mathematical knowledge for teaching. Input factors such as analysis of student assessment responses, the use of planning templates and textbooks helps to make tacit knowledge visible and supports the development of new knowledge through discussion. Despite this, difficulties transcending limitations to horizon content knowledge and specialised content knowledge were evident. Considering what influenced these difficulties has implications for designing and adapting lesson study locally to maximise learning opportunities for teachers.

Keywords: Lesson study, professional learning, teacher collaboration, teachers' mathematical knowledge, fractions.

Introduction and background

Lesson study (LS) has been described as a "collaboration-based teacher professional development approach that originated in Japan" (Murata, 2011, p. 1). As the breadth and depth of LS research expands, increased attention has been placed on its connection with the use and development of mathematical knowledge for teaching (MKT). However, the locus of attention is often on *what* MKT is drawn upon and incorporated during a LS cycle (Ní Shúilleabháin & Clivaz, 2017). Research into *how* this knowledge development occurs during LS (Clivaz et al., 2023) is still in its infancy. Processes found to support teachers' knowledge development include studying curriculum and research and observing students during research lessons (Lewis & Perry, 2014). However, it is unclear how these processes contributed to the learning. In contrast, Ní Shúilleabháin's (2015) findings show how Knowledge of Content and Students (KCS) and Knowledge of Content and Teaching (KCT) was developed by focusing on the role of viewing teaching and learning from student perspectives. The research presented here contributes to the emerging literature on *how* MKT influences and is influenced by teachers collaborative planning in LS including a discussion about the role of Horizon Content Knowledge (HCK) and Specialised Content Knowledge (SCK). This is framed in contexts where local conditions do not afford the availability of an experienced facilitator or knowledgeable other prior to the post-lesson discussion.

This is of particular interest and relevance in Scotland – the location of this research – as Scotland's Curriculum for Excellence (CfE) tasks teachers with building their own curriculum from broad experiences and outcomes (Es and Os). These Es and Os are grouped into curriculum levels that each span multiple years of schooling rather than outlining a year-by-year progression. By the end of primary school, most children will have experienced the first three levels: Early, First and Second Level. While the intention is that these less prescriptive, broad experiences provide professional space

for teachers to meet the varied needs of all children, in some situations, this has led to teachers relying on a smorgasbord of materials of varying quality (Leakey & Mynott, 2025). This may have implications for curriculum coherence and consequently learning outcomes for children.

This research was conducted with a group of four teachers from different schools who were utilising the Collaborative Lesson Research (CLR) model (Takahashi & McDougal, 2016). The group collaboratively planned a fractions unit and LS research lesson for a Primary 4 class (students aged 8–9). The qualitative analysis of this case study utilises information from all five recorded teacher meetings with a focus predominately on meetings three and four which involved collaboratively planning the fractions unit and the detailed lesson plan for the research lesson. This study is framed around the research question (RQ), how do MKT and collaborative planning influence one another in a LS research cycle on fractions? Following an analysis of the results, which focus' on four of the six MKT domains in more detail, there is a discussion specifically about the role of SCK and HCK.

Theoretical framing

When trying to implement LS, teachers' existing mathematical subject matter knowledge (SMK) and pedagogical content knowledge (PCK) is an important consideration, as is the SMK and PCK that they develop. Fernandez (2005) questions whether teachers were able to take full advantage of opportunities to learn through LS due to a lack of content knowledge. Ball and colleagues (2008) MKT framework outlines six domains that can be used to categorise knowledge for teaching which may help to understand the interconnectedness between MKT and collaborative planning in LS:

Subject Matter Knowledge (SMK)

- Common Content Knowledge (CCK) – "the mathematical knowledge and skill used in settings other than teaching" (Ball et al., 2008, p. 399)
- Specialized Content Knowledge (SCK) – "the mathematical knowledge and skill unique to teaching" (Ball et al., 2008, p. 400)
- Horizon Content Knowledge (HCK) – "an awareness of how mathematical topics are related over the span of mathematics included in the curriculum" (Ball et al., 2008)

Pedagogical Content Knowledge (PCK)

- Knowledge of Content and Students (KCS) – "combines knowing about students and knowing about mathematics" (Ball et al., 2008, p. 401)
- Knowledge of Content and Teaching (KCT) – "knowledge that combines knowing about teaching and knowing about mathematics" (Ball et al., 2008, p. 400)
- Knowledge of Content and Curriculum (KCC) – a "grasp of the materials and programs that serve as 'tools of the trade' for teachers" (Shulman, 1987, p. 8)

In relation to fractions, five subconstructs (Kieren, 1976), have been further developed including to create a theoretical model connecting basic operations of fractions to these subconstructs (Behr et al., 1983). Watanabe et al., (2017) used this framework to analyse how textbooks from Japan, Korea and Taiwan introduce and develop fraction concepts (Table 1). Some variation exists in the ordering of the five subconstructs; however, many fraction topics, such as fraction as number (Grade 3) and equivalent fractions (Grade 4) were first introduced at the same grade level in all three textbooks.

Table 1: An interpretation of $\frac{3}{4}$ according to the five fraction subconstructs (Lamon, 2007) mapped against their first appearance within three Asian textbooks (Watanabe et al., 2017)

Fraction subconstruct	Interpretation and meaning of $\frac{3}{4}$	Grade		
		Japan	Korea	Taiwan
Part-whole	3 parts out of 4 equal parts of the unit	2	3	3
Measure	3 ($\frac{1}{4}$-units); a distance of 3 ($\frac{1}{4}$-units) from 0 on the number line or 3 ($\frac{1}{4}$-units) of a given area	3	3	3
Operator	$\frac{3}{4}$ of something; is a rule that tells how to operate on a unit	6	3	5
Quotient	3 divided by 4; is the amount each person receives when 4 people share a 3-unit of something.	5	4	4
Ratio	3 of A are compared to 4 of B; 3:4 is a relationship in which 3 As are compared, in a multiplicative rather than additive sense to 4 Bs.	6	6	6

If the goal of fraction instruction is to help students "recognize nuances in meaning; to associate each meaning with appropriate situations and operations; and, in general, to develop insight, comfort, and flexibility in dealing with the rational numbers" (Lamon, 2007, p. 636), then teachers must also have a sound knowledge of these meanings (SCK); how they connect to different fraction topics and how these different meanings and topics are related over the mathematics curriculum (HCK). This brings us back to the RQ under consideration here but with a specific focus on the role of SCK and HCK – how do MKT and collaborative planning influence one another in a LS research cycle on fractions?

Context, data and analysis

This qualitative case study of a LS planning team took place over five weeks in May/June 2023. Four primary school generalists working in different schools in the north of Scotland volunteered their own time to be part of the LS cycle. Two participants had never been involved in LS and two had limited experience. Due to local constraints, an experienced facilitator was not present in any of the meetings and neither was the researcher. One team member took up the notional role of facilitator using a loose facilitator guide (created by the author of this paper) intended to support novice groups like this to understand and maintain faithfulness to the general principles of LS. One team member volunteered to teach the fraction unit (three lessons) to their class. The team chose the second lesson as their research lesson as they decided it would give them most information for their LS RQ. The team also had access to a research proposal template and an English translation of a Japanese textbook which they could use to support their planning if they wished. Due to the geographical distance between them, they conducted their meetings online using Microsoft Teams. The cycle consisted of four planning meetings (approximately 90-minutes each); a LS research lesson which was recorded using Microsoft Teams and watched asynchronously by the planning team; and a post-lesson discussion (90-minutes) which included an invited knowledgeable other who provided final comments during

the final 20 minutes of the meeting. One teacher was unable to attend meetings three and four but returned to watch the recorded research lesson and contribute to the post-lesson discussion.

Prior to analysis, the automated meeting transcriptions were adjusted for inaccuracies. As this paper's RQ pertains to collaborative planning, sections of the transcribed data relating to planning the wider fractions unit (three lessons) and the detailed research lesson (lesson two in the unit) were analysed identifying instances where planning decisions were proposed, discussed, revised and finalised. The identified data was coded using the MKT framework (Ball et al., 2008) to establish the knowledge utilised and developed during the collaborative planning. To understand how MKT was developed, the data was further analysed to understand the relationships between planning decisions and MKT.

Results

Prior to the LS cycle commencing, team members had expressed an interest in focussing on fractions; an area of teaching they found challenging. In the first meeting, the group solved a series of fraction problems themselves and discussed unknown pupils' responses (CCK, SCK, KCS). They also discussed perceived strengths and difficulties in relation to teaching fractions (SCK, KCS, HCK). Jamie, acting as note taker, periodically summarised their discussions. After summarising the group discussion about the challenges associated with a lack of school wide understanding of progression over the year (KCC, HCK), Jamie draws on his own experiences working across a group of schools.

> Jamie: …we're [the group of schools] noticing that fractions outcomes are lower than other areas, but we're not changing how we're doing or when we're doing it or the frequency of what we're doing. So I think that sort of taking it as a one year approach every year, rather than looking at as a seven year sort of longer term, is also a challenge with fractions.

This reflection suggests an awareness of the importance of understanding how fraction topics are related over the curriculum. However, at that time, details about what those relationships might be (HCK) did not surface. The shared challenges were reflected in Sam's experiences with her class. In Primary 1 and 2 her students had no experiences of fractions and only some came to Primary 4 with formal experiences of fractions from Primary 3. This was attributed to Covid and teacher differences. Sam shared an overview of the fraction topics taught over two occasions this year (KCC). Based on this, and with reference to curriculum and planning documents, Sam suggested a focus on equivalent fractions. The limited elaboration makes it difficult to interpretate the nature of SCK and HCK.

> Sam: Yeah. So my class they are familiar with recognizing fractions; are familiar with ordering fractions from the smallest to the largest; they're familiar with fractions of a number, some of them are, fractions of a quantity. I'm trying to think what else we've done so far, but we spent a lot of time on that. I try to use the language of fractions as much as I can when we're doing times tables and stuff like that, as well.

During the first two meetings, utilising all six MKT domains, the team had solved, analysed then selected eight assessment questions for Sam's Primary 4 class so they could evaluate the students existing knowledge to support their planning. Prior to the third meeting, Jamie summarised the correct and incorrect responses and analysed the data; including, looking for patterns and outlining the types of errors and misconceptions that were evident (SCK, KCS). In discussion with Jamie, Sam had reviewed these results alongside the CfE Es and Os and the Japanese textbook they were utilising (KCC) to suggest a revised focus (HCK). At the start of meeting three, Jamie and Alex were

discussing this (Sam had not yet arrived). Meeting three then consisted of more detailed discussions in relation to the unit plan using this information.

Jamie: I think we've maybe, I sort of I wondered this at the start, but I think we've overshot and I think the equivalent fractions will be too much based on the results.

Alex: Your notes on the assessment were great, and I do agree. I think, you know, like the question, they're not even recognising equal parts for some of them. So that's huge, isn't it? That's a big thing that needs covered, I suppose.

Jamie: [Sam] was talking about she thinks the better sort of plan of attack would be to look at this sort of basic unit fractions up to tenths with the specific vocabulary about whole, part and equal parts. Looking at the sort of activities that were on 2B [referring to Japanese textbook] about the folding and that sort of like practical applications of the fractions and then looking at how you can then develop that into comparison, so using the tape or the like paper and looking at the vocabulary of greater than, less than and equal to with regards to fraction sizes. And she was hopeful that that might then lead into some level of introduction to equivalence, where they might say that two halves and, sorry two quarters, and a half are the same and then using all of that above to then start placing them on the number line. So having like a one strip which is classified as the whole and then cutting it down and having half and building two of the, so you've got that sort of build up towards the whole or from the whole reduction down. So that's what she thinks would be the best series of tasks.

These exchanges revealed strengths in relation to their use of new KCS and to some extent with KCC HCK and SCK as they were thinking about the order that fraction topics should be taught, how they relate to one another and possible representations. However, potential limitations in SCK and HCK were also revealed. In the exchange above, four different fraction topics are highlighted: fractions as equal shares, comparison, equivalence and fractions as number. In the Japanese textbook, these topics are introduced over three different grade levels; however, the proposal here is to cover them within a single unit. It is not clear how much the group understand about the interconnections between these topics (HCK) or how they relate to different fraction interpretations and meanings (SCK).

A pivotal point in meeting three, which supported the group to discuss tasks in more detail and streamline the many tasks they were trying to utilise, was when Alex shared her understanding of the pedagogical approach that she felt the textbook was trying to adopt. It also seemed to act as a stimulus for the utilisation of KCS as Jamie started to role play an anticipated pupil response and considered the affordances that the task might offer (KCT).

Alex: I think the way the textbook is sort of implying it is that you give them the paper and just say fold this square paper to make half the size of the square and then you look at what everyone's done and see how different people have done it.

Jamie: That then opens that opportunity for the discussion, though. I think this is still a half even though it's different to your half because it's, the whole's partitioned into two equal parts, blah blah blah. So I would say that would be fine.

Although it waxed and waned, this more in-depth discussion increased into the final planning meeting. Discussions that drew upon and built KCS and KCT included deciding on the exact wording of tasks; anticipating responses; and planning potential follow-up questions based on what these responses revealed about student understanding. The planning template structure appeared to be a stimulus for these discussions. It included column headings relating to 'Learning task and activities'; 'Teacher support'; and 'Assessment' and rows subdivided into different phases of the lesson. This

structure is part of a pedagogical approach to teaching known as teaching through problem solving. When discussing the 'summing up' part of the lesson, for example, Sam justified the use of a model they had been discussing including its affordances and how these link to the lesson success criteria.

An ongoing issue, that related to both SCK and HCK, was the number and type of tasks they tried to include within a lesson. These tasks were often addressing different fraction topics and drew upon different fraction subconstructs. One example was the task involving placing fractions on a number line. Firstly, the lesson goals were framed around the topic 'fractions as equal shares' (part-whole subconstruct); however, the number line relates to the topic 'fractions as numbers' (measurement subconstruct). The team had discussed differences between part-whole and linear conceptualisations and Jamie had demonstrated knowledge of some of the fraction subconstructs from a previous professional learning experience; however, it appeared challenging to apply this to their planning.

Jamie: …it [the professional learning course] talks about the different schemes of fractions and how you learn them from, like, you know, partitioning and iteration up to like whole, part-whole schemes and measurement schemes and so on. And I'd never really thought of fractions as a number, and it's bad in my sense, like I've always thought of it as a quantity of an amount which has always been that context of shaded in boxes, etcetera, etcetera…

Secondly, the complexity of fractions as numbers appeared to be underappreciated, as demonstrated by Alex's remark in meeting four.

Alex: …we obviously had the Frayer model kind of as a class plenary together. Do we just pop number line in there as well?

And finally, they had different representations of a number line. Again, this confusion appeared to be related to SCK and the different interpretations (subconstructs) of fractions.

Sam: So when you've got the number line by pieces of paper it becomes your fraction wall, but then if you've got it by number, you've got your number line that you can have. So you can show both.

Jamie: Yeah, because if you had a zero at the front and like this is one strip and this is one strip being partitioned into four and we've got one of those four.

It is not clear that the others made sense of Sam's second description of the number line until the research lesson where a tape measure (from 0 cm to 100 cm) is used as the number line. Students placed fractions (e.g. one half) on the 'number line' therefore positioning one half at 50 cm. However, this no longer relates to the number one half where one is considered as the whole (although it would have done if the tape was labelled from 0 m to 1 m). Instead, the one half represents a relationship between two numbers where the original size is 100 cm.

In the post-lesson discussion, the group acknowledge that the number line was a bit of an afterthought and agree this should have been a lesson in its own right. Alex also makes a point about the potential confusion of the centimetres but also reflects on how this offered other learning opportunities.

Alex: Obviously kind of the idea of us using the linear context was kind of to get them into that knowledge and idea and understanding of, you know, a half is the kind of biggest unit fraction and then you go down to the third, the quarter. So, I was wondering, did the numbers on the number line make them focus more on the kind of centimetre aspect of it and take away from the unit fractions getting smaller or do you think it. I think in some ways it did help because they could say well twenty-

> five is smaller than fifty, so a quarter is smaller than a half. But then did we, you know, did we account for that connection, really, when we were planning the lesson. Because I don't think we did, we didn't talk about how, as much about, you know, using the measuring tape and how that would, how that would affect it.

However, the group do not appear to appreciate that the use of the tape measure does not address what they had originally wanted to draw out, which was this idea of fractions as numbers. The knowledgeable other does draw this out in their final comments in the post-lesson discussion.

Discussion and conclusion

In summary, there was evidence that teachers drew upon and developed all elements of MKT while collaboratively planning during the LS cycle as they learnt from and with each other. The planning team members' individual experiences allowed them to bring different perspectives and knowledge to the LS cycle. Specific input factors also appeared to have an important role in developing this knowledge. For example, the implementation and analysis of a fractions assessment and the use of a Japanese textbook allowed the team to consider new KCS and KCT that helped them to plan a more appropriate starting point for their fraction unit. Additionally, input factors such as a research proposal template and the Japanese textbook appeared to stimulate opportunities to make tacit knowledge visible and develop new knowledge through discussion including the analysis and anticipation of pupil responses. This also appeared to have a particular impact on KCS and KCT.

In the interests of understanding how we can maximise learning opportunities for teachers through LS, two main limitations the group appeared to have difficulty transcending will be explored. Firstly, a lack of deeper understanding of the different fraction interpretations and how these correspond to different fraction topics. Secondly, challenges in understanding how to sequence topics in the longer term and design instruction that supports learning at a deeper level. The broadness of the CfE Es and Os and lack of associated guidance for mathematics teaching may be contributing to these limitations without a universally accessible way for teachers to address this. The structure of the Japanese textbook appeared to offer some support in the development of these two areas. However, a lack of familiarity with this textbook and lack of access to associated resources like the Japanese teaching manuals may have limited its potential to support the group within the time frame of this LS cycle. A question also arises about the nature of the relationship between SCK and HCK. Do limitations to SCK, make it challenging for teachers to develop and use HCK? Understanding how fraction interpretations and topics relate to one another may be challenging if fraction understanding in general is limited in the first place. Could more robust curriculum documentation, alongside LS as a vehicle for understanding and using this documentation in practise further develop teachers' SCK and HCK?

Moving forward, a longitudinal study tracking a planning team over time may provide clarity over how SCK and HCK develop when groups have a longer period of time over which to develop this knowledge using shared materials to support their research and planning.

Learning to teach early arithmetic skills through learning study: The case of four prospective teachers

Pernilla Mårtensson[1], Angelika Kullberg[1] and Rimma Nyman[1]

[1]University of Gothenburg, Faculty of Education, Gothenburg, Sweden;

pernilla.martensson@gu.se

Abstract

This paper presents findings from an intervention where prospective teachers participated in a learning study during a course in teacher education. During the iterative process the prospective teachers collaboratively designed one lesson using variation theory as a theoretical tool, and enacted, analysed, revised the lesson, and enacted the revised lesson. The aim of this paper is to identify what one team of prospective teachers learned from the intervention, shown as the changes made from the first to the second lesson. Variation theory is used as a theoretical framework to analyse their teaching and thereby what the prospective teachers learned. The findings show that the prospective teachers from the first to the second lesson; a) identified more critical aspects of the object of learning and specified the critical aspects, b) focused more on pupils' difficulties, c) developed more demanding tasks. The findings have implications for teacher education.

Keywords: Learning study, prospective teachers, teacher education, early arithmetic skills.

Introduction

Prospective teachers' (PT) teaching skills is primarily developed during periods of school-based practicum. It is argued that teacher education needs to develop pedagogies for the enactment of teaching and combine them with pedagogies of investigation (Grossman et al., 2009). Studies suggest that working in a collaborative process with peers in investigations of teaching and learning can support PTs' development of teaching skills (Cheng, 2014; Hiebert et al., 2007). There are good grounds for expecting that variation theory-driven learning studies (Pang & Marton, 2003) can support PTs in such a way (e.g., Royea & Nicol, 2019). Studies have reported on PTs' own experiences of taking part of learning study in teacher education, showing a common opinion that the learning study process supports a deeper understanding both of how to prepare and improve lessons and into pupils' ways of understanding (Cheng, 2014; Royea & Nicol, 2019; Turu, 2017). Although we know a lot about PTs' own experiences of learning studies, we know less about how learning study affects their teaching skills. More extensive studies investigating PTs' teaching of subject matter are lacking. The aim of this paper is to identify what one team of PTs learned from taking part of a learning study. The research question addressed in this paper concerns in what ways the PTs developed their teaching about part-whole relations of numbers when participating in a learning study incorporated in a mathematics education course?

Learning study in teacher education

Learning study is a teacher-driven, collaborative and iterative inquiry of practice that is used by in-service teachers to develop teaching that enhance pupil learning (e.g., Pang & Lo, 2012). The learning

study cycles of planning and analysing lessons and pupil learning are framed within a theory of learning, commonly variation theory (Marton, 2015). Variation theory can be seen as an explanatory and pedagogical tool that guides teachers in understanding and analysing the relationship between teaching and learning a particular object of learning (the content and capability to which learning is directed during a lesson). As learning study has come to play a valuable role in supporting professional development for in-service teachers, the approach has been incorporated in teacher education programmes at several universities worldwide (e.g., Cheng, 2014; Mårtensson & Ekdahl, 2021; Tan et al., 2020) to help PTs developing their instructional design skills and teaching competence. It has been argued that participation in learning studies during education also could facilitate continuous professional development in future careers (Pang & Runesson Kempe, 2019). There have been a number of studies reporting on experiences of implementations of learning study in initial teacher education. Most of these studies are based on self-reported reflections and/or interviews focusing on PTs' own experiences and learning from participating in learning studies. Most of the PTs in Royea and Nicol's (2019) study expressed that variation theory has engineering power, since it is directly applicable to teaching and stands out in comparison with other learning theories they have previously learned. In that and other studies (Cheng, 2014; Davies & Dunnill, 2008; Wood, 2013), PTs report that learning study and variation theory have the potential to support them in focusing on pupils' learning and their different ways of understanding, as well as in preparing and improving lessons.

However, research shows that it is challenging for prospective teachers to learn fundamental principles of variation theory (Ko, 2012; Royea & Nicol, 2019), for instance it seems easier (or more common) for PTs to focus on activities and methods when planning lessons than on how to use variation theory to structure the content (Turu, 2017). Some fundamental principles of variation theory are critical aspects and variation/invariance as the theory stipulate that learning is being able to discern new aspects of what is being learned (critical aspects), and that such discernment presupposes an experienced variation against a background of invariance. In the context of teaching, it is therefore, necessary to identify and teach the critical aspects of the object of learning (Kullberg et al., 2023; Marton, 2015). Even though, it may be demanding for prospective teachers to learn and practice these principles it is apparent that principles from variation theory may be learned even in courses that last only a few weeks (Brante et al., 2015; Ko, 2012; Royea & Nicol 2019). However, how prospective teachers' make use of variation theory and develop their teaching skills is not much known.

Methods

The analysis reported on is a part of the ongoing research project *Prospective teachers' ability to teach early arithmetic skills* that aims to determine how PTs' (grades K-3) teaching of early arithmetic develops through participation in learning studies (100 PTs at two universities in Sweden, divided in 25 groups). In this paper we draw on data from one of the groups, the rationale behind the selection is two folded: First, we wanted to generate hypotheses for the wider study by focusing on concrete in-depth knowledge of the issue. Second, we expected that this group most likely could maximize the information and highlight prototypical characteristics. This particular group of four PTs was assigned to work with the object of learning "Discovering the inverse relationship between addition and

subtraction, that is the complement principle ($a + b = c$ then $c - a = b$)". As part of the course design, the PTs took part of two intervention cycles closely following the steps of planning, teaching, analysing, and revising lessons in a learning study set out by Pang and Marton (2003). During this period, five learning study tutorial sessions were conducted (each of them lasted for 3,5 hours), oriented towards a systematic inquiry into pupils' learning difficulties, the nature of the object of learning and critical aspects and, teaching the content from a variation theory perspective. Moreover, resources such as course literature, two research articles on pupils' learning regarding the object of learning, two lectures on variation theory and one lecture on task construction were given. Based on insights from analysing a pretest that was administrated to two Grade 3 classes, the PTs planned and enacted one lesson (L1) and a post-test in their first class. After analysing the post-test and L1, they made revisions in the lesson plan and enacted the revised lesson (L2) in their second class. Both lessons lasted for 45 minutes. Data was gathered during the course, for this paper we have analysed two video filmed lessons (L1 and L2) and the groups' written documentation of their planning and analysis of teaching and pupils' learning. In our analysis we focused on 1) what the PTs considered to be critical aspects, the rationale behind this and how critical aspects were expressed by the PTs 2) what was made possible to learn in each sequence of the lessons from a variation theory perspective (Marton, 2015), that is how the PTs handled the critical aspects in terms of variation and invariance, 3) differences and similarities between L1 and L2.

Results

Lesson 1

Sequence 1: Marking and naming parts and wholes

The lesson started with four equations (figure 1a) to illustrate the part-whole relation 22|14|8. First, the position of the whole (the sum) varied, and the numbers were kept invariant in the two first addition sentences, hence it was possible for pupils to discern that the whole can be placed in the right-hand side as well as in left-hand side. The PT emphasized this by letting the pupils express the difference between the two addition sentences and concluded that "The equal sign means that it is the same on both sides, so it doesn't matter which side to place the whole".

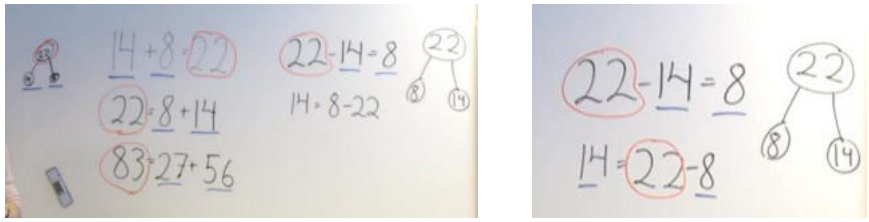

Figure 1a and b: The part-whole relation written on the board by the PT

However, as *discern parts and the whole* was identified as a critical aspect from the pretest, several questions focusing on naming the terms and sum as parts and wholes were posed, e.g. "What are these called, which words do you use [pointing at 14 and 8] and "What do we call this [pointing at 22] as shown in figure 1. In parallel the PT circled the whole in red and underlined the parts in blue. To generalize the difference between parts and wholes, the same procedure was performed on $83 = 27 + 56$. Hence, the numbers varied while the position of the whole were kept invariant.

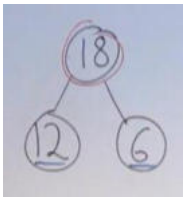
Next, the operation sign was varied, and the numbers remained invariant when introducing $22 - 14 = 8$. To make it possible for pupils to *discern the reading order* (subtraction is not commutative) which was considered a critical aspect, the incorrect number sentence $14 = 8 - 22$ was noted on the board. The PT asked the pupils to explain in different ways why the subtraction was incorrect. After concluding that the value is not the same when changing the position of the terms, the expression was erased and replaced with $14 = 22 - 8$ (Figure 1b). However, as the whole and the parts once again were named and marked in different ways and as the incorrect number sentence was erased and replaced, it can be questioned whether it was possible to discern the critical aspect.

Sequence 2: Marking parts and wholes

Pupils worked in pairs with items on a worksheet. In a similar way as in sequence 1, the pupils were asked to underline the parts and circle the wholes, and to write the relation between numbers in triads.

Sequence 3: Filling in the missing number from the triad and showing a number relation

In this sequence, *discern parts and wholes* was handled once again. The triad (figure 2a) was on the board, and in a similar way as before, the whole was circled, and the parts were underlined. The PT wrote four items on the board (figure 2b) and asked the pupils to use the triad to solve each item without counting. Furthermore, she invited the pupils to explain whether the missing number is being a part or the whole. Each item was erased and replaced with another item, so that just one item at the time was on the board. Even though there were a variation between the parts and the whole (the part 12 was missing in the two first items and the whole 18 was missing in the third), the pupils were not offered possibilities to pay simultaneous attention to the relations due the fact that there was just one item on the board at a time and that they just could pick the missing number from the triad.



$$18 = _ + 6$$
$$18 - _ = 6$$
$$6 = _ - 12$$
$$12 = 6 - 18$$

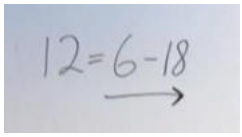


Figure 2a, b and c: The items on the board written by the PT

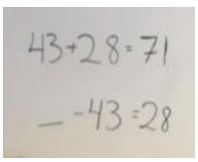
When introducing the fourth item *the reading order* was once again handled. The PT challenged the pupils and red the last subtraction from the right to the left (18 minus 6 equals 12) and asked if and why it was right or not. Several pupils expressed that "you must read the subtraction from left to right" and the PT added an arrow (figure 2c) to mark the pupil's statement. Next, to make it possible for pupils to *discern the relationship between addition and subtraction* a new part-whole relation was used. Based on the addition $43 + 28 = 71$, the pupils were asked to find the missing number in the subtraction $_ - 43 = 28$.



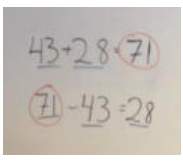


Figure 3a and b: PT asked the pupils to find the missing number in the subtraction

The PT summarized by pointing out that "you get the whole by adding the parts in addition. And here you have the same whole [pointing to 71 in the subtraction in figure 3b and circling the whole in both items], and by taking away one part you have the other part left." Thereafter, the pupils practiced their knowledge (filling in missing numbers from triads) in a worksheet for the rest of the lesson.

Lesson 2

Sequence 1: Focusing more directly on the object of learning and making more challenging tasks

Based on the analysis of L1, the PTs concluded that they should focus more directly on the object of learning and challenge the pupils more. As a consequence of this, the critical aspect *discern parts and the whole* was brought out in a different way. The same relationship 22|14|8 as in L1 was used, but the PT directly varied the operation sign to focus on subtraction ($14 + 8 = 22$ and $22 - 14 = 8$). To draw the pupils' attention to whole and parts, these were marked in the same way as in L1, however, the pupils were not asked repeatedly to name the numbers as parts and wholes. In a similar way to L1, another part-whole relation was discussed, this time 78|6|72 (figure 4).

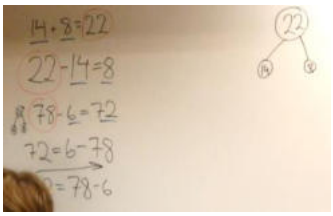

Figure 4: A new critical aspect was handled in L2, even though the same part-whole relation was used

But, as the PTs after the analysis of L1 had identified a new critical aspect *that subtraction must be made from the whole*, and furthermore, that *the reading order* had to be more emphasized, the subtractions were handled differently in L2. After $78 - 6 = 72$ was brought up and parts and whole were marked, the incorrect subtraction $72 = 6 - 78$ was contrasted to $72 = 78 - 6$ (the placement of the minuend and subtrahend varied). The incorrect subtraction was not immediately erased as in L1, therefore, it was possible for pupils to experience a simultaneous variation of the critical aspects when the two subtractions were juxtaposed. After the pupils had concluded that $72 = 6 - 78$ is incorrect as "you must subtract from the whole", *the reading order* was handled. The PT asked, "but what if I read the number sentence from the right to the left" pointing at $72 = 6 - 78$ saying "seventy-eight minus six equals seventy-two". In the discussion, an arrow from left to right was drawn under the incorrect subtraction to emphasize the right way.

Sequence 2: Adding a new task to link to the next sequence

As in L1, pupils worked in pairs on a worksheet. However, a new task was added as the PTs had identified a new critical aspect *that subtraction must be made from the whole*. In this new task pupils were asked to create as many subtractions as possible by using the triad 18|12|6.

Sequence 3: Creating part-whole relationships and handling the unexpected

The subtractions from the worksheet were noted on the board (figure 5a). This time, the triad was not used to ask the pupils to pick the missing number from the triad but to handle the critical aspect *discern that subtractions must be made from the whole*. Therefore, the placement of the whole varied

from the right- to the left-hand side. The number 18 was circled in each subtraction and the PT asked the pupils to explain which patterns they noticed. The pupils noticed that "The subtraction sign must always come after the whole" and "You must subtract from the whole". Next, in a similar way as in L1, the PT made a contrasted by varying the minuend (last item in figure 5b). A difference, though, was that both items were on the board at the same time so that it was made possible for pupils to discern similarities and differences between subtracting from 18 or 6. The item highlighting the relationship between addition and subtraction (43|28|71) was handled in the same way as in L1, but in L2 it was not just showed. As the PTs had noted from the analysis of L1 that pupils also must *discern how part whole relationships can be used* (i.e discern the different meaning of the whole—from the sum for addition to the minuend for subtraction) the pupils were once again asked to create subtractions, now by using the parts 21 and 13 (figure 5c). After pair work, the PT asked the class "How did you start?" The class suggested to add the two parts to get the whole. The PT confirmed by saying "Right, you must start with an addition to get the whole, and then it is possible to create a subtraction" and she wrote 21+13=34 on the board. The PT continued "Given this, which subtractions did you made?" The example $34 - 21 = 13$ was given, hence, the meaning of the whole 34 was varied—from a sum to a minuend.

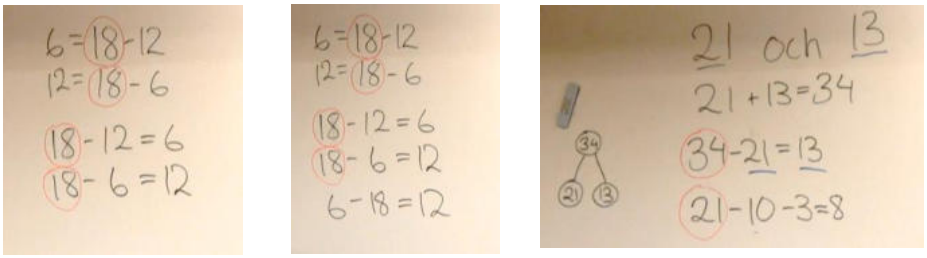

Figure 5: The pupils created subtractions by using the triad 18|12|6 and a subtraction by just using the parts 21 and 13

One of the pupils objected and gave another suggestion. Even though this solution was incorrect and not something the PTs had counted on the PT listen carefully and wrote the incorrect suggestion on the board $21 - 10 - 3 = 8$. Furthermore, she asked the class first to compare the whole 21 with the whole 34 in the item above and also the number 21 in both items. Hence, it was made possible for pupils to discern the contrast between 21 as a part and a whole. After summarizing that the whole must be found before knowing which number to subtract from, the pupils practiced their knowledge in a worksheet.

Discussion

Our analysis of the teaching showed that the PT developed their teaching about part-whole relations in a notable way during the learning study process. The findings show that the prospective teachers from the first to the second lesson identified and handled more critical aspects of the object of learning, and also, specified the critical aspects. The PT also focused more on pupils' difficulties and developed more demanding tasks. The PT group developed the tasks used in the second lesson to be more in line with the object of learning. For example, when they asked the pupils to write a number sentence in subtraction when only two parts were known. Hence, the PT seemed to become more aware of the object of learning and what the pupils need to experience, that is the critical aspects. In

this sense they became more sensitive to the pupils' learning when planning and enacting L2. Previous findings on PTs' learning from learning studies have shown that PTs learn to use and reflect about the variation theory when they plan their lessons (Royea & Nicol, 2019). We add to this research by showing the changes made in teaching during the learning study process. In this study we only analysed one group of prospective teachers' teaching of the same content in two lessons. Studies with more groups of PT are needed to see if similar changes are found in other groups as well. What prospective teachers learn during teacher education is of utmost importance since this most likely will affect their teaching when working as teachers in schools and in turn pupils' learning. We suggest, as other (e.g., Royea & Nicol, 2019; Cheng, 2014) that conducting learning study in teacher education programme likely is one way to develop more powerful teaching skills.

The findings about critical aspects and specification of them can be used by prospective and in-service teachers to improve instruction about the object of learning. However, the critical aspects should be seen as something that can be further develop regarding different classes. Hence, it is possible that there are more critical aspects and that there could be different critical aspects for different groups depending on what the group have already or not discerned (Kullberg et al., 2024).

Collaborative Lesson Study in initial teacher education: Joint focus on students' learning

Camilla Hellsten Østergaard[1]

[1]University College Copenhagen, Denmark; choe@kp.dk

In this paper, we present a new inquiry-based approach in initial teacher education: Collaborative Lesson Study. The study is a case study conducted in Denmark, with data consisting of video observations and field notes from open lessons, reflective discussions, and related coursework activities. Collaborative Lesson Study belongs to the paradigm of questioning the world, where pre-service teachers and teacher educators collaboratively explore how to teach mathematics and how students learn mathematics. This approach appears to offer valuable insights into bridging the gap between traditional coursework, theory, and teaching practice. Collaborative Lesson Study also exposes some unaddressed shortcomings, and new approaches are needed that involve cooperating teachers, aligning theory more closely with practical teaching experience.

Keywords: Collaborative Lesson Study, inquiry stance, the Anthropological Theory of the Didactic, study and research paths, praxeologies.

Introduction

Understanding the nature of mathematical knowledge for teaching is key to grasping the complexity of the mathematics teaching profession. However, mathematical knowledge for teaching does not develop in insolation; it is shaped by broader professional contexts, including activities beyond the classroom (Clivaz, 2018; Miyakawa & Winsløw, 2019), and requires an *inquiry stance*, where collaboration becomes a norm within a teaching community (Jaworski, 2006). In this regard, frameworks such as lesson study provides a structure for collective inquiry, enabling teachers to refine their practice through joint planning, observation, and feedback –thereby fostering both professional growth and contributing to elevation of the teaching profession (Sachs, 2016).

The benefits of using lesson study for both initial teacher education and professional development are well-documented, but several conditions and constraints remain. At the micro level, success depends on teachers' mathematical knowledge for teaching, their inquiry-based approach, and the quality of collaboration within professional learning communities (Chokshi & Fernandez, 2004). Teachers' commitment to growth and support from knowledgeable colleagues are also essential for promoting student-focused instructional practices (Takahashi, 2014). At the macro level, cultural values, professional development systems, and leadership play a critical role. Barriers such as cultural norms and bureaucratic challenges can hinder implementation, requiring a shift toward a more collaborative teaching culture (Kusanagi, 2014). Within initial teacher education, lesson study has been adapted in innovative ways to navigate these challenges. Some studies involve pre-service teachers teaching research lessons to peers in university settings, rather than in traditional classrooms (Fernandez, 2010). Others integrate lesson study into school internships, allowing pre-service teachers to engage in lesson planning, although they may not always have the opportunity to teach the lessons themselves (McMahon & Hines, 2008). In other cases, pre-service teachers engage in full

lesson study cycles, teaching research lessons in actual school environments (Skott & Østergaard, 2015). Despite these innovations, integrating lesson study into initial teacher education remains complex.

This paper presents the design and analysis of the initial teacher education project, *Collaborative Lesson Study*. The project addresses on both micro and macro levels, emphasizing a collaborative and dynamic network for teacher engagement. Our research is guided by a key question posed by Hiebert and colleagues (2007): "To learn from teaching, what would such a program look like? What knowledge, skills, and dispositions would teachers need to learn from teaching – not in an informal, haphazard way but in an intentional, systematic way" (p. 48). Using the Anthropological Theory of Didactics as a framework, we address two research questions: RQ1: How can Collaborative Lesson Study be conceptualized as a paradidactic system, and to which paradigm does it belong? RQ2: What mathematical and didactical praxeologies emerge in the context of Collaborative Lesson Study?

Collaborative lesson study

In Denmark, initial teacher education is structured according to the grade levels teachers intends to teach. To qualify for teaching primary and lower secondary school (grades 1–9), candidates complete a four-year professional bachelor's degree at a university college, combining subject-specific content, general didactics, pedagogical theories, and internships. Studying educational theories in isolation, without connecting them to classroom practices, is inherently problematic. For theories to be meaningful and effective, they must be grounded in authentic learning experiences that bridge the gap between theoretical learning and practical experience in real-world teaching contexts. University College Copenhagen has introduced a Collaborative Lesson Study design into its three-year mathematics education program. This includes a series of open lessons where approximately 200 pre-service mathematics teachers and 15 teacher educators observe and analyse structured problem-solving lessons. The lessons are taught by teacher educators, experienced in-service teachers, and pre-service teachers (see Figure 1).

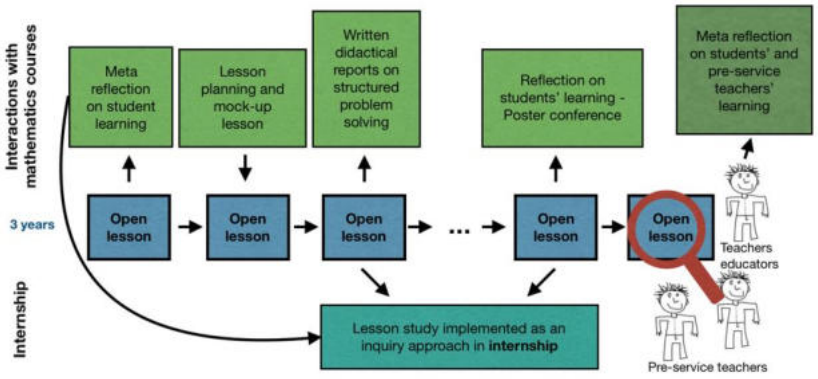

Figure 1: Collaborative lesson study more than a sequence of open lessons

A central focus of this collaboration is students' learning of mathematics. Drawing on Hiebert and colleagues (2007), we propose that focusing on students' learning and understanding the factors

behind their success or challenges “provides a targeted but comprehensive and systematic path to becoming an effective teacher over time” (p. 48). The open lesson serves as a pivotal element of this collaboration, offering a shared foundation for joint reflections and further elaboration. Observations and insights from the open lesson are integrated into coursework, providing opportunities for meta-reflection and written analyses of both didactical and mathematical issues. Additionally, the open lesson enables pre-service teachers and teacher educators to engage in complete lesson study cycles, encompassing studying, planning, teaching, and reflecting—some of which are taught during the open lessons or during internship.

The Anthropological Theory of the Didactics

Our study is grounded in the Anthropological Theory of the Didactic (ATD; Chevallard, 2019), which models knowledge as *praxeologies*, categorized into mathematical, didactical, and paradidactic praxeologies. In praxeologies, *praxis* refers to practical knowledge or "know-how," encompassing tasks and techniques for solving the tasks. *Logos,* on the other hand, represents explicit knowledge about praxis, including technology—knowledge of the technique—and theory, which provides abstract discourse to further explain or justify the technology. The praxeologies of mathematics teachers, including pre-service teachers and teacher educators, form a complex structure that integrate these three types. Both mathematical and didactical praxeologies are shaped by the conditions and constraints of the institutional systems in which pre-service teachers study and teacher educators work. Paradidactic praxeologies refer to the practices and explicit knowledge developed outside the classroom (Miyakawa & Winsløw, 2019).

The current educational paradigm, also in initial teacher education, is often referred to as the *paradigm of visiting monuments* (Chevallard, 2015). The paradigm of visiting monuments conceptualises education as the transmission of established knowledge—referred to as "monuments"—with the curriculum organised as a collection of prescribed works for pre-service (mathematic)s teachers to study. Within this paradigm, learning resembles a guided tour orchestrated by the teacher educator, where pre-service teachers engage with carefully selected pieces of knowledge, such as algebra concepts or approaches to classroom discussions. While paradigm of visiting monuments may allow pre-service teachers to develop praxeologies, it often lacks critical reflection on the relevance of the answers obtained. As a result, pre-service teachers may perceive the knowledge encountered as disconnected from their future roles as in-service teachers. The alternative paradigm, the *paradigm of questioning the world* (Chevallard, 2015), focuses on addressing meaningful questions – here about mathematics teaching and student learning. These questions are taken seriously and not just used to revisit pre-established knowledge. Paradigm of questioning the world aims to engage pre-service teachers and teacher educators in real inquiry, where they learn to pose and solve authentic teaching problems and critically reflect on the knowledge produced (Bosch, 2018).

The concept of *study and research paths* serves as a design tool for teaching within paradigm of questioning the world (Bosch, 2018; Chevallard, 2015). Within this framework pre-service teachers engage in milieus to explore a generating question, Q_0, examine established answers, $A^{\diamondsuit}$, and interact with relevant works, W. The goal is to collaboratively discuss and validate a final answer, $A^{\heartsuit}$.

The paradidactic system in initial teacher education can be modelled as a structure involving pre-service teachers X and mathematics teacher educators Y around a didactic goal ♠, denoted $S_{TE}(X, Y, ♠)$. When examining ♠ more closely, we find that it represent the didactic system of teaching mathematics, S(x, y, ♥), where x is the class of students, y is the teacher or pre-service teacher who teach the lesson and ♥ is the didactic objects of the lesson (Otaki & Asami-Johansson, 2019). This relationship can be summarized as $[S_{TE}(X, Y, S(x, y, ♥)) ➦ M] ➥ A^{♥}$, indication that the didactic system interacts with the *milieu,* M. In ATD, the milieu includes existing answers, $A^{◊}$, from media or prior knowledge, and encourage critical assessment by pre-service teachers and teacher educators, who can provide objective feedback about possible answers. *Media*, such as books, lesson plans, journal papers, convey information and answers, while milieus are designed to facilitate exploration and investigations of Q.

Methods

This study employs a descriptive case study design (Yin, 2013) to provide an in-depth analysis of local Danish practices in initial teacher education. The data collection process incorporated a range of sources, including lesson plans, audio and video recordings of seven open lessons and subsequent joint reflections, field notes, meta-reflections, and 12 didactic analysis reports authored by pre-service teachers. Selected video recordings, particularly those capturing lesson reflections, were transcribed and analysed using NVivo software. The study also incorporated official curricula and contextual information about initial teacher education in Denmark. By integrating these diverse data sources, the case was systematically constructed, organized, and refined into a comprehensive account centred on Collaborative Lesson Study.

In this study, we utilised theoretical tools from the ATD to analyse the complex network of systems and praxeologies involved in Collaborative Lesson Study. Our approach consisted of two main steps. First, we applied the concept of study and research paths to model the paradidactic system Based on the analysis, we concluded which paradigm it belongs to. Second, we conducted a detailed examination of specific mathematical and didactical praxeologies, focusing on the tasks, techniques, and underlying logos. In the praxeological analysis presented in this paper, we did not examine all open lessons, associated reflections, or the broader coursework. Instead, we focused on a single open lesson and a written didactic analysis produced by a group of pre-service teachers. The analyses allowed us to capture both the broader structural dynamics and the finer details of how Collaborative Lesson Study fosters professional development.

Analysis of collaborative lesson study

In Collaborative Lesson Study pre-service teachers, X_1, and teacher educators, X_2, jointly engaged in the overarching inquiry, Q_0: How do we teach mathematics? Q_0 was approached with seriousness, engaging both pre-service teachers and teacher educators in a joint inquiry into students' learning. The didactical contract between X_1 and X_2 differed from traditional coursework, which typically involves a predetermined curriculum and answers already known by the teacher educator. Instead X_1 and X_2 adopted a shared an inquiry stance, concentrated on the study of students' mathematical learning. In Collaborative Lesson Study X_1 and X_2 posed a series of derived questions (Q_1.. Q_n) to guide their inquiry. These included broad questions, such as Q_1: How do students learn mathematics?

And Q_2: How can structured problem-solving serve as a milieu for students' learning? Additionally, they formulated more specific student-focused questions, such as Q_3: How do students identify the relationship between steps and perimeter of a staircase figure? And Q_4: How can *bansho*, organisation of the blackboard, support students' learning and their understanding of early algebra?

Collaborative Lesson Study was non-linear and took various pathways. The works, W, consulted were elected based on their relevance to Q_0 and the subsequent derived questions. These questions were explored across different milieus, M, such as in the open lessons, M_1, and subsequent lesson reflections, M_2, while other derived questions were posed, studied and researched as a part of the coursework content, M_3. X_1 and X_2 continued their (re)search for already existing answers, $A^{\Diamond}$, using various media (e.g., textbooks, research papers, teacher journals, classroom videos), such as $A^{\Diamond 1}$: The framework of structured problem-solving, $A^{\Diamond 2}$: Bansho, $A^{\Diamond 3}$: Five Practices for teaching. They studied relevant mathematical works, W, and validated the answers, $A^{\Diamond}$, which were then implemented in resources such as lesson plans and subsequently taught as mock lessons in initial teacher education or during internships. In Collaborative Lesson Study X_1 and X_2 worked toward a final answer, $A^{\blacktriangledown}$, a question that can remain central and be continuously explored throughout their teaching careers.

$$S_{TE}(X_1, X_2, S(x, y, \blacktriangledown)) \rightarrow M_1, M_2, M_3] \rightarrow A^{\blacktriangledown}$$

Building on the preceding analysis, we conclude that Collaborative Lesson Study is situated within the paradigm of questioning the world.

In the following sections, we will zoom in and analyse various aspects of the paradidactic system.

In the first zoom, we examine the mathematical praxeology developed in an open lesson. The system, $\boldsymbol{S}(x, y, \blacktriangledown)$, refers to an open lesson, where x represents16 fifth-grade students, y is a second-year pre-service teacher, and ♥ refers to early algebra. The task, T_1, of the research lesson was: What is the relationship between the number of steps and the perimeter of a staircase figure? The students' techniques were primarily based on inquiry into the development of the figure, drawing staircase figures and counting perimeter (see staircase figures in figure 2). They then constructed a table, identified that increasing the steps by one add four to the perimeter, and further concluded that if the number of steps is known, multiplying it by four gives the perimeter (see table on figure 2).

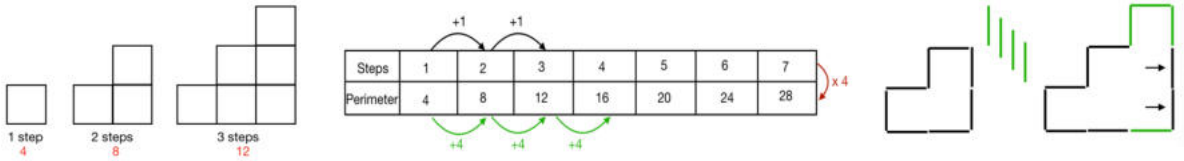

Figure 2: Grade five students' mathematical praxeologies: techniques, technology and theory

A derived question, T_2, from T_1 is Why '+ 4'? The techniques used include exploring the relation in the table and constructing new staircases by adding four more sticks (green) to transition from one staircase to the next. During the whole-class discussion students and pre-service teacher worked to develop geometric reasoning and attempted to generalize the +4 pattern. They did this by adding four sticks, one stick for the case and three sticks for the top, a technique that applies generically when

moved from an n-step staircase to an n+1 staircase. However, some students proposed techniques that could not be generalized. Students' learning was discussed during the post-lesson reflection: $S_{TE}(X_1, X_2, S(x, y, \heartsuit)) \rightarrow M_2] \rightarrow A^{\heartsuit}$.

In the second zoom, we examine a didactical praxeology developed in $S_{TE}(X_1, X_2, S(x, y, \heartsuit)) \rightarrow M_3] \rightarrow A^{\heartsuit}$. The System, S_{TE}, operated between the open lesson and coursework, where X_1, under the supervision of X_2, posed derived questions (re)study and (re)research students' learning, in the system $S(x, y, \heartsuit)$, guided by specific didactical perspectives (from media: research papers (Tan et al., 2023)). One group of X_1 explored the tasks, $T_{1'}$: How can *bansho*, organization of the blackboard, support students' learning and their understanding of early algebra? The techniques primarily relied on observations of a research lesson, such as the use of the blackboard (Figure 3). In their analysis, the pre-service teachers incorporated various theoretical concepts, including the four steps of organising the blackboard, the use of multiple representations (such as drawings, algebra, and color coding), and subsequent reflections on students' learning. The techniques and theories of bansho were explored in a written didactical report communicated $A^{\heartsuit}$ through the concept of multiple representation. In the report the pre-service teachers concluded that "by positioning students as active contributors, bansho enhances their engagement and fosters a dynamic, student-centered learning environment." (Report, p. 10).

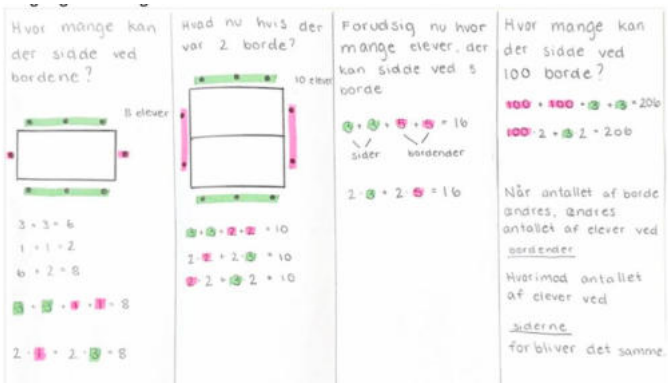

Figure 3: Bansho from research lesson 'how many students are seated at the tables?'

Discussion

Collaborative lesson study brings important insights but also reveals significant shortcomings that remain unaddressed in this study. While pre-service teachers and teacher educators jointly explore how to teach mathematics and promote student learning through inquiry, the realities encountered during internships often stand in sharp contrast. In school practice, pre-service teachers are typically exposed to more traditional forms of teaching, where inquiry-based mathematics is largely absent. The emphasis during internship tends to be on general teaching strategies, such as classroom management, rather than on mathematical subject-specific instruction or students' learning. This disconnect is strongly felt by pre-service teachers, who experience a mismatch between campus-based learning and internship practices. Bridging this gap calls for new forms of collaborative lesson study that integrate coursework, school-based practice, and the internship experience. Involving cooperating teachers in the inquiry process—alongside pre-service teachers and teacher educators—

may help create a more cohesive and aligned learning environment where theory and practice mutually inform one another.

Conclusion

This study examines Collaborative Lesson Study through the lens of the ATD, addressing two central research questions. First, we conceptualise Collaborative Lesson Study as a paradidactic system situated within the paradigm of questioning the world (RQ1). This framework fosters inquiry communities where pre-service teachers and teacher educators collaborate to develop and refine mathematics teaching practices. By positioning Collaborative Lesson Study within this paradigm, we underscore its potential to integrate inquiry-based approaches into initial teacher education. Second, our analysis reveals the emergence of specific mathematical and didactical praxeologies within the context of Collaborative Lesson Study (RQ2). At the micro level, these praxeologies are shaped and refined through collaborative observations, discussions, and reflections between pre-service teachers and teacher educators. Concrete examples illustrate how tasks, techniques, and justifications are negotiated. At the macro level, Collaborative Lesson Study demonstrates its broader impact by promoting a more transparent and inquiry-driven teaching culture within initial teacher education, bridging the gap between theoretical knowledge and practical application. However, addressing the disconnect between campus-based learning and internship realities is crucial, highlighting the need for further development of the Collaborative Lesson Study intervention. Involving cooperating teachers in future Collaborative Lesson Study interations could create a more cohesive environment.

Using the didactical contract to untangle the complex dynamics of a lesson study group in initial teacher education

Sara Presutti

University of Teacher Education Valais, Switzerland; sara.presutti@hepvs.ch

This paper addresses the issue of understanding the dynamics between the participants of a collaborative setting like lesson study (LS) in an initial teacher education program. The case study presented is a LS course held for prospective mathematics teachers at secondary level at Lausanne University of teacher education, in Switzerland. The changes in the didactical contract and in the postures of both the educator and the preservice teachers are analysed using qualitative methods. Results show a gradual change in the group dynamics through the process, and the progressive reinforcement of clauses of the didactical contract that are characteristics to LS.

Keywords: Lesson study, initial teacher education, didactical contract, facilitator, role.

Introduction

At the beginning of the 2010s, Krainer and Llinares (2010) literature review identified the social dimension and the reflective practice as key features for mathematics teacher education, as well as new challenges for the future. Since then, the interest towards collaborative settings in this field has significantly increased (Borko & Potari, 2020), especially regarding initial teacher education (ITE). Due to its features, *lesson study* (LS) is one of such settings. This form of professional development, founded upon the Japanese practice of *jugyou kenkyuu*, gained popularity outside of the Asian continent at the end of the 1990s. Although in Japan LS is used for both in-service and preservice training, outside this country, preservice implementation has taken place only at a later stage. The reason of this late development is that LS is subject to several constraints and challenges when practiced in ITE, like time limitations or the difficulty of access to real classes (Ni Shuilleabhain & Bjuland, 2019). In this context, the task of teacher educators is particularly challenging, as the imbalance of power and experience between the participants may hinder the establishment of truly collaborative relationships (Ponte, 2017). Moreover, they are at the same time facilitators, experts and educators to the LS group, which implies a different approach to knowledge depending on the role they chose to take.

For these reasons, in order to explore LS potential for ITE, it is important to better understand how its implementation affects the interactions and the dynamics between the members of the program. The study presented here is part of a broader doctoral research (Presutti, 2024) addressing two main issues regarding LS in ITE. On the one side, it seeks to examine the conditions and adaptations that affect LS key features, in the context of an ITE program held at Lausanne University of Teacher Education, Switzerland. On the other side, it aims to explore the possible contributions of LS and the learning outcomes for its participants. This paper addresses the first aspect, providing a follow-up to a precedent study presented at CERME13 (Presutti, 2023), with a specific focus on the evolution of a LS group dynamics through the analysis of its didactical contract.

Theoretical background

The main object of study of this research is, as previously stated, LS. This process is based on the collaboration of a group of teachers trying to solve a teaching or learning problem. To achieve this, they engage in an action-research process: they study the problem and analyse the curriculum, then plan a lesson and collectively observe its outcomes. Subsequently, they discuss their observations and either disseminate the results to the professional community or re-engage in the first phase of the process, giving it a cyclical structure.

LS is usually coordinated by a *facilitator*, who helps the flowing of the process by involving all participants and promoting the dialogue (Lewis & Hurd, 2011). During some phases, and particularly the post-lesson discussion, the group's work can be supported by an external expert, or *knowledgeable other*. These two figures have hence different attitudes towards the knowledge at stance, with the former potentially retaining some of it, while the latter is invited to state it explicitly. It is although important to note that in countries where LS is not yet well-established, these two roles may overlap, since the facilitator should possess knowledge about the LS process, as well as pedagogical and disciplinary expertise (Hourigan & Leavy, 2021). To account for this complexity, some authors have modelled the facilitator as a figure with multifaceted roles (Clivaz & Clerc-Georgy, 2020). The picture is even more complex when LS takes place in ITE, as the role of educator come into play. According to Clivaz and Clerc-Georgy (2020), whose research was on LS with in-service teachers, all the roles can coexist and evolve throughout the LS, depending on the relationships within the participants, but also the subject of the LS and the facilitator's expertise in it. Using the framework of Brousseau's Theory of Situations (1997), it is possible to interpret this evolution as changes in the *didactical contract*.

The didactical contract is in fact a set of norms, mostly implicit, that regulate the mutual expectations of the teacher and the students concerning the mathematical knowledge at stake (Hersant & Perrin-Glorian, 2005). It encompasses two dimensions: one epistemological, related to the mathematical knowledge, and one social, concerning the reciprocal expectations between the stakeholders in the production of knowledge. Hersant and Perrin-Glorian (2005) developed Brousseau's concept of didactical contract by considering four aspects that characterize it at different scales. The first one, acting on a *macro-level*, is the teaching object. The second and third aspects are the didactic status of the knowledge and the existence of an adidactical potential of the milieu. These aspects characterize the contract at the *meso-level*, i.e. the realization of an activity (for example the resolution of a problem). The fourth aspect is the distribution of responsibility in the construction of knowledge, acting at a *micro-level* (at the scale of an episode: the set of interactions around a unit of knowledge). According to this framework, the complex interactions between the participants of LS in ITE influence both the epistemological and the social dimensions, particularly in the distribution of responsibility, i.e. at the micro-level.

With respect to this theoretical framework, the research question may be stated as follows: *how does the (micro)-didactical contract of a LS group held in a ITE program evolve through the process?*

Data and method

The case study presented in this paper concerns a university course based on LS that took place at Lausanne University of Teacher Education during the autumn semester of 2021. The LS group was composed by five preservice middle-school mathematics teachers. It was facilitated by a university educator with experience in LS, who was also in charge of their evaluation, while two experienced schoolteachers participated to some of the sessions. The LS consisted of two cycles, with one mock-up research lesson and one lesson held in the class of one of the schoolteachers. The total was of 12 sessions of 1.5 hours each, plus one 45-minutes lesson. As a researcher, I designed the LS and each session with the teacher educator, and I observed their implementation without intervening. The LS subject was decided in advance during the design of the course, to better anticipate the teaching and reading material. The chosen topic was the teaching of integers at grade 7, a pivotal moment for the extension of the number system and the passage to algebra (Rezat, 2019). During LS, the preservice teachers decided to focus on integer multiplication and its mathematical justification, one of the first examples the pupils encounter where the justification relies only on intra-mathematical arguments, namely Henkel's permanence principle[1]. For the teacher educator, the goal was for the preservice teachers to acquire mathematical knowledge about the permanence principle, and to be able to justify their decisions regarding its didactical transposition to the class.

Data collected for this part of the PhD research consist in video recordings of all the meetings. Other data consist in texts written by each participant at the end of the course, the lesson plan, and all the documents and the artefacts produced during the process. All the video recordings were summarized in a synopsis, and arranged according to three levels (macro, meso, micro), following Hersant and Perrin-Glorian (2005) method (see Presutti, 2023, 2024 for further details). Macro-level consisted of LS phases. Meso-level consisted of training tasks proposed by the educator to the preservice teachers. Micro-level consisted of episodes. To grasp the interactions and the evolution of the didactical contract, each episode involving the permanence principle or its didactical transposition was qualitatively coded according to the knowledge at stake, the elements of the milieu, the kind of micro-contract[2], the preservice teachers postures (namely pupil, student-teacher, teacher, and researcher-practitioner, following Guille-Biel Winder et al., 2018), and the educator's posture.

Coding of the teacher educator's posture required a specific procedure, since very little research is done about his role in the ITE case. The first step consisted in theoretically defining and separating the *roles* from the *postures*. The educator's *roles* stem from the institutions to which he or she is subjected. *Postures*, on the other hand, depend on his or her positioning within the roles and influence how the educator acts, thinks or speaks in a given situation, as well as his or her attitude towards knowledge. All postures hence coexist, but for each episode it is possible to identify a predominant

[1] The idea that algebraic operations should be consistent in all number systems, particularly in the development of their extensions.

[2] Hersant and Perrin-Glorian highlight seven kinds of micro-didactical contract, depending on whether the teacher retains full responsibility (four), shares it with the whole class (two) or with each student in the class (two)-see Table 1.

one based on the educator's actions and speech. The second step was the creation of a list of roles and postures. This was made according to a literature review, from which all the possible roles and postures were listed (most of the articles didn't differentiate between the two terms). The first list, L_0, comprehended 20 terms. Step three was the refining of L_0 by associating similar terms, e.g. *koshi*, external expert and knowledgeable other. During step four, the terms indicating institutional roles were extracted: educator, facilitator, and teacher. The resulting list was then tested on the data set and refined by taking away the remaining ambiguous terms. The retained roles and postures are shown in Figure 1.

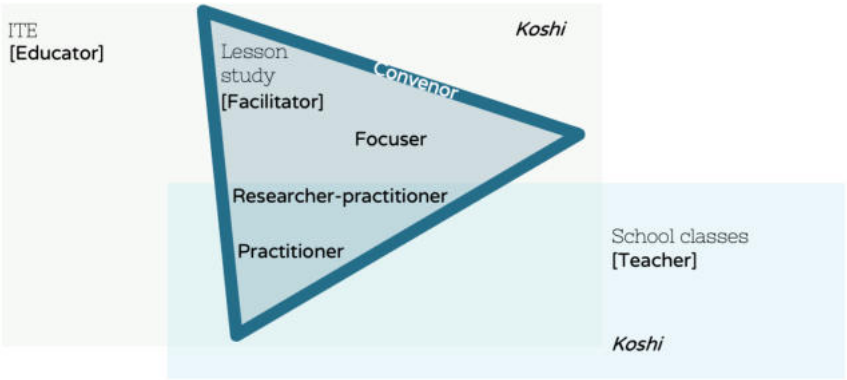

Figure 1: Institutional roles [in brackets] and postures of an educator doing LS in ITE

The analysis at the micro-level highlighted some particular moves of the educator on the didactical contract and on the milieu (presented in Presutti, 2023), as well as some key moments in LS process with regard to the knowledge at stake. Those key moments were analysed at the meso-level to better understand the dynamics of the interactions between the participants during the mathematical and didactical activity. Some results of these analysis are presented in the following section.

Results

A first result concerns the evolution of the micro-contract of distribution of responsibility with respect to the construction of the knowledge at stake.

Table 1: Frequence of the micro-contracts of distribution of responsibility

Micro-contract category	Type of micro-contract	Number of episodes identified (total=161)
The educator retains full responsibility	Information	4
	Assumed ostension	34
	Disguised ostension	4
Responsibility is shared between the educator and the group of preservice teachers	Adherence	28
	Collective production	83
Responsibility is shared between the educator and each preservice teacher	Individual production	8
	Tutoring	0

In total, 83 out of 161 episodes were coded with the micro-contract of *collective production*, more than each of the other kinds of contract. Most of these episodes (63) are distributed in the second part

of the LS course, between session 6 and session 12. Besides, in sessions 5, 10 and 11, many episodes show a didactical contract of explicit ostension of knowledge: these episodes are marked by the presence of the schoolteachers, who undertake the posture of *koshi*, or experts, in most episodes.

To get a closer look of the evolution of the social and epistemological dimension of the didactical contract, three training tasks have been chosen from the beginning, the middle and the end of the LS course. Task 4 took place at the beginning of the LS process, during session 2 (00:40:39-1:05:35). This session was the beginning of the study phase and aimed at understanding the mathematical reasoning behind the sign rule through the analysis of some textbook tasks. After a discussion about textbooks, Thomas, one of the preservice teachers, directedly asked the educator why $(-1)\cdot(-1)=+1$. The educator first proposed to the group to look for some common answers (Figure 2, E01), to which the preservice teachers answered by suggesting a pattern explanation (E02). The repeated moments of silence and hesitation during this episode led the educator to propose a task found in a lesson plan of a previous LS group (E03). The preservice teachers' expectation of an answer from the educator led him to take an expert posture (*koshi*) and to set up a kind of dialogue lesson in which he finally stated the concept of the permanence principle. In E03, preservice teachers assumed a pupil posture. This kind of move of the educator on the didactical contract, named M1, has been presented in a previous study (Presutti, 2023).

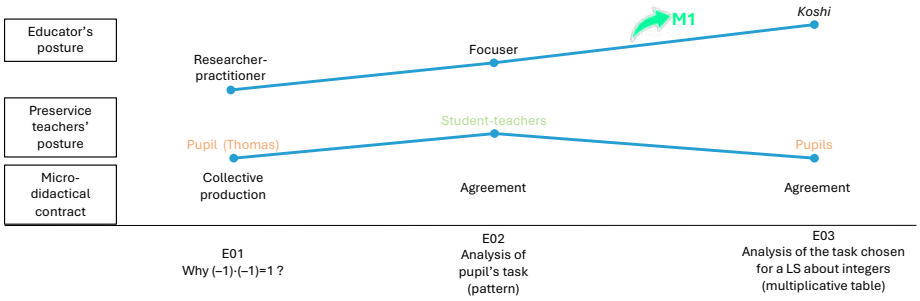

Figure 2: Educator and preservice teachers' posture changes in session 2, task 4

Task 3 (0:35:56-1:17:12) took place in session 6, devoted to the planning of the first research lesson. During this task, the LS group discussed the first part of the lesson, in which an illustration of the integer multiplication is shown through the use of arrows made of cardboard representing vectors on the number line in four different cases. After the discussion upon the first case, $2\cdot3$, the group analysed the two multiplications $(-2)\cdot3$, $2\cdot(-3)$ and their respective representations with the arrows. During the discussion, in episode 2 the educator took a researcher-practitioner posture by saying that he *really* didn't know the best way to present it to the pupils, and the group could only make assumptions and validate them during the research lesson. With this move (M2) the educator took a participant perspective and strengthen the didactical milieu, as it was the only way to validate the mathematical and didactical knowledge at stake. In episode 3, the prospective teachers took themselves a researcher-practitioner posture and produced hypothesis about the vectorial representations of the multiplication, which led in episode 4 to the emergence of knowledge about the commutative property of the multiplication, the "symmetry" of the representation and the minus

sign as an opposite operator. After M2, the micro-didactical contract turned to one of collective production of knowledge for the rest of the training task (Figure 3).

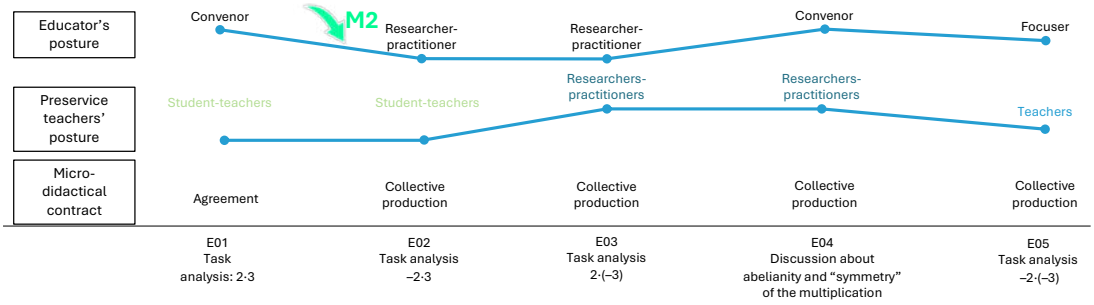

Figure 3: Educator and preservice teachers' posture changes in session 6, task 3

Task 3 (0:48:26-1:22:51) of session 11 took place during the analysis of the second research lesson. Session 10 was devoted to a first debriefing, while session 11 was devoted to a deeper analysis of the observations. One of the schoolteachers, Yves, joined the meeting. During this task, the preservice teachers assumed a teacher posture and put into perspective their observations about the timing, the place for "mathematics theory" during the lesson (episode 1, Figure 4), or pupils' activity (episode 2). During episode 3, Yves was invited to express his thoughts on these topics. He explained that when he taught integer multiplication, he made different choices, questioning the group's will to tackle the mathematical justification of the sign rule. In this case, the educator felt it appropriate to regain his *koshi* posture by taking explicitly his "teacher educator hat" (Presutti, 2023) and mediate between the positions. This move (M3), together with Yves intervention, marked the micro-didactical contract as one of explicit ostension of the knowledge at stake (in this case, didactical knowledge). During episodes 3 and 4, the preservice teachers maintained their teacher postures by drawing parallels with their previous teaching experiences and analysing classes similarities and differences. In episode 5, the educator finally asked the participants how they would redo the research lesson, taking a convenor posture. Eventually, each participant answered with a different version of the lesson. All but one preservice teacher maintained their teacher posture, while one of them took a research-practitioner one by directedly linking her lesson to the LS issue. It is important to observe that in this phase of the LS, the teacher posture was predominant over the researcher-practitioner one. Episode 5 was also the only episode in which the schoolteacher took a practitioner posture.

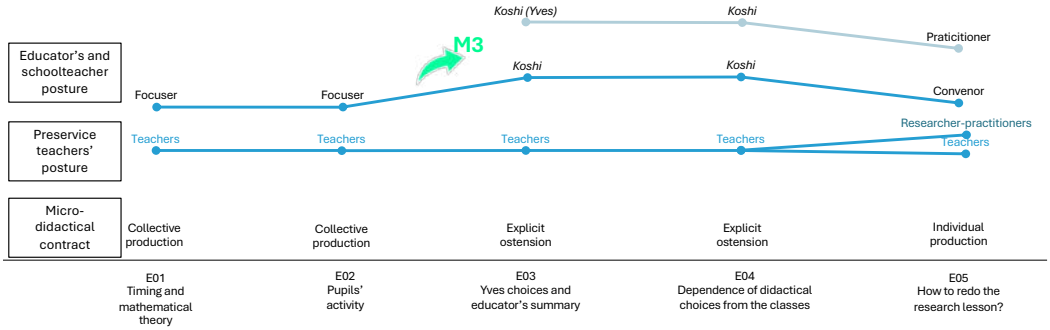

Figure 4: Educator and preservice teachers' posture changes in session 11, task 3

Discussion

The focus of this case study was the understanding of the dynamics between the participants of a LS set in ITE through the theoretical lens of the didactical contract. For this purpose, the analysis of the changes in the micro-didactical contract was enriched by the study of the postures of both the teacher educator, the preservice teachers and, when present, the experienced schoolteachers. The observation of the evolution of the didactical contract shows that there is a significant shift in the second part of the LS from the point of view of the sharing of responsibility in the construction of knowledge, which is more and more a collective effort instead that an initiative of the teacher educator. This aspect is also illustrated by the comparison between the training tasks in sessions 2 and 6. In fact, in session 2, the educator's move (M1) led to the assumption of an expert posture, ending up in an explicit clarification of the attended knowledge. On the contrary, in meeting 6, the educator move (M2) consisted of the assumption of a researcher-practitioner posture, resulting in a change in the epistemological and social dimensions of the didactical contract and in a stronger interaction of the preservice teachers with the milieu. Besides, the distribution of these two moves during the LS course (Figure 5) show that M1 is more present in the first half of the LS process, while M2 in more present in the last half.

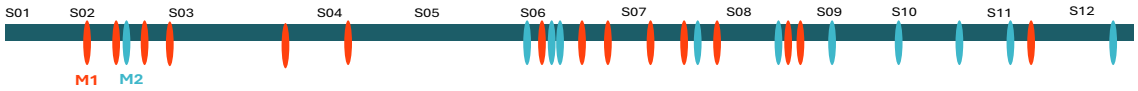

Figure 5: Distribution of M1 and M2 during LS

Session 2 and 6 also show a "mirror effect" between the educator and the preservice teachers' postures, resulting in a distancing of the postures (M1) or an approaching (M2). This can also be read as a more teacher-student dynamic (M1), or a researcher-researcher one (M2). Interestingly, this mirror effect is no longer present at the end of the LS, as shown in session 11. In this case, the assumption of an expert posture by the educator (and the schoolteacher) doesn't end up with preservice teachers taking a pupil or student-teacher posture. They persist instead in their teacher posture. This may suggest a "maturing" of the teacher posture over time, which also assumes a more reflective standpoint, but doesn't become a researcher-practitioner one.

In conclusion, this study shows a significant evolution of the group dynamics during LS, marked by the transition from a more traditional university training to a LS one (i.e. a collective, teacher-led activity). These analyses also highlight the fact that, in ITE, adapting to LS might require significant time for the participants to adjust to the "LS clauses" of the didactical contract. Regarding this aspect, it might be insightful to test other forms of LS in ITE, such as practicum-based. Finally, it is important to note that in this study the posture of the prospective teachers and of the educator are not symmetrical, as they come from different frameworks. Further work is needed on investigate these postures and their consequences on the actual effectiveness of LS in ITE.

In lesson studies carried out in Western countries, a key role is played by the facilitator, who organizes and leads the entire process. Despite the contributions regarding this issue provided in the literature, the knowledge about the preparation that facilitators need and the challenges that they face in their activity is still fragmented. Thus, the aim of this communication is to present a systematic literature review on the role of the facilitator in lesson studies in mathematics, identifying and synthesizing the necessary skills and knowledge and the challenges faced by facilitators and suggesting directions for future research.

Keywords: Lesson study facilitator, knowledge, skills, challenges.

Introduction

Lesson study (LS) is a collaborative and reflective professional development process focused on improving student learning. In a LS, a group of teachers works in cycles of planning, teaching and observing a research lesson, and reflecting on this lesson. In the lesson studies carried out in Japan, the so-called "knowledgeable other" plays an important role, as an external expert who, in most cases, intervenes mainly in post-lesson reflection in order to enlarge and deepen the participants' understandings about students learning. In lesson studies carried out in Western countries, another figure tends to assume a key role, the facilitator, who is responsible for organizing and leading the entire process (Hourigan & Leavy, 2021; Huang et al., 2021; Lewis, 2016).

Recent studies indicate that the role of this facilitator is complex and underline its relevance in structuring LS and leading its sessions (Hourigan & Leavy, 2021; Lewis, 2016; Mynott & Michel, 2022). This facilitator "must be strong enough to guide, yet invisible enough to give participants agency to determine their learning" (Mynott & Michel, 2022, p. 57). To perform these functions, the facilitator needs to understand the many facets of school life and teaching, have knowledge about LS, and a broad and deep mathematical and didactic knowledge to be able to guide teachers in a process of collaborative learning and continuous improvement (Hourigan & Leavy, 2021; Lewis, 2016).

Despite the various contributions on the facilitators' role in LS provided in the literature, the knowledge about the preparation necessary and the challenges they face in their activity is still fragmented (Moeller et al., 2022; Mynott & Michel, 2022). A systematic review of the literature therefore can help to provide a clearer and more articulated view of the various facets of the facilitator's role in a LS. Thus, the aim of this review is to synthesize the existing literature on the role of the facilitator in LS in mathematics, seeking to identify what this literature says about the

necessary skills and knowledge and challenges faced by facilitators in LS and to suggest directions for future research.

Methods

On November 14, 2023, we conducted a systematic search of the Scopus, Web of Science, and ERIC databases, using a specific search strategy to identify relevant articles on the topic of study. The search strategy was configured to search in the title, abstract and keywords of the articles, with the following formulation: ("lesson study" OR "learning study") AND ("facilitator" OR "facilitation" OR "teacher educator" OR "teacher of teacher"). To ensure the quality and relevance of the results, we apply filters to restrict the results to peer-reviewed scientific articles, with no limits on year of publication, written in English. We included articles that met the following criteria: (i) empirical studies; (ii) studies focused on LS with in-service teachers, from primary to secondary education, or in the preparation of facilitators. Articles related to LS in the initial teacher education, pre-school or higher education educators were excluded.

The process of identification and selection of articles was conducted by two independent researchers. Initially, the researchers analysed the titles, abstracts, and keywords to select articles for the eligibility study. The selected articles underwent a comprehensive analysis to determine their inclusion in the final corpus of analysis. In case of disagreement between the researchers, a third researcher was consulted to solve the issue. Cohen's Kappa coefficient was calculated to measure inter-rater agreement, resulting in strong agreement for the inclusion of articles in the eligibility study ($k = 0.895$, $p < 0.001$) and inclusion in the final analysis corpus ($k = 0.885$, $p < 0.001$). The steps of this identification and selection process are given in Figure 1. This process led to the identification of thirteen articles which summary is provided in Table 1.

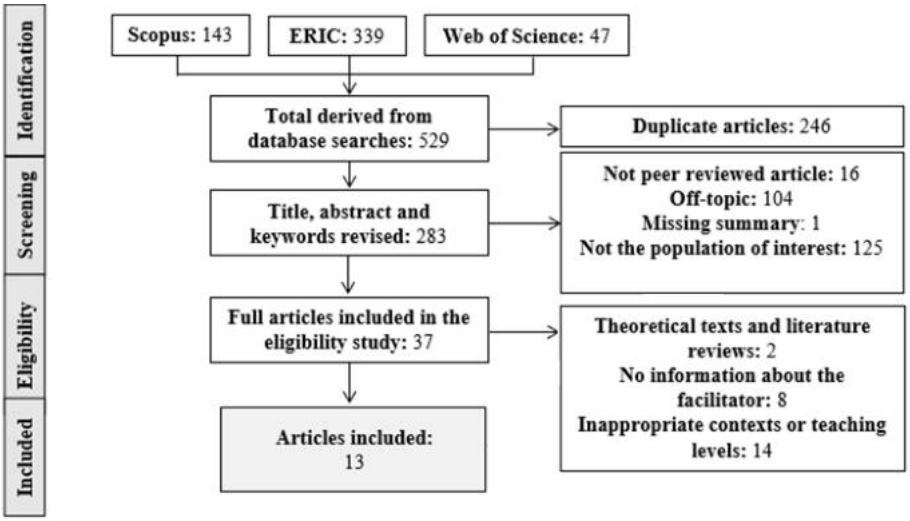

Figure 1: Identification and selection process of the articles for the literature review

In the first stage of the analysis, SciSpace software was used to identify relevant information regarding the two dimensions of interest: the "necessary skills and knowledge" and the "challenges faced by the facilitator". Based on this, three researchers carried out a detailed analysis of the articles,

identifying main categories in the previously identified dimensions.

Table 1: Brief description of the articles

Authors	Aim of articles	Main results
Akiba et al., 2019	To examine which design features of mathematics LS support effective teacher collaboration and professional development	Facilitators significantly influenced teachers' learning by focusing on student thinking and providing relevant resources. Effective facilitation of in-depth discussions enhanced critical thinking and fostered collaboration. Facilitators needed strong knowledge of content and student reasoning to lead discussions for meaningful teacher learning.
Clivaz et al., 2023	To examine how dialogic interactions contribute to knowledge construction	In lesson planning, both facilitators and teachers used their knowledge of instructional practices and of students. The facilitators, particularly the math teacher educator, mainly adopted a guidance role, although new ideas came mainly from teachers. As a teacher, the other facilitator played a key role in the dialogue for arousing reasoning development.
Hourigan & Leavy, 2021	To explore the practice of two mathematics teacher educators acting as novice facilitators of LS	Having noted participants' resistance in the first session, the facilitators sought resources to fit teachers' needs and context, while balancing supporting and promoting their agency. Managing the participants' involvement and considering their busy schedules, is challenging for facilitators and can limit teachers' learning.
Huang et al., 2021	To analyze how digital platforms facilitate teacher learning and collaboration by an online cross-cultural LS	The LS cycle and expert facilitators were crucial for teachers to develop their content knowledge (concept of probability). Although several technical challenges emerged, teachers and facilitators collaborated to improve the lessons, linking research to practice. Teachers' learning also included technology, pedagogy, and instructional design skills.
Jiang et al., 2022	To understand how and what teacher and teacher educators learn collaboratively in LS	The facilitator realised the importance of addressing teachers' concerns, moving from being the one "to learn from" to the expert who works with teachers to understand how they learn and the decisions they make in practice. This form of collaboration may impact teachers' work and professional learning, as well as the facilitators' knowledge.
Joubert et al., 2020	To explore the use of LS in a blended format to help isolated teachers to integrate technology into their teaching	Facilitators were essential in providing guidance and prompting teachers' reflective practices, along with peer-facilitators that emerged during LS. Smaller groups, reflection questions and lesson planning forms enhanced collaborative learning. Nonetheless, the allocation of teacher time was vital for successful collaboration and teacher learning.
Lewis, 2016	To analyse how novice facilitators learn to lead LS	Facilitators enhanced their knowledge by drawing on their prior LS experience and addressing challenges such as teacher resistance and time

		management, while balancing guidance with teachers' autonomy. They emphasized collaboration and combining pedagogical, content, and school-based knowledge to address participants' needs.
Lim et al., 2016	To investigate how LS can enhance teaching practices and improve student learning	Facilitators played a crucial role promoting the development of teachers' pedagogical practices and beliefs, namely by promoting collaborative work at lesson planning, facilitating productive discussions, providing feedback and encouraging reflective practices. The authors also highlight the importance of considering the local cultural needs.
Moeller et al., 2022	To understand how facilitators influence the implementation and effectiveness of a professional learning program (PLP)	Local facilitators played a critical role in adapting PLP, like LS, ensuring fidelity to its core principles while making contextual adjustments. Collaboration between teachers, school, district and external facilitators was crucial for scaling up PLP effectively. Facilitators benefited from program experience, but their needs varied based on roles and expertise.
Mynott & Michel, 2022	To analyse how two facilitators from different continents support and lead LS cycles	Facilitators needed to prepare teams for effective collaboration, avoid dominating discussions, and guide participants, yet be invisible enough to give teachers agency to determine their learning. Sustaining LS cycles required participant-focused facilitation, establishing strong relationships, norms, and considering standards of LS facilitation.
Preciado-Babb & Liljedahl, 2012	To understand common and differential elements of groups of teachers, involved in collaborative design processes	The authors highlight the value of collaboration in empowering teachers and improving their ability to creatively address classroom challenges. Facilitators played a crucial role in guiding teachers into a collaborative process by structuring the sessions, organizing discussions focusing on student learning, and maintaining focus on goals.
Richit, 2020	To analyse LS in Portugal, identifying their challenges, adaptations, and specificities.	Facilitation of LS by an external team and adjusting the number of sessions according to the LS cycle goals are important adaptations to the context. The specificities include the exploratory approach as teaching approach, the development of micro-investigations on teaching, and collaboration, highlighting the importance of understanding the context.
Schipper et al., 2017	To investigate whether LS promotes teachers' professional development in adaptive teaching	The LS facilitator significantly influenced teacher professional growth by managing the process, stimulating teachers to apply theoretical knowledge, and fostering a focus on student learning and collaboration. Time constraints remained a challenge for full teacher participation.

Results

In these articles we find several categories, with some articles fitting in more than one of them. For the issue *necessary skills and knowledge*, the categories emerging concerned: (1) the creation of a

collaborative work environment and promotion of communication (with a subcategory of guiding teachers) and (2) the organization of professional learning situations, appearing in 10 papers, (3) the general planning and organization, appearing in 8 papers, (4) mathematical, pedagogical and didactic knowledge and knowledge about the LS process in 7 papers, and (5) reflection skills in 5 papers. As for the *challenges faced by facilitators*, the categories identified were: (1) managing the logistics of the process in 11 papers, (2) promoting the teachers involvement in the LS, in 9 papers, (3) promoting communication and creating a collaborative environment (with a subcategory of conducting discussions without dominating them) appearing in 5 papers, (4) making the necessary adaptations, (5) dealing with work pressure and other professional issues, both in 4 papers, and (6) getting the support of the administration in 3 papers. In the following, we provide a brief description of what we found in these categories and indicate their frequency in the articles.

Necessary skills and knowledge

All thirteen articles on the LS facilitator have relevant ideas about necessary skills and knowledge required for effective facilitation. First, 10 articles give especial attention to the capacity of the facilitator to create collaborative environment in the group in which there is a stimulating communication among the participants. One example is Lewis (2016), who highlights that facilitators should be able to co-design learning opportunities with teachers so they can tailor the learning experiences to the specific needs and interests of the group, thereby enhancing the relevance and significance of the learning process. Within this category, some articles refer that facilitators need the capacity of playing a pivotal role in guiding teachers (7 articles). For instance, Schipper et al. (2017) state that "the LS facilitator seems to play an important role in guiding teachers ... and stimulating the teachers to use theory and new insights in terms of PCK" (p. 299). They highlight the importance of facilitators "introducing the team members to LS, stimulating the LS team to focus on content and to exchange ideas" (p. 297).

Second, another group of articles concern the role of the facilitator in organizing the content of sessions, providing the opportunities for professional learning and the necessary materials to use in each session (10 articles). For example, Jiang et al. (2022) suggests the facilitator should create a learning space for mutual learning, pointing that "using teaching language with care to reach students", "anticipating students' misconceptions with forward-thinking", "addressing students' misconceptions", and "understanding students' perspectives/voices" (p. 66) prompt it. This is also referenced by other researchers (e.g., Clivaz et al., 2023; Schipper et al., 2017) that emphasize the importance of promoting "in-depth discussion of student thinking and actively engaging teachers in discussions" (Akiba et al., 2019, p. 7). Additionally, Lim et al. (2016) and Richit (2020) point to the importance of discussions in lesson planning and post-lesson reflection, which led to changes in teachers' beliefs and practices, and allowed them to acquire new professional learning.

Third, a set of articles refer to the facilitator's skill of planning and making the global organization of the LS, including the structure of different phases (8 articles). One example is the paper by Akiba et al (2019) which identifies specific design features that enhance teacher participation and learning in LS, namely facilitator's focus on student thinking and active teacher participation in the inquiry process. Richit (2020) emphasizes the significance of understanding the needs and cultural features

of the setting where LS is carried out, while Joubert et al (2020) focus on organizing LS in virtual settings and conclude that, while online LS is feasible, it requires smaller teacher groups for success. By organizing the different phases of the process, selecting appropriate resources, and adapting LS to the specific context of each school, facilitators contribute to the professional development of teachers and the improvement of teaching quality.

Fourth, several articles refer that facilitators need mathematical, pedagogical and didactical knowledge as well as a comprehensive understanding of the LS process (7 articles). For example, Akiba et al. (2019) and Clivaz et al. (2023) identify content and pedagogical content knowledge as fundamental, encompassing the selection of tasks with high cognitive demand and the ability to select materials based on research, as well as knowing students and teaching practices. Akiba et al. (2019) stress the need for expertise in LS. This knowledge is vital for selecting challenging tasks, guiding student-centred discussions, and ensuring in-depth dialogues, thus enhancing teachers' learning.

Fifth, there is also reference to the reflective capacity that facilitators need to have, to improve their facilitation practice (5 articles). This is seen as a capacity that allows the facilitators to deepen their knowledge about their role and improve their practice. For example, Lewis (2016) highlights the iterative nature of facilitator development, as they gain confidence and adaptability over successive cycles, being "more comfortable presenting less, [and] expressed more confidence in their ability to respond to teachers in the moment" (p. 535).

Challenges faced by facilitators

Concerning the challenges faced by facilitators, eleven of the thirteen articles point issues to consider. First, the most common category related to the challenges faced was managing logistical aspects (11 articles), primarily involving the management of available resources. For example, Hourigan and Leavy (2021) highlight the "inflexible timeframe" (p. 663) as a key constraint, while Jiang et al. (2022) pointed out the difficulty of coordinating lesson observation schedules.

Second, another category is to achieve the involvement of teachers in the LS (9 articles). This includes recruiting teachers to participate and also to get an effective participation of teachers in the sessions. For example, Hourigan and Leavy (2021) acknowledge that they "under-estimated the complexities of engaging teachers in LS" (p. 658), noting resistance from teachers. Moreover, they perceived a lack of interest in individual professional development among teachers. Lewis (2016) highlights the challenges associated with managing teacher resistance, particularly when facilitators possess inadequate training to address this issue.

Third, another challenge identified in five articles is to promote the communication withing the group and create a collaborative environment (5 articles). Four of these articles, as Jiang et al. (2022) and Mynott and Michel (2022), address a specific aspect of communication: to lead discussions without dominating them, allowing the participants to actively engage and make independent decisions. Lewis (2016) and Lim et al. (2016) highlight how a dominant facilitator can hinder teacher participation.

Fourth, another category concerns the need to make adaptations taking into account the cultural context and the curriculum (4 articles). This is pointed, for example, by Richit (2020). Sometimes, modifications are necessary to accommodate local needs, as demonstrated by Lim et al. (2016), who

encountered challenges related to finding availability to re-teaching the lesson.

Fifth, another challenge for facilitators is to manage teachers' work pressure (4 articles). In Hourigan and Leavy (2021) research, teachers were unwilling to dedicate their free time to professional development which, additionally to schedule issues, led to a significant number of teachers missing one or more sessions and limited the teachers' involvement. Participants in the study of Schipper et al. (2017) also reported "being under pressure to realize the objectives within the given time frames" (p. 298).

Sixth, there is yet another aspect mentioned in three articles: the need to get support from the school leadership and other administrative instances. For example, Moeller et al. (2016) emphasize the need for funding and time allocation as well as the importance of school administration to provide time for collaboration. Schipper et al. (2017) and Richit (2020) similarly underscore the importance of administrative support, arguing that without it, teachers lack the time and resources necessary for full engagement in professional development.

Conclusion

This systematic literature review provides the identification of important features regarding the necessary skills and knowledge of facilitators and the key challenges that they face. Taken overall, the articles reviewed indicate that facilitators need mathematical, pedagogical and didactic knowledge as well as knowledge about the LS process, need knowledge about the general planning and organization of LS, need to know how to organize professional learning opportunities as well as how to create collaborative work environments and how to promote communication in the group, guiding the teachers along the way, and, finally, as in any other complex activity, need reflection skills. Taken together, these are all relevant aspects regarding the skills and knowledge of facilitators, and the issue that remains is the depth and specific features of each of them.

As for the challenges faced by facilitators, the categories identified were making adaptations in the LS structure, content and process, promoting communication and creating a collaborative environment, including the challenge of leading discussions without dominating them, and getting teachers involved. Further challenges were managing the logistics of the process, dealing with work pressure and with professional issues and getting the support of the administration. Another issue, that we do not address here, is to know what research says about how these challenges may be faced in order to deal with them. That may be the subject of further study.

This review shows that there is already important knowledge about the facilitator's necessary knowledge and skills and about challenges faced by them. This knowledge, which is scattered through many different journals, provides a rather impressive global picture. However, other issues remain to be studied, such as to know what the literature says about how facilitators may be prepared to undertake this complex activity.

Socio-cultural practices and behaviours in collaborative inquiry

Geoff Wake[1] and Bruce Lander[2]

[1]University of Nottingham, Observatory for Mathematical Education, Nottingham, United Kingdom; Geoffrey.wake1@nottingham.ac.uk

[2]Matsuyama University, Japan

Centrally here we report a conversation between academics from the United Kingdom and Japan. It arises after a study visit of a group of colleagues from the UK to mathematics classrooms in Elementary Schools in Tokyo. This visit brought together the authors of the paper for the first time. Both are experienced in Japanese Lesson Study (JLS) but work in the different socio-cultural settings of the U.K. and Japan. The other visitors were meeting JLS for the first time and this prompted much discussion of the different socio-cultural environments of maths classrooms, schools and JLS as well as society more widely. The conversation draws on the experiences of the visit and JLS more widely to consider what is lost in translation in the interpretation of JLS to Lesson Study as practised in the U.K. and other socio-cultural contexts more widely. Drawing on a specific but limited number of issues we discuss the problems of translating JLS as a socio-cultural practice into different countries.

Keywords: Lesson Study, socio-cultural practices, cultural awareness, translation

Introduction

This article is concerned with issues that the authors consider should be more prominently visible and more widely discussed in research that is informed by the practice of teachers in Japan that has become known internationally as Lesson Study (LS). Throughout this article we refer to LS as practised in Japan, as Japanese Lesson Study (JLS) to differentiate from LS as manifested more widely in other jurisdictions. We use JLS as a catch-all term, however, we wish to recognise and emphasise that although there are aspects of JLS that vary considerably across space and time. For example, JLS that takes place within and across schools nationwide, can at times be more exploratory whereas at other times is more of an opportunity to be summative and a showcase for what has been learned. Here we minimise these differences to be able to consider the socio-cultural context(s) of JLS and LS more widely.

It is our intention to consider how the translation of terms and words associated with JLS, and the adoption or adaptation of this practice as LS, can obscure to some extent deeply embedded cultural norms and behaviours.

As a mathematics education community internationally, we increasingly look to other countries and jurisdictions for ways in which we might better educate young learners. In this paper, we caution that we need to look deeper than taking a surface view of practice and focussing primarily on the visible, overt and explicit. Here we argue that understanding socio-cultural practices such as JLS and other manifestations of LS requires more than a surface view and is a crucial element to certain areas of LS. Consequently, the translation of lesson study across the world whilst not necessarily misinformed may be under-informed and may be lacking sensitivity in translation if you are to acquire a deeper understanding of the wider picture of LS.

The main body of the article comprises an ongoing email conversation between us as authors. This discussion began in June of 2024 while on a lesson study trip to Japan then continued by email again until around mid-September the same year. The empirical material for this study consisted entirely of the conversations therein. Through this exchange we start to explore some of the issues that are emerging as we discuss the socio-cultural world of lesson study that we had experienced together during a study visit that focussed on schools, maths lessons, and lesson study in Tokyo, Japan.

At this point in our ongoing discussions, we draw some emerging conclusions and signal a warning for future lesson study researchers and practitioners. Such studies, conducted in different international settings we believe need to be more aware of, and sensitive to issues of socio-cultural practices and as researchers we should consider how to handle these in our work that draws on JLS and Japanese cultural understanding, the cultural origins of LS.

Beyond the translation of words

This article emanates from a collaborative exploration of lesson study that the authors undertook in Tokyo, visiting a number of schools with UK based colleagues that were encountering JLS as school-based collaborative research for the first time. Both authors had previous extensive experience of lesson studies in Japan with the first author having little knowledge of the Japanese language and the second author, although being a first language English speaker having lived and worked in the Japanese education system for almost thirty years. The second author carried out real-time interpretation from Japanese to English in classrooms and in discussions with teachers and academics and in discussions outside of the classroom, also interpreted from English to Japanese. All the JLS activity took place in mathematics lessons in elementary school classrooms and in addition some mathematics lessons that were not part of lesson study cycles were also observed.

The authors have not found discussion of translation issues prominent in the LS literature. However, of course, there is much to read regarding issues of translation elsewhere. Here, our main concern is that of the socio-cultural context of translation, not merely of language and we have found academic work of relevance in the socio-cultural activity academic community.

In discussion of culture in translation Teilanyo (2007) takes a literary work, an African saga and, as a starting point, considers its translation from its source text in the Izon language to a target text in English language. There is general agreement that the translation by Clarke (1977) is well crafted and captures the meaning and nuances of the saga in many ways. There is, however, criticism that the translation does not capture the relevance of the socio-cultural context. In discussion, Teilanyo points to possible different approaches to translation as being lexical translation, literal translation, free translation and figurative translation, suggesting that the latter two are target language focused and discusses how free translation has problems because words and expressions in the source language when there are culture-bound notions/constructs are involved, especially those imbued with philosophical meaning.

As researchers in LS this issue is immediately apparent as words such as *koushi*, *hatsumon*, *neriage*, *hansei*, plus many more that do not necessarily have cultural equivalents in other languages. In our discussion of JLS we often include these terms as untranslatable words which are often seen to remain

in their original Japanese form in English language literature. This may appear confusing to many as we believe their current English equivalents do not suffice as a sufficient translation of a deep-rooted Japanese cultural concept. As Teilanyo in his writing (ibid. p.7) further discusses, the use of such words from the source language that remain untranslated, in the target language helps achieve a "foreign flavour" that is recognised by those as the audience of the lingual and cultural translation. Before turning to our conversation that unpicks some of these ideas in the context of JLS translation to LS we note that some readers may meet the ideas that we explore after a double translation process. Translation first from Japanese as the source language to English as the target language, and then translation from English as the source language to a further target language of the researcher.

Conversation

GW: Following our observations of teaching and learning in Japanese classrooms, for which you kindly acted as interpreter, I have been thinking quite carefully of the socio-cultural practices involved in the lessons and realise that I need some further 'translation' of these so that I can better understand what we observed and experienced. For our understanding we need more than mere translation of the words spoken. At times the socio-cultural practices involved are openly overt, such as in the post-lesson discussion with certain formalities being clear, for example the turn-taking of participants, with the observed teacher always starting the formal discussion with some reflections on the lesson, but at other times I feel that I am potentially misunderstanding much of what is going on.

Maybe we can start our conversation by considering the reflective nature of the post-lesson discussion. I've been reading some of the literature around early years education and revisiting Catherine Lewis's seminal text, Educating Hearts and Minds (Lewis, 1995). In this volume she writes of children's pre-school experiences and how much freedom children are provided with to play and through such play learn to become responsible class members. This is facilitated with quite structured and teacher orchestrated class reflections that explore what has been done during the day, and significantly, events and issues that might have occurred that caused tensions are discussed, such as when individual children might be selfish when sharing with classmates. My further explorations uncover that this process has a Japanese term, *hansei*, which translates as something like critical self-reflection. Rholen and Le Tendre (1998) write of this suggesting that *hansei* involves asking questions about what individuals have done that might be considered as kind/helpful/naughty and the implications for others. These reflective practices seem to be formalised into group/class practices in pre-school and beyond and, to date, our observations of lesson studies of maths classes, haven't unearthed this aspect of school life at all. My interest in *hansei* is not entirely in relation to school practices per se, but the socio-cultural development of the identity of young people and implications for their future interactions as individuals in collectives more widely. For example, how do early practices such as *hansei* manifest in future lesson study behaviours? In relation to this I have also come across the practice *kaizen* which relates to "continuous improvement" and seems, according to my brief reading, to be more focussed on the activities of the collective. Maybe you could comment?

BL: Interpreting for you and colleagues during your study visit was a very rewarding experience. Throughout that week of interpreting during all the class observations and in the pre- and post- discussions, I made several important discoveries. The interpreting task during the class

lessons themselves was relatively easy, but the post-lesson discussions after each session were much harder due to the many cultural concepts that were raised and hidden meanings that discussants perhaps subconsciously used. During each post-lesson discussion there was a ritual of customs that were quite evident to me that had an impact on the order of speech and hierarchy within the room. The level of authority in the room indicated who spoke first for example and how much or little each teacher could add to the discussion.

Through my involvement in LS over the years I have found that there are in fact many cases of words and customs being misinterpreted. Words that you often see in the LS literature such as *koushi*, (teacher, or knowledgeable other), *hansei* (reflection) and *kaizen* (improvement) are deep-rooted cultural concepts that are often interpreted with just one word or expression in the literature leading to confusion or misguidance. Yes, I would agree with Catherine Lewis's thoughts on this, the idea of "*hansei*" is a cultural concept that doesn't exist in English in the same way as it does in Japanese, and it is something that is taught to children from a young age in Japan. The concept is quite complex and in LS refers to reflecting on decisions made in the classroom, either good or bad, by the teacher or the student and what the impact of those decisions are. *Hansei* has a very deep meaning and translating it with just one word in another does not do it justice. *Hansei-Kai* for example, is usually the period after a lesson study where teachers, researchers get together to discuss the lesson, a collaborative exercise that helps highlight why certain decisions were made. The meaning of the hansei-kai is not only to reflect but also to learn collaboratively and collectively and to discuss in depth concepts that arose in the research lesson. This is usually done in a positive manner with lots of praise by the observers and denial of such praise by the teachers who respond by saying that they could be better. It is not an evaluative in any way and is a predominantly positive exercise.

Another example of this is, as you mention, the word *kaizen*, or to improve. In English the word 'improve' has negative connotations, i.e. that something could be better, that there was a flaw somewhere and needs to be fixed. However, in Japanese that word does not have a negative connotation. I would say that kaizen refers to making something even better with the idea that nothing is ever perfect, a somewhat Buddhist belief. No lesson no matter how good it was conducted could always be improved, for example. It is culturally taboo to gloat or boast in Japan. When praised in Japan for example, it is common to decline or politely brush off any praise.

GW: It seems that my reading in my attempts to better understand both general behaviours and those that are particular to LS keeps returning to the development of young children as it seems that many behaviours are inculcated from the very earliest years. You mention hierarchy for example. This is something that can be overtly observed to some extent in Japanese and other cultures. An obvious example is that of there being more overt respect of age in Eastern than in Western societies. I read (Hendry, 1987) that children are expected from an early age to acknowledge that older children are more experienced, and that as younger children they can learn from them. Further, I believe that this distinction and expected respect is reinforced by language with terms being used to identify 'older brother/sister' and to show respect to grandparents, for example. I suppose the terms *sensei*, *san*, and *sama*, in professional life also overtly position those to whom we are talking.

I think it's worth emphasising at this point that it's not just how these terms and how they might be understood in a rather abstract translation, but rather how they result in both collective and individual behaviours, and these are introduced in the very earliest collectives into which we are socialised at very young ages. Tobin et al's volume (2009), *Preschool in Three Cultures Revisited*, provides some insight into how, from the very earliest age, children are expected to develop a sense of responsibility and control for the good of the collective

BL: Yes, Japanese society is a very hierarchical one. You're right, there is a different suffix at the end of people's names depending on the relationship between the two parties, with *kun*, *chan*, *san*, *sama* and *sensei* given to the various levels of respect when addressing others. This is implicitly taught from a young age and these elements of hierarchy are quite noticeable in all walks of life, but particularly in education circles with dialogue between student to student, teacher to student and of course depending on the level of experience and age of the teachers between teacher to teacher.

Japan is also well known as a country that ranks relatively highly in *Hofstede's* cultural dimensions theory as a collectivist society (Hofstede, 2011). This refers to the importance placed on goals and the well-being of the group/collective as opposed to the individual. Yes, it is true that these relationships are also evident in schools between students. In many schools, particularly primary schools where students in the upper years will look after those in the lower years passing on simple tasks. There is usually a gap of several years between those playing the senior role to those in the junior role. This trait continues in high school, higher education and in the corporate community with the *kouhai/senpai* custom where new recruits to a company, or younger students (*kouhai*) are expected to look up to their elders (*senpai*) with more experience, knowledge and respect. In this context the *kouhai* (younger or newer members to the group) use more respectful language with the *senpai* (superiors, although a poor translation). We witnessed this first hand several times during the post-lesson discussions in Tokyo regarding the order of contributions made. All this is highly visible in lesson study circles and is something that is perhaps not fully understood outside of Japan.

Stigler and Hiebert's idea of the cultural code, or the DNA of teaching seems relevant here: "*The teaching methods that are handed down from generation to generation through a cultural code that is present in most classrooms*". This code they say, "*is the main reason why changing teachers does not automatically produce changes in teaching*" (Stigler and Hiebert, 2009). These socio-cultural customs are very relevant to the whole body of JLS. Many of the words that are used to describe them are insufficient and need more explaining. Every language is immersed in cultural expressions that may have deep meaning in the language they are spoken but cannot perhaps be well translated into a second language due to cultural differences. Here are a few more words that may not be fully understood in countries outside of Japan: *tokkatsu* and *neriage* which you may find in lots of LS related literature of late.

I think that as LS gains popularity globally it has morphed into slightly different methodologies in each specific country. In each country they use the words we have discussed above but adapt the procedure to the cultural norms of that particular place. Good examples of that and relevant to what has been discussed here is the example of *Koushi* and *Hansei*. *Koushi* refers to a 'knowledgeable other', or a professor from a university perhaps that holds an element of importance and pride,

something in Japan society values and respects. 'Knowledgeable other' though holds a slightly pompous connotation implying that the Koushi is more knowledgeable than everyone else which could be interpreted as taboo in English. Hansei, or the *hansei-kai* (post-lesson discussion) on the other hand are being conducted in ways that are socio-culturally acceptable to the country where they are held in. In both cases, there is a slight difference to the hierarchical socio-context of Japan where they originated.

GW: Further to our discussions around socio-cultural practices more generally I have been thinking about where the maths fits in. Let me take the conversation in a mathematical direction. Attached is a screenshot of a Japanese maths textbook that has been translated into English (see Figure 1). You will notice it talks about the mathematics of "times as much". I think that there is a Japanese word for this phrase? I am assuming that "times as much" is a translation of this word and the translation is an attempt to capture a whole different cultural way of thinking about what I might call "the constant of direct proportion" in maths situations that can be expressed as a mathematical function by the relationship $y=kx$.

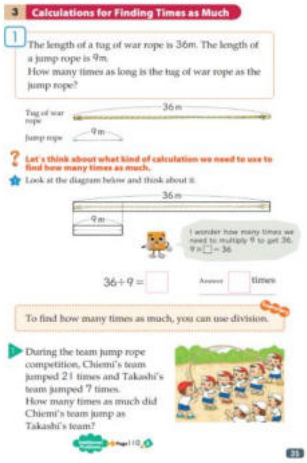

Figure 1: Page from Japanese Grade 3 mathematics textbook.

BL: I see. Yes, I can see now where the confusion with this term arises. I think the term "times as much" here is referring to the Japanese word 倍, *bai*, which refers to double, or a multiplication of a number, however the word *bai* does not have the exact same connotation as "multiply" in English. The word bai usually succeeds a number, as in: 2-bai, 3-bai, 4-bai etc etc. this would mean 2 'times as much, 3 'times as much', multiplied by two, three etc. When explaining the original text in Japanese into another language I can see where the confusion lies now. People often use this word as a noun as well which there is no equivalent of in English. For example: when talking about the price of things, one could reply simply with the word *2-bai*, or *3-bai*, meaning 2-3 times as much as it was. This could be another case of 'lost in translation'.

GW: It is noticeable that Japanese maths textbooks take a consistent approach to the development of these mathematical ideas (as directed by the Japanese mathematics curriculum guide (Isoda, 2010), and as some educators such as Tad Watanabe point out multiplication "sentences" are always written and introduced from the perspective that the number in a group is multiplied by the number of groups,

hence the “times as much”. It is my contention that this may be very different to approaches that are less consistent, one might even say, “exact”. Of course, in later stages this is extended to ideas of division. (Full details can be found in the text by Isoda and Olfos (2021).

Discussion

Mathematics is, in the main, considered to be ‘culture free’. International studies such as those of the O.E.C.D.’s PISA programme, although giving much background detail of the framework of how mathematics is conceptualised as a study domain, do little to dispel the notion that mathematical thinking and learning can be abstracted from the cultural differences of societies across the world. Our discussions reported here provide some insight into how making sense of teaching and learning, and indeed JLS as a collaborative research activity, might only be understood by having deeper knowledge and sensitivity to mathematics learning as a social, cultural and historically situated activity. Researchers such as Wenger (1989) have developed whole theoretical frameworks that consider learning from such a perspective, considering learning as involving apprenticeship into community practices but these approaches do not particularly signal that different national settings have their own peculiarities. This seems, however, to be a particularly important issue for those of us interested in LS given its provenance in Japan.

Egodawatte (2012) gives a helpful overview of how socio-cultural practices influence mathematical cognition. Our discussions as reported here provide some insight into some of the ways in which this might be relevant and important in our understanding of JLS. It seems that behaviours of teachers, both in and out of the classroom, are deeply seated in culturally and historically developed practices. Translation of words spoken is just one aspect of what is happening when teachers and students interact. Perhaps the most significant occurrence of this in relation to JLS is the practice of *hansei* which is not something that is significantly different from practices that are introduced to Japanese children from the very earliest of years. The post-lesson discussion, then, is something that one might expect to occur naturally. This is distinctively different to when it is introduced in LS in England, for example. In our use of LS, we have to work as a collective to establish ground rules for such reflective discussions so that we all adopt new individual and collective behaviours. For example, in England, class observations are often judgemental in nature, and associated with quality control of school leaders’, and the inspectorate’s expectations in relation to teaching and learning. For this reason, many teachers may oppose the idea of being observed which they may equate to being evaluated and critiqued where this is not the case at all in JLS.

We have also touched on how mathematical ideas might be mediated by linguistic tools that signify cultural models of mathematical thinking such as in the case of *bai* (times as much). In such cases we might consider the very mathematics we observe in Japanese classrooms as being situated in the cultural setting in which it is being learned and worked with and on.

Conclusion

The ideas we present here following our experiences of observing and studying lesson study in Japan provide what is inevitably a brief glimpse into how as a collaborative research collective working with lesson study we need a greater understanding of the socio-cultural aspects of JLS. This raises

issues of how we might adopt and adapt JLS in different countries and cultures, and our work in this regard might also be sensitive to the different ways in which we constitute and signify mathematical concepts in our different cultures. Alongside lesson study, there seems to be a growing tendency, certainly in England, to borrow from other countries' teaching artifacts, such as different representations, that can provide insight into mathematical structure. Again such borrowing seems to obscure how learning mathematics is in reality a deeply embedded socio-cultural practice. We advocate that future research is needed to better understand JLS and inform our own work in LS.

The classroom discussion in a TTP lesson: The challenges of a lesson study team

Gerrit Roorda[1] and Siebrich de Vries[1,2]

[1]Department of Teacher Education, University of Groningen, g.roorda@rug.nl;

Keywords: Lesson study, collaboration, teaching through problem solving, classroom discussion.

Introduction

Teaching mathematics Through Problem solving (TTP) is an approach to teach mathematics through problem solving activities. A TTP lesson consists of four phases: (1) posing a mathematical problem, (2) student problem solving, (3) a guided classroom discussion to compare and discuss students' solutions and (4) summarizing (Takahashi, 2021). The third phase, the classroom discussion, is mentioned as an important and central phase of a TTP lesson (Takahashi, 2021), but is also challenging. In this phase, teachers should avoid the often used Initiation-Response-Evaluation (IRE) patterns (Schoenfeld, 2002), but should guide interaction between students in a more pedagogical way to come to a shared understanding of possible solutions of the initial mathematical problem. Teachers appear to be able to develop TTP-lessons by collaboratively working in a Lesson study (LS)–team (e.g., Groves et al., 2016; Roorda et al., 2024, Takahashi, 2021). But how do teachers in a TTP-LS team improve the guided classroom discussion?

Methods

We implemented a TTP-LS intervention in which three teams of teachers of two secondary schools collaboratively designed TTP lessons in two consecutive LS-cycles (see Roorda et al., 2024). For this poster, we present data from one team of five teachers, during their second cycle, because this team explicitly discussed how to improve classroom discussion. The team was introduced to TTP-LS in three start-up meetings. The LS-meetings were facilitated by a mathematics educator (first author). The team prepared all four phases of the TTP lesson. The teachers choose to start the lesson with the problem in Figure 1. Teachers agreed that in classroom discussion the teacher would mainly discuss the different 'formulas' that could be used. The teacher would also discuss problem solving skills, such as making a sketch of the situation.

You see the table of a quadratic function:

a. Calculate the y-value for $x = 7$.

b. Calculate also the y-value for $x = 100$.

x	…..	1	2	3	4	……	7
y		0	-3	-4	-3		?

Figure 1: The problem *Table of a parabola*

The research lesson was conducted twice in respectively one grade 12 and one grade 11 class. Minutes and logbooks were made of the preparatory meetings. The research lessons were audio-recorded,

transcribed and analysed for patterns of initiation by de teacher (I), response by a student x (R_x) and evaluation by the teacher (E).

Results

In research lesson 1, it turned out that the teacher made the students work too long. In the limited time left (only 6 minutes) for the classroom discussion, the teacher shortly discussed different formulas, using three IRE-patterns for three solutions and one more interactive IR_aIR_bE-pattern. There was one minute left for discussion about problem solving strategies.

During the reflection meeting and an additional preparatory meeting for the second research lesson, teachers agreed that more time should be reserved for classroom discussion. Additional questions were formulated to help focussing on the central mathematical goals of the lesson.

In research lesson 2 the classroom discussion lasted 13 minutes. The teacher started with more interactive patterns (p.e. $IR_aIR_aIR_bIR_bE$), in which students were asked to reflect on ideas of other students. After a while the lesson became less interactive and the teacher used more IRE patterns. The additional questions proved helpful in organizing the focus on the essential mathematical aspects. Discussing and explicating problem-solving strategies, such as 'sketching' and 'checking answers' took 8 minutes. Our poster will present the team-development with respect to classroom discussion.

Conclusion and discussion

With respect to classroom discussion in a TTP-lesson, we conclude that the discussions in the LS team resulted in improvements, such as, more interaction, asking specific questions to highlight central mathematical goals, but that the teacher still frequently used IRE-patterns in the classroom. We presume that part of the problem lies in the social norms in the classroom. In addition to a different attitude from the teacher, this also requires a different attitude from the students. This challenging change requires explicit attention from the LS team. We therefore recommend to specifically train student centred classroom discussions, for example in mock-lessons (see Takahashi, 2021). Teachers could also train their skills by using lesson plans from already tested and described TTP lessons.

TWG 29: Embodied and Material Studies of Mathematical Behaviour

Searching for formats: How to share embodied and material studies. Introduction to TWG29 at CERME14

Anna Shvarts[1], Giulia Ferrari[2], Elizabeth de Freitas[3], Ricardo Nemirovsky[4], Nathalie Sinclair[5]

The development of the TWG focus

This year, we held the TWG Embodied and material studies of mathematical behaviour for the second time. We welcomed all researchers interested in mathematical embodiment and materiality. The range of topics is diverse, covering a very broad phenomena in mathematics teaching, learning, and doing. Just as before, we invited researchers investigating multimodality and sensory-motor processes, including gestures, eye movements, drawing, touch, language use, proprioception, physiological processes, etc. We specifically hoped to gather studies not only on sensory-motor processes performed by a student or a teacher, but also running across the bodies. The second focus lay in making and using material artefacts, technologies, as well as engaging in dance and other aesthetic forms. Affect and emotion as socio-material phenomena, pointing at atmospheric conditions of learning, were of great importance in our call for papers: already from the previous year, we felt how studying cognitive aspects of learning as isolated from affective energy is limiting for understanding mathematics learning. Even more than previous year, we hoped to gather researchers who appropriate embodied and/or material lens to study the diversity of racialized, gendered, dis/abled bodies in formal and informal learning settings, thus opening the room for discussions of political as indispensable from our attention to bodily processes that highlight idiosyncrasy and freedom over control. Discussions at the previous CERME brought in two new focuses. Firstly, we noticed how the investigation of teaching practices and teacher education lags behind the studies of students and learning environments, so we specifically invited the researchers to focus on teacher-oriented inquiries to support in transforming mathematical classrooms toward embodied teaching (Macrine & Fugate, 2021). Finally, we strived to discuss alternative research methodologies and means of dissemination that better address the embodied nature of mathematical activity, and/or avoid representationalism and strive for difference making (Barad, 2007), such as, diffractive, performative, historical, design-based, activist methodologies, etc.

Overall, the coherence of the thematic group lies in the perspective of consideration rather than on specific topics, as we are committed to a wide range of theoretical perspectives that highlight the role of the body and material environment in fostering mathematical behaviour. We intended to work on clarifying core theoretical and methodological issues per se, as well as their educational implications. Bringing the diversity of phenomena and theoretical lenses, yet staying committed to appreciating embodied and material processes, we aim to re-imagine future education as passionate and accessible.

Exploring alternative conference formats

At the previous CERME, a format of presenting research on embodied and material aspects of mathematics education was a recurrent theme. We discussed that the textual format of articles, including transcripts of activities, limits the possibility of transferring our findings and struggles. We

also noticed how a standard format of conference presentation is helpful by allowing the dynamics of videos to explicate embodied processes. Nevertheless, while listening to a presentation, we still felt alien from the real creative process that the authors of each contribution and their participants were living through—as it might be characteristic to a positivist rather than participatory paradigm (Heron & Reason, 1997). CERME has a long-lasting experience in avoiding long boring presentations, as participants are always invited to read the papers ahead and discuss them at the conference, sometimes with the help of pre-assigned opponents or thematic panels.

Yet, this year, we decided to radically experiment with the conference format, inviting our participants to invent new forms for sharing their work. In line with the spirit of embodied and material studies, we do not believe in transmitting mathematical knowledge from one head to another; instead we commit to an affective, creative process of engaging in mathematics (re)invention. Similarly, we thought, research findings and struggles shall be *lived through* rather than told about (Sinclair, 2024). So, we tried to provoke the authors to create collaborative environments consonant with each paper, where participants could *feel and explore* rather than hear about other researchers' results. Such a collaborative environment might include a brief reminder of a paper's focus, followed by an embodied/material exploration in the form of activity tryouts and/or moderated discussions.

As exploration requires sufficient time, we split the group into parallel sessions, offering the authors of each paper 30-minute timeslots. To secure some coherence along parallel sessions, we divided all the papers into five thematic lines of 4 papers: two pairs of thematically coherent papers were presented in parallel, so that everyone would be in touch with each thematic line. Each thematic line was supported by a set of leading questions that we derived from reading the corresponding papers. After parallel sessions, we would gather all together to have a short exchange on what had been happening. Furthermore, we planned two times an hour for the small group work, in which participants who attended different sessions would bring their insights together. Again, striving to support knowledge exchange as a material and embodied process, we invited participants to express their insight in *artistic form*, supplied with colorful paper and crayons.

As a thought-provoking kick-off, we gathered participants for a pre-conference online meeting where we invited participants to join this format exploration. We discussed a few ideas of possible ways to deliver the papers through exploration, showcasing a possibility of a moderated discussion or exploration of learning materials from the paper. Yet, we expressed our uncertainty and exploratory stance, inviting the participant to co-create their own conference experience. The commitment and enthusiasm of our authors were unprecedented. Many met before the conference to discuss how the panel stays coherent; others worked hard on adapting and transforming their materials so that a short exploration would make sense and on setting up the environment during the conference itself.

Thematic overview of the contributions and presentation formats

Overall, 30 authors of 20 papers and 5 posters joined TWG, coming from the UK, Italy, Brazil, Greece, Hungary, the Netherlands, USA, Canada, Israel, Austria, Switzerland, the Netherlands/China, Chile, Germany, and Australia. We started from a traditional ice-breaker in the form of a speed dating where participants meet each other while randomly walking in a room and

exchanging their various preferences and experiences, from food to research focus. After this, the parallel sessions dedicated to thematic panels began.

The first panel was on *Teaching and learning environments*. One of the parallel sessions was mostly arranged around teaching, and the other around learning. Alessandra Boscolo invited participants to discuss the limitations and major concerns for the effective implementation of Active Bodily Experience Mathematics learning activities in schools. The interviews in Boscolo's paper highlighted the need to transform school culture and classroom practices in a situation where institutional support is lacking and teacher awareness of existing methods is limited. During the CERME discussions, the issue of implementing ready-made embodied activities versus co-creating those activities directly with the teachers was raised. Claudia Corriveau and Benjamin Nicolas-Noir invited the participants into a mini design challenge, similar to the one that pre-service teachers in their research engaged in: using provided making materials, such as various papers, cardboard, wires, paperclips, we needed to create a manipulative that would allow exploration of integers. The unexpected complexity of this seemingly trivial task struck us, revealing how designing reveals to us, as experts, students' potential challenges. In a parallel room, Andrea Ghersi and colleagues engaged the audience with a selection of tasks using GGB+, which interprets gestures and shapes indicated by their arms, in relation to quadratic functions. They also introduced the theoretical framework of conceptual blending. The presentation was active and thought-provoking. Further, Jennifer Way shared examples of activities with groups of children collectively enacting mathematical representations. The children switched between egocentric and allocentric perspectives, formed number sequences by aligning themselves after number counting, and drew a polygonal shape using a loop of string.

The second panel was dedicated to *Mathematical concepts in embodied and material mathematics*, challenging traditional understanding of concepts as idealistic and abstract. Michael Rumbelow introduced Friedrich Froebel's mathematical objects and invited participants to observe how block construction is ultimately a process of breaking symmetry. Karel Boonstra and Marjolien Kool engage participants in symmetry exploration through see-through mirrors, inviting participants to reflect on teaching and learning opportunities that the environment-task provides, and how the shape of human bodies supports the exploration of symmetry with a see-through mirror. In the *joint discussion*, participants exchanged the excitement of playing and seeing mathematics in a new way in the suggested artifacts, noticing how embodied and materiality support mathematical exploration in various forms: from movement through interconnections and rotations to observing the materiality of polyhedra and crystals. Hang Wei introduced the group to the activities that required them to engage with bi-manual coordination in a digital environment where dynamic nomograms could be explored through multitouch dragging. The participants had the occasion to focus on the emerging feeling when synchronous movement was achieved and on the color-changing feedback, which would be probably difficult to gain in a standard presentation. Such experience also allowed the participants to gain a deeper understanding of the diagrammatic rendering of the data collected during the study, which illustrate how a student achieved fluency in the process of coordinating hands (and with the technology in use). Then, Christina Gkreka and Chronis Kynigos challenged us to reproduce specific patterns shown on the screen where relative positions of objects were to be preserved. The experience created space for thinking about angles as turns, and more broadly in relation to spatial orientation,

which was at the core of their contribution. The *discussion* around the papers presented in this panel also gravitated around the materiality of space, the diverse demands of the technological tools at play, and the different scales at which the body might be involved: from minute hand coordination to whole-body experiences.

The next panel, *Philosophy of embodiment, materiality, and maths*, was meant to create space for a deeper dive into what mathematics is and how it operates in a politically charged society, drawing from non-dualist embodied and material perspectives. Elizabeth de Freitas and Nathalie Sinclair presented a paper that addressed a concern raised at our previous 2023 CERME TWG meeting: the need to reckon with a more political perspective when discussing embodiment. They showed how embodiment and materiality are crucial concepts for making sense of the politics of mathematics education. The authors emphasized how mathematical concepts from geometry can be studied for how they embody political and cultural norms about space and interaction. They started by showing a series of slides (a two-column proof of the Isosceles Triangle theorem, an image of indigenous Quipu calculations, an image of a gnomon) and asked the other group members to discuss, "How are these political, as well as mathematical?" Anna Chronaki then presented a paper about the affective intensity of mathematical concepts enacted by young people in Greek schools, where convergent and divergent movements were studied as ways of engendering mathematical forms of belonging. She showed images from her research, and asked the audience to reflect on their assumptions about basic shapes. *The two papers* shared an interest in the aesthetics of mathematical practices, and the ways that mathematics is always lived through materiality. Together, they brought attention to political and ethical questions about inclusion and diversity in mathematics Education. They both emphasized monist theories of mind/matter, drawing on ideas found in Deleuze, Whitehead, and Spinoza, as well as feminist thinkers such as Donna Haraway, Rosi Braidotti, and Claire Colebrook. In a parallel session, Jorge Soto-Andrade asked participants to work on experimental situations with diverse materials and instructions, such as a collection of sticks and an algorithm to be bodily enacted. The results were extremely diverse, illustrating ideas under development by the Chilean School of Enactivism in Mathematics Education Research on creativity of mathematical perception as metaphorizing. Ricardo Nemirovsky and colleagues asked the participants to create trefoils with a piece of rope. After introducing the Gauss notations for knots, they discussed the correspondence between a trefoil and a number sequence of three odd numbers. *Both presentations* revealed how mathematics is present in engagement with material and how mathematical aspects open up in action and perception, thus fundamentally criticizing the view on mathematics as abstract and suggesting instead that processes of abstraction/concretion are constantly present in perception and action that reveal structures and patterns.

The third thematic panel was *Mathematics and movement*. Here we gathered specifically the papers that focused on how mathematics emerges from diverse types of movement: full body exploration of space, dance, large gestures grasped by technology, finger movements in exploration of tangible figures, etc. Myrto Karavakou highlighted the movement involved in students' creation of dances using trigonometric functions in a constructionist learning environment MaLT2 designed by Chronis Kynigos. Myrto highlighted the aesthetic responses guiding the students' "choreographies", which were expressed in the coding language of the learning environment, showing how the dancing was

used to express students' sensorimotor ideas about periodic functions. The authors draw on inclusive materialism to highlight the novel conceptual meanings of covariation that emerged in the students' creations. Then, Nadav Marco presented his research on "Blindfolded Mathematics," where learners engage in mathematical tasks using tangible artifacts while temporarily deprived of sight. One task involved determining whether three sticks glued to a card were parallel. Nadav highlighted the ways in which the body learns to move in new ways, becoming more efficient in solving the task. Participants could experience shifts in their own movements as they worked on different cards, and observed others doing so as well. In the parallel session, Réka Szász presented her work with co-authors on exploring plane transformations through large arm movements captured by GeoGebra Dance AR technology. Participants were invited to try out different modules and contribute to the design improvements during the small group discussions. The issue of congruency between mathematical action and participant movement emerged as critically relevant in such movement-oriented designs. Lena Radünz engaged participants in a large game on understanding place values through finding numbers that form a 100 square on the floor. Participants were surprised by unexpected struggles but also insights into how numbers below a hundred relate to each other. Embodied participation in the game differed drastically not only from reading about it, but also from simply watching the others playing the game. *All presentations* highlighted the importance of movement in mathematical activity, but focused on different aspects of movement. For Myrto, movement was a way of communicating ideas, while for Nadav, movement played a more epistemic role. Presentations by Lena and Reka specifically raised the issue of passivity versus agency, and how even repeating some action through a gesture is an active process. Discussion touched upon the issues of mirror neurons that activate not as a copy of another person's movement, but as an active interpretation of their movement aims (Rizzolatti et al., 2014).

The final panel was dedicated to *Methods for the study of embodiment and materiality*. As we hoped in the call, methodological considerations covered a variety of aspects. In their contribution, Francesca Ferrara and Giulia Ferrari approached the idea of the materiality of data and proposed a methodological reflection on data presentation, focusing on the creation and use of diagrams in our field, and their potential to transform data. During the panel, the experience proposed to the participants engaged them in choosing a classroom situation or a diagram presented in one of the papers discussed in the TWG. The groups of participants were then (respectively) tasked with the creation of a diagram or with a close analysis of the chosen diagram. The following discussion fueled the ongoing issue of the TWG around the ways of reporting and sharing our research. Christoph Oberbucher created a paper version of the digital task he reported on in his article, which concerned the concept of continuity. We were all engaged in placing paper strips on different graphs of functions, in order to delimit the vertical and horizontal regions (δ or ϵ- region respectively) that are at play in evaluating the continuity of a function represented in the cartesian plane. This activity (and the questions that accompanied it) served as an introduction to talk about the implementation of "impurities" in the design of tasks (referred to as doping) in the specific case of continuity within the framework of radical embodiment. Anna Baccaglini-Frank and Nathalie Sinclair focused on a new methodological approach for data analysis, namely re-enactments, introduced in Sinclair (2024). They invited participants to re-enact a small video clip with dynamic digital environment exploration

so they could experience how certain body movements themselves—movements of the hand on the screen, posture changes, tone of voice, etc.—differed significantly from reading about them in a transcript. This difference points to the need for more "embodied validity" (to use Patti Lather's term) in research that seeks to understand the nature of embodied meanings in mathematics thinking and learning. An activity by Anna Shvarts and Karel Boonstra was intended to showcase a similar point but on a broader scale. Participants were invited to role-play researchers, teachers, and students in embodied studies, working within different paradigms: strict measurement and controlled environments of positivist science, interviews in constructivist science, and, finally, collaborative co-creation of learning environments in transformative/participatory science. Comparing their experiences, participants could exchange how positivist and constructivist paradigms are limited when studying flexible, multimodal, discovery-based embodied processes. *Overall*, re-enactment of the data as analytical methodology, the role of diagramming in data presentation, the specificity of design research, and broad issues of embodied and material studies surfaced. These discussions presented a paradigmatic shift in social science which highlights how embodied and material studies of mathematical behaviour repositions not only study participants, but also researchers who are similarly engaged in material and embodied activities, and yet often forced to translate these into mostly disembodied and reified scientific discourse.

Finally, we had an embedded poster session, as such a format allowed participants to get into more detailed conversations around the projects that are still at a very early phase. Particularly, the insights from non-Western traditions, such as, Al-Khwarizmi's work on mathematical visualization of algebra and challenges of creating mathematical education consonant with Amerindian cosmology where relational dynamic ontology dominates (Thiago Pinto and João Viola; Vinay Kathotia and colleagues). Those issues formed a unique contribution to the scope of the group and pointed to important future directions for research in this area. Also, the core questions on embedding teachers' perspectives (Benjamin Nicolas-Noir and Karel Boonstra), methods to study affect (Jacoliene van Wijk and colleagues), and the theme of mathematics and art (Claudia Flores and colleagues) inspired many discussions during the poster sessions and afterwards.

Form and content: Looking back and forward

To integrate the richness of gained experiences, participants worked in small groups on artistic projects where they had an opportunity to express their insights not only in verbal but also in affective and diagrammatic formats. The outcomes varied from word clouds and networks to colorful metaphoric presentations and videos, which are difficult to capture in text (see for example Figure 1). The following themes were recurrent.

Firstly, we noticed very many aspects and perspectives on conceptualization of the *body* as taking part in mathematics learning and teaching: body as a whole and as a special part of assemblages in doing mathematics, extension of the body through tools and discourses, body as a tool itself, body as senses and as a source of emotions as feelings, as well as body of mathematics and mathematical knowledge presented as artifacts and physical objects such as crystals, wooden blocks and sticks; moreover, body was thought as relational as it participated in framing interactions and perception of physical objects. Similarly, the *movement* was present in very many forms: dance, walking actions in

finding mathematically specific positions, arm gestures in interaction with technology and with each other, hand manipulations and dragging, touch explorations, and so on. The variability of those perspectives shaped our experience of diversity in possible senses, materials, learning paths, technologies—while traditional research might strive to choose the best options, our group illuminated the variability and richness of possibilities that research opens, letting the community engage and evaluate them rather than presenting a final judgment.

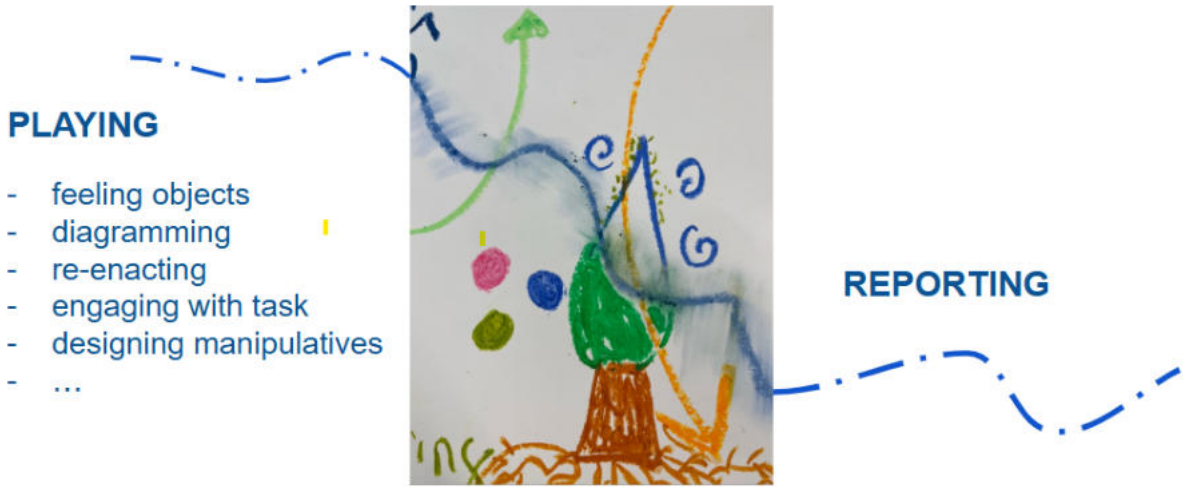

Figure 1 The drastic difference between playing with mathematics, educational design and research versus reporting about them

We sensed a *methodological* shift from static to dynamic that lit research results and mathematics education in practice as vibrant, unpredictable, fluent, affective, untransferable. Our methods called for alternative temporalities in a search for slowing down strategies, dwelling in, and thus disrupting typical ways of making sense. New methodological directions pointed towards connecting with arts-based practices, re-enacting, re-making, performing, symbolizing relations, co-creating, participating, transforming, rather than representing, assessing, judging, or taking for granted. These new directions raise numerous challenges, such as: How to capture and report a genuine and a holistic view? How to address and justify subjectivity? How to deal with policy and privacy issues? How to relate to established research norms and which new quality criteria might emerge?

Critically, such a radical reconsideration of what research might look like calls for thinking about possible infrastructures that would bridge the gaps between policy-makers, researchers, teachers, and students. We need forms that would engage those often isolated communities in a respectful and creative embodied flux where relations are of mutual learning rather than hierarchy. It also calls for a radical reconsideration of the nature of mathematics itself - the need to problematize, as always, assumptions about where and how mathematical activity occurs.

Such a transition is fundamentally *political*, challenging the established political system and revealing the political in small educational choices. For example, a choice of a task format or educational design: contrasting open-ended and closed problems, designs that privilege specific learning paths versus those that open diverse learning landscapes, technologies that respond to specific sensory-motor sensitivities and ignore others. Such pedagogical research needs to also engage with sociological, philosophical and historical investigations into the nature of mathematical concepts,

exposing the political framing of mathematical embodiment at the level of curriculum and policy, underscoring concerns about *which bodies produce which mathematics*.

The experimental *format* brought great enthusiasm and inspiration—we felt positive affect running through the bodies of the conference participants. The sessions became affectionate and memorable. Participants were free to raise their fundamental concerns about freedom, joy, and restrictions of normative mathematical culture. During the conference, we could not find a participant who was critical of our format experiment, apart from ourselves within the co-leaders team. We also enjoyed the freedom and playfulness that the formal experiment brought in. Yet we also felt we were sometimes lacking depth in our discussions and careful work on discursive components of theoretical work that embodied and material studies assume. The invitation to feel and explore fitted perfectly with some contributions, yet was challenging for others. How can the diversity and affectivity of bodily exploration and enactment complement careful theoretical work and reflection on past research in this and related fields, to allow for community synergies, mutual recognition, and some advancement in our collective understanding? This question, in application to both mathematics education and mathematics education research, will inform future iterations of our TWG. At future CERMEs, we will continue to experiment with formats, and search for collaborations with teachers, policymakers, and scholars with kindred interests. We hope to further enrich our meetings by attracting researchers who study learning processes in diverse cultures and contexts, attending to gendered and racialized bodies, as well as alternative sensory and motor profiles

[3]University of Florence, Italy

This paper focuses on an episode in which two 10th-grade low-achieving students are learning about unknowns and equations with a tutor in a dynamic digital environment. We initially conducted a commognitive analysis, which provided insight into the students' emerging mathematical discourses. To address issues of embodied validity, we then used the method of re-enactment, which enabled us to understand techno-affective aspects of the interactions in the episode.

Keywords: Low-achievement, digital technology, inclusive education, embodiment, re-enactment.

Introduction

Within the ongoing research project DynaMat (https://www.carme.center/progetto-dynamat/), we are conducting case studies of Italian high school students (10th grade) with a history of low achievement in mathematics. Our study concerns the use of a dynamic digital tool designed to address students' difficulties in algebra (Weingarden et al., 2024). The tool is a digital version of the balance model, commonly used to introduce linear equations and to deal with the equal sign and with unknowns (Otten et al., 2019). The episode discussed in this paper caught our attention. It features two classmates, Alba and Elsa, who spent considerable time during an early part of the didactical sequence, on finding the weight of the "red balls" even though they were not asked to do that, and who interacted with each other and with the tutor in interesting ways. The activity is developed within Desmos and is embedded in a sequence dealing with a dynamic scale that has known (squares labelled with numbers) and unknowns (red circles) weights (Figure 1). The user can move them, together with the ones in the blue box on the left, and the scale adjusts accordingly.

The sequence of activities, which is effective even for students with severe arithmetical difficulties (Robotti et al., 2023), promotes strategies of adding or removing object(s) from each pan of a scale while keeping the scale balanced. It then aims to shift students' attention to objects with an unknown weight and to ways of finding its value, which can be akin to the procedure of solving linear equations (Bonadiman, 2023). Such a shift was not yet promoted when the following activity was assigned: *Here you see a balanced scale. If possible, remove 3 objects from the scale so that it is still balanced afterwards. If it is not possible, explain why* (Figure 1). We expected students to find a combination of objects to remove, such as the 4 from the left pan and the two 2s from the right pan, to keep the scale balanced. Moreover, the tutor followed a script which included prompts for both justifying the strategies and finding the value of the red balls.

This study investigates Elsa and Alba's participation in the activity. We focus on: (A1.1) Why all this interest in the red balls? (A1.2) What did they want to achieve by moving them? (A1.3) Were they successful (from their point of view)? (A1.4) Were they successful (from the tutor's point of view)?

In addressing these questions, we worked first with the discursive tools of commognition, which yielded some insights, but did not seem to adequately capture other aspects of the students' actions and interactions. We therefore decided to try re-enactment, a methodological approach that aims towards the embodied validity of Lather (1993), as recently undertaken in mathematics education (Sinclair, 2024). The re-enactments enabled us to experience what Elsa and Alba had both done and possibly felt, which provided us with additional insights into these questions.

Figure 1: The activity described in the paper

Theoretical framework

In accordance with the DynaMat project, the initial analysis was commognitive (Sfard, 2008). According to Lavie et al. (2019), a *task situation* is a situation in which an individual feels compelled to act. Task situations in a classroom typically involve the teacher's assignments and questions. The *task* is how the student interprets the task situation. Students may perform different *routines* (each comprises a task plus an implemented procedure) in the same task situation because their tasks are different; these can be considered *rituals* (applying memorized procedures to please someone else without concern of the products) or *explorations* (producing meaningful narratives with a focus on the products). Commognition also provides lenses for discussing identities, which are defined as "a collection of stories" that are reified, endorsed, and significant (Sfard & Prusak, 2005).

With the re-enactments, we focussed not only on discourses, but also on affects and senses, which are seen as being important in theories of embodiment, and which often refuse cognitive/affective and mind/body binaries that are common in most mathematics education theories (see de Freitas & Sinclair, 2014). In digital environments (and even more so in physical environments, but these were not a part of our study), the senses are often more significantly at play than in typical paper-and-pencil environments, which invites students and teachers into novel sensory experiences, including not just the visual, but the haptic, the kinesthetics, and much more (Güneş et al., 2024). A re-enactment involves simulating an event as closely as possible, with the aim to aestheticise experience (Fuller & Weizman, 2021), which is to say, heightening the sensory dimensions that are frequently ignored when the focus remains on words and written transcripts. The way in which people are affected by what happens on the screen, or what their hands do as they drag objects can be very hard to see in a video, which is why the re-enactments were undertaken.

Methods

Alba and Elsa, the protagonists of this study, consider themselves to be low achievers, as does their teacher (the two students come from the same class). They took part together in five two-hour sessions with digital environments. For Alba, Italian is a second language. Data collection took place in an out of school learning centre (CARME) and includes audio-video recordings of the sessions and screen recordings of the iPads (students' written works and digital environments they interact with). The

participation of both during the interview was highly ritualistic and focused on recalling procedures. Both students developed stable failure identities over time. Elsa tended to describe herself using catchphrases such as dyscalculic, dyslexic, or not being cut out for math. Alba explicitly referred to her feelings while doing math, expressing that she felt overwhelmed, tired, and got headaches.

Data were initially processed using MAXQDA, a computer-assisted mixed methods research software. We conducted a discursive analysis led by the aims of identifying task situations proposed by the tutor (T) and of inferring tasks addressed by Alba (A) and Elsa (E) (Figure 2). We labelled the transcript considering the prompt of the tutor as task situations, while the students' tasks were identified looking at the procedure they implemented (what they said and what they did, on the scale or in the notes). The aim of this analysis was to gain insight into what triggered Alba's focus on finding the weight of the red balls (had it been a shift promoted by the tutor?), as well as to establish each student's discourse about scales and its analogies with discourse about principles of equivalence of equations (which is not the focus of this paper). In response to interesting phenomena arising from this original analysis, that we describe below, we also conducted two re-enactments (see Sinclair, 2024). The first re-enactment was done to zoom into the students' (and Alba in particular) interaction with the dynamic virtual scale; the second one to further explore the interactions between the participants (Elsa, Alba and the tutor) and the technology.

The first re-enactment was done by the first (AA) and second authors (AN), concentrating on Alba and Elsa's actions in the digital environment and words accompanying such actions. AA and AN sat next to each other on a couch, each holding a laptop computer: on AA's they played a video made of a collage of footage of Elsa and Alba's, synchronised with the screen capture of the iPad with the digital environment of the activity. In the analysis section, we refer to Elsa/AA and Alba/AN to highlight the re-enactment-created data. The re-enactment took about 2 hours, during which time AA and AN took notes on what they newly noticed and felt. The second re-enactment was different: it was done by first author AA playing Elsa, the third author AE playing Alba, while the fifth author AC played the tutor and the fourth author ACH the director. It took place in a similar setting as Elsa and Alba's original one. AA and AE sat next to each other on two chairs and had a table in front of them with two iPads, one having the same activity assigned to Elsa and Alba and the other having a blank page. AC had some space to walk behind them. On the sides, there was a laptop showing the same collage video as in re-enactment 1, and another laptop with the transcript of the episode. The footage was made with a third iPad handled by ACH. The actors watched some seconds of the original video and reproduced as closely as possible actions, words, gestures and interactions with the iPads. The re-enactment took about 2 hours, after which a discussion about the actors' impressions took place. The footage was then edited similarly to the original video (by making a synchronised collage of the footage and the two screen recordings of the iPads) (Figure 3). Even though the original episode was in Italian, as were both re-enactments, we have translated them to English for this paper. We will use a composite labelling to refer to the players in the re-enactment: Elsa/AA Alba/AE, the tutor/AC.

Findings

In Figure 2 we report on the MAXQDA tool *Codeline* in which the columns display the ranges of paragraphs of the transcript while in the rows there are the speaker-sensitive labels. We differentiate

between labels starting with "TS" and "T". The former denotes instances in which the tutor directly formulated task situations. On the other hand, the latter refers to parts of the discourse where we can observe a procedure carried out by Elsa (E) or Alba (A), which allows us to infer the task being interpreted at that moment. For example, the label *TS-initial (T)* refers to the instances in which the initial task situation is recalled by the tutor, as in line 20. The label *T-initial (E)* refers to the instances in which we infer that Elsa task is the initial one, as in line 19.

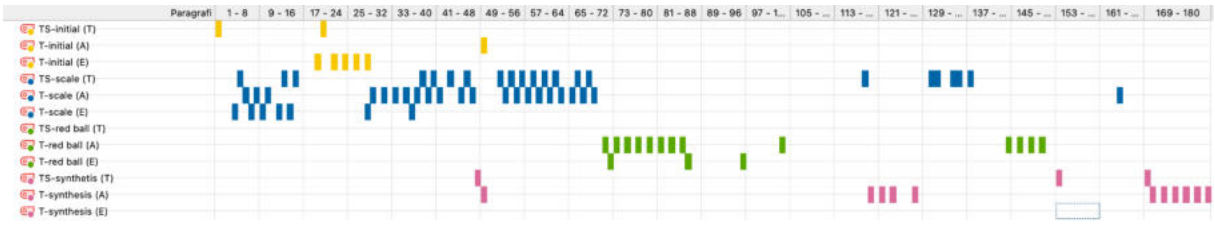

Figure 2: The *Codeline* of the episode used for the commognitive analysis

19 Elsa: Thus we have to remove three objects…
20 Tutor: It says to remove three objects. I leave you to work alone

Looking at the episode, we realise that the students are eager to investigate the relationship between the scale and the three red balls. We labelled these tasks as *T-scale*. Observing the fourth line of the Codeline, we notice how, following Elsa's prompt (line 4 "Why are there two little balls? I mean three little balls"), the tutor formulates TSs about the movements of the scale related to the three red balls and about justifying the dynamic feedback (we labelled these with *TS-scale (T)*). For instance, in line 38 the tutor asks what happens if all the red balls are removed from the pan. The aim of her intervention was to focus on the feedback of the scale and in particular to find a justification for it (line 40) based on their previous experience and on the scale's features. This leads to an exchange between the tutor and Alba: the tutor aims at promoting meaningful narratives about the feedback of the scale, Alba at answering the question, but seeming focused on something else.

37 Alba: There's something... okay, let's remove all the little balls [removes all the little balls from the pans]. So, if we remove all the little balls…
38 Tutor: What happens if you remove all the little balls?
39 Alba: So, there's one that's lighter, and there's, yes, the lighter one and the heavier one, so…
40 Tutor: Does this make sense to us?

Indeed, in line 71 Alba starts to deal with the red ball left on the right pan. The label T-red ball, which appears from that moment, signals the students' shift of attention towards the task of finding the value of a red ball. As highlighted in the Codeline, while Elsa does not take part in the process, Alba addresses this task of hers (line 71-85). At this point no task situation about finding the exact weight of a red ball is formulated by the tutor (line 7 of the Codeline is empty). Alba claims that "the sum of this one [the left pan] and the sum of that one [the right pan] make the same product" as she adds the weights on the left pan, finding 18. Thus, by subtracting gradually from 18 the weights on the right, she reaches 7 and she says, "So with this logic it would be seven" (line 81).

71 Alba: Wait, wait. I think this little ball has something... these have the s... the sum? Uh, the sum of this one and the sum of that one do the same product, gosh, my Italian. So I'd like to try here, no. If we do 4 plus 5 plus 1 plus 8, and here there's 3 plus little ball plus…

72 Elsa: But how much is the value of the little ball?
73 Alba: We'll find out now. Because, uh, if we add this 4 times 5, 9, 10, 18.

This analysis provides evidence of Alba's involvement in the activity and her continuous effort to discover and explore, but most of all to understand what the red ball "has" (line 71). Additionally, thanks to the Codeline, we notice that Elsa tries to participate in the discourse, too (e.g., in line 19 she goes back to the initial task and tries to accomplish it), but she gives up. From line 28, she does not act on the scale anymore and just watches Alba and tries to follow (line 72). Moreover, Elsa never responds to the tutor's request of synthesis (*TS-synthesis (T)*), such as "After you removed the same weight (red balls) from both pans, you did other things. Tell me more" (line 169). Alba instead offers a synthesis of her action and adds other considerations (line 49, lines 119-127, lines 170-180).

New findings after the re-enactments

The first re-enactment offered two main insights. The first relates to A1.1. By re-enacting all of the movements of objects that Alba and Elsa made on the screen, many of them not captured in the transcript because they were not associated with utterances, we realised that the red balls were moved extremely frequently (27 times in less than a minute, way more than other pairs of students). This movement is of course visible in the video, but we only attended to it because of the effort required to drag the ball on the screen. The varying ways in which the red balls were moved make it seem that Alba/AN, especially, did not have a particular strategy, but was trying to gain information about the red balls by seeing what changes they would provoke. In other words, for Alba/AN, finding out about the unknown had to happen by moving the unknown itself; instead, in solving a (linear) equation, the value of the unknown becomes known by acting on the numerical parts of the expressions, that corresponds to moving other known weights on the scale.

The red ball was also frequently moved back onto the scale, where it had already been. By re-enacting this movement, which at first seemed unnecessary, it became clear that Alba/AN was expecting something different to occur. As with a real scale, she was expecting that adding a weight to an unbalanced scale would make it even more unbalanced, which is not the case in the design of the digital tool (line 29). This is not an expectation that is ever uttered, but one that became felt in the re-enactment. The red ball becomes interesting not (only) because it is the unknown that the tutor is asking about, but because not much can be learned about it by manipulating it and because moving it does not always produce an effect on the screen (A1.1). There is a sense in which it was hoped, perhaps not even consciously, that moving it would divulge information about it, or causal relations it had with other objects on the screen.

Re-enacting the video, which involved not just simulating the actions on the screen, but also the tone of voice and the facial expressions, also dramatised Alba/AN's enthusiasm and sense of satisfaction. This satisfaction is not only felt in relation to solving a task, but also when she smiles, heightens the pitch of her voice and sits back to admire what has been done, like when she succeeds in putting a single red ball on the right. An exclusive focus on solving the task or "learning the math" neglects to adequately capture the affective nature of her experience, and the positive emotions that are so crucial in creating strong (positive or negative) memories about mathematics (Nemirovsky, 2011). The satisfaction does not stop at solving the task. Alba/AN also finds different ways of solving problems

and different ways of proving that her solution is correct. For example, when she works out a solution by hand, shifting to pencil-and-paper on her own accord, to work out the difference between 18 and 11, which gives her the weight of the ball (lines 148-150).

In relation to Elsa/AA, who seems to participate so little throughout the episode, the re-enactment offers insight as well. She may not say very much, but she is involved in manipulating the objects on the screen as well. And in fact, these actions sometimes come in response to something said by Alba/AN and therefore constitute a non-verbal interaction. Indeed, the re-enactment revealed that it was Elsa/AA's action that enabled the pair to find a way of removing only weights with given values of which two sum up to be the other.

One of the motivations for doing the second re-enactment was the realisation that the role of the tutor had been ignored in the first re-enactment, which made it difficult to understand the contributions of both Elsa/AA and Alba/AE. In the second re-enactment, it became more evident to the actors that both Alba/AE and the tutor/AC hindered Elsa's learning opportunities. This was felt in two significant ways. First, the re-enactment highlighted the fact that Alba/AE frequently completed Elsa/AA sentences. Sometimes Alba/AE would "speak for" Elsa/AA. For example, in line 164, "You took one from here and one from here, so you took the same weight. That is what you wanted to say?": here Alba/AE draws the tutor/AC's attention to herself, while Elsa/AA confirms with a "Yes" (line 165) what her mate says and leaves the pencil on the table. Alba/AE also invades Elsa/AA's space at a certain point, saying, "I need to think, sorry" (line 33, Figure 3). Alba/AE physically dominates the space, taking away opportunities for Elsa/AA to participate, or forcing her to participate passively.

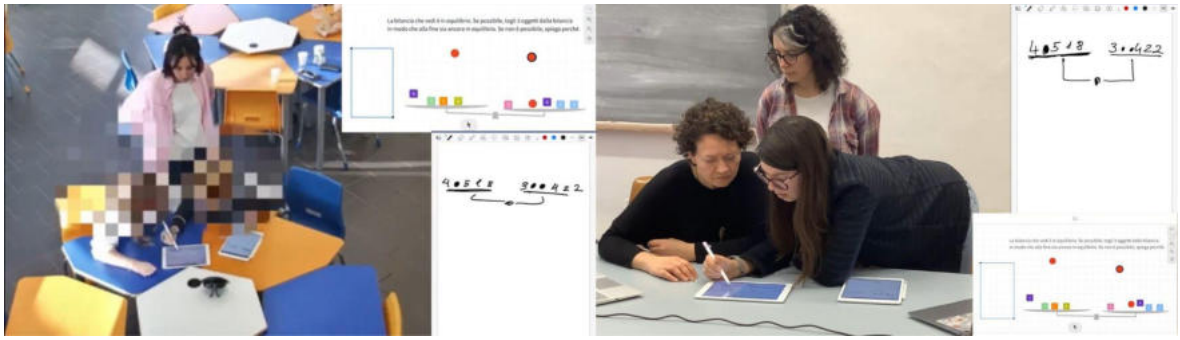

Figure 3: Space invasion of Alba/AE into Elsa's/AA's (comparing re-enactment videos)

Second, Alba/AE positions herself as the teacher and Elsa/AA as the learner, as when she explains to Elsa how she found the weight of the balls in response to her request ("Wait, but how did you find it?", line 86). In this, there's a sense that Alba/AE and the tutor/AC participate and position themselves more as equals. The tutor/AC tends to direct her gaze towards Alba/AE, even if Elsa/AA frequently looked towards the tutor/AC. Elsa/AA, in the beginning, is interested and engages to some extent (e.g., line 19, line 72). But then she ends up participating only through a few words and interacting with the digital environment. Elsa/AA is never asked to write, and she never answers tutor's/AC request of synthesis explicitly directed to her (line 153). She is willing to "give up her words" and leave sentences to be completed by Alba/AE. At a certain point, when Alba/AE explained to her how she had found the weight of the red ball the first time, Elsa/AA puts her head down, like in the initial interview with Anna, which felt like continued antipathy or disengagement.

Discussion and conclusions

Through the combination of the commognitive analysis, which highlighted significant aspects of the students' discourse, and the analysis of the re-enactment, through which we noticed different actions, interactions and feelings, we were able to address our four questions. Overall, we discovered that it was Elsa who first mentioned the red balls (line 4) and shifted the discourse in that direction. Only much later (line 71) does Alba's task shift to finding the weight of a red ball, which does not justify all the movement of the red balls at the beginning. The re-enactment helped us notice how Alba was affected by the red balls (A1.1). The discourse analysis allowed us to infer several tasks related to the red balls, taken on especially by Alba (A1.2), who was successful in solving them (A1.3). Elsa seems to be focused on the initial task situation, but it is unclear to what extent she managed to follow Alba in finding the weight of the red balls. In re-enacting her actions, Anna realizes that Elsa let Alba speak for her and did just a few actions on the scale (A1.3). The tutor seems to acknowledge Alba's success, directing her gaze and attention mainly towards Alba (A1.4).

These findings provoke reflection on the kind of inclusive learning setting we had designed. First, Alba's "speaking for" Elsa may perpetuate discursive routines from the classroom. While these two students had been intentionally paired so that Alba could help Elsa, the result was a "taking away" of opportunities for learning. Elsa ends up contributing "only" to simple answers. Second, in terms of the teaching: with all the best intentions, the tutor treated the students differently. This propagated discursive routines in which the weaker student gets fewer chances to participate. All this in a context in which we were all "trying our best" (through design principles, interactive digital environments, etc.) concerning the inclusion and participation of struggling students. We maintain that the design of the environments can enrich learning for students like Alba and Elsa, but that we need to further study how to the students' actual needs and ways of participating in mathematics.

On a methodological note, we acknowledge the practical and ethical tensions that arises from trying to experience other people's lives (see Sinclair, 2024). There are significant differences in terms of position and knowledge between the actors and the students. That said, the re-enactments enabled us both (1) to surface things that the discursive analysis left invisible and (2) to gain conviction about the significance of emotions and other non-verbal events that cannot be expressed in words. These felt experiences bring to light significant affective aspects of mathematical activity, as de Freitas et al. (2019) evoked in their study of sympathetic bonds, such as Alba's compulsion of moving the red balls and the nuanced shifts in positioning people's roles in interaction.

Moving towards abstraction: An embodied design for reflection symmetry

Karel Boonstra[1], Marjolein Kool[1], Anna Shvarts[2] and Paul Drijvers[2]

[1]Utrecht University of Applied Sciences, Utrecht, The Netherlands; karel.boonstra@hu.nl

[2]Utrecht University, Utrecht, The Netherlands

This paper reports about a design study on creating a learning environment for fostering the process of abstraction in geometry. Through manipulating chess-towers and a see-through mirror, primary school children showed conceptualization of equidistance and orthogonality as properties of reflection symmetry. The fostering of embodied abstraction benefits from introducing relevant artifacts, promoting the verbalization by the students of the apparent structures in the action space.

Keywords: Geometry, abstraction, embodied cognition, field of promoted actions.

Introduction

Inspired by the research field of embodied cognition we seek to design a learning process, based on realistic geometrical experiences, which invites students to engage in a process of abstraction. Generally, embodied cognition posits that we learn through interaction with our body and the environment (Wilson & Golonka, 2013). Focusing on the role of the body in interaction with the environment can bring the inherent geometry into experience. A learning environment that invites a student towards discovering, through promoting certain directions of moving, is referred to as a 'field of promoted action' (Abrahamson & Garcia, 2016). The action-based embodied design genre (Abrahamson, 2014), offers guidelines for arranging such a field of promoted action. Where usually action-based embodied design studies make use of digitally arranged environments (touchscreens, augmented reality, motor sensors), we in this study, seek to use a non-digital environment. Although recent studies on applying action-based embodied design ideas in various domains, show that conceptual understanding indeed can originate from students' actions elicited in a field of promoted action; see for example, studies on sine-graph (Shvarts et al., 2021) and gradient (Bos et al., 2022), the notion of abstraction is not addressed explicitly. In this study we aim to arrange a non-digital action-based embodied design where the fostering of abstraction is central. To this end we set up a design study targeted at developing such a learning environment while gaining knowledge on the process of abstraction through an embodied approach. The learning environment targets the geometrical subject of reflection symmetry.

Theoretical background

Reflection symmetry is an important element of primary school geometry (Ferrari & Saldano, 2023; Sinclair et al., 2016). Where reflection symmetry is often presented in modern curricula as a static concept (Ng & Sinclair, 2015), we seek to use a dynamical approach. Imagine standing in front of the mirror with arms stretched forward. What do you see? There seems to be an image of you on the other side of the mirror. Each part of the 'image' you is positioned exactly opposite to, and at equal distance from the mirror as, yourself. We seek to develop a field of promoted actions in which the aspects, equidistance of object and image, and orthogonality of object and image to the mirror line,

are discovered. In a field of promoted action (Abrahamson & Sánchez-García, 2016), the student is presented a specific motor control problem in such a way that self-exploration is encouraged. Such a motor control problem is one of the three criteria for an action-based embodied design as described by Alberto and colleagues (2022). To both encourage and guide students' self-exploration, constraints are applied to the environment and the task. In this way students are guided to reinvent ways that "were never dictated, demonstrated, explained, or cued," (p. 214). The second criterion for the embodied design is to provide some form of continuous feedback on students' movements. In this way the student can easily observe whether the objective of moving is met. The third criterion is to not use measuring artifacts in the initial phase of the design. Of particular importance for embodied design is the notion of attentional anchors (Abrahamson & Sánchez-García, 2016). An attentional anchor is a perceptual structure that emerges to the student when acting, and helps students' steer their movement. The aim of the current study is to clarify how such type of designs can be enhanced to trigger a process of abstraction. We follow Dreyfus (2014) in considering abstraction as a process of understanding the structure of a mathematical concept. Bringing in the embodied perspectives to the process of abstraction led Boonstra and colleagues (2023) to describe a definition of embodied abstraction as "a process of reflecting on, describing, explaining, and structuring of sensory-motor actions in the experienced world through developing and using mathematical artifacts" (p. 8). Just like in all instances of action-based embodied design, to foster the development of a mathematical discourse on student's actions and perceptions, a careful stimulation by a tutor is needed (Abrahamson, 2014; Alberto et al., 2022). By using artifacts such as mathematical words, or objects (sticks, ruler) a re-description of the (transformed) action space is brought about that elicits the verbalization of perceptual structures inherent, leading to a conceptualization and abstraction of the concepts at hand. In fostering abstraction, the tutor, when noticing such structure emerging to the student, can build on this notion through reflecting and re-description. Since abstraction is an idiosyncratic process, it does not necessarily require the student to use a particular (formal) wording or description, instead the appropriateness of the wordings used, is discussed and agreed upon within the tutor-student dyad. The central question in this study is, how can a non-digital action-based embodied design foster students' process of embodied abstraction regarding reflection symmetry?

Method

Our research methodology is that of design research. We develop and test an action-based embodied design for reflection symmetry. We hypothesize that this embodied design invites the student, with aid of a tutor, to engage in a process of embodied abstraction. The design process, consisting of three cycles, is driven by a hypothetical learning trajectory (Simon, 1995). A Hypothetical Learning Trajectory (HLT) consists of three components (1) a learning goal, (2) a set of learning tasks, and (3) a hypothesized learning process. How these components are used in this study is described next. The central idea in this embodied design is that the mirrored image of a white chess tower can be made manifest by using a see-through mirror and a second tower. When this second tower is placed in a reflective symmetry position of the first, the image of the white tower coincides with the second, see Figure 1a. This 'coinciding' forms the basis for the continuous feedback of the 'system'. This set-up makes it possible for a student, when physically manipulating the towers in order to let these coincide,

to discover two aspects of reflective symmetry: equidistance and orthogonality, which are the learning goals (1) of the HLT.

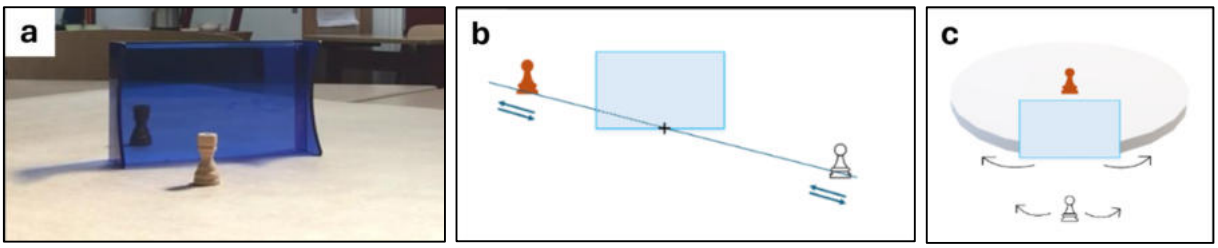

Figure 1: a-b-c the setup of the towers and disk: (a) Task 1: free dance; (b) Tasks 2 and 3: equidistance; (c) Tasks 4 and 5: orthogonality

The learning tasks (2) of the HLT are the following. *Task 1*. 'A free dance'. When looking in the mirror, the student moves both towers (as in Figure 1a, but towers not yet coinciding), thus freely exploring the setup. The goal is to discover the coinciding of both towers. *Task 2*. Goal: discover equidistance. Student moves the towers continuously on the line and keeps them coinciding, see figure 1b. *Task 3*. Goal: apply the experience from task 2. A stick is placed orthogonal to the line to resemble the mirror (not in the exact position as the mirror to avoid copying). The brown tower is placed on the line. The student places the white tower so that the towers 'coincide'. *Task 4*. Goal: discover orthogonality. Student moves the mirror and the white tower (standing on a base) and keeps towers coinciding. The brown tower is placed in the center of the disk, the mirror against the disk, see figure 1c. *Task 5*. Goal: apply experience from task 4. The mirror is removed. The stick is placed alongside the disk, see figure 4b. The student places the white tower, so the towers 'coincide'. *Task 6*. Goal: apply experiences from tasks 2 and 4 outside of the action field. On paper, a dot, resembling the brown tower, and a line, resembling the mirror, are drawn. The student writes an instruction, as to where to put the white tower. *Task 7*. Goal: apply experiences from tasks 2 and 4 outside of the action field. On paper two dots are drawn resembling the towers. The student writes an instruction on where to place the mirror. The hypothesized learning process (3) of our HLT is that, in engaging in the series of tasks and with the aid of the tutor, a process of embodied abstraction (Boonstra et al., 2023) is brought about: the student's discoveries (perceived structures) in the action space in task 2 and 4 are applied in task 3, 5, 6 and 7, where re-arrangements and (semi)-abstractions of the initial field of promoted actions are presented. The student, making use of artifacts, then verbalizes these structures, leading to the conceptualization of equidistance and orthogonality. For each task, the student's expected actions and multimodal behavior were aligned with the other two elements of the HLT and the tutor's expected interventions, leading to an exemplified and elaborated hypothesis of the embodied design. The testing of the embodied design was done in three cycles and eleven tryouts (3-3-5), each with a single student from grade 4 or 5, the first author acted as tutor. These tryouts were videorecorded. After each cycle, design sessions with the first, second and third author were held, during which observations from the videos were shared and discussed in relation to the elaborated arrangement mentioned in the above. From here adjustments were made to the design.

Results

In this section we share a series of vignettes from the tryouts. We describe key observations on how students engage in the process of abstraction related equidistance and orthogonality.

Equidistance: Abe confirms his measuring with his perception

In task 1, Abe has found multiple places where the towers coincide. When asked how he found these, Abe says, "by setting them opposite to each other." It is not clear whether Abe means orthogonal to the mirror, nor if he refers to the same distance. The tutor asks, "how do you do that? I see you doing different things with each hand." Abe: "No, you need to do something like," Abe grabs the towers, moves both in opposite directions alongside the mirror, (see figure 2a) and then to and from the mirror. "One needs to go to the front and the other to the back." Through trial-and-error Abe has found a way of letting the towers coincide, yet this pragmatic achievement is not yet supported by any abstraction. In task 2, Abe moves both towers one after the other further away on the line (not

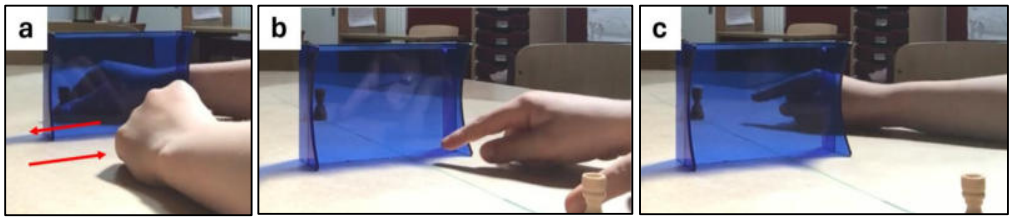

Figure 2: a-b-c Abe moves and gestures

simultaneously). Tutor: "Where do you pay attention to?" Abe: "that they are in each other." Tutor: "how do you do that?" Abe: "by placing them equally far from the mirror." Tutor: "what do you mean with equally far?" Abe goes on to measure with his hands. He first grabs the distance between the towers with both index fingers, see figure 2b. And then points to the position of the brown tower, see figure 2c. He relates distance to position, which is in consonance with his actions; first 'making a distance' by moving the white tower forward and then adjusting the position of the brown tower. Tutor: "Do you know this is so by looking in the mirror, or do you just know?" Abe: "by looking in the mirror it is clearer." Abe uses what he perceived in the mirror to motivate 'equally far.' A sign that the process of abstraction is grounded in experience.

Orthogonality: Abe's difficulty in being precise on 'opposite' and orthogonal

Where in task 1 Abe already talked about 'opposite to each other', he struggles in task 7, raising uncertainty about his conceptualization of orthogonality. Abe places the stick correctly between the two towers. When asked how he can see that the stick is placed correctly, his response is: "they are opposite to each other and on the same distance." He gestures with his arm, see figure 3a. Note that he refers to the towers and not the stick; he says 'they'. Where Abe is able to correctly 'place' the mirror, he has difficulty in writing the instruction. At first, he writes, 'in the middle of the towers.'

Noticing that Abe does not refer to distance nor oppositeness, the tutor places the stick skewed and points out that now the stick also goes through the middle of the towers. Abe says: “Ehm, how do you say that?” Where Abe was able to mention the towers being opposite, he is unable to find a suitable term for the stick related to the towers, or he thinks ‘opposite’ is not accurate. “Where do you pay attention to apart from distance?” Abe replies, “that he goes straight to the middle.” Tutor: “Through the middle of what?”, Abe, hesitatingly: “through the middle of the distance between the towers?” Here Abe shows being aware of a cross-like figure that would be formed by a mirror and a line connecting a tower with its reflection, which serves to him as an attentional anchor. After writing the instruction, the tutor asks to draw what he means with distance between the towers. Abe, while drawing, says, “ehm, if this is the distance, then you should also draw the distance there, and where they meet the stick goes,” see figure 3b. Note that Abe uses distance in the same way as in task 1, first ‘making’ a distance on one side of the mirror and then applying this on the other side. When the tutor asks how the stick should go, Abe cannot find a verbal expression that suits his drawing, yet the drawing itself perfectly represents the geometrical structure of the action field. The above shows that the term ‘opposite’ does not suit the notion of orthogonality. As we will show in the following stories on orthogonality, the use of artifacts is key. In this case the elicitation of verbalizing a cross would help Abe, since he showed to use such attentional anchor.

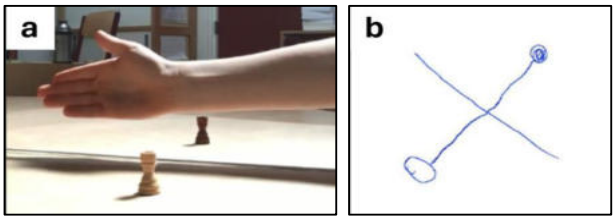

Figure 3: a-b Abe’s gesture and drawing in task 7

Orthogonality: Matt’s motivation gives an indication for a perceptual structure

In task 4, Matt moves the mirror and the white tower carefully clockwise, see figure 4a. The tutor, wanting to trigger Matt’s awareness of the orthogonal position of the line between the towers and the mirror, asks, “do you notice something?” Matt: “No.” The tutor decides to invite the student to change perspective, and asks, “what do you notice about how the towers and mirror are placed, when looking from above?” Matt looks from above and says, “hm, almost directly opposite to each other.” Tutor: “Can you check that in the mirror.” Matt looks again from sitting position, moves the white tower a little and says, “so, now they are opposite to each other.” Tutor: “Can you move again, the mirror and tower, to see if this remains so?” After moving the mirror and the tower for a while, the tutor asks, “what do you notice?” Matt says, “they are still directly opposite to each other.” It seems that the concept of orthogonality, in the form of ‘directly opposite to each other’, is noticed by Matt. The structure is noticed when Matt looks from above, and coupled with his actions and perception, when moving. In task 5 Matt uses this structure again. Here the mirror is replaced with a stick, see figure 4b. When the tutor asks if the stick is placed correctly, Matt says “no, it should go directly opposite,” and gestures between the two towers, see figure 4b. Tutor: “Opposite to what?” Matt: “to the tower.”

After Matt has moved the stick in the correct position, the tutor asks, “how do you know this is opposite to each other?”

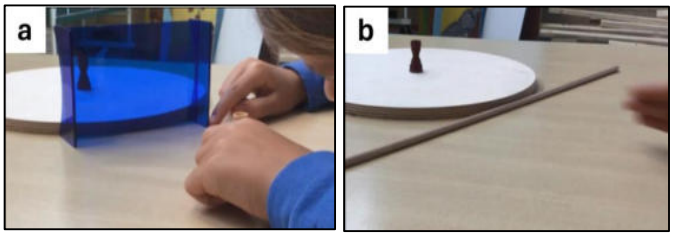

Figure 4: a-b Matt moves and gestures

Matt: “because this is also opposite.” (camera did not catch what Matt was referring to). Tutor: “how do you see that?” Matt: “well, it was like just before.” Here Matt, who showed no difficulty in placing the stick and tower correctly, motivates ‘directly opposite’ with his earlier experience with the disk. Matt uses his perceptual structure in a more abstract situation. The term ‘directly opposite’ however is not a clear indication for orthogonality, as we also saw in Abe’s story. In making the transition from student’s perceptual structure to the concept of orthogonality, the embodied design would benefit from using suitable artifacts, for example by referring to a cross, as we see in the next vignette.

Orthogonality: Tania uses artifact and makes a cross

The accompanying questions for task 4 developped in the design to open-ended questions like: ‘what do you notice?’, ‘where do you look at?’, ‘where do you pay attention to?’ The aim is to trigger the student’s perceptual structure of the orthogonal line between the towers and the mirror. The case of Tania shows that such questions do not lead to immediate result per se, but could very well pave the way for students’ verbalization of the structure in a re-arrangement of the action space. This is clearly visible in the tryout with Tania. In task 4 the above questions did not lead Tania to refer to the structure, she only referred to the towers coinciding. When the mirror is replaced with the stick (task

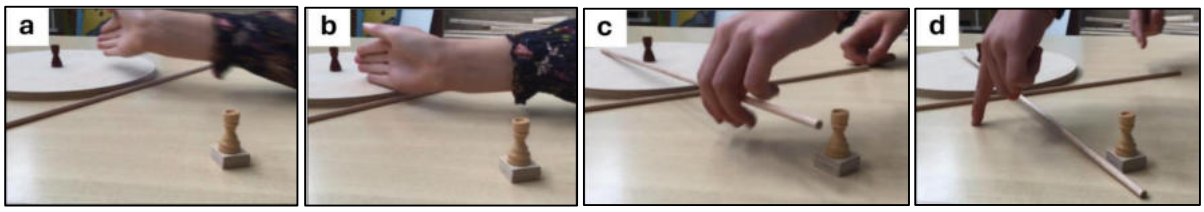

Figure 5: a-b-c-d Tania gestures the orthogonal line, makes a cross and points out the quadrants

5), it becomes apparent that Tania was aware of the perceptual structure of orthogonality earlier. In task 5, Tania checks whether the stick is placed correctly. She says: “if it goes here, and this,” she points at the touching point of the stick with the disk, “would be the center of the mirror, then it will look past it,” she gestures with her hand from the white tower to the place where she imagines the image would be, see figure 5a. She then turns the stick clockwise in the correct position and says, “if it would go here, then it would look in this way,” gesturing a line from the white over the touching point of the stick with the disk to the brown tower (figure 5b). Tania gestures a line orthogonal to the stick, physically representing the perceptual structure from task 4. Considering that verbalization of the structure is key in the process of abstraction, the tutor asks: “and why is it positioned correctly now? You can also look from above.” Note that here the tutor invites to change perspective. Tania

stands up, looks from above, “if the mirror would be straight,” she gestures with her left hand along the stick, “then you look at it like this,” and gestures a line from the white to the brown tower. Tania just gestured a cross! To let Tania verbalize this structure and relate this to an artifact, the tutor decides to ask, “do you recognize a shape, in what you just pointed to?” Tania gestures again over the line between the towers. The tutor asks, “together with the straight line of the mirror it forms a…?” When Tania does not respond the tutor hands a second stick to her, “maybe this could help?” Tania places the second stick on the line between the towers, see figure 5c, and immediately says, “a cross.” Tutor: “a cross. What is special about a cross?” Tania: “it has two straight lines.” The tutor places the second stick skewed and says, “but these are also two straight lines.” Tania gestures over the sticks and says, “now they are not equal, because,” she places the second stick again correctly, “if you place it here, then you have one-quarter here, there a quarter, there and there,” and touches each quadrant with her index finger, see figure 5d. Tutor: “ah, could we call this a straight cross?” Tania: “yes.”

Discussion

Our embodied design focuses on the fostering of student’s process of embodied abstraction related to reflection symmetry and led us to developing a sequence of tasks and the hypothesized learning process. Although the tasks successfully elicit actions and perceptions related to the concepts equidistance and orthogonality, the process of abstraction does not happen entirely by itself; as expected, careful fostering by the tutor is necessary for conceptualization (Abrahamson, 2014; Alberto et al., 2022). This encompasses re-arranging the action space (changing perspective or placement of objects), and bringing in artifacts (stick, words) to highlight perceived structures and elicit reflecting and verbalization. Incorporating these considerations into the embodied design improved students’ abstraction process. Although in tasks 1 and 2 students are able to position the towers correctly, this does not mean per se that equidistance is discovered, as Matt, who stayed in action-perspective, showed. More attention needs be paid to verbalizing the concept of equidistance. For this, it is helpful to direct the student’s attention to the relative position of the towers to the mirror, for example by letting them observe the action space from above. ‘How are the towers positioned?’, ‘what do you noticed how the towers are positioned to the mirror?’ could serve as accompanying questions. When this does not lead to relevant verbalization, measuring artifacts like a ruler, or a grid can be introduced. Regarding orthogonality, the design showed that most students grasp the idea of ‘opposite’ but struggle with the concept of orthogonality. Although students do not mention a perceptual structure when moving the mirror and the white tower, the performance in the subsequent task shows that such attentional anchors often were present, since in most cases a cross-like structure was indicated. Although verbalization often lacks, this does not mean that the actions performed did not bring about perceptual structuring of the action space in a new way. As the story of Tania showed, bringing in the concept of a cross by using artifacts such as a second stick, assists in the student progressing in the process of abstraction. In embodied abstraction structuring by the student is key for conceptualization. It is therefore crucial that the teacher elicits the perception and description of the inherent structures. Even when students’ actions lead to correct positioning, eliciting verbalization of the structure is crucial, as several stories in the above show. Overall, answering the research question, how can a non-digital action-based embodied design foster students' process of embodied abstraction regarding reflection symmetry, we highlight three new design heuristics for the HLT

relevant for the tutor. (1) Stimulate the changing of perspective on the restructured action space, (2) bringing in artifacts to depict the structure of action space and (3) elicit verbalization of the structures and conceptualization, even when students actions lead to successful accomplishments in the task. Incorporating these into the embodied design we believe improves on student's abstraction process.

Acknowledgment

We thank the participating students as well as their caretakers and teachers.

Factors influencing the implementation of active, bodily experience mathematics learning activities: the perspective of educators

Alessandra Boscolo

University of Genoa, Italy; alessandra.boscolo@edu.unige.it

The study explores the implementation of active, bodily experience mathematics learning activities (ABM activities) within schools, focusing on factors that hinder or support teachers in integrating them. The exploratory research involves online interviews with selected mathematics education researchers from Australia and Italy. They identified, as determinant factors, individual characteristics of teachers, including their knowledge, beliefs, and openness to change, as well as contextual factors like school culture, availability of resources, class size, and organizational flexibility. Furthermore, limitations strictly inherent to the specific attributes of ABM activities have been identified. The results suggest the need for familiarization with embodied education and that promoting dedicated training courses, including reflective teaching practices, examples of activities aligned with curricular content learning, and direct observations, can facilitate the implementation.

Keywords: Embodied cognition, enactive learning, implementation research

Introduction

In recent decades, there has been a growing research interest in embodied education (Abrahamson et al., 2020). Even if a variety of perspectives and profound differences are recognized, the PME-46 working group (Palatnik et al., 2023) testifies to a nascent attempt to bring together research groups interested in the design of embodied mathematics learning activity to address common challenges with a collective effort. Hence, it seems the time is ripe to delve into how research in mathematics education can actively promote a wide integration of the embodied education perspective in schools. As expressively remarked by Felmer (2023), in its process of evolution, research in mathematics education should advocate for a change that seamlessly encompasses teaching-learning in schooling.

The direct involvement of teachers is essential to address the challenge of implementing in school contexts learning activities possibly consistent with the embodied education design (Abrahamson et al., 2020). Teachers play a pivotal role in spreading educational innovations in schools, acting both as promoters of their introduction and as primary users (Century & Cassata, 2016). Particularly, bridging the gap between research and practice requires investigating the factors that teachers perceive as barriers or facilitators for the implementation. To this end, a teacher survey was planned to mind the gap. However, the specificities of a teacher survey design (i.e., a questionnaire reaching a no-specific audience of teachers) do not allow to refer to a specific theoretical background (e.g. the enactive pedagogy, the inclusive materialism, the multimodal approaches, etc.). Therefore, this necessitated the involvement of researchers to identify an operational construct easily communicable with teachers, overcoming the theoretical differences within the research field. The resulting operative construct is the ABM activities (Active, Bodily experience Mathematics learning activities) (Boscolo, 2022), defined as activities that actively engage students in exploring mathematical concepts through manipulatives, tools (virtual or physical), or whole-body movements. This construct

encapsulates two primary components: students' active engagement in mathematical exploration and their perceptual-motor involvement as connected to mathematical meaning (Boscolo, 2023). Although this definition may appear trivial, it encompasses commonalities across various theoretical perspectives within the field of embodied cognition in mathematics education, with some limitations.

It is further relevant to characterize ABM activities at the research level. For this purpose, a selected group of researchers in mathematics education —whose interests are possibly related to the study topic and who had extended experience working with teachers—were interviewed. The objective of these interviews is twofold: first, to identify the inherent characteristics of ABM activities (including their importance, limitations, and core features) and of their implementation (e.g., teachers' necessary knowledge, awareness, and beliefs); second, to explore possible directions for investigating teachers' beliefs through a survey. It will be relevant to examine whether factors deemed critical by researchers are also considered significant by teachers, to inform the research efforts delve into implementation. Furthermore, researchers' perspectives may offer valuable insights into interpreting the survey results, especially in light of the specificities of the educational contexts under investigation. Indeed, cultural differences may play a role in shaping the conceptualization and implementation of ABM activities.

In light of this complexity, researchers from two distinct educational contexts, Italy and Australia, were involved. Their involvement may provide insights into cross-cultural and cultural-specific characteristics relevant to ABM activities conceptualization and implementation (Boscolo, 2023), and enhance the interpretation of survey results. The presented study focuses, in particular, on researchers' perspectives concerning factors that may influence ABM activities implementation. Specifically, it investigates both the limitations considered specific to ABM activities, along with factors that could hinder or support teachers in incorporating them into their practice. The following research questions guide the study: According to educators, what factors could inhibit or support teachers to incorporate ABM activities in their school practice? What are the main limitations of the integration and use of ABM activities in teaching practice?

From the meta-analysis offered by Century and Cassata (2016), the main typologies of factors considered for investigating the transfer of research findings in school environments are the following: 1. Characteristics of the individuals involved, which can concern students (e.g., school levels, motivations, knowledge) and teachers, including knowledge, experience, beliefs, values, attitude, motivation, and self-efficacy related to the change they face or psychological characteristics generally related to change (e.g., readiness, openness, and the perceived capability to handle change); 2. Contextual factors, encompassing organizational factors internal to the school (e.g., class size, available resources, spaces, lesson schedules), managerial factors (decision-making freedom for individual teachers), and factors determining the organizational culture (collective attitudes and behaviour within the school system); 3. Attributes of innovation, both features inherent to the proposal itself (e.g., complexity, objectives, empirical evidence, costs, design, specificity), or perceived by users (clarity, attractiveness, ease of use, familiarity, perceived relevance, perceived advantage over current practices). Some attributes are hybrid, like the adaptability of the proposal to circumstances; 4. Support strategies for implementation, which can vary from structural proposals to sporadic ones. Examples include operational plans integrating the proposal into practice, resource provision, training courses, mentoring periods, and sharing assessment processes; 5. Implementation

of the proposal over time, which involves assessing the implementation phases, adaptation times, the time before becoming potentially routine, and modifications over time.

The findings of this study highlight factors belonging to all these five dimensions.

Method

The exploratory study involves online semi-structured interviews with six selected mathematics education researchers, familiar with the Australian context, belonging to MERGA (Mathematics Education Research Group of Australasia) and nine Italian experts, seven academics and two teacher-researchers. Seven of them are members of the AIRDM (Italian Association of Researchers in Mathematics Education). They have experience in implementing innovation at school and research interests akin to the object under study. The selection process consisted of contacting researchers with these characteristics: the interviewees in the sample are the ones who voluntarily joint the project.

As part of a more extensive interview (see Boscolo, 2023), to understand what factors, according to researchers, might influence teachers to incorporate in their practice ABM activities, we asked them to answer the following questions: 1. *In your opinion, what are factors that could either inhibit or support a teacher to implement active, bodily experience mathematics learning activities in school?* 2. *What are the main limitations of the ABM activities integration and use in teaching practice?* Researchers' answers were transcribed and further analysed according to an inductive thematic content analysis methodology (Patton, 2002). The narrative materials were organized into units of meaning (i.e., core themes derived from the analysis of researchers' answers), encoded using MAXQDA software. The resulting framework was represented in maps (realized with XMap, MAXQDA Analytics Pro 2022) illustrating an overview of the totality and variety of researchers' opinions. Each node in the map corresponds to a code that signifies a unit of meaning. The numbers attached to each link indicate the cumulative frequency with which the core theme (represented by the code on the node) recurs in the answers, accounting for multiple mentions by interviewees. Further details on the data analysis and reliability process can be found in Boscolo (2023).

In the following section, two resulting maps and a narration with exemplary contributions that relate to these themes (attributed to the researchers with a pseudonym, e.g., AR1 for the first Australian one, and accompanied by the paragraph number of reference) showcase the main themes highlighted.

Results

Influencing factors

The concept map (Figure 1) summarizes the possible factors negatively influencing a teacher to integrate ABM activities into school practice, identified by the researchers interviewed. Hindering factors can be external to teachers (FOE, in darker yellow, at the top of the map in Fig. 1). They could be determined by the specific context, as organizational factors internal to the school, like desk disposition, "I learnt mathematics in classrooms where the desks were arranged in twos […] And I sat next to one person and we didn't move from that desk ever" (AR3, p. 72), or "how is the school timetable structured" (AR4, p. 42). However, researchers mainly referred to an unsupportive school culture (FOE6): "[…] the teachers feeling is they can't implement those kinds of activities, and that comes back to the culture of the school and the culture of their colleagues" (AR1, p. 62).

> Every school has its own version of what's expected from the teachers, what's expected from the students, and when you go and you want to do something different, it's like you've challenging the contract. (AR3, p. 46)

This contract involves often implicit norms that obstacle the implementation of such activities (FOE1), i.e., no written rules inconsistent with the principles of these activities: "[…] the teachers and the school beliefs about what a math lesson should look like, and what a math class should look like" (AR3, p. 106), "[…] based on students' beliefs which come from many years of experience of having been taught mathematics" (AR4, p. 28). Often, hostile cultures are related to insufficient institutional support (FOE2). As highlighted by multiple researchers, e.g., "[…] there are so many pressures on teachers' time to actually learn how to use and find out about the activities" (AR1, p. 34). This pressure encompasses wondering about time to cover the curriculum, and reach standard in the national assessment program, which disincentives these initiatives (FOE3): "[…] there's a lot of pressure on schools to improve performance on Naplan [National Assessment Program Literacy and Numeracy]. So, […] there can be an emphasis on the preparation for Naplan, rather than spending time developing students' conceptual understanding. (AR1, p. 34). Finally, lack of resources and classroom size (FOE4) is identified as one of the main hostile conditions: "there's limited resources or basically the organization of bigger classes to have each kid manipulating" (AR6, p. 27).

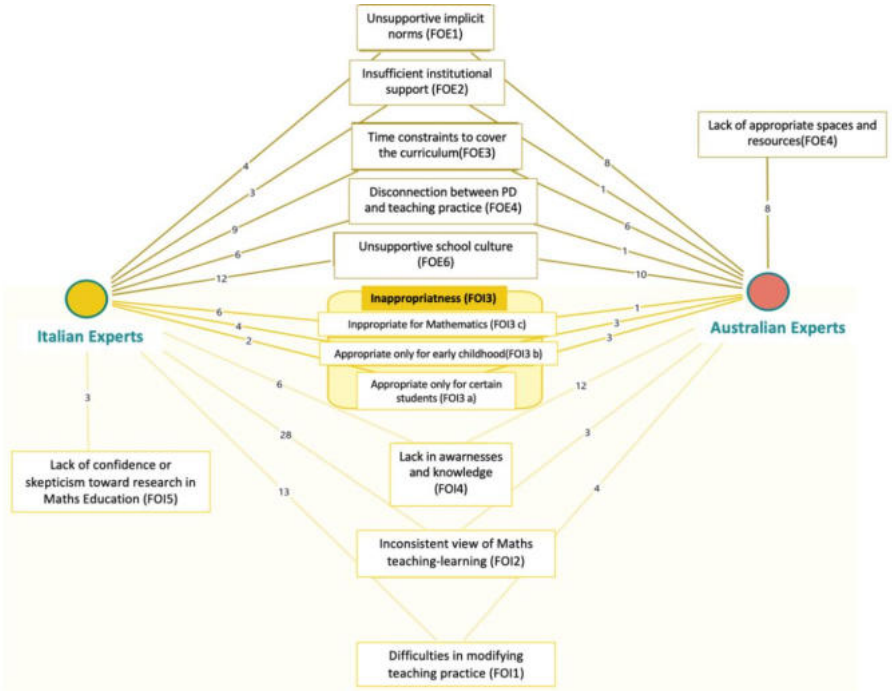

Figure 1. Overview of researchers' opinions on factors that could inhibit to implement ABM activities.

Otherwise, hindering factors can come from the individual characteristics of teachers like beliefs, awareness, and knowledge (FOI, in light yellow, in the lower part of the map in Figure 1). They may regard difficulties in modifying their own teaching practice (FOI1), in general, or specifically referring to the change requested for ABM implementation. Moreover, teachers may have a view of mathematics teaching-learning that is inconsistent with the one promoted through ABM activities (FOI2): "If you got a teacher who has strong beliefs that the way to learn mathematics is explicit

teaching and coughing examples, you probably not going to get them on board" (AR3, p. 80). Some researchers mentioned other specific beliefs: "You have to believe that all students can do mathematics. Not in the same way, not the same speed, not the same level, but everyone can do mathematics" (AR4, p. 34). Further, teachers may not have appropriate knowledge (FOI4), and this influences their teaching practice, "If you are not even a qualified mathematics teachers, then you are not going to or want to do anything out of the ordinary" (AR4, p. 40), particularly toward ABM activities implementation: "[…] teachers are open to embodiment, but they maybe lack the knowledge mathematically of how they might link that to the math lessons" (AR3, p. 112). Finally, they can perceive some limitations in the attributes of innovation itself (FOI3), such as they are only appropriate for lower grades students or they cannot fit with the mathematical contents teachers have to cover: "[…] like secondary teachers, they need to see that it's appropriate to use those materials and not only in primary school" (AR5, p. 30). Further, they can believe ABM activities are only appropriate for certain students, e.g., either lower or high-achieving students.

Among factors that possibly foster teachers to implement ABM activities, there are conditions and initiatives that may contribute to creating a supportive environment and providing guidance and resources (FFE). One is the promotion of PD (Professional Development) training courses (FFE5) which are not sporadic, in which examples and materials are provided but, otherwise, a reflection on the own teaching practices is promoted: "To truly impact the way teachers teach, the first step is to make them aware of how they teach" (IR8, p. 19). In particular, Italian researchers even indicated the importance of enhancing the experience of exchange between schools and universities, rewarding the teachers involved. At the organizational level, researchers mentioned the institutional support (FFE2) and it involves different roles in the school: "I think the role of the principal, head of department, the leadership in the school is very important. Because that establishes the culture about what is possible and what is not possible" (AR4, p. 40), "It's important to have some technical support and not all schools might have a person who does that job" (AR4, p. 50). Moreover, flexibility in the school's internal organization and collaboration with other colleagues is considered a high-impacting factor (FFE4). Further, researchers mentioned initiatives and experiences that can change teachers' individual characteristics (FFC), such as their beliefs towards ABM activities. For instance, showing the consistency with the curriculum and educational policies of such activities (FFC2) "In Australia, the biggest thing that enables teachers to try something is if they can connect it clearly to the curriculum" (AR3, p. 84), or:

> […] Helping teachers understand that what I'm proposing can actually replace some of the things you are doing, without losing anything. So, by doing things this way instead of some other things you will still be able to achieve - or the students will still be able to achieve - the learning outcomes in the curriculum (AR4, p. 34).

Moreover, especially Italian researchers emphasized the relevance of enhancing teachers' awareness of the complexity of the teaching-learning process and bringing research evidence to teachers. Even Australian researchers suggested providing evidence of the efficacy of ABM activities implementation toward a conceptual understanding of mathematics (FFC4): "[…] They actually have a valid reason for using them […] There is value in the material being able to be used for a purpose, to actually further student understanding that you couldn't easily achieve in the past" (AR5, p. 30).

Also, promoting initiatives to directly experience and observe the positive effect can be precious (FFC5): "Before they try an activity, they would like to know from another teacher 'how it works'. So that, it would be good if I can see the activity being implemented by another teacher" (AR4, p. 50).

The only two factors indicated as ambivalent are the availability in schools of appropriate spaces and resources (FA1), listed also among hostile factors when interviewees refer to as an obstacle, and, only by Italian researchers, the stability of teachers in relation to the opportunity to plan long-term (FA2).

Limitations

As Century and Cassata (2016) indicated, the implementation is mainly influenced by the specific *attributes of the innovation* itself. Among these, there are possible limitations.

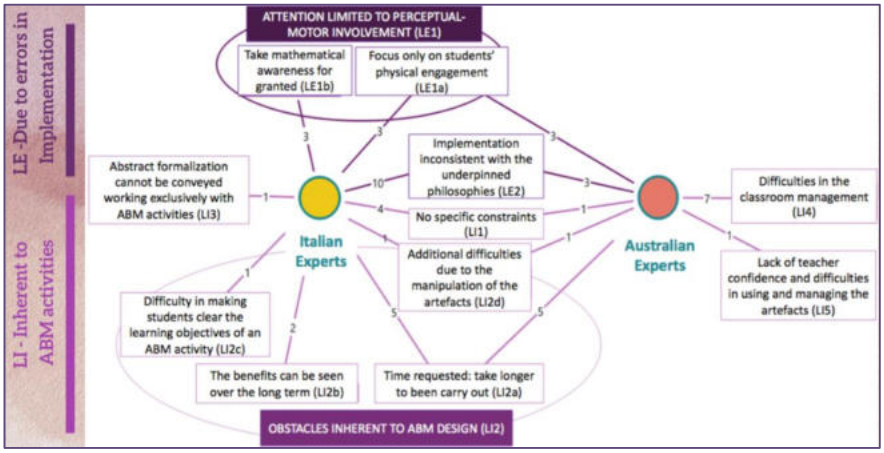

Figure 2. Overview of researchers' opinions on limitations for ABM activities implementation.

Both Italian and Australian researchers stated possible limitations due to an incorrect realization of ABM activities in the classroom (LE, in darker purple, on the upper part of the concept map in Figure 2). Those can be related to an inconsistent implementation, due to a distortion, on the part of the teacher, of the philosophy underlying these activities. That limitation is a lack of fidelity with respect to certain characteristics identified as essential components (Century & Cassata, 2016). It can result from a lack of awareness of the philosophy underpinning ABM activities design (such as an exploratory, inquiry-based learning approach, constructivist or socio-constructivist paradigm, ...) (LE2), and insufficient attention to link core mathematics meanings involved in the activity and the students' perceptual involvement. Indeed, referring to primary school, in particular, considering this proposal limited to the perceptual-motor aspects of student engagement, neglecting the bonding and awareness-building of mathematical knowledge (LE1), is considered a second major limitation. Other limitations are due to inherent characteristics of ABM activities (LI, in lighter purple, on the lower part of the map in Figure 2). Among the obstacles structurally characterizing the activity (LI2), the class time that needs to be invested in implementation (LI1 a) constitutes the most critical point according to the experts, while the difficulty in classroom management (LI4) comes up as a feature that seems to be of some concern, but on which the Australian experts focus particularly. Others can be students' difficulty in focusing on the learning goal (LI2c) and in manipulating artefacts (LI5). Especially the Italian researchers highlighted obstacles that may concern a lack of theoretical

systematization of mathematical knowledge (LI3). Finally, the advantages of spending this time may be seen over the long term (LI2b) and the schooling often requests an evaluation over a short period.

Conclusions and further directions

In the exploratory study, we have identified a hypothesis on the main factors that possibly influence Italian and Australian teachers for the implementation of ABM activities in schools, analysing the opinions of selected researchers in two different educational contexts.

Among the individual characteristics of teachers, knowledge and awareness of both mathematics and the principles of embodied education, as well as how to connect these two aspects, were highlighted. Additionally, the reflection on the own teaching practices and the openness to change were emphasized. Beliefs concerning the effectiveness of ABM activities, especially regarding curricular content learning, involving all students, are widely mentioned.

Researchers identified contextual factors, like class size, the availability of resources, and the flexibility of the school organization as extremely relevant. Other significant factors are supportive school culture, the presence of reference figures (both technical and managerial) to support teachers' initiatives, and the opportunity for dedicated Professional Development (PD) time, particularly focused on collaborative planning.

Concerning innovation attributes, besides the challenges related to having materials and tools available, along with technical support personnel, the need to familiarize teachers with the perspective of embodied education was stressed. Further than being appropriate for all students, the proposal should demonstrate its attractiveness by showcasing perceived advantages over current practices, making it appear integrated rather than an additional activity.

In terms of support strategies, researchers pointed out the necessity of offering specific PD training. This training should not be sporadic and should include reflection on one's teaching practice, accompanied by concrete examples of activities integrated into the curriculum. Teachers should have firsthand experience with these activities: e.g., directly observing their implementation in the classroom and engaging in reflection sessions with more experienced teachers.

Regarding the implementation over time, the period of familiarization with this teaching approach is considered a challenging initial investment. Some of these factors may be generally involved in the implementation of educational innovations, while others might be more specifically related to the ABM activities, e.g. limitations concerning attributes of the innovation. However, when considering the implementation, both specific and non-specific influencing factors need to be taken into account.

Some needs highlighted have already been considered by Palatnik and colleagues propose (2023), e.g., the creation of a resource database. Others may give new insight to researchers in the field of embodied education, who are delving into the diffusion in schools of the activities designed from this perspective. Through researchers' answers, many features of ABM activities conceptualization emerged: e.g., they are relevant for inclusion and appropriate for all school grades, they require much time to be implemented and planned, the benefits can mainly be seen in long-term period and for conceptual understanding. Further, there are some assumptions concerning their implementation: for instance, it is supposed that their implementation implied a disruptive change in how teaching-

learning maths is generally conceptualized in schools. Moreover, the issue of the lack of fidelity, i.e., a potential misalignment in ABM activities implementation, prompts us to investigate how such activities should be designed to ensure consistence with actual practice.

Considering groups of experts from different Countries can provide insights into contextual and cross-cultural factors, both shedding light on features of educational environments immersed in different cultures and aiding in decision-making for interventions aimed at fostering change in schools. Considering the two groups involved, greater attention to the exchange between universities and schools, as a key component for fostering implementation, emerges in the Italian context, while Australians highlighted to link these activities with the curriculum demand. Looking at attributes of innovation, while Australian researchers emphasized the issue of classroom management, the Italians focused on teachers' awareness of how to link mathematical knowledge to ABM activities. However, since the study is exploratory, the insights provided may only represent initial hypotheses. Furthermore, the overall framework mixes together the interviewees' different theoretical perspectives influencing their answers; therefore, it is strictly dependent on the researchers involved.

A further direction may be to compare the findings with the ones that may emerge from other groups of experts and in different countries, which may complete and differentiate the overall framework. Relating these findings with the results of a teacher survey, built upon the hypothesized influencing factors, is the natural next step.

Concepts and Bodies: Creating together in affective bodying

Anna Chronaki[1,2]

[1]Malmö University, Malmö, Sweden; anna.chronaki@mau.se

[2]University of Thessaly, Volos, Greece

The present paper discusses the importance of making space and time for affective bodying in mathematics education so that to open conditions for concepts and bodies to engage together and for sad affects to be affirmed as core for the learning experience. Affective bodying allows to explore our capacity to act together in-common and for our commons by moving together with our bodies, languages and minds toward exploring ways to sense and express thinking and feeling. It can be a response to oppressive learning experiences with mathematical concepts in early year teacher education. With affective bodying, the research aims to move beyond the deadening bipolar discourses of children failing and succeeding in mathematics -a dichotomy that perpetuates alienation from the materiality of knowledge. Instead, the paper argues for the need to affirm creative experimentation in affective bodying with mathematical concepts, bodies and difference.

Keywords: affect, affective-bodying, failure-and-success, mathematical concepts, teacher education

How (not) to create a concept?

> How can you teach 'area' to so young children!? (…) This class has many Roma children and children with special needs... You cannot do normal math with them.
>
> **Schoolteacher addressing three female student-teachers, January 2010*

> We cannot continue... We are afraid that we will fail.
>
> **Student-teachers addressing their educator after meeting the schoolteacher, January 2010*

Figure 1. Young children experiment with the concept of area

The concept of 'area' is created out of cultural, communal, earthly and collective knowledge experiences around problems focusing on how a certain surface (of two, three or n-dimensions) can be studied, compared and calculated. Historically, the idea of area sparkled within the social needs of

addressing the just distribution or redistribution of land when, for example, flooding events changed or destroyed cartographic boundaries at the banks of the Nile, Tigris and Euphrates rivers. Although, the concept of 'area' started by focusing on questions concerning the earth's de/re/formation, it has proceeded toward mapping and studying ways of recording and measuring the qualitative and quantitative characteristics of geometric and topological surfaces. Thus, the art and craft of geometry and topology is grounded in embodied contact, understanding and exploring issues that directly concern our bodying with soil, water, air, cultivation, sharing, but also the commonly shared as practical or metaphysic inquiry with the concrete and abstract nature of concepts such as unit, length, perimeter, radius, area, volume, etc. Through critical problematizations, such embodied experiences create conditions for the invention of appropriate artifacts, tools, concepts and techniques, facilitating calculations in direct relation to questions of measurement, sometimes by means of estimation and other times with the need for pursuing a relative accuracy, for detecting potential limits, for proving, and for arguing the value of utopian quests or the truth of answers. For a detailed discussion of measurement as relational, intensive and analogical see also de Freitas and Sinclair (2020).

However, despite the importance of a physical contract (Serres, 1990/1998) where geometric concepts are included and studied through bodily relations, today's curricula and textbooks accelerate the rigorous foundation of geometry by examining concepts such as 'area' through abstract geometric and algebraic formulas tied with the principles, values and aspirations of a royal science as they emphasize axiomatic definitions, accuracy of descriptions and validity of proofs (Deleuze and Guattari, 1994). At the same time, certain pedagogic and didactic interventions for young children have appropriated, for more than five decades now, the developmental logico-mathematical thinking offered by Jean Piaget (1896-1980) where the possibility of concept creation is related with specific stages of developing logical and mathematical behavior and is tied with children's mental, moral and health development. It is argued that the transition from one stage to another requires maturity (or child-readiness) which is recognized through children's capacity to coordinate bodily kinesthetic movement, language-use and moral behavior in appropriately organized environments.

Despite critique (Donaldson, 1978; Walkerdine, 1990), the influence of such research perspectives on educational policy and reform has been decisive toward determining a rhetorical relationship of 'readiness' between children and mathematics in the field of early mathematics education in linearly structured stages where children develop their relation to number and space by developing maturity from sensory motor to language related activity. Specifically, the relation to geometry thinking is seen, by and large, as developing around the van Hiele learning stages of: supervisory perception, analysis of forms and relationships, formal reasoning and inductive rigor (Pegg, 2014). When such cognitive stages serve mainly the intended curriculum, mathematics learning becomes recognized through discourses of readiness in relation to age, ability, and maturity. Moreover, it cannot accept the virtual/actual potentialities of chaotic passages where orality (reasoning as verbal use of mathematical register) strives to function through body movement. Such agonistic strivings expressed by children as they attempt to transverse learning stages need to be recognized as opening up emancipatory lines of flight (Deleuze & Guattari, 1994).

The formal teaching and learning of mathematical concepts run the risk to lose their connection with the limits and affordances presented by the natural and social environment and, together, to lose their

ability to be read culturally, socially and politically as Michel Serres (1990) urges. At the same time, we, as educators, researchers, and learners, lose the oortunity to get in touch with conceptual creation processes that arise effortlessly through the unexpected corporeal re/connection with different fields of knowledge releasing new life-giving forces. In the field of education, including mathematics education, the biopolitical colonization of mind and body dominates through a psycho-cognitive culture of developmental stages that prescribes what might be appropriate mathematics teaching. And formal curricula tend to either silence difference amongst children, student-teachers and teachers. This is where alienation resides as disconnection from concept creation and as fear of difference perpetuating the fear of failure. It is, thus, important to explore a return to minor mathematics as also discussed by de Freitas and Sinclair (2014).

Fear of Failure: Dis/Connection from concept creation

The fear of failure expressed by student-teachers, teachers, parents and, ultimately, all participants in the education of young children becomes visible in the two quoted passages at the paper entry. The nursery schoolteacher is critical of the student-teachers's desire to experiment with a material-discursive apparatus for the teaching and learning of area. In this, the concept of area is introduced *first* through the known story of the three little pigs where the floors in rooms of their pig-house need restoration and they must calculate the number of tiles needed and *second* though material models of room floors and tiles. The apparatus design goes beyond the didactic norm as it requires the capacity to transverse motor and mental functions such as the filling up of given model-shapes with smaller tiles of equal shape, counting the tiles and comparing the results. When the student-teachers presented the schoolteacher these ideas and before, even, trying with children, she said 'you cannot do normal math with them' (see entry and Figure 1). The student-teachers felt unable to defend the desire to act experimentally with children. As they encounter the schoolteacher, they confront the authority of curricula repeated in the normative discourse of what children could and should do. Thus, fear takes over their bodies, prompting them to resign. What is, then, fear and how does it move so comfortably among us? Gabriel Tarde (1843-1904) describes the body's submission to fear as follows:

> The momentary paralysis of spirit, language and limbs, this deep agitation that descends to the core of our being, this deprivation of self that we call bullying (...) It is a nascent social condition that occurs every time we pass from one society to another. (quoted in Massumi, 2005, p. 31).

In a similar way, the schoolteacher mediates to the student-teachers her embodied fear of a possible failure involved in the timid passage from a cultural situation dominated by discourses of learning bounded to strictly defined developmental stages to another situation that strives to open toward the indeterminacy of learning and its relation to thinking as feeling. It is there, where the need to create new concepts becomes grounded. In these passages, a dense articulation of knowledge/power is experienced which does not hesitate to humiliate itself for safeguarding the established order. It is perceived physically as "*the unfolding reality of an emotion of fear"* (Massumi 2005, p. 38), making resistance difficult. Here, we must ask: Is there a way out of such an oppression creating alienation and disconnection from concept creation? How could one re/connect with concept creation?

Affective Bodying: Re/Connection with concept creation

The mind-body distinction can be traced back to the seventeenth-century philosopher Descartes (1596-1650) who argues that the mind can exist without the body (I think, therefore I am). Cartesian dualism requires the unruly emotional body to submit to the rational mind which becomes a vehicle for disciplined thinking, reliable knowledge and truth (Burkitt, 1999). Today, post/Marxist feminist approaches focus on the body as the primary tool of capitalist economy to increase production and productivity in the workplace where the female body (of teachers and student teachers) experiences the precariousness of unpaid reproductive labor, vulnerability, and violent behavior in care sectors. Furthermore, the Foucauldian genealogies for sexuality, the prison system, and the clinic recognize the biopolitical inscription of legislative, cultural, and pedagogical norms on the body itself (Martin et.al., 1988). The body is increasingly becoming the product of bio/psycho/socio/technological processes mediating current norms in medicine, psychiatry, biology, technology, administration, and education capturing the self-regulated, self-controlled, and self-disciplined subject. As these norms are mainly supported by mathematics, artificial intelligence, and digital media, it is crucial to ask the question: How can we envisage the mind-body assemblage and the body itself beyond learning norms that tend to reproduce dichotomies, hierarchies, oppression, and fear?

Baruch Spinoza (1632-1677), at about the same time as Descartes, denounced the mind-body distinction, proposing a return to viewing the body as an assembly of elementary units intertwined in trajectories of motion that mobilize both thought and emotion. There is no thought and emotion without the body and its movement in the world, argues Spinoza in Ethics, giving precedence to affect through beneficial reconnections of bodies and as Deleuze explains:

> A body, of any kind, is defined by Spinoza in two simultaneous ways. First, a body, however small, consists of an infinite number of particles, it is the relations of movement and rest, velocity and slowness between particles that define a body, the individuality of the body. Second, a body affects other bodies or is influenced by other bodies, it is this ability to influence and be influenced that also defines a body in its individuality (Deleuze, 2005, p. 58).

A crucial issue here concerns how the body's difficulty in performing the norm and/or reacting to oppressive normality can be reconsidered as a fluid continuum of body-concept-movement-world-thought-affects? Brian Massumi (2005) distinguishes between affect and emotion arguing that whilst emotion signifies affect in a social structure, affect is a pre-conscious autonomous intensity of the body supporting to appreciate the non-rational aspects of sociopolitical phenomena despite critics who call for bridging the affect/emotion divide. Here, the artistic and philosophical work of Erin Manning and Brian Massumi (2014) responds to Spinoza's exhortation *"We don't know what a body can do!"* and inquire affect through the creative process of an open experimentation that emphasizes the movement of bodies along with concepts. By asking "*What else can a body do?"* they create moving practices such as improvised choreographies that are directed toward processes of exploration and co-synthesis of the empty spaces inhabited between bodies and concepts. These processes highlight how the body remembers, expands its boundaries, realizes its limits, and allows to become different. They involve a kinesthetic slowing down of body movement along with concept movement aiming for the aesthetic expression and the political mobilization of thought itself.

The above theorizing has motivated me, in my teacher-education work, to organize a choreographic workshop that diffracts the student-teachers' school experience where their material/discursive apparatus design on area was enacted. Even though the young children were engaged playfully, and the activity was evaluated as success, the student-teachers stayed with the fear of failure. Thus, the choreographic workshop aimed for memory work with the material/discursive components of their experience. Together with student teachers we worked choreographically (for more details see Chronaki, 2019) with our collective memories of feeling and thinking in the early years classroom. These memories were unfolded as affective bodying with moments of teaching the concept of area with the children. The student-teachers worked in pairs and in the whole group with choreography, video and geometry techniques allowing for a caring return to school-time and go deeper into experiences with the mathematical concept itself.

For example, while working with the mathematical concept of area they moved from the apparatus of floors and tiles toward their own bodies attending the very act of touching, sensing, feeling. By using the palm of their hand as a kinesthetic tool or a measuring they explored a specific surface. The palm as a tool (or unit) goes beyond the normative practice of area calculation working as minor mathematics. Their contact with the concept of area returns to a physical experience and its choreographic performance sets the concept of area in movement and e-motion as it mobilizes the bodies through a return to sensing specific relations and correlations felt during school-time. This, potentially, expands towards a joint creative synthesis and redistribution of the sensible by means of the concept of 'area' as affective bodying moving them beyond the 'sad affect' of the fear of failure. With Massumi (2005), this is a move toward experiencing e-motion (i.e. setting the emotion of fear of failure in motion) and concentrating more on the movement itself and how it motivates the in-between bodies assemblage to be set in motion. The emphasis on working with concept creation as an affective process where bodies-concepts-movements come together is what has been discussed as affective bodying in Chronaki (2019).

Figure 2. The choreographing workshop after the area classroom activity with children

As already discussed in Chronaki (2019) when the bodies come together in these choreographies, they act beyond a tool for communicative clarity and representational accuracy of the concept of area.

Instead, they consist of an assemblage that disrupts the force of developmental models that tend to determine what (who or when) are the bodies able to perform and/or fail to cognitively perform the concept. They, instead, focus on how else the bodies could act and enact together by encountering the mathematical concepts and, especially, their anarchic and chaotic motion trajectories moving beyond normative movements of thought expression. This condition stands in contrast to an axiomatic logic of mathematics that subjects the mind with discourses of precise definitions, conjectures and hypothesis linked with truthful theorems and modelling application. In contrast, it opens toward the anarchic potential of diverse bodies sensing together the concept otherwise through the modest act of moving and producing a novel politico-aesthetic redistribution of what is taken as sensible.

Concept Inquiry in Affective Bodying: *Beyond Curricula Discourses of Failure-Success*

Through this choreographic workshop experience, the student teachers become re/connected with the concept of area and its diverse expressions through a novel material/discursive relation with their bodies producing a political and aesthetic inquiry of the concept of area and its elements. Their thinking-feeling of area is being expressed in the following excerpts (Student teacher 1 and 2) but also in the videography and the series of photographs in Figure 2.

> *Movement, movement of the body greatly affects conception, understanding of the concept (...). Through the sense of touch we come into direct contact with the objects we are* called *to imagine (...). Following the outline of the tiles we realize their existence and realize the space they occupy.* (Student-teacher 1, diary notes, February 2010).

> *A key element in measuring a surface was the sense of touch. Through touch we could perceive the boundaries of any place. From floor to ceiling. From one side of the room to the other. And from our feet to our heads. In the end, we were able to define the outline (...) using small pieces of paper that provided opportunities through the sense of seeing and comparing different shapes* (Student-teacher 2, diary notes, February 2010).

The above excerpts note how the choreographic workshop of affective bodying focuses directly on performing the political and aesthetic aspects of mathematical concept inquiry through memory work in school-time and improvisation in choreography movement. The affective bodying assembles the process of studying the teaching and learning of mathematics by, strategically, en/countering the failure-success dipolar discourse. As such, it aims to counter the fear of failure. Both failure and success as teleological positions for learning become un-important. As the political and aesthetic dimension of an affective bodying with concepts and difference opens, the mathematical inquiry expands through the continuum of body-concept-movement-world-thought-affects. As already explained before: This process involves a kinesthetic slowing down of feeling and thinking as a synchronous movement of bodies and concepts aiming together for aesthetic expression and political mobilization of mathematical thought that counters the oppression embodied through institutional bodies of formal and informal educational structures.

Designing a tangible manipulative as a socio-material process integrating empathic and mathematical imagination

Benjamin Nicolas-Noir[1,2] & Claudia Corriveau[2]

[1] HEP-Vaud, Lausanne, Switzerland; benin1@ulaval.ca

[2] Université Laval, Canada; claudia.corriveau@fse.ulaval.ca

This paper analyses the design process of a prospective teacher in a course focused on creating tangible manipulatives for mathematical learning. Building on considerations of empathy in design and on material frameworks of mathematical activity, we aim at shifting from an individual to a socio-material perspective on the design process. Using the prospective teacher's design journal, we analyse how empathy and imagination partake to the design phases. When defining the design problem, lived experiences of teaching ground the manipulative (empathy); when ideating solutions, possible learners' actions are entertained to evaluate manipulatives (empathic imagination); when prototyping a solution, new body-tool-symbol interactions are entertained (mathematical imagination). From the analysis, we finally highlight design drawings as sites of socio-material mathematics.

Keywords: Design, manipulatives, empathy, imagination, number concepts.

Problematising the design of tangible manipulatives

Our paper explores the working group's ongoing reflection on the material and embodied nature of mathematics, focusing on material creation in mathematics teacher education. We explore how designing a tangible manipulative can be approached as a socio-material process integrating empathy and imagination. Let us first situate the study with respect to its context and to the literature on designing tangible manipulatives.

The design process took place at Laval University (Canada), within a secondary school mathematics education program. This four-year program culminates with a course where students analyse their journey and outline short- and medium-term plans for ongoing professional development through various cultural activities (museum visits, book fairs, cinema, etc.). As part of this course, they also conduct investigative work on a question related to the teaching and learning of mathematics. In 2023, we explored with five students the possibility of engaging in a design activity: creating a tangible manipulative for learning mathematics, based on an analysis of a specific mathematical content.

As part of an appraisal and perspectives course, designing a tangible manipulative aimed to present teaching as creating resources, rather than implementing existing ones (Akuom & Greenstein, 2022). This aim can be situated in the field of research on the design of tangible manipulatives. In a review of this emerging field (17 articles, 7 of which from the same team), Stigberg (2022) found that most research takes place in the context of teacher education, focusing on the knowledge prospective teachers leverage in design settings (p. 7). The theoretical grounds of such research are oriented towards learning, especially constructionism with roots in constructivism (Papert & Harel, 1991) and Learning by Design (Koehler & Mishra, 2005) (Stigberg, 2022, p. 8). Frequently, designing a tangible

manipulative is studied as solving a teaching and learning problem, by "embedding" curricular and pedagogical knowledge into an artefact (Akuom & Greenstein, 2022).

In this paper, we aim to broaden the frame of designing a tangible manipulative, shifting the focus from an individual endeavour of "transforming" ideas into artefacts (Akuom & Greenstein, 2022) to a social and material process. The previously mentioned Learning by Design approach (Koehler & Mishra, 2005) lies in the research field connecting *design thinking* to teaching (Henriksen et al., 2020). Inherent to this approach is the consideration of "teachers as designers", as professionals faced to creatively solve open-ended problems, aimed at addressing others' needs (ibid., p. 213). Thus, a core feature of "teaching as designing" is the consideration of learners' needs across the design process. We find this social dimension lacking in research on the design of tangible manipulatives, focusing on "describing learning from an individual perspective" (Stigberg, 2022, p. 7). Moreover, we are concerned by the polarization of the design process around an immaterial "idea", transformed into a material "artefact". First, because the consideration of others (learners) does not seem to settle into these two poles, but to pervade the whole design process. Second, because this polarization risks locating mathematics in an immaterial human mind, as "ideas" pre-existing manipulatives and outliving them. Thus, we strive to study the design of a tangible manipulative as a social and material process, investigating how these dimensions might be entangled.

More specifically, we find resonance with Henriksen et al. (2020) design thinking model for teacher education, including *empathy* as a first phase: "empathize, define, ideate, prototype, and test". The process of "understanding" learners' needs is deemed crucial and challenging (p. 215) and invites researchers to study the influence of "empathy strategies" (as observations, interviews) on the design process of prospective teachers (Chen et al., 2023). Building on these considerations, we aim to understand how prospective teachers empathize with learners in the design of tangible manipulatives. In other words, how do they "think and deal with problems from the perspective of others, experience their emotions and thoughts, and understand their positions and feelings" (Chen et al., 2023, p. 471, as they refer to "human-driven innovation")? Let us ground this aim on existing theoretical ideas.

Theoretical background

As a first step, we define the "design process" according to Henriksen et al. (2020) five phases. The first phase is "empathising", as relating to the people involved with the created product. This might be accomplished by several strategies, as observing people's behaviour, interviewing them about their perspectives and needs, or thinking about an experience from their perspective. The second phase is "defining", as synthesising the diverse perspectives into a defined problem to be addressed with the creation. Third is the "ideating" phase, as envisioning and evaluating potential solutions to the defined problem. From there, the fourth phase, "prototyping", describes the choice of a solution and its creation. The last phase is "testing", as trying out the prototype to inform future modifications.

Having detailed the process of designing, we now deepen the question of empathy. Framing empathy as an embodied and material phenomenon gains interest in studies of social cognition. On the one hand, based on neurocognitive data, social behaviour can be framed as an intercorporeal process, involving a "second-person perspective" on others through "embodied simulation" (Gallese, 2014). Experiencing otherness, from this perspective, can happen by activating neural circuits to simulate

others' physical states. Empathising would not only involve explaining others' behaviour (taking a "third-person perspective" on them, Gallese, 2014) but also simulating their motor goals through neural activation. These mechanisms of simulation deploy when observing others' actions and may also be triggered when "imagining" oneself or others performing actions (Alibali & Nathan, 2018).

On the other hand, investigating empathy through the neuronal activity of the designing pre-service teacher would risk centring back the design process on the individual[1]. Our aim is to understand how the perspective of learners is involved in the process rather than in the individual brain. Nemirovsky and Ferrara (2009) put forth that grasping others' behaviour also relies on being aware of the culture, norms, immediate past and goals it relates to (their "lived context/culture and surroundings", p. 163). Thus, *empathy* might intervene in the design process of a tangible manipulative through contextual elements grounding its creation, attempting to grasp the learners' perspective. These elements might stem from observations, direct interactions with students, or indirect accounts of their behaviour from other actors in education (as in the empathising stage of Henriksen et al., 2020).

This consideration of the social and the material through empathy is still close to the analyses of Akuom and Greenstein (2022): the design appears as a creation process grounded in learners' needs. However, the design process not only involves defining a problem, but creating a solution to it. When designing manipulatives, the material process of design is not only social when "understanding" the learners' needs, but also when "dealing with" them (Chen et al., 2023, p. 471). There is an interaction of empathy with the material process of designing manipulatives, beyond grounding a handleable object into a social problem. The defined problem triggers and determines a material creation, as much as the existing and the possible material creations trigger and determine the solution. The social dimension of the creation process is entangled with its materiality. This is cyclically experienced by designers through a "reflective conversation" with the materials (Schön, 1992, p. 5).

We find *imagination* (Nemirovsky & Ferrara, 2009) to account for this creative interplay between the social and material dimensions of designing manipulatives. "Imagining", as the authors propose, is "entertaining possibilities for action; entertaining (in the sense of 'holding' or 'keeping') a state of readiness for the enactment of possible actions" (p. 159). In this perspective, manipulatives do not embody mathematical ideas, but "expand the possibilities for action students can entertain" (p. 173). When manipulatives are perceived in terms of possibilities for learners' actions, their evaluation and creation may involve imagination. Thus, the "ideating" phase of design may involve *empathic imagination*, as entertaining possibilities for learners' actions for evaluating potential solutions. In turn, the "prototyping" phase may involve *mathematical imagination*, as entertaining possibilities for actions that constitute, from the perspective of the pre-service teacher, "new ways of moving with the tool as well as new mathematical relations" (Ferrari & Ferrara, 2023, p. 7).

Given these theoretical groundings, our research question reads: How are empathy, empathic imagination and mathematical imagination involved in the design of a tangible manipulative?

[1] A similar risk is highlighted by de Freitas and Sinclair (2014), in the context of accounting for the role of the body in learning (pp. 19-20).

Analysis of a prospective teacher's design of a manipulative

The analysis tracks instances of empathy, empathic and mathematical imaginations in the design process of Camille, a prospective teacher engaged in designing a tangible manipulative. Her journal constitutes our analysis material. As part of the course, the prospective teachers were required to keep a journal recording their design experience. The purpose was to gather information on the design process to understand the project's evolution, the questions and challenges faced, how they were addressed and any collaboration that occurred, as it was highly recommended. The layout of the journal differed from one student to another. Nonetheless, it encompassed both textual (reflections, summaries, syntheses, work notes) and pictorial elements (drawings, diagrams, screenshots and photos). In Camille's case, we analyse a 35-page document including "Annexes 1 and 2" and a 23-slide PowerPoint that documents her work with a colleague, named "Annexe 3".

The analysis is guided by the theoretical framework. First, in the "defining" phase of the design process, we identify instances of *empathy* when Camille relies on contextual elements to account for the learners' perspective. Second, in the "ideating" phase, we conceive as *empathic imagination* when the prospective teacher entertains actions students can explore with different tangible manipulatives. Third, Ferrara and Ferrari (2023) highlight the materiality of *mathematical imagination*, as new ways of coordinating the bodies and the tools. Thus, to analyse mathematical imagination, we analyse how, in the "prototyping" phase, body-tool interactions relate in new ways to mathematical relations.

Defining phase: empathy as grounding the manipulative in contextual learning needs. The design process starts with the analysis of a mathematical content deemed challenging by Camille. She chooses integers, according to reasons underlined in her journal:

> I decided to explore this concept further since **operations with negative numbers are a challenge for students, according to my observations**, even in secondary school. I am particularly thinking about the famous "two negatives make one positive" or the distributive property of subtraction in algebra. Many rules concerning negative numbers are applied as if they were recipes or algorithms, rather than being rooted in understanding. **My experiences during internships and tutoring have revealed that students often confuse the different meanings of the "-"** (the sign of the number, the operator, the opposite). Therefore, **I hope to design a manipulative that will help clarify the various meanings of "-"** (Journal, p. 4).

Relying on observations from teaching internship and tutoring experiences, Camille defines the problem she perceives for the learners. She gradually precises it, from operations with negative numbers being "a challenge for learners", to operative rules conceived as "recipes or algorithms", finally centring on the "confusion" between "the different meanings" of the "-" sign. We see here accounts of the learners' needs, resembling those produced by an empathy strategy advocated by Henriksen et al. (2020) and Chen et al. (2023): observing the learners in their own environment (here school and tutoring sessions). We note that this observation is active, as Camille was involved in these teaching situations, so the problem is also defined through her interactions. These experiences construct what she perceived as the learners' needs, situated in a specific culture (mathematics teaching in primary and secondary school of Québec) and in related norms (operative rules applied as "recipes"). Thus, the material process of creating the manipulative is grounded in empathy, in the sense that the design problem is defined in the "lived context/culture and surroundings" (Nemirovsky

& Ferrara, 2009) of learners. Contextual social challenges determine the "hope" to help learners understand the unary (sign of a number), binary (subtraction operator) and symmetric (sign of being opposite) aspects of the "-" sign.

Ideating phase: empathic imagination as comparing and evaluating manipulatives. Camille then compares different manipulatives related to integers and evaluate them as potential solutions to the defined problem. These manipulatives correspond to existing "models" of integers found in research articles (e.g. Vig et al., 2014): the "thermometer", the "two-colour" or "double-sided tokens", the "number line" and the "hot-air balloon" (Journal, p. 5). For each model, Camille entertains possibilities of actions with it. These possibilities are entertained to address the problem and especially to anticipate learners' difficulties. Regarding the two-colour token model, she writes:

> Students understand that a red token cancels out a blue token (and therefore 1 + (-1) equals zero) after **overcoming the difficulty that zero can be represented by multiple tokens**, which is not the case with a collection of objects (represented by a natural number). The tokens thus allow to work on the concept of opposites. However, the problem arises when solving operations such as 3 – 5. Here, it is necessary to add pairs of tokens (1 red, 1 blue) until it is possible to remove 5 blue tokens. However, this adaptation does not necessarily correspond to the mathematical process involved in this operation. Here, **the adaptation would be seen by the students as an algorithm and would not necessarily promote understanding** (Journal, p. 6, we underline).

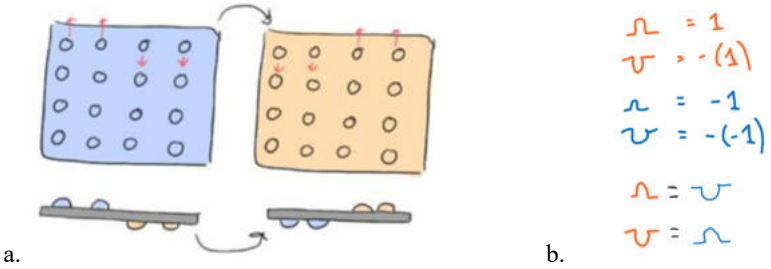
Several possibilities of actions are entertained: "cancelling out" a red token with a blue one, "representing" zero and "solving operations" with tokens. Each time, these possibilities are put in the perspective of learners, anticipating the potential difficulties they involve. First, the "cancelling out" and "representing" actions may conflict with a previous definition of numbers as cardinals of sets. Zero becomes not only associated with the absence of objects, but with pairs of objects that "cancel out". Second, provided this difficulty is overcome, "solving" a subtraction with the tokens may conflict with the "mathematical process involved". It might be that the strategy of adding "cancelling pairs" for performing 3 – 5 is deemed unlikely to align with future written computations (as it would correspond to 3 – 5 = 3 – 5 + (2 – 2)).

We see here an entanglement of the social and the material dimensions of the design process, which we termed empathic imagination. In this ideation phase, the social intention of addressing learning challenges takes the form of entertaining possible actions with manipulatives. Conversely, entertaining possible actions exist as an evaluation of manipulatives with respect to the learning challenge. This seems to be an instance of imagining as "juxtaposing" partial viewpoints of the same situation, that Nemirovsky and Ferrara (2009) analyse in the case of mathematical imagination. Indeed, in the above paragraph, the perspective of the learner, entertaining actions, is juxtaposed with the prospective teacher's perspective, anticipating difficulties for learning.

Prototyping phase: mathematical imagination as entertaining new body-tool interactions. Entertaining possible actions from the perspective of learners allows Camille to choose a solution for the design, as she brings possibilities of actions that avoid the pitfalls of existing ones. Camille names the manipulative "Numeric Pop-it", drawing inspiration from the fidget toy. In her Journal and in

Annexe 3—created when reflecting with Simone, a fellow prospective teacher—she outlines what they consider as the foundation of their solution (see also Figure 1a):

> Pushing down a "pop" is equivalent to subtracting a value. For example, if it's orange, it corresponds to subtracting a positive integer (pressing two orange "pops" represents – 2). On the other side, the same number is represented: two blue "popped" out, which implies +(-2). Its main advantage over other models comes from the fact that it's possible to visually understand the concept of opposites when flipping the Pop-it, for example, 6 = -(-6). It therefore provides a visual aid to the symmetrical meaning of the minus sign, making it easier to understand without going through subtraction's binary meaning (Annexe 3, slide 4).



a. b.

Figure 1: a. Drawing of the Numeric Pop-it (Annexe 3); b. Correspondences between actions and mathematical symbols (Journal, p. 11)

As one of their "desires for the manipulative" they add: "the movements/interactions directly engage with the concept at play" (Annexe 3, slide 5). It might be that, compared to the previous manipulatives, both the "binary" and "symmetric" meanings of the "-" sign involve the body-tool interaction of opposite displacements. Indeed, from any side of the manipulative, pulling and pushing a button constitute the "subtraction's binary meaning", by respectively adding and subtracting units. Moreover, as the two sides of the manipulative are connected, pushing a button from one side is equivalent to pulling a button from the other, such that adding a unit from one side (say 1) is equivalent to subtracting a unit from the other (here (-1)). Thus, the actions of pushing and pulling buttons and of "flipping" the plate also constitute the "symmetric" meaning of the "-" sign.

These body-tool interactions emerge as new ways of constituting relations between integers, involving mathematical imagination. Further, the new interactions rely on a "juxtaposition" (Nemirovsky & Ferrara, 2009) of different spatial and temporal perspectives. As shown in Figure 1a, the juxtaposition of front and top views of the manipulative constitutes the opposite relationship between adding and subtracting a unit (pulling and pushing). Similarly, juxtaposing views of the blue and orange sides constitutes the equivalence between actions performed on both sides (pulling a blue button and pushing an orange one). Importantly, empathic imagination is also at play, as new body-tool interactions are entertained as solutions to the defined learning problem.

We can develop how body-tool interactions here constitute new mathematical relations. The initial problem was strongly related to the symbol "-". The concept of Symbolically Structured Environment (Coles & Sinclair, 2019) usefully describes how mathematical relations would emerge in the use of this manipulative. It frames how mathematical relations can emerge in a mutual structuring of body-tool dynamics and mathematical symbols. Figure 1b, produced by the prospective teachers, shows how body-tool interactions directly relate to the binary (first four correspondences), and symmetric

(last two correspondences) aspects of the "-" symbol. Further, all the tasks they envisioned involve generating written symbols from the start (relating opposite numbers or adding and subtracting integers, Journal, Annexes 1 and 2). Thus, mathematical relations not only emerge as body-tool interactions, but as written symbolic relationships. As body-tool interactions and relationships among written integers structure each other, we see here how mathematical symbols can also partake in emerging "assemblages" of bodies, tools and mathematical concepts (Ferrara & Ferrari, 2023).

Discussion

Across the analysis, we centred on the interactions between the social and the material dimensions of designing a tangible manipulative. One might say that this interaction is resumed by involving the learners' perspective in the definition of the design problem, which we termed empathy. However, we argued that several phases of the design process involve and entangle social and material aspects. Ideation entailed empathic imagination, as entertaining possibilities of actions with manipulatives from the leaners' perspective. Prototyping involved mathematical and empathic imagination, as entertaining new body-tool-symbol interactions depending on the learners' needs.

Socio-material frameworks of mathematical activity greatly informed this research. Mathematical imagination allowed to analyse the design drawing of Figure 1a as a site of emergence for new body-tool interactions. This might be a rich way of pursuing the investigation of designing a tangible manipulative as a socio-material process. Indeed, mathematical diagrams are central to understanding mathematical activity as socio-material, as framed by de Freitas and Sinclair (2012). Diagrams are seen as material entities animated by "potential", prone to generate gestures and mathematical relationships. From this perspective, we understand how the materiality of Figure 1a allows new mathematical relations to emerge: inviting a third dimension into the planar sheet allows to "capture" (ibid.) possibilities of actions, using vertical arrows for pushing and pulling buttons and curved ones for flipping the plate. The same potentiality allows juxtaposing several spatial perspectives, involving front and top views of the same object. As these juxtapositions also address the learners, design drawings may be seen as sites of "mathematical agency as a socio-material encounter" (ibid.).

Importantly, this decentres the "agency of creating" (in teaching as designing) from the individual teacher leveraging resources, to a "distributed agency" (ibid.) across perspectives, individuals and materials. Thus, it enriches how designing can be situated at the "interplay" between "designer and materials, and between designer and audience" (Akuom & Greenstein, 2022, p. 111). Conversely, design technologies may enrich ways of thinking about the material potential of drawings. Consider, for example, how the "extruding" function in a 3D-design software can create a solid by "stretching" out a planar figure into a third dimension (creating a prism from a polygon, a cylinder from a circle…) and "carving out" a third dimension out of the plane (de Freitas & Sinclair, 2012).

The politics of mathematical embodiment

Elizabeth de Freitas[1] and Nathalie Sinclair[2]

[1]Adelphi University, New York, USA; defreitas@adelphi.edu

[2]Simon Fraser University, Burnaby, Canada; nathsinc@sfu.ca

What constitutes the political? How does the political designate something different from the social or cultural? How does the designation 'political' come to be seen within mathematics education research? In a historical moment of polarized 'identity politics', digital imperialisms, and 'post-truth' conditions, how might we need to rethink the space and manner of the political? In this paper, we push 'the political' past the ideological and the psychic, and argue for a political agenda that more adequately concerns the body in all its unruliness. We discuss new materialist philosophies of mathematics that emphasize the 'political ecology' of mathematical participation. We ask two entangled questions — Whose bodies become individuated and marked (gendered, racialized, disabled) through mathematical agency? And how are mathematical concepts themselves political?

Keywords: Embodiment, Materiality, Political, Aesthetic, Ecological.

Introduction

In the Topic Study Group (TSG) on visualisation and embodiment at the 2024 ICME conference, after three days of group meetings, a new researcher asked, "does anyone ever talk about the political in this group?" An extensive discussion ensued, during which different participants talked about how they could imagine the political being relevant to questions of embodiment in mathematics education research. It became evident, however, as the discussion evolved, that the ideas we have been working on for over a decade (see de Freitas & Sinclair, 2013), which have been centred on the notion of inclusive materialism (IM), were not seen as political, despite the critical, feminist origins of this work. In search of allies, we have decided to highlight, in direct and succinct terms, both the initial political intentions of IM and its continued articulation with scholarship more easily recognized as political—in Disability Studies, Anthropocene Feminisms, Posthumanisms and Anti-Colonialisms.

What constitutes the political? How does the term designate something different from the social or cultural? How does the designation 'political' come to be seen within mathematics education research? In a historical moment of polarized 'identity politics', digital imperialisms, and post-truth conditions, how might we need to rethink the space and manner of the political? The field of mathematics education research often falls back onto simplistic ideas about what constitutes the political, with a bias towards theories of the political that target (a) sociological perspectives on policy and ideology and (b) psychic perspectives on subjectivity and identity. Such work has often drawn from Marx, Althusser, Freire, Foucault, Butler, and Lacan. This is all necessary and excellent work, but also limited. All too often contributors designating their work as political position themselves as critics or pessimists, without taking a creative action or risking a proposal. The work of researchers who design alternative mathematic curricular practices or proposals are then seen as apolitical (or naively complicit) because they are working within the confines of the system. This means that the field typically bifurcates along two axes, each encoded in terms of varying degrees of political

engagement. The first axis is *criticality*, where research that simply seeks to understand or describe an as-yet unexamined context of learning is seen as apolitical (neutral or complicit, depending on your view), while research that explicitly critiques that which it describes or studies is seen as political. This axis seems to sanction a separation between description and critique, which needs to be problematized. The second axis is *scale*, where research that seeks to study the micro-ethnographic or physiological human body is seen as apolitical, while research that studies groups or people is seen as attending to the political. In our 2019 edited ZDM volume, *Body Studies in Mathematics Education: Diverse Scales of Mattering*, we tried to open up a discussion about how the political operates across these different scales.

In our opinion, this sorting of the field according to these two axes is incredibly dysfunctional. Not only does it overlook the radical contributions to political theory from feminist thinkers ("the personal is the political") but it also overlooks the widespread shift in 21st century theory towards different scales of political action and agency, as well as the fragmentation of typical humanist and Marxist notions of political voice and agency. The bias in the field has, despite its good intentions, affirmed a problematic image of the political, even as it claimed to offer insight into political dimensions. Beccuti (2024) discusses the importance of ideology critique, while also troubling the simplistic assumption that ideology functions deterministically, and that critical mathematics education will always be a kind of false consciousness. Various post-colonial and anti-racist revisions in the humanities (e.g., *Becoming Human*, by Zakiyyah Iman Jackson, 2020 or *Posthuman feminisms*, by Rosi Braidotti, 2022) have shown how such a sorting of the political often reflects a *ressentiment* that keeps one trapped in subjection to the very thing one needs to overthrow. We believe the critical theory that formed the foundation for much of the political work in mathematics education research (MER) in the last decades, and which has often fuelled the work on identity and subjectivity, needs to embrace new theories of molecular and more-than-human geo-politics, in order to deal with new modes of governmentality in an algorithmic-control society, under a new climatic regime. In our case, "the ontological turn" brought to our attention thinkers in science and technology studies (STS) like Karen Barad, Myra Hird, Bruno Latour, Donna Haraway, and Isabelle Stengers, who offered new ways of studying the politics of more-than-human agencies, as well as more recent scholars working on the "creolization" and post-colonial revisions of STS, scholars like Juan José Saldana and Viveiros de Castro.

Most importantly, we believe this shift in the theoretical underpinning of the political better equips us to examine mathematical embodiment as a political practice. Rather than simply study the way that experiences in mathematics education shape identity and subjectivity, leaving the mathematical ideas outside and untouched by critique, and leaving the body as the mere passive carrier of social imprinting, we show how mathematical concepts are themselves historical and political and materially bound up in bodying processes. This has been our way of demonstrating how the political runs deep, past the cultural framing of subjects and institutions, and into the very mixtures of concept and matter – what Latour calls our "political ecology". For instance, when we analyze how the number line is a historical apparatus for merging discrete and continuous notions of magnitude, we are exposing the way that particular humans try to manage the material mixture of these onto-epistemic concepts, which are themselves bound up with other competing agencies. When we

examine concepts like proportionality (de Freitas & Sinclair, 2022), the infinitesimal (de Freitas, 2020), conditional probability (de Freitas & Sinclair, 2018), ordinality (de Freitas & Sinclair, 2016), and spheres (de Freitas, 2023), we show how these mathematical concepts reflect and feed-into cultural and political space. Our efforts follow other thinkers with kindred methods, like Michel Serres (2017) and Châtelet (2000), who shows how Western mathematical and scientific concepts are bound up with historical and political and cultural values. Similar lines of inquiry have propelled the IM-infused and more racially oriented political work of Dominguez et al. (2023) and Peralta (2024).

In the sections that follow, we highlight some of the main political implications of Inclusive Materialism. We discuss some of the ways that IM recasts the body as ecological – as we articulated over a decade ago, we understand the "human body" as "an assemblage of human and more-than-human mathematical concepts" (de Freitas & Sinclair, 2013, p. 453) – which has enabled us to contribute to the recent socio-ecological movement (see de Freitas et al., 2022; Coles et al., 2024).

Not constructionism

Given the early work in what became known as embodied cognition, particularly that of Lakoff and Núñez (2000), but also the enactivism of Maturana and Varela (1980), and the growing importance of the work within phenomenological-informed studies, none of which explicitly attended to what MER conventionally names as 'the political', perhaps it is not surprising that a book entitled *Mathematics and the Body* (2014) would be seen, wrongly, as extending the constructivist/constructionist paradigm. In this paper, we aim to articulate the specific philosophical assumptions and political ambitions of IM, both as it was framed in 2014, and as we (and our colleagues) have elaborated since then.

IM was not motivated by the question of how students learn mathematics or how they can be taught in better ways. It grew from our own historically informed and critically oriented philosophical investigation of what constitutes situated practices associated with mathematical knowledge writ large, whether it be by experts, learners, maverick engineers, ancient Mesopotamians, etc. This objective entailed examining examples from both in and outside of contemporary schools, a pluralist perspective that pushed past epistemic relativism to more ontological questions about material practices (an ethico-onto-epistemological perspective). IM is a philosophy of mathematics, first, with an accompanying philosophical method for investigation. While we attend to pedagogical issues and agendas (studying problem-posing habits in classroom discourse, tracking visual and dynamic manifestations of concepts, destabilizing the essentialism associated with psychometric research, etc.), IM does this work as part of a larger philosophical and historical project, exploring how mathematical concepts are material, and have/will/can never be fully extracted from the material contexts that give rise to them. This is not constructivism or constructionism because the ontology is literally at odds with the anthropocentric tenets of all such approaches, derived as they are from the Kantian Enlightenment image of reason. Constructionisms and constructivisms tend to centre the human as the fundamental synthesizer of sensory information by positing mental faculties and internal schema that derive from psychological premises about individuated cognition. The specific theorists we draw from, especially Gilles Deleuze and Karen Barad, offer a radically different ontology, which better recognizes the agency and virtual potentiality of more-than-human ecologies.

Moreover, our work has always been deeply historical. If there is a European theoretical lineage we inherit from, it is that of Deleuze (Leibniz, Spinoza, Nietzsche, Bergson, Foucault) which informs our *archeological* approach to the history and onto-genesis of mathematical concepts and allows us to expose the multiplicity of mathematical practices, and the resurgence of "minor mathematics" as a constant destabilizing force in mathematical communities over time (Deleuze & Guattari, 1987). This focus on *minor mathematics*, rather than state-sanctioned mathematics, has helped us surface all kinds of neglected and erased mathematical practices, and to both destabilize the conventions of school mathematics, and offer images of alternative approaches.

In IM, mathematical concepts embody or express political forms because mathematics is as much of the earth and our situated material practices as any other practice. A sphere is never just a sphere. It is part of a cross-cultural and historically repeated fascination with particular spatial territory (de Freitas, 2023). Spheres are *both* abstract forms and political forms. In other words, our project is a political analysis that seeks the force of the political *within* the mathematical, rather than only in the institutions where it occasionally lives. This takes back from those who would guard mathematics as their own pure or ideal politically neutral activity, to show how mathematics is itself bound up in the messy material conditions of its diverse formulations.

Aesthetics and dis/ability

The new materialism of Karen Barad (2007) came as part of a chorus of critical responses to second wave feminism, which had emphasized gender as a performance, to use Butler's (1993) term. Second wave feminism was intended to free women from being defined *a priori* by their biological bodies, and enable women to access many new forms of participation in society – the exigencies of a fixed Nature gave way to the possibilities of a more flexible Culture. This was crucial work, in shifting civil rights towards more inclusion and opportunity. However, IM looked instead to third wave feminism which problematized the nature-culture divide that had shaped the second wave, in part because the second wave positioned the body as a passive container (Bennett, 2010; Haraway, 1991), ceding all power to human discourse and socio-cultural norms, and in part because it had failed to address the specific intersections of race and class, and the heteronormative images of female sexuality. Both the emphasis on discourse and the lack of attention to intersectionality led to important theoretical developments, as a way to correct those two aspects of second wave feminism. Third wave feminism sought to agentialise the intersectional body by decentring the human (as in Haraway's cyborgianism) and fashioning a non-dualist NatureCulture mix. With Da Silva, Wynter, Haraway, Stengers and other feminists, Barad refused to simplistically position the sciences as the enemy of Woman and instead worked towards creating new forms of science (in her case, physics) that ceded fantasies of Humanist objectivity and universality to feminist commitments to emergent and agential, but no less realist, material-discourse mixtures.

Scholars in critical disability studies in mathematics education understood our agenda and took up our ideas as political interventions, particularly those working with neurodiversity, and therefore interested in our alternative image of mind-body relations (Tan et al., 2019). In 2015, we published research interrogating the faulty assumptions of neurological research on dyscalculia, carefully examining the experimental apparatus and its built-in bias towards a limited conceptualisation of

number itself. In other words, we showed how one could critique such research for its assumptions about the nature of mathematical concepts, to better undermine their simplistic assessments of human number sense and disability. We saw our effort as strategic, getting under the hood of their research, looking at the details and the specific image of number sense that was assumed. The target was their flawed image of mathematics – which was a target that mattered to them. Their built-in bias about number was significantly over-determining what the researchers were able to see in their data, continuing decades-long Piagetian-informed narratives of developmental cognition. To critique the medical research at this level – the level of their mathematical concepts – meant they would take notice. Identifying these assumptions allowed us to then disrupt them, and proceed to lay bare the many alternative ways that number thrives in diverse bodies and *neurodiverse learners*. From this work, it is possible to see how no developmental trajectory (or pathway) is neutral because it privileges certain conceptual constellations over others, typically those aligned with the practices of white, anglo-euro, male, heterosexual human bodies. Thus our research aligns with the efforts of critical mathematics education research, but goes about this work differently.

By drawing on the political aesthetics of Rancière (2004), we traced some of the sensory-material aspects of classroom environments in terms of a 'distribution of the sensible'. Rancière insists on the way in which the aesthetic functions politically to produce communities of sense-making. In other words, there is a significant connection between what can be sensed – in mathematics, we might take a simple example of what can be seen – and what is taken to make sense within a certain set of practices. For the Bourbaki, for instance, mathematics was to be a discursive, symbol-driven practice in which diagrams were not permitted. This is an aesthetic move (restricting what can be known through the senses) that has political consequences (determining what counts as knowledge). The history of mathematics is chock full of such political-aesthetic conjunctions and these play out in mathematics education as well. A recent example is the shift from banning the use of fingers in the classroom to promoting them as ways of making sense of number. We have explored other material-aesthetic practices in the mathematics curriculum relating to proof practices, where the formal manner of engaging with the diagram in classical geometric deduction is also a kind of aesthetic practice (de Freitas & Sinclair, 2014).

Conclusion

Because mathematical concepts are linked to specific material-sign-making practices, we think it's important to complement the recent calls for (re)humanizing school mathematics (see Gutiérrez, 2017; Tan et al., 2019) with specific proposals for problematizing the centering and continued emphasis on the exceptionality of the human as a deeply gendered and racialized category (Jackson, 2022). This entails revealing the ways in which mathematics has never been modern (Latour, 1993) – i.e. it has never been only the achievement of the human. In the face of mass extinctions and climate crises, IM places the human in the midst of other life agencies. Drawing on both "sympoiesis" (see Haraway, 2016), and imagination, we describe more-than-human mathematical worlds (that of wolves, spiders, ants) which allow us to further reflect on the precise ways in which human mathematics is (and is not) a reflection of human agency (de Freitas, 2024; Barwell, 2022). Indeed, we have argued that it is only by addressing the onto-ethico-epistemological nature of "majority" mathematics that we can dethrone it from its current hierarchical, discipline-defining status, allied

with a particular 'human' (with all the resulting violence entailed), not to cast it away, but to understand it historically and philosophically, and thereby become empowered to engage with it.

We take as given that the universalising impulse of movements such as "math for all" are fictitious at best and viciously reinforcing of existing exclusions at worse (Martin, 2015). With IM, we are interested in the force of difference and disorder within Western mathematics: what differences were not actualised in the differentiating of mathematics from religion or from magic? What differences were sidelined in the convergence of calculus towards a particular set-theoretic formulation? But also, which differences emerged precisely and powerfully at these historical junctures when mathematics was forced to become something different and unrecognizable? We seek different *minor mathematics* that bubbles up everywhere, to show how mathematics is not the monolithic static or dead thing it is taken to be. Our work complements or supplements other work in ethnomathematics and socio-cultural studies of non-Western mathematics, but our recent efforts are distinctly focused on exposing *the minor in the major*: we find a disruptive minor mathematics in the work of European mathematicians who pushed back at the conventions of the field and invented new controversial mathematical concepts; we find it in the decolonizing efforts of Creole scholars in 17th century New Spain who offer an entirely new "mixed mathematics" more responsive to the particular environment of the Americas; we find it in the speculative mathematics of Lewis Carrol and Charles Hinton (de Freitas, 2019). In this way, we treat mathematics as a kind of non-innocent artful and evolving material practice whose objectivity or claim to universality is itself situated and grounded in a vast ecology of people, atoms, guns, water and planets.

Our effort is fundamentally ecological because it recognizes the way that *temporal/spatial scales* of relevance expand out from the personal to the climate crisis, a crisis that is experienced differently depending on the specificities of racialized and gendered bodies. Who is amalgamated into this common stratum of "human being" at the moment of the Anthropocene? Who is counted in this newly globalised planet-wrecking species? How does this planetary concern wash away other socioeconomic differences that have mattered (Da Silva, 2022; Latour, 2017; Yusoff, 2018)? Without denying the effects of the massive redistribution of the earth's biomass, or carbon emissions or nuclear waste, Colebrook (2017) points out that the very idea of the human (and thus also the idea of the posthuman) is caught up in entangled differences (racialized, gendered, sexualized, commodified) that have come to produce both the conception of a stable, predictable Nature (with orderly seasons, orbits, migrations) and the concept of the Anthropocene which disrupts that stability. "We" are called on to reckon with the human in ways we never did before, precisely because of this contested term "Anthropocene". The claim that the personal is geological is an assertion about scales of mattering that are often ignored in the separation of disciplines and the phenomenological focus on the intact individuated human body. As a gesture of both collapse and opening, the geo-personal reminds us of how bodies straddle different modes and scales of geo-political relevance.

A research focus on the body contributes to political analyses of mathematics education for all kinds of reasons. In our case, this focus is sourced in a distinctive philosophy of mathematics. We ask: How might this philosophy change mathematics education, and cultivate different and more inclusive images of Nature, images that affirm distinctive singularities, exceptions, and also multi-scale bodying and relationality? In following the personal to the political, geological, and ecological, we

have doubled down on the historical entanglements that expose the fundamental earthboundedness of mathematics, with the aim of crafting a foundation for a future mathematics education.

Diagrams and mathematics education research: A methodological reflection

Francesca Ferrara and Giulia Ferrari

University of Torino; francesca.ferrara@unito.it

In this paper we address a methodological reflection on data presentation and visualization in our field, especially concerned with ways to display bodily and material engagements as relevant to mathematical activity. We narrate a story of methods in mathematics education research, which focuses on the need for alternative ways of showing and presenting data if we want to adequately address the body and the interaction body-tool in mathematical activity. We focus on diagrams as a research method to explore learning events where the bodily, the tactile, the kinaesthetic, the affective, the cognitive, etc. are all entangled in shaping the activity. We discuss examples of the use of image and diagrams in research practice and develop lines of flight around a desire to use them creatively, how they transform data and the issue of the entanglement between researcher and data.

Keywords: Body, diagrams, material, mathematics education, research methods.

The embodied turn and its demand on research methods

In this paper, we want to address a methodological issue that, in our view, lies at the heart of the Thematic Working Group "Embodied and material studies of mathematical behaviour" (TWG29), that is, the presentation and visualization of data in mathematics education research. Our aim is to exemplify this issue by drawing particular attention to ways in which researchers in the field have dealt with the broad question of how to visually display bodily engagement and materiality in research papers as relevant to a discussion of mathematics teaching and learning. Moreover, we want to discuss lines of thought concerning the fact that the way data is presented and visualized influences the analysis, while capturing the entanglement of the researcher with data.

Theories of embodiment (Lakoff & Núñez, 2000) have brought forth the role of the body in mathematics thinking and have sprouted a great interest in how sensory motor experiences shape and ground the ways in which we create mathematical meanings. Since the 2000s, many researchers have drawn on the idea that mathematics learning could be better theorized as a multimodal activity, in which not only verbal utterances, but the whole complex entwinement of words, gestures, gazes, movements, voice modulations, and so on, play a crucial role (e.g., Radford et al., 2009). This theoretical perspective has posed for researchers the methodological question of enriching the field notes or transcripts of the learning situation under study with a rich description of gestures, movements and actions in it. These were necessary ingredients for discussing "what was going on" besides the sole verbal register, and for capturing the complexity of the learning event. In most cases, gestures and movements were not interpreted as a mere subsidiary of what was being told, but as the texture of the cognitive processes at play in the classroom: the need to include such descriptions in the papers was therefore not accessory, but a direct consequence of a change in the theoretical paradigm. However, there are differences in the interpretation of the role that tactile and kinaesthetic bodily experiences and their interaction with artifacts and material culture play in how we make sense of the world. In this paper, we strive to make these differences emerge, when possible, but we stress

our interest in a somewhat transversal line of investigation, which is not independent from a specific theory or conception of cognition, but also not bound to it. In the following, we articulate our reflections around strands that we consider significant for grounding a discourse on the methodological aspects of data presentation in mathematics education research. We do not intend to provide a literature review on this topic, but rather to discuss innovative elements that have emerged from some studies that could stimulate rich meta-level discussions about our work as researchers.

The materiality of data and editorial format

Video is probably the most widely used kind of research data in educational practice nowadays, partly because it is now easier (than in the past) to gather videos from the (mathematics) classroom. Even though it is often perceived as the best resource for adequately grasping the learning event, it is still not so widely problematized or theorized (Hall, 2000; Derry et al., 2010). The attention towards the body and bodily engagement surely increased the interest towards this type of media, as a video could be replayed several times, and many aspects (like gestures) could be observed, scrutinized and analysed more closely. Still, the video captures only a particular perspective, with all its limitations, on the complexity of mathematical experiences and does not provide alone all the answers to our research problems. Furthermore, to "appear" on paper, students' and teachers' interactions are then documented through detailed transcripts, paying attention to expressions, gazes, and movements, which reconstruct a description of what was captured in the video. As an example, the methodology of the semiotic bundle (Arzarello, 2006) accounted for the multimodal nature of mathematical cognition, beyond the focus on linguistic elements. The analysis involves a "timeline", a specific table where the actions of different actors at play are thoroughly described over time by unpacking the different modalities they engage with (Arzarello et al., 2011).

Another interesting element for our discourse here is the role of the technical aspects of video data. Think of the use of multiple recordings from different perspectives (which can be synchronized later by audio and displayed close to each other); or the use of video recordings using cameras placed on participants (like GoPro cameras). All these material constraints or possibilities, created by the very means in which data can be captured, influence the ways in which we, as researchers, are able to tackle research questions (Nemirovsky et al., 2018).

A very well-known special issue of Educational Studies in Mathematics published in 2004 and entitled "PME Special Issue: Bodily Activity and Imagination in Mathematics Learning", which arose from a previously conducted PME Research forum, proposed an interactive editorial format called "video papers". The papers published in the special issue were not only made up of words and static pictures, but also of animated and interactive graphical representations, and motion pictures with sounds ("video-clips") of the tools and devices involved and of students, teachers and researchers working together (Nemirovsky et al., 2004). While this was a first-time (and, at present, unique) attempt in history, not so much has changed in publication formats since then, even though some journals are now experimenting with more visual templates like the "graphical abstract" and more interactive resources (e.g., digital applet) are commonly shared by researchers via web links as supplementary materials of the paper.

On the other hand, different attempts have been made in writing by different researchers to better capture and interpret the materiality of the mathematical activity, and to profit from the materiality of data. For example, Staats (2018) has proposed poetic structure as an additional discursive modality, alongside prosody, gesture and writing, relevant to multimodal analyses of mathematical activities that value a broader theory of embodied knowledge, for which mathematical concepts are also amplified by layers of syntax. Mikulan and Sinclair (2019) have introduced educational stratigraphy as a method (and meta-method) to address various scales of mattering in mathematical activity. They propose to see an event, an utterance or a gesture or drawing, as issued in a time and space detached from those that came before and overlapping with past events so that each is a novelty. Rather than thinking of events in a continuous, chronological time, events may therefore be seen as superimposed and granted their own force of folding and unfolding or mode of existence, actualized or potential (that might have been or still to come, that did not happen or might be imagined). In this way, we can read the movements, the tool, the concept (or the biological and the social, the affective and the cognitive, the abstract and the concrete, etc.) as different modes of mattering alongside each other in mathematical activity and better account for the multiplicity or plurality of ontological possibilities that shape the activity. More recently, Rumbelow and Coles (2024) draw methodologically on theories of embodiment to study children's interactions with physical materials (Cuisenaire rods) and an AI app to work with number as length (or measure). In this case, interactions are taken to exist in complex dynamic (body-artefacts-task) systems that never reach states of equilibrium (following Shvarts et al., 2021), so they can only be locally stable, for a while. These researchers introduce diagrammatic notation of the body-rods-app triad as a research method to explore the presence and flow of forces such as affect in the activity. They use different colours to capture where the flow of activity (the interaction) is smooth or disrupted (thus, generating tension or frustration).

All these few examples offer occasions to experiment with data and pose new points of view for their interpretation. Looking at them, it is already clear that the visual dimension is not the only one that has been explored and exploited from the research methodology side. However, it is the one we are most interested in discussing in this paper due to the force of image in our knowing of the world nowadays. Briefly speaking, we see diagram as a potential, powerful way of capturing data and producing readings that are not necessarily representational, sequential or unidirectional. In the following, we will refer to some diagrammatic uses of data while exemplifying issues around the relevance of visualization and experimentation in the research methodology.

Diagrams that transform data

Diagrams are ubiquitous in mathematics as well as in mathematics education: in the latter, they are often used to describe relationships among actors, institutions, cognitive processes or pieces of knowledge. In a semiotic mediation perspective, for example, a diagram with lines illustrates the links between tasks, the mathematical knowledge, the material used, the individual and collective productions (e.g., Bartolini Bussi & Baccaglini-Frank, 2015). Here, we are interested in different kinds of diagrams, namely diagrams used by researchers in their practice to present or analyse data. Since we would have had the possibility of including only a few diagrams in the paper, we decided not to include any. We particularly focus on their role in generating new meanings and actively partaking in the transformation of data, describing only certain aspects of the mentioned diagrams.

The first two examples we discuss are related in that they share the need to study movement as a broad concept, involving human and non-human bodies, including mathematical concepts, and the complex entanglement of affects circulating among different agencies (de Freitas & Sinclair, 2014). De Freitas and colleagues (2019) used diagrams with arrows to describe the movements of students who were coordinating to create a circle by moving two remote controls, which were part of a particular technology, WiiGraph. The diagrams helped the researchers to analyse the microscales at which coordination was achieved or lost and to highlight the different scales of mattering along which the concept of circle emerged in the girls' sympathetic negotiation. Ferrari (2019) crafted a movement notation derived from Labanotation (a system for recording dance moves) to capture the motion experiments that students performed in the classroom with the same technology. The creation of a notation for the specific case at hand was driven by both a theoretical and a methodological question: on the one hand, treating movement as an overarching concept (which includes, but is not limited to, bodily movement) required new ways of "talking about" it; on the other hand, in most research studies presenting motion sensor activities, the motion experiments themselves are extensively described in words, and the qualitative aspects of movement involved in the activity are often lost.

These challenges required the research to open towards diagrammatic attempts. Interestingly, in trying to capture the qualitative dynamics of movement, both attempts necessarily deal with the interplay between discrete and continuum, which is not fully resolved inside the diagram, but is evoked in its virtual dimension. The researchers' work in creating the diagram entails a different stance towards data than simply coding it, as well as decision-making on the choices regarding the diagram's articulation. At the same time, the diagram requires the reader to approach the situation under study through a new medium, which actively demands interpretation.

Beyond the inevitable examples' limitations and inherent pitfalls in representing data, we consider them relevant to our discourse as the diagrams offer a novel perspective on the event, striving to bridge the gap with the complexity of movement and expand it, from a post-human perspective, beyond the consideration of the human body alone as the centre of the activity.

Another example we wish to discuss is the diagrammatic rendering of eye movement, which is made possible by tracking technology (Strohmaier et al., 2020). We do not want here to enter the details of how data are captured and then interpreted: rather, we want to draw attention to two significant aspects. First, it is worthy of consideration that this technology allows for the creation of a new representation that the researcher can use to make sense of the aspects of a task/activity that have the greatest influence on the subject's orientation. For example, Krichevets and colleagues (2014) perform an analysis of eye movements as a method for investigating the transformation of perception at different levels of competence: by looking at gaze paths and the number of visual fixations (rendered through diagrams) of experts and novices when solving a mathematical task, the authors observe that the two groups of participants *see* very different environments. Secondly, we can say that eye-tracking technology uses sensors that allow perception to be studied beyond our perception, possibly expanding the researcher's perception of an event. This aspect poses theoretical challenges to the nature of perception, our knowledge of it and the role of the researcher in interpreting and questioning the data captured by the technology.

The entanglement of data and researcher

Recent post-human perspectives, also drawing on feminist studies (e.g., Haraway, 1988), have been questioning the objectivity of the researchers and positivistic stances on science. This implies resisting claims of authority and the understanding that the proposed account is only one among many possible ones. Related to this, a key point of data collection, within a critical postmodern paradigm, is that the researcher is no longer at the centre of the process, but s/he provides space for new and different data, without imposing her/his point of view (Stinson & Bullock, 2015). Dominguez and colleagues (2023), for example, draw on both feminist materialisms and Indigenous Knowledges to account for the possible as emerging in philosophical conversations with students around the concept of space. Instead of following traditional research patterns, for which video data is first translated into a transcript, then coded and subsumed into main themes and finally summarized into key findings, the data is treated differently, expanded rather than reduced. The paper contains comics, which act not just as "a representational device, or a mediational tool at the service of language." (Dominguez et al., p. 1157). Comics allows the authors to break the linearity of language and embrace data through the "agentic materiality of drawing" (*ibid*., p. 1157), engaging the researcher in a creative process. This is in line with considering "data as alive, agentic, and full of possibilities." (*ibid*., p. 1156). While it is now common to see line drawing reproducing on paper a sketched version of human bodies' interactions (e.g., Radford, 2021), the method employed by Dominguez and colleagues serves as a reconfiguring of data, offering new opportunities for interpreting them through a reworking of language and drawing.

We see a similar attempt to different experimentation with data in Sinclair (2024), where the author discusses narrative and re-enactment as research methods that allow for recovering the flow and richness of the experience and increase situated and embodied validity. She considers a short video clip of a four-year-old child interacting with the multitouch app *TouchCounts* to work on number sense. The attempt here consists first in providing a narrative account of the event to give a sense of the whole event and to situate it, then in inviting the reader to re-enact the event through selected images, focused on a particular aspect of the experience: movement (of arms, hands, fingers). The image component is still fundamental in the qualitative experience of research and for an intensive encounter with data. One novelty in Sinclair's (2024) approach is that her reading of data strives to engage the reader in the same research process or, according to the author, to enable the reader "to experience the experience" (p. 32). Being invited to re-enact images taken from videos, readers in fact explicitly *mimic* the learning event rather than simply *read about* it.

In this way, re-enactment becomes a way of positioning (see Herbel-Eisenmann et al., 2016) the reader beyond the researcher and valuing what may make sense or become sensible to the reader. It becomes a way of positioning the reader as partaking in the research process, engaged 'in conversation with' the researcher, therefore enabling a relationship between researcher and reader. This implicates "the potential for the reader to create their own interpretations" (Sinclair, 2024, p. 34) or narratives around the event. We can ask: How does it change the reader's experience? But it is also a way of positioning mathematics education research so that alternative, challenging storylines, for example about the role of the body, or the tools or the methods, in mathematical activity might be possible, might come or be imagined. The issue is strictly related to the theme of the working group

since it speaks directly to the material dimension of the researcher's act of knowing and to the virtuality of research as a process, or of research data and research methods.

Final remarks

In this paper, we have tried to narrate a story of methods in mathematics education research, which focuses on the need for alternative ways of showing and presenting data, for the sake of adequately addressing the body, as well as the interaction body-tool in mathematical activity. We have drawn attention to diagrams as a research method to explore classroom situations and learning events where the bodily, the tactile, the kinaesthetic, the affective, the cognitive, etc. are entangled in shaping the activity. We have seen examples of the use of diagrams in this direction and have discussed them to develop lines of flight around a desire to use them creatively, the way that they transform data and the issue of the entanglement between researcher and data. Following Stinson and Bullock (2015), the examples we presented seem to fall within paradigms of inquiry more related to both *emancipation* and *deconstruction*, without exhausting or completely fulfilling them. We consider these two aspects as essential to our research practice if we want to treat (as we do) research as an open-ended process rather than a product-oriented activity. What we really see as valuable in the examples is precisely that they give rise to new questions, issues, and directions more than to definite answers, generating knowledge differently and stimulating new knowledge. The approaches are then relevant to research practice in the field because they open room for dealing with the agency and the potentialities of data, allowing us to reimagine our encounters with data and to engage in creative research processes that move "toward the probable and away from the possible" (Dominguez et al., 2023, p. 1169) and toward a broad consideration of what matters in research practice studying the role of the body, movement and materiality in mathematical activity.

Finally, if we think of methods as "technologies of research", as Sinclair (2024) suggests, then we can question how future new technologies will impact research. For example: What will be the implications in terms of/for research design(s)? Or: How will AI change our data and will implicate the need for alternative methods / futures / imaginations / storylines in educational research? These are just some possible questions that may be raised in relation to our methodological reflection, but we feel that they are relevant to a discourse of educational research in post-human times, when we are also engaged with demanding contemporary issues involving science education research: "climate change, multiculturalism, the flourishing of new interdisciplinary domains (like cognitive neuroscience, artificial intelligence, digital humanities to name a few), as well as issues stemming from living in the digital and post-truth era" (Levrini et al., 2021, p. viii). Levrini and colleagues point out that the preferred way to address these challenges is deepening our understanding and that science education can play a key role in this effort. As they stress, and we agree with them, the deep and novel character of these challenges "necessitates collectively searching for new narratives, languages, and forms of beauty that capture our attention and trigger new ways of thinking", while demanding "exploring new theoretical perspectives and crafting novel methods as appropriate" (*ibid*., p. x).

Use of conceptual blending to investigate students approaching functions in an emerging embodied technology

[2]Amsterdam University of Applied Sciences, The Netherlands

When emerging technologies meet embodied activities, new mathematical learning opportunities arise together with new questions about underlying conceptualization processes. In this paper, we present the results of a study involving secondary school students developed upon the use of an emerging embodied technology, GeoGebra plus. To analyse the students' cognitive processes, we used conceptual blending (Fauconnier & Turner) and we built a model to describe the complexity of integrating embodiment, a new technology and mathematics. In this paper we show that GeoGebra plus can support the object-oriented and dynamic view of functions. Moreover, we suggest that such technologies are the engine to move from the paradigm of 'humans-with-media', introduced by Borba and Villarreal, towards a 'humans-in-media' one.

Keywords: Conceptual blending, emerging embodied technology, GeoGebra plus, function, secondary education.

Introduction

Over the last two decades, mathematics education research has provided evidence for the benefit of using digital technologies in mathematics learning (Clark-Wilson et al., 2020; Drijvers & Sinclair, 2024; Lagrange & Kynigos, 2014). In these digital environments, several embodied approaches have been adopted to foster functional thinking, for instance, bimanual coordination connected to a monitor to engage with proportions (Abrahamson & Sánchez-García, 2016), bimanual coordination through a multi-touch digital interface to promote correspondence and covariation approach (Wei et al., 2023). More recently, even the so-called emerging technologies (Veletsianos, 2010) (e.g., augmented reality, virtual reality, and artificial intelligence) have started to be used in mathematics learning, and some of their affordances exploited to incorporate the use of the body in the digital environments and support the learning process.

In this paper, we will examine a pilot study (consisting of two experiments) designed to support an object-oriented and dynamic view on functions making use of the emerging embodied technology GeoGebra plus (GGB+ from now on). GGB+ is an extension of GeoGebra (GGB) developed by David Hornsby (JKU, Linz, Austria). By adding a pose-estimation model (Posenet) via camera to GeoGebra, GGB+ enables embodied interaction with digital mathematical elements. GGB+ identifies specific points of the user's body (e.g., eyes, shoulders, elbows) and builds an avatar of the user in the GGB graphics view that moves in accordance with the user's movements. In this way, the avatar coexists with representations of mathematical objects (e.g. points, lines, or shapes) interacting with them both statically and dynamically. As a result, when the user moves in front of the screen, their own avatar mirrors the movements, allowing them to interact with mathematical objects and to

receive different visual types of immediate feedback from GGB+ (e.g., the simultaneous movement of the avatar with the user's body, a green Ok! appearing on the screen, or numerical values associated with some coefficients changing with the body's movements). The immediate feedback loop guides the user to align with specific poses or movements and, from now on, we will refer to the process of intentionally adjusting the body posture or pose in response to real-time feedback displayed on a screen with the word *positioning*. This experience goes beyond typical multisensory interactions with technology in mathematics education (Arzarello & Robutti, 2010; Nemirovsky & Borba, 2003), because here the user, through the avatar, co-exists with the representation of mathematical objects.

The pilot study here presented was carried out in the context of the European Widera project TransEET – Transforming Education with Emerging Technologies – and we use the *conceptual blending* model (Fauconnier & Turner, 2002) to describe the students' cognitive processes that emerge in the learning experiences with GGB+. Such a model was chosen for its suitability to describe the complexity of integrating embodiment, a new emerging embodied technology and mathematics.

Theoretical framework

The theory of conceptual blending, developed by Fauconnier and Turner (2002), explains how we unconsciously and instantly integrate inputs from diverse knowledge domains to create new knowledge. This process is represented through a network of mental spaces: *input spaces* (knowledge domains), the *cross-mapping space* (connecting corresponding elements), and the *blended space* (the outcome of merging and elaborating inputs). The same inputs can produce different blends. Fauconnier and Turner also introduced *double-scope blends*, where inputs with distinct organizing frames (e.g., a computer desktop blending a desk and software) combine to form unique structures. These blends support specific actions or meanings, such as "moving a file to the trash bin."

Earliest studies on multimodality, related to the field of cognitive science on embodied cognition (Wilson, 2002), supported mathematics education research in deepening and outlining the relevance of gestures and body movements in teaching and learning processes (e.g., Arzarello et al., 2015; Ferrari, 2020; Shvarts et al., 2021). Similarly, the construct of *grounded blends* was born (Yoon et al., 2011) within the framework of conceptual blending, with the aim of investigating how gestures can be endowed with and used to communicate mathematical meanings. In this type of conceptual blend network, one of the input spaces is the person's *real space*, including gestures and non-verbal communication that actively contributes to the elaboration of the final blend. Several studies adopting the conceptual blending model have also carefully reflected on the role of technology in conceptualization activities: for instance, Gregorcic and Haglund (2021) analyse a learning activity on celestial motion in which several digital tools are involved, offering various external stimuli, and each one of them (e.g., computer simulation or touchscreen device) is considered as an input space.

In light of the previous considerations, the research question guiding our study is: *What are the blending processes of secondary school students while exploring linear and quadratic functions in an emerging embodied technology such as GGB+?*

Method

Participants and research context

In this contribution, we will adopt the blending network introduced and described before to analyse two short pieces of data from the pilot study in the TransEET project.

The first experiment was conducted in Italy with a pair of 10th-grade female students from a linguistic secondary school. The experiment took place in the context of a summer maths stage and lasted 75 minutes. The activities were administered by the first and third authors who were present during the whole duration of the experiment, with the role of participant observers. The teacher informed the authors that the students had not studied the Cartesian plane or functions, but they may have encountered them in their previous grades.

The second experiment was conducted in the Netherlands and involved six 10th-grade students (four girls and two boys) of a secondary school devoting special attention to dance education. The activity took place during an extracurricular class, lasted 90 minutes, and was structured as a field experiment, with the second and fourth authors present with the role of participant observers. The students had already studied functions (e.g., linear, polynomial, exponential functions), their representations and their general properties. In the data selected for this study, we will present the activity of the two girls.

Task design

In both experiments, students received tasks to be solved in GGB+. After an initial exploration, aimed at letting students familiarise themselves with the new technology GGB+, three structured tasks followed, each to be solved in a specifically designed applet: (1) *GeoGebra Mirror*, in which students should fit the graph of given linear or quadratic functions on the screen with their body; (2) *Get the coefficient*, in which students' positioning affects linear/quadratic function coefficients, whose values vary in real time (Figure 1, this to enable students connecting how the changing of the coefficients affect the graphical representation; and (3) *Level Up*, in which students should reproduce the graphs of given linear or quadratic functions whose formulas are shown on the screen and so connect two different types of function representation.

In the first experiment, given the little mathematical background of the two students, the task focused only on the case of linear functions, while in the second experiment, the task involved both linear and quadratic functions.

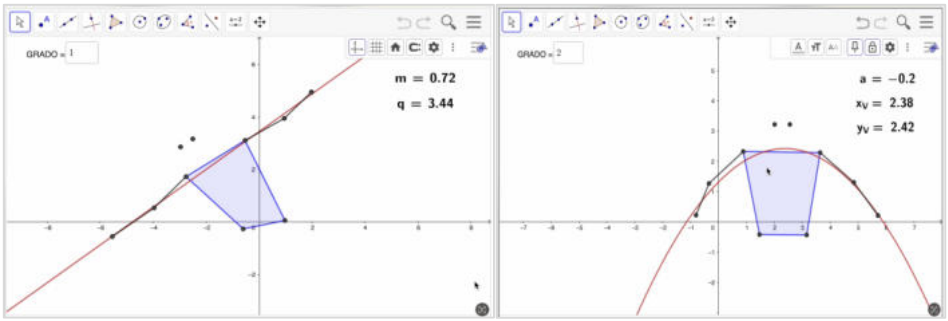

Figure 1: Interface of a GeoGebra+ applet called *Get the coefficient*

In this contribution, we focus on the second task (see Figure 1). In this task, groups of two students were involved in solving the task in GGB+ and filling in a worksheet which asked for a reflection on what they observed. One student at a time moved in front of the screen to position her body in order to: statically represent a function (linear or quadratic) and dynamically vary her positioning. Then both the students observed how the variation of the position of the one in front of the screen determines a change in the values of the function's parameters (m and q if $y=mx+q$, or a and vertex coordinates if $y=ax^2+bx+c$), and which of these variations were involved in this change. After this, students filled in their worksheet asking to reflect first on the static representation of the student position in front of the screen and corresponding to a linear or quadratic function, then to the dynamic representation of the variation of such positions corresponding to function transformations (e.g., translation). In this task, by means of the avatar in GGB+, students can link the meaning of the parameters' values to the graphs of the functions, building a mathematical meaning for them.

Our adaptation of the conceptual blending model

In our study, the emerging embodied technology GGB+ is considered a micro-learning environment by itself. The construct that seems most appropriate to frame the richness of GGB+ is that of the *double-scope blend*. Indeed, it can be seen as the result of the blend of input spaces with different organising frames, in our case the mathematical Cartesian system offered in GeoGebra and the virtual avatar controlled by the human body.

The cognitive processes can be represented through a conceptual blending network, adapted from the one by Fauconnier and Turner (2002) in which continuous lines indicate the matching and the cross-space mapping between the inputs and dashed lines indicate the connections between inputs and the blended space (see Figures 2 and 3); we coloured some words and images to highlight the corresponding elements between different spaces. The network consists of three input spaces: (i) the *maths space* referring to the mathematical knowledge that students possess and on which they draw, (ii) the *real space* with the bodily expressions of conceptualization, and (iii) the GGB+ environment intended as both an input and a blended space, that is a double-scope blend (the input spaces contributing to GGB+ as a double-scope blend in Figures 2 and 3 are grey). While we recognize (i) and (ii) the role of input spaces, (iii) is the result of a further blend involving (iii-a) maths in GGB and (iii-b) the user's avatar positioning as input spaces. Therefore (iii) should not be seen as a standalone technology, but as an integration of students' thoughts, words and actions that makes sense only within the GGB+ environment (e.g., a student saying "If I lift the function…"). It also works as an interface providing multiple forms of feedback, triggered by both students' body movements and the GGB tools.

Data collection and data analysis

In both experiments, we video-recorded the students' activity with a camera and the computer screen recording. The videos of students' activity and the screen recording for each experiment were synchronously coupled, to be seen side by side. For the preliminary analysis presented in this contribution, we selected two critical incidents (Tripp, 2011), namely representative episodes of the students' activity, relevant to our research question. Such incidents were selected because they

revealed the blending of the three main conceptual components at play: maths, body, and technology. These two episodes were transcribed and then qualitatively analysed using the blending network.

Results

In this section, we contextualise each of the two critical incidents (the first focused on linear functions and from the Italian context, the second focused on quadratic functions from the Dutch context), and provide a qualitative analysis both in a descriptive form and using a blending network representation, adapted from Fauconnier and Turner (2002).

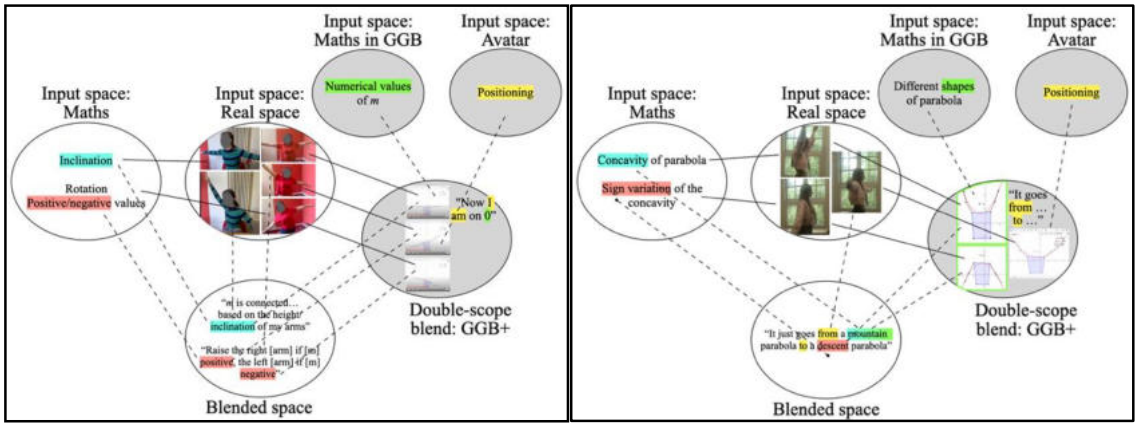
Critical incident 1 on linear functions

During the task, the researcher asked the two students (S1 and S2) how the number *m,* displayed in GGB+ while working with linear functions, was associated with their body position. S2, who was sitting at the table, started moving her open arms in different positions, describing then her variation of position as a "circular movement". S1, who instead was in front of the screen, positioned her arms horizontally ($m = 0$) and then started raising her shoulders while claiming that it was connected to her arms height, and then to her arms inclination. The researcher then asked "How is this number [*m*] connected to your positioning?". And S2 claimed: "Now I am on 0", a sentence making sense only *in* the GGB+ environment where her avatar's positioning can be connected to a numerical value (0). The horizontal positioning of the arms was simultaneously assumed also by S1. And again, under the researcher's prompts, S2 inclined her arms differently to have on the screen a representation of *m,* first positive and then negative. S1 intervened by adding that she raised "the right [arm], if [*m*] positive, the left, if [*m*] negative". Thereby the blending network representation (see Figure 2) shows that S1 and S2 linked: (i) their mathematical knowledge about positive/negative values and inclination (*maths space*); (ii) the arm movements done by S2 in front of the computer (*real space*); and (iii) the numerical values of *m* provided by GGB+ and controlling the linear function created through her arms (*GGB+ space*). The conceptual blending of these elements generates new knowledge in which the students collectively elaborate on the mathematical meaning of *m* by connecting the variations of body position to its corresponding numerical values.

Critical incident 2 on quadratic functions

In the task students were asked to think about how the shape of the quadratic function had changed when the concavity changed from positive to negative. In this fragment, after having read the task, S3 asked S4, "What changed in the parabola with [...that] movement?". While speaking, S3 was moving her arms up and down in front of the computer, in order to test and explore how the quadratic function's graph was changing on the screen. S4 looked at S3, while she was moving, and then at the avatar on the screen, which was embodying a quadratic function fitting to the avatar's arms points. Hence, S4 replied "It just goes from a mountain parabola to a descent parabola". S4 elaborated on already known mathematical concepts, i.e. a mathematical property of the quadratic function (mountain and descendent, to refer to concave-down and concave-up quadratic function) conceiving it as a mathematical object. The network representation of the blending process (see Figure 3) shows that S4 linked: (i) her mathematical knowledge of the concavity of a parabola and its sign variation (*maths space*); (ii) the arm movements done by S3 in front of the computer (*real space*); and (iii) the

feedback provided by the avatar controlling a quadratic function through its arms (*GGB+ space*). The conceptual blending of these elements generates new knowledge: S4 elaborated on a mathematical transformation by linking bodily movements to mathematical expressions.



Figures 2 and 3: Network representation for critical incident 1 and 2 on linear and quadratic functions

Concluding discussion

In this study we introduced an emerging embodied technology, GGB+, developed within the TransEET project, that can support meaningful learning of abstract mathematical concepts by providing students with means to explore and to grasp these concepts in embodied forms that make sense to them. We provided two critical incidents of the use of this technology, and we discussed its potential for learning about functions adopting the analytical lens of conceptual blending.

First, GGB+ allows the students to build their own embodied representation of the mathematical objects, which were in this case linear and quadratic functions, and explore their properties. The technology, together with the proposed tasks, engaged students in making conjectures, testing and adapting them starting from their embodied experience. The novel aspect of GGB+ is that students position themselves as the mathematical object, thereby simulating specific functions with their bodies. For instance, in critical incident 1, students discovered the slope *m* by moving their arms and causing a change in the avatar's position, while in critical incident 2 they explored a change of concavity in a quadratic function by means of variation of their own position. The reasoning accompanying these variations is directed to noticing properties rather than calculations helping students to build and develop an object-oriented and dynamic view of the function concept. Wei et al. (2023) pointed out that these approaches to functional thinking are scarcely promoted in learning practices and so our study practically contributes to research on this matter.

Secondly, in this experiment, we elaborated on the model of conceptual blending to include learning situations in which technology allows for the embodiment of mathematical objects. Thanks to affordances of GBB+, which allow the user to "live" within a world of mathematical representations, this model aligns with the perspectives like those of Sinclair et al. (2023), and as earlier proposed by Borba and Villarreal (2005) with the *humans-with-media* paradigm, fostering a more integrated view

of human and technological interaction. For that reason, we frame this new kind of technology as emerging embodied technology, in a paradigm that we want to call *humans-in-media*, to strengthen the one by Borba and Villarreal. This model provided the analytical method to study the critical incidents and to reveal the special role of GGB+ in them. Framing GGB+ as a double-scope blend within our conceptual blending network (see Figures 2 and 3) provides a means to describe the mathematical concepts as understood by the students while keeping track of the elements that contribute to it (the conceptualization process). This was valuable in our experiment because it highlighted a new form of technology which students are working *in* rather than just working *with*. The network revealed how students were interacting and reasoning *in* a technology and the mathematical meanings built through it. Future research is needed to analyse longer-term use and learning with GGB+ and compare it to other humans-in-media technologies. Further deepening of our study should also consider how the cultural background of the involved students determines their processes of building mathematical concepts, the way they approach the tasks and engage within the technology.

Navigating Angles: A Spatial Approach to Angle Measurement

Christina Gkreka[1] and Chronis Kynigos [2]

[1,2] Educational Technology Lab, Department of Educational Studies, School of Philosophy, National Kapodistrian University of Athens; [1]xristgreka@eds.uoa.gr, Greece

The notion of angle as turn is fundamental for understanding angle measurement. Given the close relationship of mathematical and spatial thinking, in this paper, we adopt a spatial approach, aiming to study what kind of meanings about angles 12-year-old students develop when using multiple linked spatial representations during navigation in physical and digitally simulated space. In our design students initially navigated physical space and tracked their paths using a Global Positioning System application. They then recreated them using a textual programming language in a digital environment which simulated the physical space they physically navigated. In the results we analyse an indicative critical episode that shows how students exploited their sensimotor experience in order to develop their understanding about angles as turns and apply angle measurement with the protractor.

Keywords: angle, angle measurement, protractor, spatial navigation, GPS, textual programming

Introduction

Angle is considered one the most abstract and difficult concepts not only for students to conceptualize (Mitchelmore & White, 2000) but also for mathematicians to define (Keiser, 2004). It has been defined as a geometric figure (a pair of rays with a common endpoint), as a dynamic figure (a turn or rotation), and as a measure (Smith et al., 2014). In typical school education, angle is basically approached as a static geometric figure, a shape formed by two-line segments which meet at a common point and the surface between these segments. This emphasis on the visible parts of the angle often results in students' confusing the size of an angle with the size of the surface that is included by its two-line segments (Latsi & Kynigos, 2022) or thinking that the size of an angle depends on the length of its sides (Psycharis & Kynigos, 2008). On the other hand, approaching angle as a turn refers to the process of changing direction in the plane or the space. In this case students identify easily the vertex of an angle but they find it difficult to identify the angular relationship (Keiser, 2004) which is essential for understanding angle as a measure, represented by a number (Psycharis & Kynigos, 2008; Smith et al., 2014;).

Recently researchers have turned their attention on the role of the sensimotor experience in understanding mathematical concepts (Hall et.al., 2014). While most of the research in the field has focused on the role of gestures (Latsi & Kynigos, 2022), few studies have investigated how the whole-body experience can influence the way students develop mathematical meanings. At the same time a growing number of studies highlights the spatial aspects of mathematical learning and the need to bring forward the connection of school mathematics with students' spatial thinking (Mulligan, 2015). Even though the close relationship of spatial thinking with the development of mathematical concepts is well established by researchers (Lowrie et al., 2020), empirical data on how spatial thinking aids geometry understanding is insufficient (Bruce et al., 2016). This study employs an embodied design to explore the role of spatial thinking in mathematical understanding focusing on the meanings

students develop about angles when they navigate the physical and digitally simulated space using multiple spatial representations that embed all characteristics of angle definitions. The study aimed to provide insights in two research questions (RQ):

RQ1: What is the role of physical experience during navigation in the development of angle meanings?

RQ2: What kind of meanings about the angle do students develop in the context of spatial navigation in physical and digitally simulated space?

The angle as a turn

Angle as a turn refers to the process of changing direction in the plane or the space and it is considered essential for understanding angles as measures (Psycharis & Kynigos, 2008). It is considered the most instinctive aspect of angle (Latsi & Kynigos, 2022) bringing to the surface students' meanings that derive from their embodied experiences. One example where angles are represented as turns is LOGO programming where students program the movements of a digital entity, traditionally a Turtle, in a digital scene. In this context the digital entity functions as an enactive metaphor (Gallagher & Lindgren, 2015), allowing students to relate angles with bodily actions (Papert, 1980) and develop a relationship between "turn-as-body-motion" and "turn-as-number." (Clements et.al, 1996; Latsi & Kynigos, 2022).

However, researchers highlight the difficulties students face in applying their knowledge of the static representation of angles to activities involving the formation of angles as a result of turning (Clements et.al., 1996). Turning in LOGO-like environments represents the relationship between two different orientations of the digital entity, so the sides of the respective angle are not clearly distinguishable. Consequently, students find it difficult to identify the angular relationship to be measured in order to represent the angle as measure. In our research we aim to address this difficulty by contextualizing the digital entity movements into spatial orientation context where students can refer to the change of direction by using the spatial relationships of distinctive landmarks.

Methods

Even though, spatial thinking has been associated with the development of geometric concepts (Lowrie et al., 2020), there is lack of qualitative research describing the processes and ways in which spatial reasoning is related to mathematics (Bruce et al., 2016). In our study we followed a design-based research methodology (Bakker & van Eerde, 2014) aiming to analyse the ways students employ spatial reasoning in order to understand angles as turns and thus angle measurement. In our design we propose spatial orientation as a context for the development of meanings about angles as turns, bringing forward the strong connection between mathematical understanding and spatial thinking. Following we provide the outline of the activities implemented.

The activities

In our study 22 12-year-old students, divided in groups of four, firstly navigated physically in the surrounding neighbourhood of their school. They used a GPS application to track their paths, which they later saved as .kml files. In the next phase they uploaded their paths in Google Earth. In Google

Earth map they could see the map of their school's neighbourhood, the landmarks of the neighbourhood which were indicated with pin points of different colours and the paths they walked during the first phase (Figure 1).

Figure 1: Students could link the spatial representations through the landmarks which were represented with the same colour in both digital environments, Google Earth (on the left) and MaLT2 (on the right)

Students were then asked to recreate the paths they walked physically in a MaLT2 (http://etl.ppp.uoa.gr/malt2/) (Kynigos & Grizioti, 2018) a textual programming environment where the user programs the movements of a digital entity, using simple LOGO commands like forward, left and right. (Figure 2a, 2c) on a scene that simulated the physical space they navigated initially through corresponding-coloured landmarks (Figure 1). In order to insert in the LOGO commands the values that represented the according distances in Google Earth, students could measure the length of straight paths using the Google Earth measurement tool (Figure 2a, 2c). They could measure the angles that represented their turns using a digital protractor which was added as an extension in the browser students used (Figure 2b).

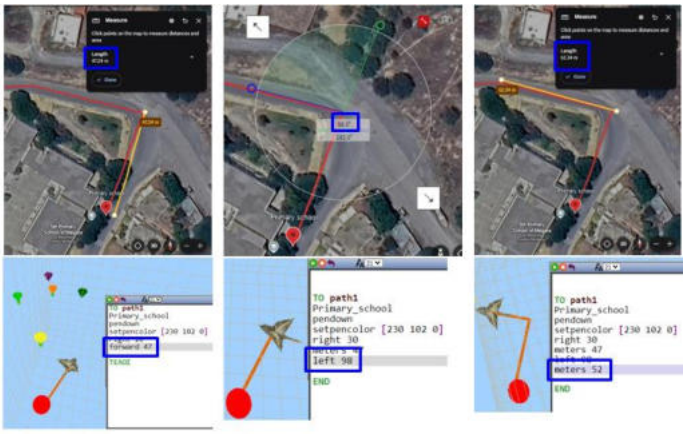

Figure 2: Students could measure the distances with the Google Earth measurement tool (a, c) and the angles using a digital protractor (b)

In this context the concept of angle is addressed as a body turn during physical navigation but also as a shape on the digital environments formed by the lines that represent paths walked, encompassing two out of three angle definitions. The LOGO microworld brings into play the third definition of the

angle, angle as a measure (Smith et al., 2014), since students have to express the turns in the LOGO editor window using arithmetic values (Figure 2a and 2c). At the same time, we contextualized students body movements in a digital space that simulated the physical space they navigated during the first phase, allowing them to use the spatial relationships of distinctive landmarks to conclude angular relationships.

Data collection and analysis

The data collected included audio recordings of children's conversations during the activities, screen recordings from the devices they used, and video observations from the activity. For the analysis we used the critical episodes approach (Angelides, 2001), identifying in our data episodes where children faced a problem and came up with a solution regarding the recreation of their turns as represented in the Google Earth environment, as geometric figures drawn by the movements of the digital entity on MaLT2 scene.

Results

As expected, students faced difficulties in grasping angles as turns and using the protractor effectively. Intuitively students measured the angle formed by the line segments representing their paths, rather than the angle of the turn itself. An indicative episode is the following. Students try to program the entity to draw the path represented by the red line in Google Earth, beginning from their school (red pin), and ending to the Lyceum (yellow pin) (Figure 3). They have led the entity in the node depicted by the blue arrow in Figure 3 and now they need to head south.

Figure 3: On the left the figure displays the path students followed beginning from the Primary school (red pin) and heading to the Lyceum (yellow pin) as represented in Google Earth environment. On the right, the path students have programmed the entity to draw is shown. Students have programmed the entity's movements path until the node indicated by the blue arrow

Episode

Student3:	We have to turn, place there the protractor.
Student4:	Ok but how?
Student3:	The one is going to be this line (Figure 4, segment 1); we are coming from here (means they are coming from northeast).
Student4:	Then the other one is the other line (Figure 4, segment 2), we go towards there (towards the south).
Student3:	Yes, so the blue shows in front of us (Figure 4, segment 2).

The protractor counts 134 degrees and students program the entity to turn right 134 degrees (Figure 4c).

Figure 4: Students initially measure the angle formed by the two-line segments that meet at the node on the map

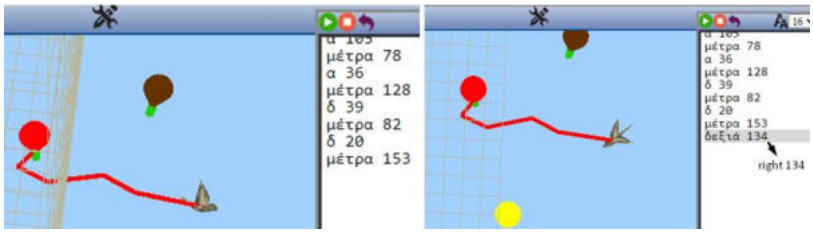

Figure 5: Students program the entity to turn right 134 degrees

Student4: No, it's too much, here we turned a little, look we are already like this (Figure 6a)…And we just want to do this (Figure 6b)…

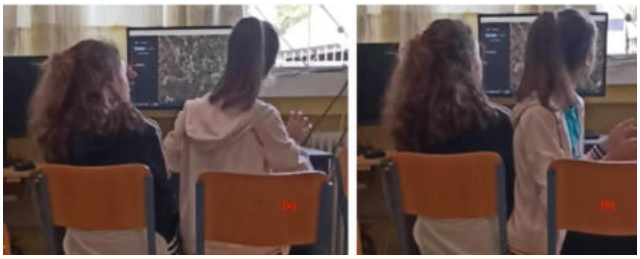

Figure 6: The student represents the turn they have to program the entity to take turning her corso

Student4 realizes that the turn they have measured does not correspond to the turn they want to make and explains her opinion representing with her body the change in direction they made when they were physically at the node aiming to show that it was 'a little' while 134 degrees is 'too much'. She also uses her palm to indicate the initial and final direction making clearer the angular relationship. Taking into account other episodes in our data, while not directly mentioned in this episode students realized that the turn the entity took was not correct taking also into account the spatial relationship between the entity's direction and the Lyceum landmark (yellow pin) (Figure 5). Aiming to correct the value of the angle, students used their previous physical experience as a starting point. They finally managed to relate the angle as a turn which they had previously physically experienced with the value that had to be used to represent angle as a measure. S3 observes her peer and analyses her movements.

Student3: Wait so we look there (shows southwest) and then we turned like you said, so it is like this, we look there (places the axes of the protractor, Figure 7, segment 1) and then we turned like this (places the other axis of the protractor (Figure 7, segment 2)…try 60 degrees.

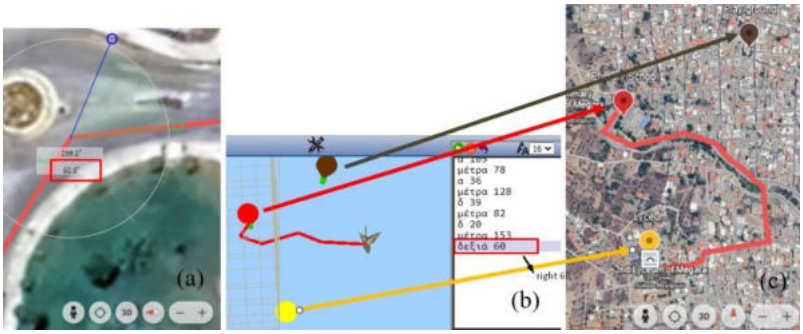

Figure 7: Students insert the correct value in MaLT2 editor. They conclude that the value is correct since they can compare the representations using the known landmarks (b). The spatial relationship between the landmarks and the direction of the entity proves indicates to them that they are heading south as they were supposed to

Student4: Yes, this was correct, now we are heading south like we are supposed to (Figure 7b).

Observing her peer's movements, S3 realizes that they have to start measuring the angle from the axis that corresponds to their initial direction. She places the centre of the protractor to their initial position on the map, the vertex of the angle represented by the red path. She finally places the blue axis of the protractor towards the direction 'they look'. (Figure 7a) and the green axis towards the direction the 'turned', their final direction. The student combined thus elements from different definitions of the angle, which are embedded in the multiple representations they used. They used the previous experience of the angle as turn, an enactive representation in order to represent angle as a measure.

Concluding Remarks

Given the strong relationship between spatial and mathematical thinking, in this paper we aimed to study students understanding about angles in the context of spatial navigation activities in physical and digitally simulated space. While previous research has identified challenges in understanding angles as dynamic figures (Clements et al., 1996), our findings demonstrate the effectiveness of spatial navigation contexts, where students link iconic representations of angles with embodied experiences of turning in physical space, aligning with research on the role of spatial reasoning in mathematics (Lowrie et al., 2020), providing though a detailed description of the processes through which students establish spatio-mathematical connections.

Previous research has also shown that engaging the human body in the learning process plays a crucial role in students' understanding of angles (Smith et al., 2014). However, most of these studies focus on the use of gestures (Robutti, et al., 2022) or study angle concept development through synchronous embodied interaction with technology (Smith et al., 2014). Our study highlights how the whole-body movement in physical space provided students with an experiential basis to understand the angular

relationship between two different directions and conceptualize angles as changes in direction. This also allowed them to use the protractor effectively, one of the most challenging tools for the students to use (Van de Walle et al., 2014). In line with previous research (Bartolini Bussi & Baccaglini-Frank, 2014; Baccaglini-Frank & Mariotti, 2022) the combination of different kinds of representation including the embodied metaphor of the digital entity with which students could synchronize their bodies supported students' understanding. Framing this activity into a spatial representation that simulated the physical environment encouraged students to use spatial orientation in applying the concept of angle as a turn in the LOGO environment addressing difficulties that previous research with LOGO-like activities has demonstrated (Clements et al., 1996). Concluding, studying geometry concept development in spatial contexts can provide further insights on how spatial reasoning can be exploited to facilitate students mathematical understanding.

This study explores the integration of embodied learning in mathematics education through the development and implementation of "GeoGebra Dance," a novel educational tool combining geometric transformations with Augmented Reality (AR) induced physical movement. Grounded in the theoretical framework of embodied cognition and body-artefact functional systems, the research investigates how the designed embodied interactions enhance students' understanding of mathematical concepts, particularly spatial abilities. A pilot intervention was conducted with sixth-grade students, employing thematic analysis of qualitative data. Findings indicate that AR induced embodied interactions improve student engagement, the Interactive Geometry environment enhances conceptual understanding, while further iterations of embodied design are needed in order to specify the effect of the embodied AR element on conceptual understanding.

Keywords: Embodied learning, educational technology, spatial ability, transformations (mathematics).

Introduction

Spatial abilities play a critical role in the cognitive and motor development of learners, enabling them to effectively engage with both every day and academically focused spatial tasks (Kwon et al., 2022). Enhanced spatial skills are strongly correlated with academic success, particularly in the Science, Technology, Engineering, Arts, and Mathematics (STEAM) disciplines (Cheng & Mix, 2014). Recent advancements in educational methodologies emphasise the significance of embodied learning, where physical movement and sensory experiences are integrated into the learning process to enhance cognitive development and knowledge retention (Abrahamson et al., 2020). Incorporating gestures and movements into mathematics instruction has been shown to deepen students' understanding and improve problem-solving skills by making abstract concepts more tangible and accessible. However, challenges remain in designing effective embodied learning experiences that are accessible, scalable, and adaptable to various educational contexts. This study seeks to address these challenges by developing and evaluating a prototype that leverages GeoGebra and Augmented Reality induced body movement into the prototype "GeoGebra Dance" to teach mathematical transformations, contributing to both theoretical understanding and practical application in the field. The primary research question guiding this study is: “How can embodied interactions with GeoGebra be designed to support and improve students' understanding of mathematical concepts?”

Theoretical framework

We use the framework of embodied cognition, which posits that thinking, learning, and understanding mathematical concepts are deeply interconnected with bodily experiences, movements, and sensory engagement (Abrahamson et al., 2020). Duval (2006) claims that understanding of a mathematical concept happens if learners are able to *treat* the concept (transform representations within the same register), or *change* (transform representations to a different register). Shvarts et al. (2021) theorize embodied cognition and design through the genesis of body-artifact functional systems, and Shvarts (2023) looks at embodiment on three levels: (1) Mathematical concepts are "coordinated systems of cultural artifacts as they participate in cultural actions" (p. 45). (2) Embodied learning in mathematics with a technological tool is a genesis of a body-artifact functional system, where the students' body-mind is in a constant perception-action loop with the artifact (technological tool), and through the artifact with the environment. In a perception-action loop the student constantly readjusts their actions based on their perceptions (Figure 1). (3) Embodied design fosters the genesis of body-artifact functional systems.

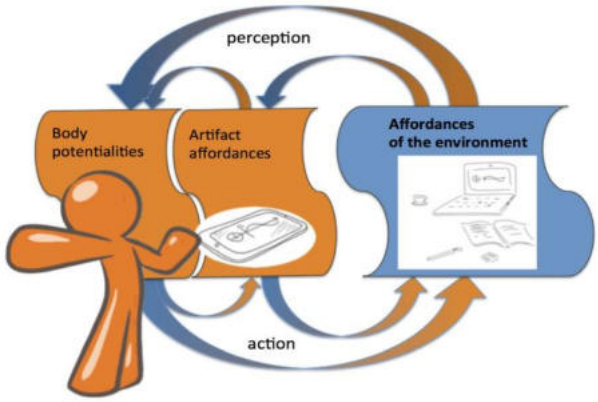

Figure 1: Body-artifact functional system in interaction with the environment (Shvarts et al., 2021

Methodology

The current study was our first attempt at the design, implementation, analysis, redesign cycle of embodied design outlined above (Shvarts et al., 2021).

Design

We designed the GeoGebra Dance artefact by integrating Augmented Reality (AR) embodied interaction features into GeoGebra. Previous research has explored similar integrations of augmented and virtual reality in mathematics education, demonstrating their potential to significantly improve student engagement and understanding. For example, a narrative review by Mouali, Lamarti Sefian, and Bakkali (2024) discusses how these technologies, when combined with tools like GeoGebra, can provide immersive and interactive learning experiences that enhance the comprehension of complex mathematical concepts.

The prototype development was guided by the following criteria. (1) Authorability: Designers of lesson activities such as teachers should be able to create new materials without requiring high

technological expertise. (2) Low technological requirements: The prototype should only require technology that is typically available in a classroom that engages in digital activities. (3) Privacy: The prototype should collect and store as little data as necessary to answer the research questions. All the data should be processed on the device and no student data should be sent to external services. Since many excellent authorable technology solutions already exist for mathematics education, extending existing tools with embodied interaction possibilities was preferred over creating new software. The GeoGebra Calculator Suite[1] was chosen as the basis for the prototype for its wide range of possible interactions and its open licensing model.

To enable embodied interactions, a web app was developed which maps the human body key points (limbs such as eyes, wrists, shoulders) obtained from the webcam with a pose estimation model[2] to the GeoGebra coordinate grid. The software only relies on the computer webcam, no further equipment is needed. The mapped points (limbs) from the person facing the camera can be used to create geometrical constructions like any other point created in GeoGebra. Additionally, a menu to configure simple interactions was developed to lower the barrier for creating new activities. The interactions are defined by 4 parameters: a limb or key point, two-dimensional object, slider, and a speed value. Whenever the limb (e.g., right shoulder) is aligning with the area of the object (e.g., circle, Figure 2) the speed value is added to the slider value. If the slider value is then used in the definition of an object, that object will undergo a transformation based on that value. E.g., the circle centre, a point with x and y definition, if the x value is defined by the slider value, moving the slider will create a horizontal translation of the circle. In short, if the user moves their right shoulder in a way that the corresponding point aligns with the area of the circle, the circle will translate right. We will refer to these interactions further in this paper as “limb commands”.

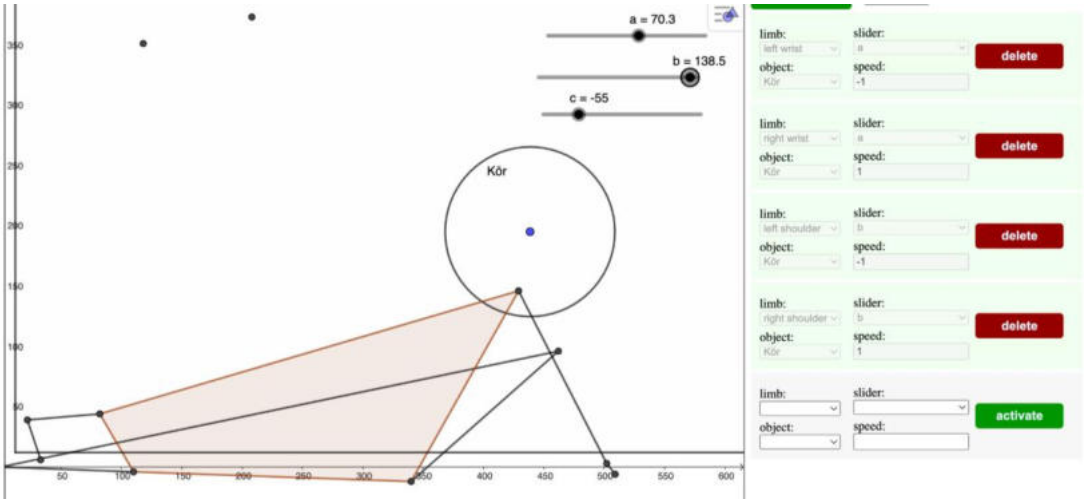

Figure 2: Screenshot from the activity: the right shoulder is presently inside the circle, hence slider ‘b’ is increasing, which causes the circle to translate right.

Implementation

We implemented an activity with GeoGebra Dance in a grade 6 classroom in Hungary, whose mathematics teacher is one of the authors. The students have varying mathematical attitudes and skills, including various special needs (dyscalculia, learning disability, ADHD, autism). For the topic of the lesson we chose the properties of two specific geometrical transformations: translation and dilation. The implemented lesson of 60 minutes length had the following activities (1) students experimented in pairs with a premade geometrical shape of their choice (e.g. circle, pentagon, parallelogram), which was programmed with limb commands for translation and dilation, as described in the *Technology design* section. (2) Students worked in pairs to add further limb commands for translation. (3) Students in a think-pair-share structure worked on a printed worksheet where they needed to decide if translation and dilation have certain properties (e.g., "distance of two points stays the same", "angles stay the same"). (4) There was a whole class wrap-up discussion of the worksheet.

We chose the topic because on the one hand transformations involve complex spatial manipulation, on the other hand it was a curricular requirement for the group. When designing the lesson we sought to meet the embodied design principles of Palatnik et al. (2023): DP1: Involve students' bodies in the learning process DP2: Offer immediate sensorimotor interactions with artifacts DP3: Attend to the semiotic sensitivity of the design DP4: Include a variety of semiotic registers and artifacts that potentiate mathematical perception and discourse DP5: Foster multimodal engagement and "languaging". Engaging with the software in the first part of the lesson involved bodily experience (DP1) and immediate sensorimotor interaction (DP2). Carrying out a more abstract, discussion based worksheet task relying on embodied experiences, and immersing students in further representations in later lessons (collaborative whole body movement, manipulating with tracing paper, using ruler and compass) are in line with DP3, DP4, and DP5.

Data Collection and Analysis

A qualitative study using thematic analysis (Braun & Clarke, 2012) was carried out related to the classroom implementation. The following data was collected:

- Observer notes: an external researcher observed the lesson and noted descriptive and reflective observations about the lesson.
- Post-lesson interview with observer: the observer was interviewed after the lesson about his reflections about the lesson and his ideas about possible ways to develop and use the software.
- Teacher reflections: the teacher wrote reflective notes after the lesson about her experiences of students' attitudes, learning, and the role of the software.
- Student questionnaire: students were asked in an anonymous google form about their likes, dislikes and difficulties concerning the lesson, their learning, and their suggestions.
- Student group interview: students were interviewed as a group about their experiences, learning and suggestions.

During the thematic analysis (Braun & Clarke, 2012) recordings were transcribed and translated into English. One of the researchers coded the data with inductive codes related to the research questions. Then two consecutive researchers recorded the data and revised the codes. We organised codes into themes and used the themes to represent the narrative in this paper.

Results and discussion

We identified the following themes:

- Movement & technology
- Motivation / engagement
- Learning
- Suggestions / improvement

The first three themes describe learning through the body-artifact functional system, while the last theme points towards the redesign phase of the embodied design (Shvarts et al., 2021). We restructured the narrative in a way that we distributed suggestions among related themes. Therefore, for the first three themes we present a summary of the results, an analysis in the body-artifact functional system framework, and related ideas from the Suggestions / Improvement theme. We refer to the students with alphabets in this narrative.

Movement & technology

The theme describes how technology catalysed movement in the classroom. According to the observer "students started experimenting right away, they discovered the software by themselves". First, they experimented with how the stick figure on the screen followed their movements without any instructions from the teacher. When later the teacher instructed them to move the geometrical shapes with their limbs, some of them experimented with the task, but some of them kept engaging only with the stick figure: "H is dancing, I, J are experimenting translation, enlargement", "B found out that they can move it with their face" (observer). In the framework of the body-artifact functional system (Shvarts et al., 2021), we can see perception-action loops on two levels. On level 1, when students interact only with the stick figure, their action is moving their bodies, and the perception is seeing the stick figure moving according to the way they move their body parts (the ones visible to the webcam). During the perception-action loop they try to activate the stick figure as much as they can by showing more body parts to the camera (standing on a chair) and moving intensively (dancing). On level 2, they use limb commands to transform the geometrical shape. Here the action is putting an appropriate limb in the area of the shape to perceive that the dot representing the limb is within the shape, and the resulting transformation of the shape. Level 1 is necessary to move onto level 2, but mathematical learning is only happening on level 2. Therefore, we deduced that the teacher needs to create circumstances in which the student moves to level 2 using the software. Hence, suggestions that may aid students in moving from level 1 to level 2 includes making it easier to use limb commands and make the software assign tasks itself.

Motivation / engagement

The theme describes the levels and sources of student engagement and motivation during the lesson. In the questionnaire and the group interview students expressed a highly positive attitude about the software, they said they liked it because "it was unconventional", "very funny and interesting", and most of them said they liked it because it was tracking their movement. In the observation protocol the observer noted many instances of individual students being engaged with the software, and in the post-lesson interview he said:

Observer: It definitely increased their motivation to do it, I think that was true for everybody. Let's say that everybody without exception tried this interface and they were interested in it. I think it was such an exciting thing for them.

The teacher also noted that even students who are less active usually were involved, including a student with dyscalculia. “They kept being engaged during the mathy-worksheet part.” There were also instances when some students were disengaged. The sources of engagement through the framework of the body-artifact functional system (Shvarts et al., 2021) seem to be the perception-action loops (both level 1 and level 2 described in the previous theme) themselves. It is novel and surprising for students to see their own body movements and their effect as transformations on the screen. The word “experiment” is linked to engagement multiple times, which expresses directly the nature of perception-action loops: students experiment with the consequences of their actions perceived on the screen. Many of the students' suggestions for improvement related to how to make the software even more motivating to use: e.g., track the whole body and show a real body shape with contours rather than a stick figure.

Learning

The theme describes mathematical learning taking place in the lesson, and in what ways and to what extent GeoGebra Dance contributed to it. Some instances of mathematical understanding came from observing the screen directly (*treating*, in the framework of Duval, 2006). For example, when the teacher asked why dilation is angle preserving, the reply was:

Student: The form doesn’t change, only the size [that is why dilation is angle preserving].

In other instances further mental abstract manipulation was needed (*conversion* in the framework of Duval, 2006). For example, the pair manipulating a circle had difficulty checking whether transformations are angle preserving, which then they were able to do by considering sectors of the circle:

Teacher: If you have a circle, how do you check it? [whether translation is angle preserving]
Student: Slice it like a cake.

When the students were asked about what they learned in mathematics in the questionnaire and in the interview, answers included “I got a better overview of geometry”, “I was able to visualise the shapes better”, “not much in maths” and “thinking”.

Both the observer and the teacher pointed out that students did not use the software during the worksheet task, but they referred back to their experiences with the software during the whole-class wrap-up discussion.

Observer: [based on] what they said, they had the experience with the concepts, they weren't just thinking about them speculatively, but they could see them, they could imagine the transformations better through trying them.

Hence they inferred that GeoGebra supported mathematical learning. They both said that it is difficult to judge how much the added AR element (transforming geometrical objects with movements rather than with the mouse) added to the mathematical learning directly. According to the observer it mostly added to learning through motivation, while the teacher supposed it had more direct influence.

Let us interpret these observations through the framework of the body-artifact functional system (Shvarts et al., 2021). Both the students and the observer mentioned that "visualising" and "trying" transformations aided learning, and these two words correspond directly to "perception" and "action". It seemed evident to all research participants that engagement catalysed by embodied instrumentation had a positive effect on learning. Students perceived learning various general skills, but they did not perceive learning about the curricular topic of transformations. This aligns with the decentralised and multilevel nature of embodied instrumentation: students do learn complex skills besides the curricular topic (e.g., "thinking" and "overview"), but learning about the specific curricular concept is less explicitly visible. Both the observer and the teacher stated that they could not directly perceive the effect of the added embodied element of GeoGebra Dance (gross motor control through AR) versus the original GeoGebra (fine motor control through the mouse), and their indirect inference is probably influenced by their beliefs.

Suggestions / improvement

In several suggestions embodiment through AR has a strong connection to mathematical concepts, hence the direct effect on mathematical learning is more apparent, for example:

- making limb commands more intuitive by relating them to the transformation itself (software), and creating a choreography related to the composition of transformations (activity)
- tracking the movements on the screen (software), and students creating a mirror image of a given shape (activity)
- coding movements, e.g. projection (software), pairing movements to codes or decoding movements (activity)

The AR nature of the software makes it a challenge to implement some of these changes, as it is difficult for the software to recognise the intention of the user, for example, to assess when a certain movement starts and finishes.

Conclusion

The aim of this study was to find ways GeoGebra can support embodied learning in mathematics, and as a first step of the embodied design process we added an AR element to GeoGebra and used it in an activity with geometrical transformations in a grade 6 mathematics classroom. We found that the use of Geogebra enhanced mathematical understanding and the AR had a motivational effect, but it was not clear to what extent embodiment through AR supported mathematical understanding. In the redesign phase we will aim at making embodiment more explicit by integrating suggestions received during the study, e.g. making limb commands more intuitive and inline with the mathematical concepts, and involving various other forms of embodiment and further mathematical topics.

A limitation of the study was the limited classroom data collected. In the next implementation phase we are hoping to gather data that reflects classroom actions closer, e.g., video-recording, eye-tracking and screen recordings, providing a more comprehensive analysis of the instructional approach.

Dancing with trigonometric functions: aesthetically guided covariational reasoning while creating periodic dynamic models

Myrto Karavakou[1] and Chronis Kynigos[1]

[1] Educational Technology Lab, National Kapodistrian University of Athens, Greece;
karavak@eds.uoa.gr, kynigos@eds.uoa.gr

We draw upon a materialist perspective to report on 11th grade students' meaning making on periodic functions guided by their aesthetic responses while interacting with digital tools to create dancing animations. The students acted as 'choreographers' and coded digital models to move according to periodic functions (simple trigonometric functions or trigonometric polynomials) of their choice, based on their graph, in order to capture their sensory-motor ideas of what periodic movement better matches a song. They became involved in a continuous shaping of their covariational reasoning expressed multimodally and framed as the iterative re-formation of their evaluative lens regarding mathematical attributes. After addressing the synthesis of theoretical ideas, we discuss initial insights on the interplay between the material activity afforded by the digital tools and students' shaping of aesthetically-guided covariational reasoning on periodic functions.

Keywords: Covariational reasoning, periodic functions, aesthetics, music, educational technology.

Introduction

Technology has revolutionised the types of interactions with abstract mathematical concepts, as they uniquely provide them with material, dynamic, perceivable forms, bridging them with students' embodied experience (de Freitas & Sinclair, 2013). New materialistic approaches have introduced new ways of viewing mathematical meaning-making connected to material acts enabled by the digital tools (Latsi & Kynigos, 2022; Sinclair et al., 2013). Learning is situated within a complex system of collective interactions among human (students, teachers) and material (concepts, artefacts and tools) actors with distributed agency. Thus, technology functions as active participant in the meaning-making process. This aligns with Pickering's (1995) metaphor of a "dance of agency" that ascribes the elements of dynamicity, symmetry and interconnectedness among different actors in the creation of scientific knowledge. Recently, concerns have been raised over the way tool-dependence carrying the designer's intentions could lead to students' passive participation (White, 2019). We address this concern for the case of the concept of function, which has gained increased research attention. The majority of studies use digital simulations of physical phenomena and explore students' reasoning as they interpret or construct graphs within problem-solving tasks (Moore, 2014; Thompson & Carlson, 2017). Material acts are pre-determined by the researchers-designers, while students take the role of the observers and passive actors with limited space for creative activity. Following the dancing metaphor and adopting a constructionist approach, we claim that students should not just take the role of the actors (dancers), but also that of the choreographers, i.e., to be creative actors (Sinclair et al., 2013). In this study, we took this metaphor even further by exploring a case where students became actual choreographers of dynamic figural artefacts that move according to periodic functions of their choice, in order to match to a specific song. Drawing on the key role of aesthetics in enabling this shift from passive to embodied, affective and creative engagement, we placed the material act of

aesthetic evaluation in the centre of the designed environment (de Freitas & Sinclair, 2013; Karavakou et al., 2023). Periodic functions were 'animated' (in a dual sense) and put under iterative evaluation, in the context of free exploration and artistic creation. Students' creative activity was guided by their own sensory-motor ideas of *what periodic movement better matches a song*, shaped by the digital tools. Reasoning on periodic covariation, defined as 'periodic covariational reasoning' (PCR), is analysed as part of the formation of students' aesthetic criteria (i.e., subjective evaluative lens regarding mathematical attributes) rather than respecting objective norms. To shed light on the relationship between meaning-making and the material activity, we discuss the questions: What types of PCR do students develop as they form and express aesthetic criteria on aspects of periodic functions? How the material acts afforded by the technologies influenced the shaping of their PCR?

Aesthetically guided covariational reasoning within a materialist perspective

Covariational reasoning (CR) has been defined as the ability to coordinate the parallel changes of two quantities that covary (Thompson & Carlson, 2017). Researchers have introduced models with developmental levels for the description of students' evolution of CR. Such levels involve students' ability to adequately describe aspects of covariation, such as direction and (discrete, average or instantaneous) rate of change of the two quantities. However, these models have been developed within discursive theoretical approaches, that prioritise mental processes over the material interactions. Drawing upon a neo-materialist perspective, CR emerges from students' embodied interactions within an assemblage of materials (graphs, diagrams, manipulatives, artefacts) and contexts (e.g., physical phenomena) with distributed agency. Rather than framing CR as the alignment of pre-defined variables, new materialism highlights its multiplicity and fluidity within a process of becoming (de Freitas & Sinclair, 2013). CR is framed as students' creative acts, which, according to Sinclair et al. (2013) involve 'acts that introduce the new in an unpredictable way that transgresses current habits of behavior and exceed existent meanings', and are 'sensible to the distributed and collective enterprise of the classroom' (p. 252).

New materialism integrates aesthetics into students' reasoning by emphasizing the embodied, sensory and affective dimensions of their creative acts. In this perspective, aesthetics is not confined to subjective judgments of beauty or elegance, neither attached to fixed, inner properties of mathematical results, but is interwoven with the dynamic interplay of bodies, concepts (functions) and (digital) tools (de Freitas & Sinclair, 2013). Students form aesthetic criteria, i.e. evaluative lens for something to be liked or not, on a mathematical concept (e.g., of a function), which is materialised and under assessment. Aesthetic criteria and mathematical meanings are under co-formation in an appropriate learning environment. The latter can be 'aesthetically rich' as it fosters appreciation for the beauty and coherence of the mathematical concepts. Such an environment emphasizes embodied and material entanglements that evoke wonder, curiosity and a sense of harmony or disruption. It can be supported by technologies with constructionist, dynamic, exploratory features, and through open artistic expression and creation (Karavakou et al., 2023; Sinclair, 2004). In this context, aesthetic criteria serve as heuristics, guiding students' CR. They explore what is *beautiful*, *harmonic* and *aesthetically pleasing* within the subjective context of their artistic creation, rather than what is the *correct* solution in a pre-fixed context (e.g., a physical situation with predetermined conditions).

Methodology

Periodic functions were selected for bridging the abstract concept of covariation with the dynamic arts of dance and music through their periodic nature. Students explored and used periodic functions of two types (a. simple trigonometric functions of sine and cosine, and b. trigonometric polynomials) in order to create animated figural models of periodically varying geometric magnitudes in a digital resource, called MaLT2. MaLT2 (http://etl.ppp.uoa.gr/malt2/) is a freely available online Logo programming tool that embeds 3D Turtle Geometry, but also allows for dynamic manipulation of the graphical output through sliders changing variable-procedure values, temporalizing the functional behaviour (Kynigos & Grizioti, 2018). Students could use a periodic function as input in a logo-movement command (e.g., *forward 10*sin(2*:t)*, or *right 12sin(:t)+50*cos(2*:t)+30*cos(4*:t)*) and, by steadily-moving the slider of the variable *t* to the right (through the right-arrow key), they could create a simple oscillating movement of specific amplitude and frequency-period or a more complex periodic movement (in the case of polynomials). MaLT2 provided means for open expression and exploration of functional properties, which were materialised, animated and under aesthetic evaluation. For selecting the appropriate function formula to input within the code, they were also given a supplementary tool for plotting the function graphs by dynamically changing coefficients values through sliders; the GeoGebra Graphing Tool (https://www.geogebra.org/calculator).

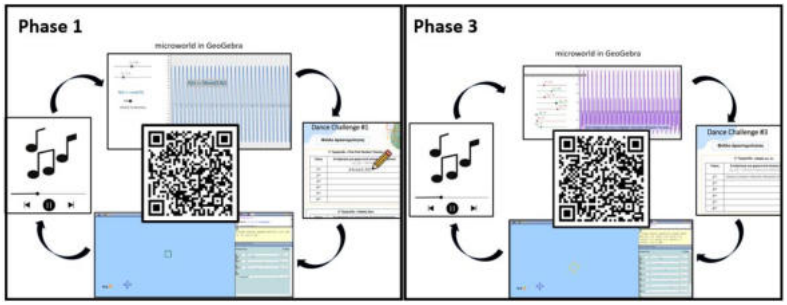

Figure 1: Resources designed for Phase 1 and Phase 3 (can be also viewed by scanning the QR codes)

The designed tasks were divided into four phases, all framed as "dance challenges". Phase 1 and 3 involved four and three songs respectively, with six rounds (for each song) of: 1) exploring the parameters through sliders to adapt the graphical characteristics of the function, to capture their dancing-movement idea that matches the music; 2) noting down the formula on a worksheet; and 3) creating the animation in MaLT2, using the formula generated in 1 (as seen in the videos of Figure 1). Phase 2 and 4 composed the "main challenge" that involved free creation of two in parallel dynamic figures through free programming in MaLT2, to match one song: starting with simple trigonometric functions (Phase 2) and continuing it with trigonometric polynomials (Phase 4).

This study is part of a design-based project that consists of two cycles of design, implementation and thematic analysis to generate empirically grounded theories and frameworks for action. In this paper we analyse a part of the main cycle, in which eight 11th grade students (S1-S8) divided in groups of two (G1-G4) participated. Empirical data included voice and screen recordings, and students' and attending researchers' written notes. The results were framed as different patterns of aesthetically-guided PCR, whose flow is reflected in the diagram of Figure 2. Students followed similar circular patterns of engagement, where their PCR, expressed through aesthetic criteria, was continuously

under re-formation, affected by their interactions with the digital tools. While listening to the song, they expressed, either verbally or bodily, an initial sensory-motor idea of *what motion better matches the song*. Next, they addressed aesthetic criteria on the periodic functions under use, regarding graph's attributes or parameters' values on four aspects: *period*, *range*, *direction* and *rate of change*. Aesthetic criteria were both of subjective and relational nature, as they were evaluative filters on specific materialised aspects of periodic functions, under the condition to create a movement that matches the song. They then selected a formula, based on its graph, that satisfied their criteria for inputting into the code of their dynamic model in MaLT2 to create an animation that captured their motor idea. Observing and aesthetically evaluating the animated feedback while listening to the song, as well as recognizing the song's attributes, would then feed the reformation of either the initial idea or their aesthetic criteria. The mathematical properties, as materialised by the tools, influenced this creative process in these two levels, serving as agents in the process of PCR formation.

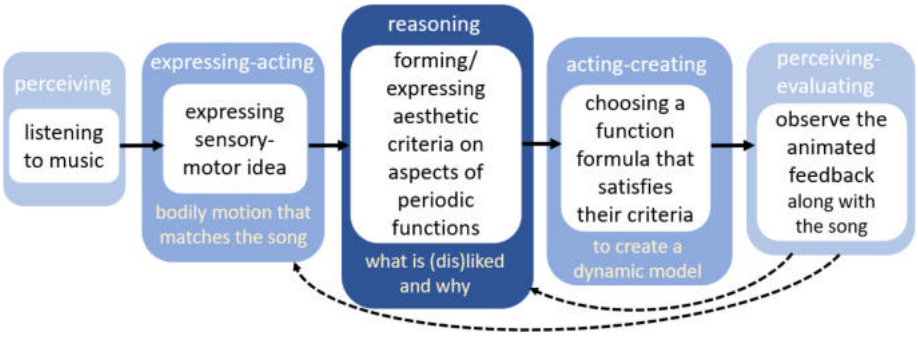

Figure 2: Flow of students' engagement in aesthetically-guided PCR

Results

In the first rounds of phase 1, three groups expressed sensory-motor ideas of dancing movements that followed the song's main melody of not steady rhythm. Students evaluated positively any plotted trigonometric function, regardless its amplitude or frequency value, without addressing any criteria. They developed PCR of *varying periodicity*, as they predicted that the trigonometric covariation would be of non-steady temporal periodicity, which matched the varying melody's rhythm. After one or two rounds of observing and disliking the animation, they altered their sensory-motor idea of dancing movement, by adjusting it to the restrictions provided by the trigonometric functions and developed PCR of *steady periodicity*. The following episodes capture the way that G3 developed this pattern of PCR. In the 2nd round of the first song, S5 claimed that $f(t)=22\sin(t)$ would perfectly fit the melody. S5 moved the mouse along the graph according to the varying rhythm of the melody (video in Figure 3a). By testing the animation in MaLT2 (video in Figure 3b), S5 revised her idea:

S5: No, no. I was wrong. It seems even slower.
S6: We were thinking wrongly about it. We need to catch the steady tempo from the background. This tountoun-tountoun (sings the song's tempo).

S6 turned to GeoGebra and changed the coefficients values, choosing the function $f(t)=20\sin(3t)$. Then she moved the mouse across the graph at a constant rate, as shown in the video in Figure 3c.

S5: You're not moving it right. We want to catch the main melody.
S6: We have to catch the steady rhythm. There is no point in catching the main melody. The motion will always be steady.

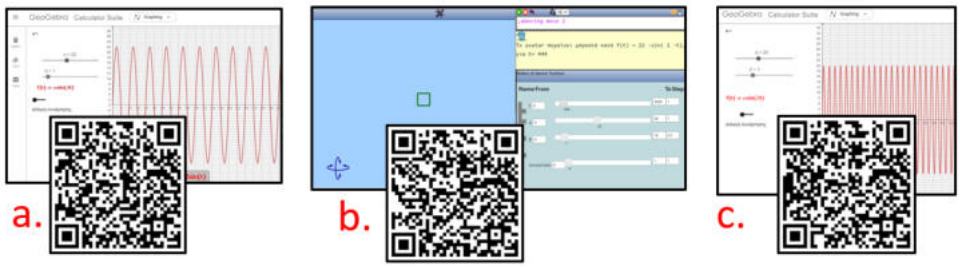

Figure 3. Videos of G3's actions: a) initial sensory-motor action captured in GeoGebra (link); b) animating the function *22sin(t)* in MaLT2 (link); c) altered sensory-motor action in GeoGebra (link).

S6's motion shows that she thought of the covariation of $f(t)=20\sin(3t)$ steadily, developing PCR of *steady periodicity*. After evaluating the animation in MaLT2, she reconsidered the initial sensory-motor idea of matching movement, based on the materialised property of steady temporal periodicity.

Following the emergence of this type of PCR, all groups started addressing specific aesthetic criteria regarding the graph's form and parameters' values, in order to capture the preferable dancing motion of steady period. Thus, in phase 1, the majority of PCR developed was focused on the concept of the period of trigonometric functions, following a similar pattern for every group. All four groups initially developed reasoning on *amplitude-dependent period*, i.e. on the increase or decrease of the amplitude value or graph height in order to respectively increase or decrease the covariation period. The following example showcasing the above case of PCR comes from G1:

S1: It's really slow. It's not even close to the beat.
S2: How will we fix it?
S1: It needs to be quicker. Make it do smaller moves.
S2: Ok, then… Should I reduce the alpha? It will take less time to reach the edges. (Changes the amplitude value from 8 to 6, plotting the graph of $f(t)=6\sin(2.5t)$.) Ok, nice. It looks much quicker. It will go like this.. (Sings the melody and moves hand).

In the above episode, G1 predicted that the graph with lower peaks would produce a quicker periodic motion, resulting in a smaller period. They bodily expressed PCR on the *proportional dependency of the period from the amplitude*. Then S1 tested its dynamic representation in MaLT2 while listening to the song (movement a of the video of Figure 4a-b). The unexpected result redirected their thinking:

S2: No, no, no! It seems even slower to me. (Opens the GeoGebra tab.)
S1: This doesn't make any sense. Here it has less points than before. So it was supposed to go quicker. Try a higher alpha.
S2: What should I do with the beta?
S1: Leave it as it is for now. We need to understand what alpha does. Try 10.
S2: (Changes the amplitude value from 6 to 10, plotting the $f(t)=10\sin(2.5t)$). Now?
S1: It certainly does not look quicker. It will need much more time to reach the edges.

S1 noted down the formula of the function and tested its dynamic representation in MaLT2, while listening to the song (movement b of the video of Figure 4a-b). After observing it, they commented:

S2: Now I feel it got a bit faster. Let's raise it even more!
S1: No, it seems just as slow. Let's not risk it. I think we should focus on the beta.

In this episode, S2 developed reasoning on the *inverse-proportional dependency of the period from the amplitude*, possibly influenced by perceiving the animation's higher rate of change. On the contrary, S1 developed reasoning on the *independency between period and amplitude* and suggested

to 'focus on the beta' in order to change the period of the movement. Both students changed their reasoning based on the way they perceived the animated feedback and reformed their aesthetic criteria regarding the parameters' values. During the subsequent episodes, the majority of PCR types was on the *inverse-proportional dependency of the period from the frequency*, based on which they managed to capture the appropriate period of the trigonometric covariation. However, *amplitude-dependent period* types of PCR kept emerging in phase 1 in reduced frequency. In phase 2, they were fully replaced by *amplitude-independent period* ones. Students' aesthetic criteria exceeded the aspect of the period and also integrated aspects of range and rate of change. G1 expressed the idea to create two synchronized squares that moved with the same period by inputting two trigonometric functions into two different logo-commands. After four trials, they chose the same function (*f(t)=60sin(9t)*) in both commands, which satisfied their criteria regarding the period. After observing the animated outcome, S1 formed another idea on one dancing figure, whose motion was an oscillating turn:

S1: It would be better if it made a full turn. (Changes the command *right 60*sin(9*:t)* to *right 180*sin(9*:t)* in the code.) 180 to the right, 180 to the left (moves hand).
S2: Now you need to change the nine to keep the same pace. Make it six. No, three.
S1: Beta should be equal to 9 for both figures. It is non-negotiable. 9 catches the rhythm.

S1 animated the two models, while playing the song in MaLT2 (video in Figure 4c). The audiovisual outcome led S2 to develop *amplitude-independent period* type of PCR and extend their dancing-turning movement idea by raising criteria to the amplitude in order to increase the intensity:

S2: Ok, I got it. They have the same period… no matter how big the front number is. But it gets more abrupt. Let's increase it more. Put 300. No, 600. 600 will be awesome! Can you imagine? (Laughs.) It will match the song's vibe completely.

In phase 3 and 4, all groups expressed complex aesthetic criteria, enabled by the diverse possibilities of trigonometric polynomials. They raised their aesthetic criteria to generalised graph's attributes, such as horizontal or vertical distance between consecutive extrema, monotony, curvature and slope, in order to capture diverse song's perceived attributes through the dynamic models, such as the tonic sequence, intensity and energy-vibe. The following episode of G4 from phase 4 includes part of their engagement to create a dancing animation of two figures. In the beginning S8 expressed his sensory-motor idea for the second figure, after they had already chosen a well-rated function for both figures' motion (Figure 4d). His idea changed while observing the animated outcome of synchronized figures:

S8: I've got a better idea. Now that I envisioned the choreography. They start synchronized, I like that. But then the blue star follows with a slower move. (Replays the song along with the animation and moves his hand next to the screen.) Look at my hand. See what I mean? I imagine it slower. Smoother. It's more natural if they lose their synchronicity for some parts.

S8's idea of 'more natural' asynchronous combination of movement was shaped through his bodily interaction with the animated figure. S8 took a photo of the first graph with his phone and used it as basis to create the one that would satisfy the aesthetic criteria. He ended up creating the graph of *60sin(t)+4cos(t)+10sin(2t)+4cos(2t)+11cos(3t)+10sin(4t)+3cos(4t)*(Figure 4e).

S7: This is really high! Are you sure? Are you sure it will be slower? It seems abrupt.
S8: Yes, I have this feeling. Here it leans more. And it has this part here (shows the turning point using the mouse) that makes it even smoother, like.. (moves hands).

While viewing the new animation (video in Figure 4d-e), they reflected on the graph interpretation:

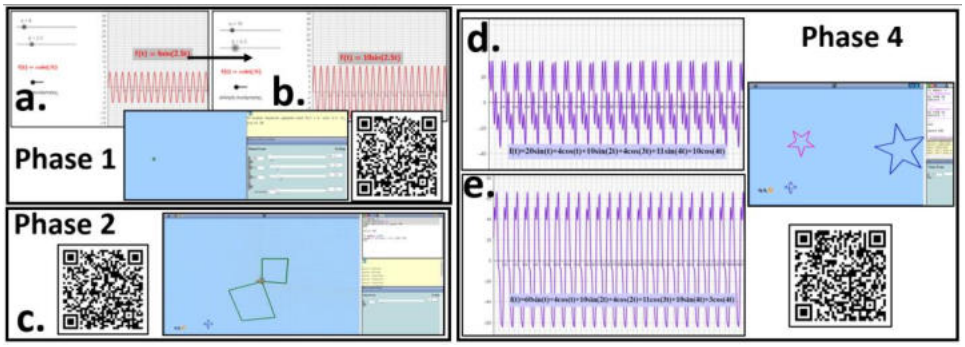

Figure 4: Dancing animations made in a-b) Phase 1; c) Phase 2; and d-e) Phase 4

S8: See the blue star? The more the line leans horizontally, the smoother it moves.
S7: It's like.. Yes! I can feel the music! The combination is wow! (…) Maybe we should smoothen this part also. (Shows the higher part of the graph-period). So that it would go like … (hand movement) calmer than the other the whole time.

S7 initially rated the graph poorly while expressing PCR on *amplitude-dependent speed*, as he predicted that bigger height between extreme points would lead to 'abrupt' motion. Then S8 defended his choice based on the bigger slope, forming *slope-dependent speed* type of PCR. After observing the generated animation, S7 extended his idea on the motion of the second figure, expressed through hand motion in coordination to the animated artefact. He addressed new aesthetic criteria for graph attributes (to smoothen its upper part) that further guided the group's material and creative activity.

Discussion

This study offers initial insights regarding the interplay between students' PCR and the material activity within the designed aesthetically rich environment. PCR was traced as creative acts arising through the material act of aesthetic evaluation. It involved meaning making on the materialised aspects of periodic covariation under evaluation. Students engaged in iterative re-formation of both their sensory-motor choreographic idea that guided their actions, and the aesthetic criteria regarding mathematical properties (Figure 2). These dynamic changes were grounded on the way they perceived (not always in the same way as shown in the case of G1) the animated feedback in relation to the music. Their ideas were adaptive to the material agents (type of functions and tools) of each phase. In phase 1, all groups focused on matching the period of covariation to the song's tempo. This focus did not emerge automatically, but arose after discriminating the possibilities of sine and cosine functions, as shown in the first episode of G3. Their criteria were consequently focused on the role of the parameters; starting with reasoning on the *proportional dependency of the period from the amplitude*, moving to reasoning on their *inverse-proportional dependency*, and finally to *amplitude-independent period* and *inverse-proportional dependency of period from frequency* PCR. In phase 2, open exploration of different types of synchronicities of two parallel dynamic models was pivotal for establishing the last two PCR types around the aspect of *period*, but also for enriching the PCR aspects towards the *range* and *rate of change* (intensity), as shown in the second episode of G1. In phases 3-4, all groups expressed more complex sensory-motor ideas for dancing movements, which captured the song's attributes in a richer way, e.g. by following its tonic sequence, or by creating a combination of asynchronized models of different intensity, like G4 did in the last episode. In order to capture these ideas, students expressed diverse aesthetic criteria on all four PCR aspects regarding generalised

graphical properties (e.g., its slope). This enrichment of ideas and criteria was enabled by the polynomials' widened possibilities. Future steps involve the integration of motion-capture technology that would provide means for richer variety of bodily ways for expressing aesthetically guided PCR.

In this paper, I aim to contribute to the mathematics education literature by suggesting an operational definition of embodied learning. I outline three general facets of learning that a desired definition should reflect: regulation, improvement, and transfer. Based on Abrahamson and Sánchez-García (2016), I propose the operational definition in the title and demonstrate its applicability in a case study from my project, "Blindfolded Mathematics," where learners engage in mathematical tasks using tangible artifacts while temporarily deprived of sight. I conclude by calling researchers wishing to capture in-the-moment emergence of learning to distinguish between different "ways of moving" and specify which ways are better within their contexts, along with justifying why.

Keywords: Embodied cognition, embodied learning, blindfolded mathematics, learning definition.

Embodiment in mathematics education—searching for simplicity in a world of complex adaptive systems

Embodiment in mathematics education has emerged as a key theoretical framework, emphasizing the integration of sensorimotor experiences and physical engagement with mathematical concepts. This theoretical framework, based on theories such as ecological psychology and complex dynamic systems, posits that cognition is not a disembodied process but is deeply rooted in the learner's interaction with the environment (Chemero, 2013; Gibson, 1986/2015; Varela et al., 1991). The embodied learning paradigm brings to light complex phenomena, such as self-organization, distributed cognition, and non-linear learning processes (Bernstein, 1967), emphasizing the interactions between bodies and the material world (de Freitas & Sinclair, 2013; Shvarts et al., 2021). Although the embodiment literature provides rich and profound descriptions of learning, these descriptions seldom cohere with the conventional understanding of classroom teaching practices.

Recent embodiment research raises concerns that many teachers, particularly those without a substantial theoretical background, may find it challenging to incorporate these theories into their teaching (Cobb & Jackson, 2011). This highlights the need for simplification and accessibility of such theories for broader pedagogical use (Macrine & Fugate, 2021). This paper addresses this need by proposing a concise *operational definition* of embodied learning. An operational definition explains a concept by specifying the exact procedures or tests used to identify and measure it. The measured properties must be publicly observable so others can independently verify or assess them (Harel & Koichu, 2010). Therefore, an operational definition of embodied learning may assist researchers in capturing and describing learning processes across various contexts.

One of the most straightforward and concise descriptions of learning was suggested by Abrahamson and Sánchez-García (2016, p. 203): "Learning is moving in new ways." These authors used it as a thematic slogan based on their investigation into the complex relationship between physical action, perception, and conceptual understanding in mathematics education. Drawing on theories from

ecological dynamics and embodied cognition, they argue that learning, particularly in fields like mathematics, is not simply the acquisition of abstract symbols and rules but is rooted in sensorimotor interactions with the environment. Through engaging in designed "fields of promoted action" holding environmental and task constraints (e.g., Mathematical Imagery Trainer), learners develop new motor-action routines and attentional strategies to solve problems. Their gradually emergent physical interactions—such as adjusting hand movements to achieve proportionality—allowed students to internalize mathematical concepts through action. In essence, learning involves students finding new ways to engage their bodies and senses in problem-solving, which leads to a deeper, more intuitive grasp of mathematical ideas represented in normative semiotic displays. Thus, "learning is moving in new ways" suggests that cognitive development is deeply intertwined with physical movement and interaction, bridging action and thought (Abrahamson & Sánchez-García. 2016). The succinctness of Abrahamson & Sánchez-García (2016) slogan and the elaborated descriptions of embodied learning they provide drove me to adopt their work as a basis for an operational definition of embodied learning for mathematics education.

Three requirements from an operational definition of learning

Typically, operational definitions are crafted to align with broader conceptual definitions (Harel & Koichu, 2010). Accordingly, I outline vital aspects the operational definition of learning should reflect.

(a) Regulation: Learning is directed towards organized behavior, instilling order and stability where disorder or nothingness previously prevailed. The operationalization of this trait is that to determine whether learning has occurred, we search for repeating patterns of behavior—for dynamic equilibrium in body-environment interactions (Harel & Koichu, 2010). This is perhaps the reason Abrahamson and Sánchez-García (2016) did not maintain learning is "performing new movements" but instead talked about "ways"—schemes of movement—emphasizing the regulatory aspect of distinguishable repeating movement patterns.

(b) Improvement: Learning is generally incremental. In an educational context, we do not want to consider any change in one's behavior as learning. Learning is about a specific kind of change: a change for the better. Learning is about improving at something. So, if we want to talk about learning meaningfully, we ought to be clear about what this "something" is: A task, problem-solving (see Harel & Koichu, 2010), discourse practices, physical exercises, or mastery of some mathematical content. In other words, learning can only be determined concerning goal-oriented activities with better and worse actions, evaluated by their efficacy in goal achievements. For instance, Abrahamson & Sánchez-García (2016) work improvement is illustrated by students adopting techno-scientific frames of reference and action (i.e., attentional anchors) and developing mathematical explanations in concert with their movement strategy.

Although we would like to think of learning as incremental, it does not always mean it is strictly linearly incremental. On the contrary, it is widely acknowledged that learning processes are non-linear and involve regressions in ability/performance towards a solution of some situated problem (Palatnik & Marco, 2024; Tancredi et al., 2021). Operationally, I suggest that regressions be considered part of learning whenever they are linked to progressions in future iterations. For instance,

if I once solved differential equations efficiently but could no longer do so after years without practice, we would not call this decline "learning." However, if I make a failed attempt, learn from my mistakes, and improve, we will consider the entire episode as learning.

(c) Transfer: Learning involves generalizations and adjustments. If attaining some ability in a first situation seems to be applied in another similar situation, we would be propelled to maintain that learning occurred in the first situation. The notion of transfer (Barnett & Ceci, 2002) here means that a first situation/environment and the behavior developed in interaction with it were generalized to allow a similar environment to be interpreted as having similar affordances (Gibson, 1986/2015)—inviting the enactment of similar patterns of productive behavior in the first situation. Meanwhile, since every situation puts different constraints (Abrahamson & Sánchez-García, 2016), adjustments are almost always essential for achieving one's goals. For example, an infant first learns to walk on her house floor. The next day, she walks on the high grass in the park. Doing so, she generalized the walkability of the environment and slightly adjusted her walking pattern to the new environment (e.g., raising her knees higher).

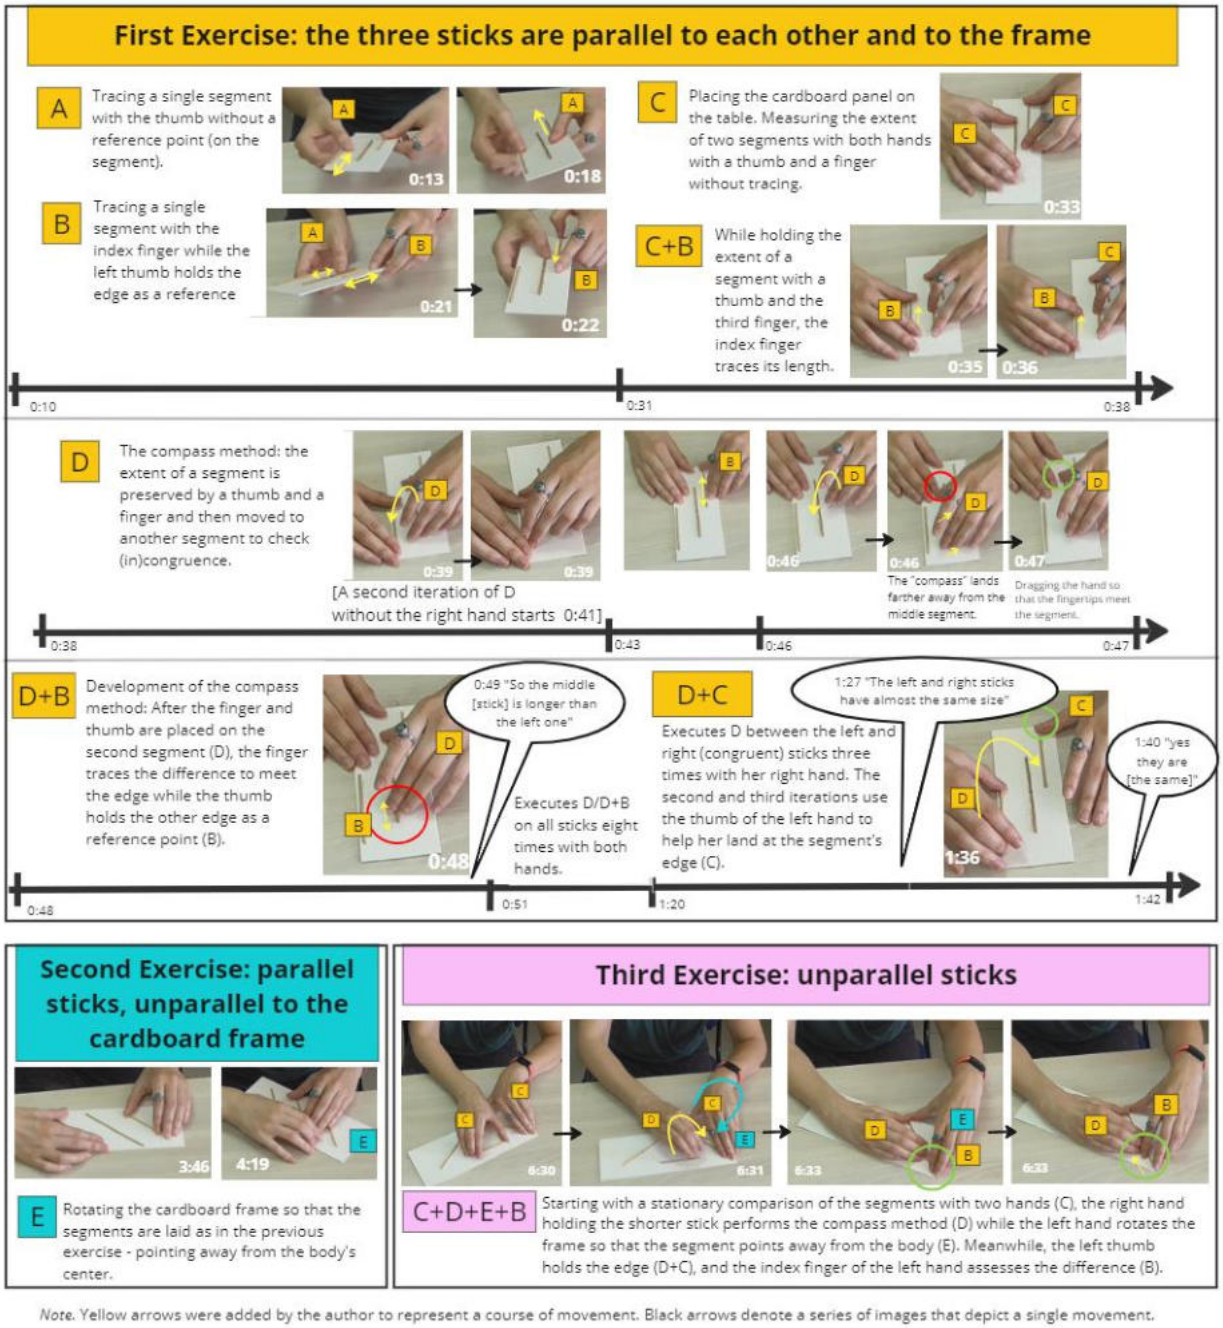
Therefore, building on Abrahamson and Sánchez-García (2016), I suggest the following operational definition of embodied learning: *"Learning is moving in better ways in and across task contexts."* This definition is embodied, conceptualizing learning through "movement," and incorporates the three operational requirements I have mentioned above: (a) *regulation*: identifying repetitions and the emergence of (relative) stability of behavior ("ways"); (b) *improvement*: identifying progression regarding specific goal-oriented activity ("better"); (c) *transfer*: capturing the generalization and adjustment aspect of learning ("in and across task contexts"). In "task contexts," I mean that transfer may be evident both when one performs a similar task in a different context or a slightly different task in a similar context. In the next section, I use this definition to analyze an episode and demonstrate its applicability.

Learning as moving in better ways—a case study

The following episode is taken from the "Blindfolded Mathematics" project, which aims to develop mathematical learning by circumventing temporal sight deprivation when engaging learners with mathematical tasks that include tangible artifacts. In a nutshell, I argue that learning occurs whenever a "better" moving scheme appears and is repeated. By "better," I mean more adapted and efficient in achieving the activity's goals. Additionally, I show that the appearance of merely "new" movement schemes that are less productive can, at best, be classified as "part of learning" if they lead to "better" movement schemes down the road to task completion.

The participant, Ella, a Ph.D. in astronomy, was a math lecturer in a math teacher education program. Her task was simple: With eyes covered, she sensed and determined the relative length of three sticks glued to a rectangular cardboard panel. The task included three phases hereafter called "exercises": (1) the three sticks are parallel to each other and to the cardboard panel sides (Figure 1, top), (2) the three sticks are parallel to each other but not to the rectangular sides (Figure 1, bottom left), (3) none of the three sticks is parallel to another (Figure 1, bottom right). After each exercise, Ella was asked to open her eyes and was presented with a ruler measurement of the three sticks to verify her answers

visually. The task served as a preparation for a sequence of more complex mathematical tasks involving geometry proofs that will be reported elsewhere.



Note. Yellow arrows were added by the author to represent a course of movement. Black arrows denote a series of images that depict a single movement.

Figure 1: Milestones in the task: "What is the relative length of three sticks?"[1]

[1] For an enlarged view of Figure 1 and to leave comments, readers are encouraged to visit the Miro board at https://miro.com/app/board/uXjVKhJCmEE=/?share_link_id=127905518767

Overall, it took Ella 6:35 minutes to complete this preparatory task successfully. Based on the literature, I expected the third exercise to be more difficult as it involves assessing the extent of the unparallel segment (Armstrong & Marks, 1999). However, it took Ella 20 seconds less to solve it (2:12 min.) than the first exercise (2:32 min.). This alone suggests that she has learned something during the performance of the first and second exercises that enabled her to complete the third, more arduous task faster. Considering her extensive mathematical experience and knowledge and the basic mathematics involved in this task, she is unlikely to learn any new mathematical content (e.g., segment length, pairwise comparisons of magnitudes, transitivity of inequalities). In what follows, I use my proposed definition: "learning is moving in better ways in and across task contexts" to argue that Ella learned during the episode and specify what she learned.

When Ella first received the panel, she held it in the air and traced the sticks with her thumb while placing all the other fingers underneath it (Figure 1, A). This movement perhaps helped her to allocate the three sticks and have a general sense of their place and relative layout. However, at 0:21 (Figure 1), movement B first appeared—assessing the sticks' extent with the thumb used as a reference point from which the index finger traces the stick. The transition from A to B is gradual, and at 0:21, Ella performs both movements simultaneously with the right and left hands, correspondingly. However, A seems inferior to B in relation to the task goal (measuring extents), and thus, it is abandoned and never re-enacted in the first exercise. On the other hand, B is reiterated many times and combined with other ways of moving throughout the entire episode (e.g., 0:35, 0:43, and 6:33 in Figure 1). Using "learning is moving in new ways" as a definition would posit that Ella learned already when performing A for the first time as it was a new way of moving and it helped her somewhat to make progress—gaining some sensory experience of the sticks. However, my proposed definition emphasizes that learning has occurred by transforming from way-of-moving A (tracing without a reference point) to the more efficient way-of-moving B (tracing with a reference point).

At 0:31, the way-of-moving C first appears: Ella places the panel on the table and, with two hands, touches the edges of two segments with her thumbs and index fingers (without tracing). Embracing "learning is moving in new ways" would determine that learning has occurred. However, Ella does not seem to gain any increased confidence regarding the stick's length performing C; she immediately elaborates on this way of moving by incorporating B into it (C+B, 0:35, Figure 1)—holding the edges of a segment with a thumb and third finger whereas the index finger traces its length. The proposed definition would say that this new way of moving could, at best, be considered part of learning as B+C is an unproductive variant immediately abandoned and replaced by D—the way of moving that will be the game changer in this episode.

In 0:39, Ella first enacts D, which I call the "compass" method: the thumb and finger hold the edges of a segment, then, while preserving the stick's extent, are moved to hold another segment for checking (in)congruence. Ella will reiterate and refine D multiple times throughout the episode (fourteen times only in the first exercise, Figure 1). At 0:43, after two iterations of D, Ella performs B on a single stick with her left hand. At first glance, it seems like a regression as B alone seemed unproductive for length comparisons in previous enactments (0:22, 0:35). Considering learning as merely "moving in new ways" would say this reiteration does not entail learning, as at this point is no longer "new." However, considering what happens next suggests that this seemingly "regression"

to B was performed to make a significant step forward—so my proposed definition would include this iteration of B as part of learning.

At 0:48, Ella incorporates B into D: After the finger and thumb are placed on the second segment (D), the finger traces the segments' difference until it meets the edge while the thumb holds the other edge as a reference point (B). B+D was found to be a very efficient movement for comparing the relative lengths of two segments, and immediately after performing it (0:49), Ella correctly stated that "the middle [stick] is longer than the left one." Accordingly, she reuses D+B multiple times throughout the episode (e.g., 0:48, 2:15, 3:57, 6:33).

When performing D, Ella faces a challenge to land with the thumb precisely on the second stick's edge (see red circle at 0:46, Figure 1). Dragging the "compass hand" to the second stick's edge may reduce precision as the fingers' extent may be shaken (0:47 green circle, Figure 1). Another improvement Ella incorporated into D is D+C, which appears first at 1:36. There, Ella uses the thumb of the other hand to indicate the landing point for the thumb of the "compass hand."

Due to space restrictions, I spare some more minor improvements and nuances found in Ella's work on the second exercise, except for one interesting way of moving, E, that first appeared in 4:19. There, Ella rotated the cardboard frame so that the segments will be laid as in the first exercise—pointing away from her body's center. The image of 3:46 (Figure 1) represents the uncomfortable layout of the sticks she worked with until she performed E. The rotation itself is not new—Ella had performed many rotations of the panel before (compare 0:18 with 0:21 Figure 1). So here it seems she made this small adjustment to allow her to move in an "old way"—actions on sticks pointing away from her, repeatedly practiced and developed in the first exercise. This progress suggests that sometimes learning can be manifested in moving in "old ways" if they contribute to effective goal achievement.

In the last seconds prior to completing the third exercise, Ella performed a very elaborate way of moving, combining C, D, E, and B in a single maneuver with two hands and five active fingers (Figure 1, 6:30-6:33). She started with a stationary comparison of the segments with two hands (C); then the right hand, which held the shorter stick, performed the compass method (D) while the left hand rotated the frame so that the target stick pointed away from Ella's body (E). Meanwhile, the left thumb held the edge (D+C), and the index finger of the left hand traced the difference (D+B). Taking separately, none of the movements in this elaborated maneuver was new. However, together, C+D+E+B satisfies my proposed definition's aspect of transfer and explains how Ella managed to solve the more difficult third exercise faster than the first one.

In one of the subsequent blindfolded tasks, Ella tried to determine whether a quadrilateral made of EVA foam, which she knew had a right angle, was of a special type (e.g., a rectangle, a trapezoid, or a square). The quadrilateral was, in fact, a rectangle. If she applied D to compare its opposite sides, she would have probably discovered they were congruent (as in Exercise 1, 1:42) and inferred it was a right-angled parallelogram—thus a rectangle. However, she did not use D. Instead, she employed a new way of moving (to be reported elsewhere). This new way was imprecise, leading her to incorrectly conclude that the quadrilateral was a general one. Hence, by my proposed definition, her in-task (i.e., in and across the three exercises) learning did not transfer to the slightly altered task context, which limits the overall significance of her learning.

Discussion

In this paper, building on Abrahamson and Sánchez-García (2016), I proposed a concise operational definition of embodied learning: "Learning is moving in better ways in and across task contexts." I strived to incorporate three desirable traits of learning in this endeavor: regulation, improvement, and transfer. Based on a case study, I showed that this definition is applicable and adequate for capturing evidence of embodied learning compared to Abrahamson and Sánchez-García (2016) appealing thematic slogan ("learning is moving in new ways").

Recently, building on Abrahamson and Sánchez-García's (2016), Palatnik and his colleagues (2023, p.162) suggested "moving in a new way, perceiving in a new way, and naming in a new way" as a possible generalized description of embodied learning. I chose not to build the proposed definition based on this description since it is less concise than the original slogan, and "moving" can be considered as including moving for perception (e.g., body positioning and repositioning; Marco & Shvarts, 2024) and verbal utterances (e.g., using mathematical terms verbatim; Palatnik & Marco, 2024). Although I did not use Palatnik and colleagues' (2023) description, their attempt to break down "movement" into smaller categories and modalities is a valuable and essential methodological step. Moreover, to apply my proposed definition of learning for assessing embodied learning, researchers would have to predefine some local specifications of the elements compounding it.

First, studies need to present the goal of the activity/task and account for in-the-moment shifts in learners' intentionality, as they may vary constantly during the activity. Second, researchers should explain how "ways" of moving are identified and distinguished based on observed repetitions. Third, researchers should provide task-oriented justifications for claiming why and by what means some ways of moving are "better" than others (e.g., take less time and effort, yield better results). Fourth, when regressions are observed, researchers should try to link them to later developments and include them in the non-linear learning trajectories. Lastly, researchers should check if transfer has occurred to provide strong evidence for learning. That necessitates capturing evidence of previously developed moving patterns in a slightly alternated task context.

I believe my proposed definition of learning as "moving in better ways in and across task contexts" has significant practical implications for mathematics education, as it can guide the design of learning experiences that promote deeper understanding and engagement. However, it has some drawbacks that I would like to mention. First, putting much emphasis on "tasks" is less applicable to broader contexts in which tasks are not salient and explicit, as in mathematics education. Second, analyzing learning through this lens may inadvertently emphasize observable evidence at the expense of participants' lived experiences, which could provide additional insights into their internal cognitive and emotional processes. A third limitation is the definition's lack of a cultural dimension to capture collaborative learning settings. I hope future studies will find it helpful enough to be improved and adapted into their studies.

As with most words, 'concrete' and 'abstract' are polysemic and used in myriad ways and situational variations. The intent of this paper is not to define them as if it were possible to place them in suitable self-enclosed boxes but to elaborate and suggest a particular philosophical perspective, whereby we think of coexisting processes of concretion and abstraction, rather than consider concrete and abstract as opposing concepts. This might offer a productive usage of these words with the potential to enrich the practices of mathematics and mathematics education, as well as draw attention to commonalities in how these processes are used in a variety of settings, and are part of the everyday activity of all, including mathematical activities at all ages and social contexts.

Keywords: Concretion, Abstraction, Experience, Making, Craft

Introduction

Several years ago, as part of the "Forces in Translation" project, we began to explore how engagement in craft projects can foster novel and rich ways of encountering mathematical ideas. This work is part of a nascent worldwide movement interlacing mathematics and craftwork, e.g., The Bridges Organization (https://www.bridgesmathart.org) or the Journal of Mathematics and the Arts. In our practices, craftwork is neither an "application" of mathematics, nor a preliminary concrete phase launching an ensuing phase dealing with mathematical symbols and its presumed abstractions. For us, mathematics and craft offer a potential for productive interactions both in terms of their correspondences, i.e., the overlapping areas of investigations and their profound differences, which offer opportunities for reflecting and for raising fundamental questions. In this sense, we are trying to move away from arguments that reduce crafts to mathematics or mathematics to crafts, and we are interested in the productive contrasts and provocations that can arise when mathematics and crafts are made with one another. In our efforts to position crafts and mathematics on equal ground, some of us felt a need to reframe, in a philosophical sense, what we mean with words such as 'concrete' and 'abstract'. How could we rethink these concepts so that craftwork and mathematics can both be concrete and abstract? Overall, the common intuitions that concretion and abstraction are dichotomic oppositions, that understanding abstractions is incredibly difficult or impossible for some people, or that the concrete is material and the abstract mental, seem to petrify the potential mobility and richness interlacing craftwork and mathematics. In this paper, we attempt to articulate an alternative perspective about the philosophy of concretion and abstraction.

The next section ("Preliminaries") articulates philosophical premises that we adopt to grasp our understanding of concretion and abstraction. The two subsequent sections elaborate respectively on our renewed understanding of concretion and abstraction. Finally, in a fourth section we reflect on potential similarities and differences with selected texts from the literature in mathematics education.

As we will conclude in the discussion, we hope that, together, these four sections will allow us to take a step forward in recognising that both abstraction and concretion can simultaneously manifest at all ages, genders, ethnicities, and disciplines and transcend a variety of personal and social categories.

Preliminaries

The terms "concrete" and "abstract" are inherently polysemic, shaped by diverse contexts and usages. This paper does not aim to rigidly define them, but proposes a philosophical perspective that, we hope, offers a productive interpretation, enriching both mathematics and its education. Our philosophy of concretion and abstraction grows around two basic premises that will permeate our forthcoming investigation. The first one is to envisage concretion and abstraction as experiential and processual. Inspired by James' thesis in "radical empiricism": "To be radical, an empiricism must neither admit into its constructions any element that is not directly experienced, nor exclude from them any element that is directly experienced" (James, 1904, p. 534), we conceive of abstraction and concretion as submerged in flows of experiences. This experiential focus allows us to eschew qualifying objects, ideas, actions, or symbols as themselves being concrete or abstract. The same object or idea can be experienced as concrete or abstract depending on the kind of processes living beings are engaged in as they encounter or enact them.

The second premise is that concretion and abstraction are not opposed as if they were the terms of a dichotomy. More of one does not indicate less of the other. They are different kinds of experiences that may co-exist in harmony or tension, but not as mutually exclusive processes. To be consistent with this premise, one needs to question common usages of these words, according to which they almost automatically elicit the expectation of their mutual denial. It is often suggested that children are "concrete" or that only adults develop abstract thinking, and, similarly, assumed that artisans think concretely and mathematicians abstractly. These claims are part of pervasive discourses according to which intelligence is distributed unequally along the lines of genetic inheritance, development stages, and educational orientations. Of course, to argue that this is not the case, it does not suffice to just claim it. We must advance and renew conceptions of abstraction and concretion along which we can reasonably assume that they simultaneously manifest with no discrimination for demographic, cultural, or educational factors. These are some of the aims of the three ensuing sections.

On concretion

According to a criterion advanced by Simondon (2017), a technical object undergoes concretion as it gets integrated, so that its parts participate simultaneously in multiple aspects of its functioning, achieving an overall coherence that makes it more reliable and self-regulated. From this point of view, biological organisms are exemplars of concrete entities. One can discern organs as parts of an organism, but organs are not *partes extra partes*, that is, they do not just work alongside each other, like adjoined Lego blocks, nor are they replaceable in a perfunctory way, as a carburettor can be replaced in an old car. The inner whole coherence of a biological organism, plunged in a milieu of matter, energy and information bathing its organs, allows for the joint organic functioning.

Since our interest is to situate concreteness amid pervasive and common experiential processes, we will consider the process of getting to know a city as an experience of concretion. At first, a city may

feel like a collection of unrelated and isolated places – a hotel, a park, a shop – dispersed across a vast, indistinct network of streets. As one navigates and connects these locations, a sense of orientation gradually develops: relationships between landmarks take shape, and a dynamic, meaningful whole begins to form and transform. This process of concretion never starts from scratch, nor does it end; it is always 'in the middle'. It never 'starts' per se, as it is always invoking prior experiences, habits, and frames of reference – such as familiarity with or differences from other cities – as well as cultural connections and disconnections that may shape one's integration with the milieu. Concretion also has no definitive end, not only because one's experience with the city continues to evolve, but because the city itself is not a fixed or static entity. Rhythms of life that animate the city are in constant flux, as streets change, shops open and close, and patterns of movement reshape its spaces. Like Simondon's concrete technical objects, the experience of the city moves toward coherence through the interrelation of its parts, which participate in multiple layers of its functioning and transformation, deepening its integration for the traveller.

In the case of mathematical experiences, instead of cities, we travel and explore what we might call "mathematical worlds". Let's think of mathematical worlds as fields of practice with certain families of symbols, diagrams and tools. A mathematical world may be populated by number sequences and limits, another by polynomials and their roots, others by algebraic operations with matrices, polyhedra, graphs, knots, and countless others. Travelling a mathematical world may entail going from certain diagrams and tools to others by means of geometric transformations, algebraic procedures, hypothetical assumptions, solving systems of equations, broadening a family of cases, encountering paradoxical objects, and many others. During such travels and particularly if occupying the "driver's seat", the explorer – whether a child playing with wooden polyhedra or an adult exploring their properties – experiences concretion, which implies a richer sense of orientation, creating significant landmarks, becoming more capable to imagine corners and the overall landscape, as well as appreciating more acutely the surrounding atmosphere.

Figure 1. Gauss notation workshop

During one of our online studio sessions, we explored a knot notation developed by Gauss. This notation can be understood as a "world" in the landscape of knot theory, where knots exist as sequences of small integers. Looking at Figure 1, a central idea of this notation is to choose a starting point on a knot (red point) and a direction of travel (red arrow) and to number the crossings encountered sequentially until back at the starting point. Within this world of small integers, we made several observations that contributed to the development of a sense of orientation. A central observation in our conversations was that, regardless of the starting point or direction chosen on our

trefoil knot, certain crossings consistently paired: 1 with 4, 2 with 5 and 3 with 6. Gauss's notation also highlights the nature of the crossings themselves by using a + or − sign to indicate whether the crossing goes "over" or "under." For example, in Figure 1 (left), the first crossing encountered goes "under" crossing number 4, resulting in −4 for the first term of the sequence. The second crossing goes "over" crossing number 5, resulting in +5, and so on with −6 (since the third crossing goes under crossing number 6), 1, −2, and 3. This sequence of numbers (−4, 5, −6, 1, −2, 3) characterises the trefoil knot in this mathematical world of numbered knots. Within this knot-number world, several questions became salient. For example, what kinds of knots could we obtain by altering the number sequence? Figure 1 (right) shows one such exploration during our studio session, where the second and third crossings (relative to the red starting point and indicated direction) are made consecutive. This results in a "twist" that can be undone, producing the "unknot"—a knot with zero crossings.

There would be much more to say, of course but we want to draw attention to how we can think of this investigation of Gauss notation as an example of concretion. At first, this world of numbered knots seemed fragmented—a set of disconnected numbers and arbitrary rules to follow to generate sequences. Yet, by engaging with the inhabitants of this world, patterns began to emerge, and a sense of orientation gradually develops. Observations such as the consistent pairing of crossings or the effects of altering sequences revealed possibilities within the notation. Importantly, this process did not start from scratch. Our prior experiences with small integers, sequences, and symbolic reasoning provided insights for engaging with this mathematical world. And, this process has no end as endless possibilities to alter, explore, and reinterpret the notation continue to unfold.

On abstraction

We begin this section on abstraction by bringing forth common and pervasive experiences of play that conjure up make-believe or as-if worlds, such as puppetry, theatre, or story-telling. These worlds provide a felt sense of abstraction, offering inspiring parallels to mathematical practices. Drama and puppet plays are acts of as-if world-making, endowed, we suggest, with those two processes: immersion and correspondences. A drama play strives to allow for immersion, captivation, or enthrallment which requires that, for the most part, everything that happens can make sense from the play itself, without posing the need for spectators to step back and consult other sources to figure out what might be going on, which would entail interrupting the immersion in the make-believe. The leeway that a play offers for engrossment is relative to the cultural background of the audience. At the same time, a drama play resonates with the world at large to the extent that it awakens diverse and often surprising correspondences with daily life, with known stories, characters, and legends, as well as shared personal and collective experiences. These correspondences make the characters, say, funny, sad, silly, naïve, inspiring, or surprising.

This idea of world-making through immersion and correspondences forms the basis of how we think about the experience of abstraction in mathematics. Abstraction can be understood as a process of as-if world-making, where one is immersed in the mathematics at play and draws on correspondances. In mathematics we draw a circle and treat it as-if it were a geometric circle, or write a short sequence of numbers and treat it as-if it were an infinite sequence. Such practices cannot be accounted for in

terms of signified-signifier pairs because inmersion entails as-if ways of gesturing and perceiving affordances fully permeated by affective currents traversing them.

During a workshop at Ruthin Craft Centre draws we explored braid theory in the context of braiding activities. During the session, we referred to Artin (1950), which historically introduced the mathematical concept of braids. The activities we ran allowed us to examine certain correspondences between braiding and braid theory. Such correspondances, as Ingold (2020) suggests, are not one-to-one mappings but involve partial and often tenuous co-responses along different worlds. Drawing on such correspondances we began to familiarise ourselves with the world of mathematical braids by exploring their properties with pieces of string of various colours, cork boards and pins. A braid in braid group spans between two parallel horizontal bars as shown on the left of 2, where 5 highlighted threads of different colours travel from the top to bottom of the cork board to form a braid of order 5. The braid in this case is made of 5 threads, but it could include any number of threads.

The threads can travel under or over other threads until each of them reaches a point on the other side. In the case shown in Figure 2 (left), the green and grey strings meet on their journey from their starting point to their end points. However, and this is a central idea in the definition of a mathematical braid, this intersection is "combable", i.e. it is possible to simply lift or move one of the strands without unpinning it so that they travel alongside each other without touching. In this respect, Figure 2 (right) shows braids that are not combable because they have a combination of non-trivial overs and unders.

A mathematical group is formed by a set of elements, and an operation that transforms a pair of elements into another one belonging to the same set (i.e., "closure"). The operation of the Braid Group is called "composition" and entails taking two braids and joining their threads one after another. Figure 2 (right) shows an example where a 5-threads braid (1) is joined to another 5-threads braid. The outcome of such a composition is also a member of the 5-thread braid family, signifying closure.

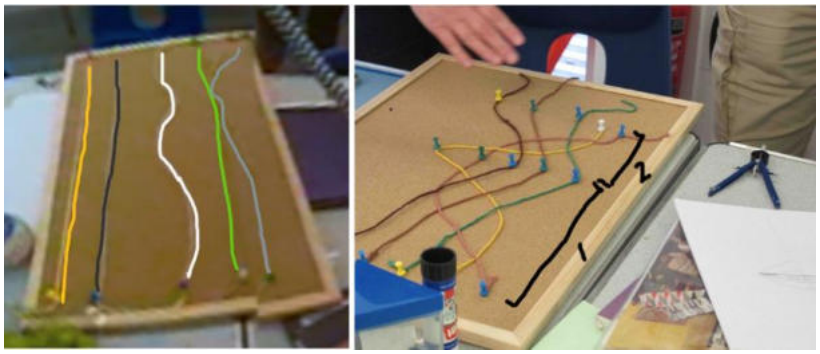

Figure 2. Braid Group workshop

In addition to closure, the operation of a group must satisfy some of the properties that are standard for addition and multiplication. One of them is that the set of elements of a group must include one that is called "identity" or "neutral" because operating with it does not change the original structure. In the case of addition, the neutral element is zero, since n + 0 = n. The neutral element of a Braid Group is a braid with all the threads parallel to each other, without any crossing as the one shown in

Figure 2 (left). Another required property is that, given a Braid Group of a certain order, for any braid the set must include another one that is its "inverse", such that composing both obtains the neutral braid — the one that can be combed. During the workshop one of the investigations was figuring out, for a given braid, another one that is its inverse. It turns out that a braid and its mirror reflection (in a horizontal mirror line for braids running vertically) are inverses of each other, so that what is obtained by composing them can be arranged as a set of parallel threads. Many other questions related to the Braid Group could be investigated, but we will turn to reflecting on how the example of the Braid Group may help us grasp the experience of mathematical abstraction.

In a similar way to discovering a puppet play, getting acquainted with the Braid Group involved for us a process of immersion in a realm populated by characters, histories, relationships such as inverses, mirror braids and properties, each with its own distinctive "personality". For example, in a braid group the threads making up the braids can only travel from one side to the other without going back in their journey to intersect with others or themselves. This behaviour, its roots and its consequences, are not simply a matter of memorisation, but the work of a continuous and never fully finished journey into the world of the Braid Group and, more broadly, of Group Theory. To experience the Braid Group as an abstraction is to feel immersed in it and to meet, question and imagine its inhabitants and their relationships. An abstract experience is immersive in the sense that it is full of potential to experiment with and welcome new inhabitants or to rethink those who already live there.

Throughout these processes Group theorists, students or mathematics enthusiasts are also likely to encounter, make and be inspired by multiple correspondences, like we did, not only with braiding crafts, but also with previously unforeseen practices, such as constraining the movement of points on a plane. As mentioned above, these correspondences do not mean one-to-one mappings, but rather areas where two practices can travel together, in the same direction, questioning and stimulating each other (Ingold, 2020). An example of this type of correspondence is the experience of the "combability" of a mathematical braid, which evokes, both in terms of language and the actions it calls for, the experience of a woven braid. And with this idea of correspondence, neither of the two practices, weaving or mathematics, prevails in the sense that the experience of abstraction does not reduce one to the other. Rather, they are stimulated by these differences by challenging each other. The thesis of mathematical abstraction as a type of as-if world-making, involving correspondences and immersion, pivots on the presumption that groups, as well as numbers, functions, symmetries, and so forth, are as much part of the world as baskets, planets, and stars. In the same ways that there are infinite possibilities for the weaving of baskets, and that different materials and tools facilitate some and resist others, there is no closure for the discovery/invention of, say, numbers or groups, and they also resist and suggest skilled courses of action.

Connections to conversations in Mathematics education

Our reflections on abstraction and concretion have certain points of resonance and dissonance with conversations in the world of mathematics education that have inspired us and provoked reflection (see Shvarts et al., 2022 and Coles & Sinclair, 2019 for some overviews). Reference to abstraction or concretion is often made to describe learning trajectories, some focusing on the movement from

concrete to abstract (Piaget and Bruner) and others on more relational and bi-directional experiences (Davydov, Freudenthal and others). In a direction that aligns with our objectives, Coles and Sinclair (2019) challenge these abstract-concrete learning trajectories, taking a more relational and enactive view, with "attending to things as a concrete mode of mathematical activity and attending to relations as an abstract one" (p. 468) which can be in play simultaneously. Their work is focused on "symbolically structured environments" which support this interplay, whereas we are considering different processes of concretion (being better oriented, grounded and connected) and abstraction (as-if world-making) which provide a framing beyond disciplinary confines or environments. Our approach finds affinities with Wilensky (1991), who sees concretion as the process of coming into 'a relationship with', though he sees abstract as being in opposition to this, where one has not yet made concretising connections.

Discussion

The notions of concretion and abstraction we have been articulating are accessible to all and yet can be very personal. Concretion has neither beginning nor end, nor a goal of easing understanding, but providing a richer sense of orientation, awareness and connectedness. Abstraction is experience of as-if world-making – the development of correspondences (similarities or incongruencies) and adding memories, which over time enables us to experience, shape and express our lives in unique ways.

These processes of concretion and abstraction do not exist in opposition to each other and can occur simultaneously. In our example of working with braids and the Braid Groups at the Ruthin Craft Centre, immersing ourselves in constructing braids to come to grips with the definitions and properties of mathematical braids, and seeing the correspondences with braids in craft work, suggests a process of abstraction (world-making) for the case of Braid Theory. Some participants saw in the requirement that braids always flow downwards, the downward passage of time while braiding. Others made a braid followed by its inverse (therefore, in totality, the neutral or combable braid) and were able to relate that to the fabric braiding technique of Sprang (en.wikipedia.org/wiki/Sprang).

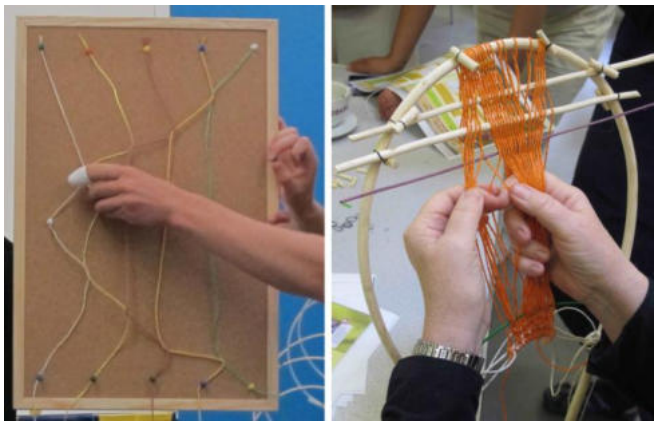

Figure 3. Sprang related work at the Braid Group workshop in Ruthin

In Figure 3, the sub-figure on the left shows the construction of a braid followed by its (mirrored) inverse, together constituting the neutral/combable braid. A pin, halfway down the board, prevents the (neutral) braid from collapsing into combable strands, foreshadowing construction of Sprang. The

sub-figure on the right shows the construction of a Sprang on a newly-crafted Sprang loom. These examples of correspondence, of seeing the flow of time in braids and of connecting braid inverses with the ancient technique of Sprang, show abstraction in play, creating a richer world of braids. Simultaneously, the work involved recognising braids that were similar to each other, developing increasing familiarity with some basic examples (such as a pair of strands crossing each other), and noticing that physically different braids (indeed a veritable infinity of them) are all equivalent to the same mathematical braid. These latter processes manifest the concretising nature of these experiences, as one gets oriented in the landscape of braids.

Thus, such a framing may allow us to recognise that both abstraction and concretion can simultaneously manifest *for all*, across disciplines, and provide an inclusive approach to mathematics. Our interest emerged from wanting to find a way of having mathematics and craft work alongside each other on equal ground without reducing one to the other. We hope this article provides an opportunity to re-engage with how the philosophies of abstraction and concretion can inform contemporary work in mathematics education around social justice and inclusion in mathematics.

Doping an embodied design

Christoph Oberbucher[1]

[1]University of Graz, Austria; christoph.oberbucher@uni-graz.at

Students in both school and university often encounter challenging ready-made mathematical artifacts – especially in the context of the concept of continuity. Within the radical embodiment paradigm actions reify and crystallize in artifacts. Inspired by the theory of concept development of the German subject-matter tradition, the process of crystallization and the involved processes are analyzed, connections between the process of crystallization and concept development are illustrated and a methodological extension of an embodied design called 'doping' is presented. As a result, a duality of reified actions comes to the fore. An embodied design for continuity will be introduced, along with the implementation of 'doping'. The embodied design for continuity illustrates how 'doping' is able to broaden the scope of concepts and determine "what is a mathematical concept of one kind" and "what is a mathematical concept of another kind".

Keywords: Radical embodiment, crystallization, doping, embodiment

Introduction

New research discoveries question the separation of the mind and body in cognition, demonstrating that the body plays a crucial role in processes of sense-making. Embodiment, or embodied cognition, seeks to acknowledge these discoveries and proposes that our bodies are more than just physical entities in space. Within embodiment, current research explores how our physical experiences (embodied processes) connect with or reflect cultural artifacts and has been established as a process of reification (Shvarts et al., 2024). According to cultural-historical ideas, over time, cultural artifacts encapsulate or reflect the essence of processes that fostered crystallization of those artifacts. In this sense, artifacts are crystallized in history (Boels et al., 2023). This paper aims to analyze the process of crystallization as depicted in current literature in the context of the theory of concept development within the German subject-matter didactics tradition. As a result, the process of crystallization should be looked at with nuance. The differentiated view leads to methodological suggestions and also contributes to the theoretical understanding, as a dual role of actions comes to the fore. A concrete implementation with empirical data of the methodological proposal is presented in the context of a learning environment addressing the epsilon-delta criterion of continuity (Oberbucher, 2024).

Reification from a radical embodied perspective

The process of reification within the radical embodiment paradigm is well described by Shvarts et al. (2024). As a first step of the enactment, a body-artifact functional dynamic system arises, which emerges from a pool of potentials (affordances and body potentialities). This can be supported by highlighting relevant affordances (Shvarts & Abrahamson, 2023). As actions become more fluent and stable, new affordances or attentional anchors can arise (Abrahamson & Sánchez-García, 2016). These fluent and stable actions reify in artifacts – the artefacts thus are seen as crystallized actions. (Shvarts et al., 2024). The preservation of past actions in the form of artifacts can also be reversed to

reveal those actions once again, as demonstrated by Boels et al. (2023) with the example of the sine graph and histogram. This reversal of the crystallization process is referred to as melting.

Classical views on concept development

Mathematical concepts have been conceptualized in various ways: Coles emphasizes the idea that concepts are material/ abstract relations, while de Freitas and Sinclair highlight that concepts undergo a process of becoming shaped by activity (de Freitas et al., 2017). In the German tradition of subject-matter didactics, the concept development is highly esteemed. According to Ruwisch & Weigand (2023) a (mathematical) concept in this tradition refers to mathematical objects, their characteristics, the relationships between these objects and mathematical activities. The process of forming these concepts is regarded as dynamic. Several psychological theoretical frameworks serve as references when describing individual concept development. *Classical Theory* holds that categories are established by creating definitions of concepts, which then help to determine whether a particular mathematical object fits into a particular category or not. In contrast, *Prototype Theory* emphasizes the identification of the typical characteristics of prototypical representatives of a concept. The assessment of whether an object belongs to a category is done by comparing it with established prototypes. *Exemplar Theory*, on the other hand, proposes that a category comprises an array of individual instances, each distinguished by their distinctive features (Ruwisch & Weigand, 2023).

Within the dynamic process of concept development *concept content*, *concept scope* and *concept network* are distinguished (Ruwisch & Weigand, 2023). These components are interrelated and serve to facilitate concept development. The *concept content* refers to the defining attributes of a concept, whereas the *concept scope* is related to the totality of all objects that can be included in this concept and the *concept network* addresses the awareness of relations between mathematical concepts.

Concept content und crystallization

By reversing the crystallization process (see Boels et al., 2023), the embedded actions within artifacts are revealed, which are the fundamental actions that define the nature of an artefact. This is pretty much in line with the *concept content,* which includes the entirety of the concept's properties and their relationships to each other. The goal, according to Ruwisch & Weigand (2023), is to know typical representatives (Protoype Theory) and defining properties (Classical Theory) of that protypes in order to classify them in categories (Exemplar Theory). The theory of concept development then emphasizes expanding the *concept content* by going beyond the concept's defining properties and highlighting its connections to other concepts. This is particularly achieved through the formation/ extension of the *concept scope* and the *concept networks* (Ruwisch & Weigand, 2023).

In contrast to this, within the context of crystallized artifacts, only the defining/essential actions – *concept content* – are elucidated. The implicitly occurring actions that have significantly contributed to the (mathematical) artifacts are not addressed. Consider, the epsilon-delta criterion of continuity, which emerged from the arithmetization of mathematics, driven by the limitations of the original definition of continuity (in the form of the *natural continuity*, according to Núñez (1998)), which could not answer certain questions. The processes involved in finding a proper definition of continuity are "hidden social practice[s]" (Leontiev, 1978, as cited by Radford, 2003, p. 124). These practices

of exploring and setting boundaries of a concept are part of the genesis of the epsilon-delta criterion and are addressed in German subject-matter didactics – but are not yet seen as part of the process of crystallization. These actions could be emphasized as a part of the crystallization process, as these actions contributed to the origin of the concept as "hidden social practice[s]" (Radford, 2003). Therefore, the process of crystallization is not reduced to the "essential" actions, but instead expanded.

Expanding crystallization process

The scope of a concept from my perspective can only be expanded if one enacts the concept – conceptualized as "coordinated systems of cultural artifacts" (Shvarts, 2024) – within the context of other concepts, by interacting with them, reflecting on them, and relating them to one another. Differences in concepts emerge when examining the actions that differ in the process of crystallization. (At which level of crystallization are differences, and how do these differences affect the finished artifacts which constitute the concept.). The idea is hence to broaden the view on a mathematical concept (*concept content*) in order to investigate "What is a mathematical concept of one kind?" and "What is a mathematical concept of another kind" (*concept scope*) and how different concepts are related (*concept networks*).

To broaden the scope of a concept – the concept of continuity in this case – the proposed methodological extension of an embodied design is a structured process of a sequence of enactments (see Figure 2). First, stable and fluid actions should be developed around the target concept of continuity, leading to a crystallization in *ready-to-act* artefacts, which facilitate further actions (Shvarts et al., 2024). Once mastered, these *ready-to-act* artifacts are further challenged by introducing deviations in the task that were not previously implemented into an embodied design. The interaction problem (IP) is therefore extended through the deliberate introduction of discontinuities. This introduction of impurities is in analogy to physics referred to as *doping*. In the same way that *doping* in physics alters the properties of materials in order to discover new potentials, *doping* an embodied design generates new action-perception loops, thereby expanding the *concept scope*. The original task without deviations will be referred to as *undoped* task – the task with deviations will be referred to a *doped* task (see Figure 2). For this reason, a learning opportunity designed to broaden the scope of a concept – to answer the question "What is a concept of one kind and what is a concept of another kind?" – must provide the opportunity to interact with other but related concepts – to perceive boundaries and to address the *concept scope* within radical embodiment.

Methodology

Within a design-based research (DBR) framework, a technology-enhanced embodied design in the form of a browser-based application was developed, allowing individuals of various levels of expertise (school students, master's students, professors) to experience the epsilon-delta criterion of continuity as an IP. The similarities and differences in engagement of individuals as well as interactions with artifacts and the interplay of these elements will be investigated in order to explore how an *doped/ undoped* embodied design contributed to the crystallization of mathematical artifacts and the learning of the concept of continuity. Using interpretative analysis following

phenomenografic methodology (Marton & Booth, 1997), the following research question is of interest: How does *doping* an embodied design affect the enactment of individuals of various levels of expertise in the context of the concept of continuity/ discontinuity?

Learning opportunity as embodied design

A digital enhanced embodied design (Abrahamson, 2014) has been created in order to promote the learning of the concept of continuity (Oberbucher, 2024) A function $f: D \rightarrow \mathbb{R}$ with $D \subseteq \mathbb{R}$ is continuous at $x_0 \in D$, if and only if $\forall \epsilon > 0\ \exists \delta > 0\ \forall x \in D: |x - x_0| < \delta \Rightarrow |f(x) - f(x_0)| < \epsilon$

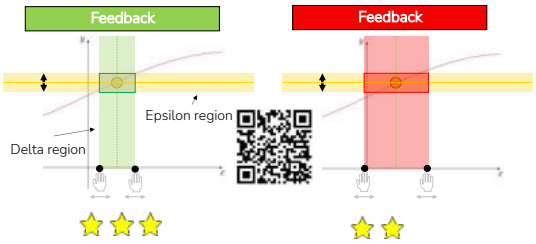

Fig 1.: Interaction Problem. Horizontal region: Epsilon region; Vertical region: Delta region; Left: solved interaction problem – green feedback; Right: unresolved interaction problem – red feedback; QR-Code: Link (Oberbucher, 2024)

This definition is basically saying that if one can narrow down the vertical region (delta region) to the extent that all of the function values within that region fall within the given horizontal region (epsilon region), then your function can be considered continuous at that point. The approach described is implemented as an interaction problem (IP) (Abrahamson, 2014) with highlighted relevant affordances – providing a specified horizontal region – and the student's task is to adapt the corresponding vertical region in order to fulfill the epsilon-delta criterion of continuity. Within the IP (see Figure 1: Scan the QR-code for iPad use) graphs of functions will be shown (see Figure 2). At specific locations (see Figure 2: squares) a horizontal epsilon region (see Figure 1: horizontal yellow region) is dynamically decreasing in size such that students are supposed to align the delta region (see Figure 1: vertical green/ red region) such that the epsilon-delta criterion is fulfilled. Meeting the epsilon-delta requirement results in positive green feedback displayed on the screen. If the green feedback is sustained for an adequate duration, it allows for the accumulation of stars. This serves as the system's feedback mechanism.

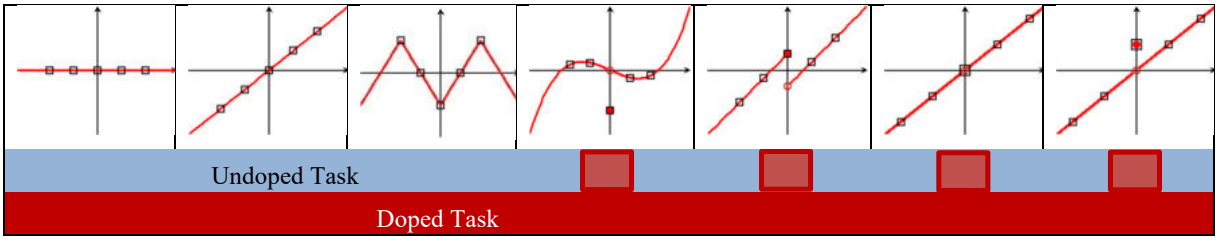

Fig 2.: Sequence of five graphs (continuous graphs: graph 1-3) used as interaction problems; blue: continuous; red: discontinuous; square: indicates locations to fulfill epsilon-delta criterion

In the first part of the learning opportunity (see Figure 2: Undoped Task), the objective is to achieve stable and fluent actions so that defining actions of continuity are crystallized as *ready-to-act* artifacts. In graph number four, for the first time a discontinuous location is shown in the IP – this expands the

concept content and offers a starting point for reflection processes. When attempting to meet the epsilon-delta criterion at this particular point and not succeeding, there are two potential scenarios from an individual's perspective: either the inability to meet the criterion is (a) due to a change in the environment, indicating a graph of a new kind, or (b) there is a need to adjust one's actions to meet the criterion, because not all the essential characteristics/ processes/ actions to define continuity have come to the fore. The first (a) refers to broadening the scope of the concept - the second (b) to deepening the content of the concept.

Research findings

In the following Episodes, research findings in the context of the role of *doping* the embodied design – introduction of discontinuities – will be exemplified and discussed. Episodes 1 and 2 are related to the enactment of a school student with no prior experience in the context of the concept of continuity, and Episodes 3 and 4 are related to the enactment of a professor in mathematics at a university. Interactions with the application will be highlighted in blue.

Episode 1 – undoped task

Episode 1 depicts the student's enactment after completing of the IP with graphs 1–3 (Figure 2).

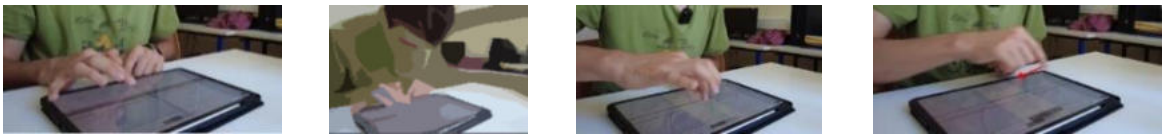
Tutor:	Okay. How does it stay green?
Student:	[…] So I have to stay within the region with the dotted red line *(Moves delta region centered over the point)*, which is now green, inside it. And the black/brown box *(points to the intersection of the epsilon and delta region)* inside there [note: in the epsilon region] must exactly contain the line. So there, the green line must be exactly within it *(points to the graph at the intersection of the epsilon and delta regions)*. And (...) if the period of time *(both index fingers are positioned at a horizontal distance from each other)*, so the region [note: delta region] becomes too big, you can see that it turns red *(points to the edges of the delta area)* and that doesn't work. And then you have to change it again (*reduces the width of the delta region on the screen)* so that it fits the size.

Episode 1 illustrates the enacted dynamics by the student in order to solve the interaction problem as perception-action loops. First, the center line of the delta region is placed over the point, and then the region is reduced in size (aligning the center line on the point) such that all function values within the delta region are green. At continuous points, this dynamics was typically enacted by the student.

Episode 2 – doped task

Episode 2 depicts the student's enactment of the IP at the discontinuous point (Figure 2: graph 4).

Student:	(The point jumps further to the location of discontinuity.) [Figure 2: graph 4] *(The delta range is positioned symmetrically around the point. The delta region is made very small.)* [Figure 3 (a)] Hm. *(Laughs.)* *(The delta region is positioned symmetrically around the point - the graph is partially red. The edges of the delta region are overlaid.) (Leans closer to the screen.)* [Figure 3 (b)] This is stupid now.
Tutor:	What do you mean by "This is stupid now"?
Student:	Well, it's just that now it's so small there. *(Points at the dashed line in the middle of the epsilon region.)* And especially, now the point would be down below *(Points with the index finger to the filled circle)* [Figure 3 (c)] at the dashed line *(Moves the index finger from left to right along the dashed line of the epsilon region)* [Figure 3 (d)], so at the gray dashed line. (Tutor: Mhm.) And the graph just goes along the top. *(Traces the graph with the index finger)*.



(a) (b) (c) (d)

Fig 3.: Enactment of Episode 2

At first, the initial stable and fluent actions (the enacted schema in Episode 1) are carried out. Subsequently, *"Hm*" suggests that there is an issue with employing the previously chosen actions to address the interaction problem. What follows is again an enactment of previous stable and fluent actions, which led to the solution to the interaction problem before (see Episode 1). This is a reflection in the original sense of the word, *epistrophé*, from the Greek meaning "to start something anew" (Bolle, 2018). Leaning closer to the screen indicates increased level of interest, because the student moves closer to initiate physical connection/ interaction. This part points to the process where the student assesses the current situation as being new and of different nature in the context of the task – respectively continuity (Dael et al., 2012). The utterance *"This is stupid now"* supports the contraction between the previously enacted stable and fluent action patterns and environment. What follows is a reflection in order to make sense of not solving the interaction problem. More precisely, it was elaborated why the original schema does not lead to a solution of the interaction problem Therefore, the changed environment led to the failure to resolve the interaction problem. In the context of continuity, the student elaborated on "What is the concept of continuity not?" and broadened the scope of the concept.

Episode 3 – undoped task

Episode 3 depicts the professor's enactment after completing IP with graphs 1–3 (see Figure 2).

Professor:	(The green feedback appears.) Ahhh. *(Laughs.)* Probably it has to do with (...) Either it has to do with the epsilon-delta definition or with continuity, because I basically have to narrow down the neighborhood on one axis so that it always remains in the neighborhood on the other axis.
Tutor:	Based on that, how would you determine this?
Professor:	The system basically tells me in which neighborhood of the function values I have to be, and I have to accordingly make the domain, i.e., the neighborhood of the point, smaller and smaller with my fingers, so that I always remain in the neighborhood of the function values. (Next graph.) [Figure 2 graph 4 – continuous locations] *(Aligns the dashed line over the point. Adjusts the width of the delta region symmetrically around the point – green feedback appears.)* And what about (...) it also works if I am smaller too? *(Decreases the size of the delta region symmetrically around the point – green feedback.)* *(Point jumps to the next location.)* *(Makes the delta region very small.)* And one must be small enough. *(Makes the delta region very small.)* *(Laughs.)* Yes, also interesting. When you look at it from this perspective, then everything makes much more sense. *(Laughs.)*

In Episode 3 the professor is making a connection between the epsilon-delta criterion and the interaction problem. The professor also provides verbal descriptions on how to solve the interaction problem *"I have to accordingly make the domain […] so that I always remain in the neighborhood of the function values.",* which corresponds to the previously enacted stable and fluent actions *(Aligns the dashed line over the point. Adjusts the width of the delta region symmetrically around the point – green feedback appears.).*

Episode 4 – doped task

Episode 4 depicts the professor's enactment of the IP at the discontinuous point (Figure 2: graph 4).

Professor:	*(Point jumps to the location of discontinuity.) [Figure 2 graph 4 – discontinuous location] (Delta region is dynamically reduced in size symmetrically around the point. Leans closer to the screen. Widens the delta region symmetrically around the point again. Holds left edge of delta region fixed – varies the right edge of the delta region.)* What's there now? *(Makes the delta region small right to the location of the point. Widens the delta region right to the location of the point. Shifts the entire delta region to the left. Shifts the delta region symmetrically around the point. Varies the size of the area symmetrically around the point.)*
Tutor:	What's different now?
Professor:	Yeah, it's not enough with the (...) It's not about a point of a function graph anymore, it's about a lower bound or something. *(Changes position and width of the yellow area frequently. Takes hands off the tablet.)*

In Episode 4 the interaction problem was to be solved at the location of discontinuity. Here, the same processes as in the student's enactment can be observed. As in the student's enactment (see Episode 2) at first, the initial stable and fluent actions (the enacted schema in Episode 3) are carried out, followed by leaning forward as indication of an increased level of interest. The exclamation *"What's there now?"* serves as an additional indication for a changed environment, which is also represented by the last statement *"It's not about a point of a function graph anymore"*. What follows is again an enactment of previous stable and fluent actions, which made up the original *ready-to-act* artifact and serve here as a reflective tool in order to find the boundaries of the concept of continuity.

Discussion

The proposed methodology of *doping* – the deliberate introduction of impurities – an embodied design was the result of the aim to address the *concept scope*, which is theoretically explained in the German subject-matter didactics, within radical embodiment. *Doping* an embodied design has been shown to initiate a process of reflection regardless of the level of expertise (see Episodes 1-4). In this sense the enacted artifact in the form of the definition is a *ready-to-act* artifact (active use in a reflection process) as it "facilitates further actions" (Shvarts et al., 2024). In the context of the sense-making of continuity it has been shown that the role of the actions involved is dual in nature: (1) the actions – *(a) aligning the center line over the point and (b) dynamically adapting the width of the delta region* – crystallize in an artifact as *the* defining processes of continuity and (2) the actions themselves, previously crystallized in an artefact, serve as a reflective tool to expand the scope of the concept of continuity. Actions are therefore genetic (Episodes 1 and 3), in that they bring the new artefact of continuity to the fore, and extensional within a process of reflection (Episodes 2 and 4), in that they are used to set boundaries for the initial enacted concept of continuity and in this sense expand the scope of the concept of continuity.

Potential of movement-based embodied learning in mathematics: Insights from German case studies on reactivating movements

Lena Radünz

University of Wuppertal, Germany; raduenz@uni-wuppertal.de

This paper presents findings from a recently completed dissertation project that explores the potential of "movement-based embodied learning" in mathematics education, focusing specifically on the role of "reactivating movements" in enhancing mathematical understanding. Utilizing an interdisciplinary theoretical framework, the study emphasizes the significance of whole-body movements and reveals how reactivating movements, exemplified by gestures, contribute to learning. Through qualitative analysis of ten case studies with German third-grade students using a "number carpet", the research highlights the effectiveness of both active and reactivating movements in supporting the development of key mathematical concepts, particularly place value understanding. The results underscore the need for further research into the cognitive benefits of movement in learning mathematics and advocate for a more unified conceptual framework to guide future studies.

Keywords: Place value, movement-based embodied learning, case study, learning environments.

Introduction

The idea of integrating movement and learning in subject teaching is not new and can be traced back to reform pedagogy. For over 35 years, movement-based educational concepts have been advocated, including in Germany, to incorporate movement into subject lessons, such as mathematics, to enhance learning readiness and understanding through physical activity (e.g., Laging, 2017). Over the past 20 years, advancements in research technologies have prompted studies into the embodied nature of mathematical activities, adopting a more cognitive and neuroscientific perspective on the link between movement and learning. The embodiment of mathematical activities varies widely, from finger-counting processes (e.g., Miklashevsky et al., 2021) to the role of gestures in developing mathematical understanding (e.g., Krause & Salle, 2019) and whole-body training concepts with task-specific movements related to mathematical content (e.g., Link et al., 2013). While there is consensus on the fundamental embodiment of mathematics (e.g., Flood et al., 2020), research on the intentional promotion of mathematical content through movement and its potential for meaningful mathematical learning remains underdeveloped. The complexity of movement, diverse embodiments, mathematical content, varying terminologies (e.g., Bailey et al., 2023), and different research perspectives (e.g., Sinclair & de Freitas, 2019) pose challenges for developing a coherent understanding and integrating perspectives. The dissertation project aimed to develop an interdisciplinary, holistic understanding of mathematics education and explore how movement-based embodied learning contributes to it. This article provides insights into the conceptual framework and focuses on the potential of reactivating movements for revealing mathematical content. The aim of this article is to integrate gestures, chosen as an exemplary form of reactivating movement, into the holistic and interdisciplinary framework. Furthermore, insights from case studies are used to explore the specific contributions of gestures to mathematics learning within the context of movement-based learning environments.

Theoretical frameworks

In many German-language research works, the term *Bewegtes Lernen* [active learning] has been used to describe the temporal and/or content connection between movement and learning (e.g., Laging et al., 2010). In international research that involves the body in the learning process, various terminologies are used (e.g., Bailey et al., 2023), or the general term *Embodiment* or *active learning* is applied. The issue with these general or inconsistent terms is the lack of an international definition, leading often to the use of the all-encompassing term *Embodiment*. Currently, there is a lack of a clear definition to differentiate and mutually reinforce diverse international research efforts. In this article, the term *movement-based embodied learning* is used, and the theoretically-analytically developed interdisciplinary and holistic conceptual understanding is applied to the context of mathematics.

Movement-based embodied learning in the context of mathematics

While active learning has primarily been influenced by sports science and embodiment has been heavily shaped by cognitive psychology, these concepts often evolve parallel to each other. There is a need to integrate these concepts into an interdisciplinary and holistic understanding regarding their potential for classroom learning: Movement-based embodied learning can first be framed within the context of movement-based school concepts like the *Bewegte Schule* [Moving School] (e.g., Laging, 2017), which emphasizes integrating more movement into everyday school life due to its central importance for learning. This approach advocates for movement throughout the school day, not just in physical education, and specifically situates movement-based embodied learning within subject lessons like mathematics. Following Lindgren and Johnson-Glenberg (2013) and the Embodied Learning concepts, movement-based embodied learning is seen as pedagogically-methodologically initiated teaching-learning processes, distinct from informal learning forms or educational concepts like Embodied Education (e.g., Francesconi & Tarozzi, 2012). Unlike other definitions (e.g., Skulmowski & Rey, 2018), this concept emphasizes whole-body movements to uncover central subject-related aspects. Thus, movement-based embodied learning is purposefully distinguished from traditional use of materials, with active whole-body movements in space becoming the core of the concept. For the purpose of this article, movement-based embodied learning can initially be defined in a simplified way as an approach that integrates full-body movements into the learning process from a pedagogical-methodological perspective. This approach allows learners to discover, experience, and understand content by engaging their whole body in spatial movements. Importantly, it is not merely about incorporating physical activities into lessons (such as short movement breaks) but explicitly about exploring and constructing mathematical concepts through movement. But key insights from cognitive research suggest that experiences through space movements can be *reactivated* through movements (e.g., Radünz, 2025), which adds a new but very central point to the definition of movement-based embodied learning in a second step:

Current theories on the *Embodied Cognition* approach assume that sensory-motor areas of the brain are activated during interaction with the environment and are reactivated when perceiving related objects or actions (e.g., Beilock, 2009). Research has explored the connection between actual actions and their mental representation (e.g., Kaltner et al., 2014), observation of movements (e.g., Calvo-Merino et al., 2005), verbalization of movement processes (e.g., Hauk et al., 2004), and self-directed

gestures with a representative function (e.g., Krause & Salle, 2019). Knowledge about objects and events includes not only their perception but also the motor information and action possibilities resulting from actual movement (e.g., Beilock, 2009). Imaging techniques have shown that (1) *gestures*, (2) *mental images*, (3) *observation*, and (4) *verbalizations* are generated by a brain system comparable to that of practical actions, are closely connected, and can thus be considered *reactivating movements*, as they reflect the reactivation of active movements (e.g., Radünz, 2025; see Figure 1). Consequently, movement-based embodied learning goes beyond the active movements of the whole body in space and also includes *reactivating movements* as the reactivation of one's own movement experiences. With its specific focus on gestures as a form of reactivating movement, this article touches on a well-established field of research in mathematics didactics and embodiment studies (e.g., Alibali & Nathan, 2012). It is important to clearly delineate that within the broad literature on gestures, this study focuses on self-directed gestures and their cognitive function as reactivating movements within movement-based embodied learning. This distinction is based on the Gesture-for-Conceptualization Hypothesis proposed by Kita et al. (2017), which posits that gestures integrate cognitive processes with movements, thereby fundamentally establishing a connection to movement-based learning. Furthermore, gestures are specifically categorized in this context as reactivations of motor-spatial information derived from one's own movement experiences and are initially distinguished from interactive and communicative gestures. Initial case studies have highlighted the educational significance of reactivating movements, which is illustrated through an exemplary case study, noting that the potential of movement-based embodied learning – beyond the context of mathematics – remains a significant research gap.

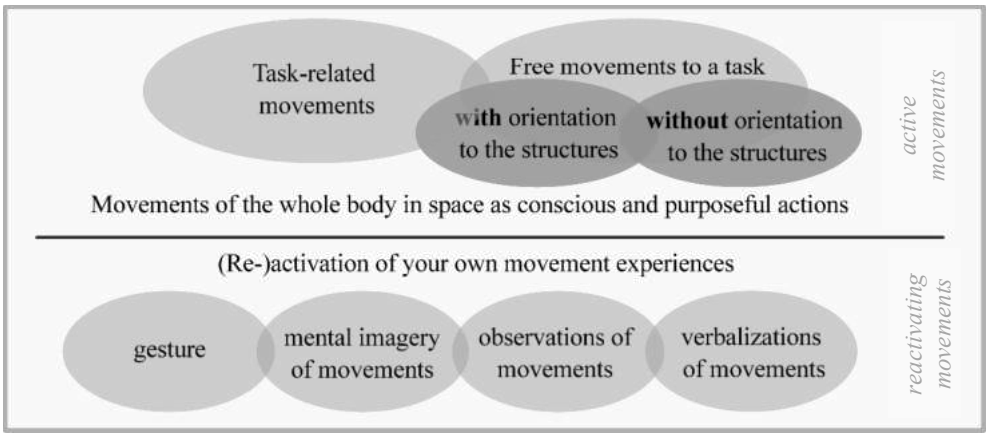

Figure 1: Forms of movement

The number carpet as systematic mathematical visualization of the place value system

Movement-based embodied learning in the context of mathematics primarily means using movements to develop key fundamental ideas in mathematics. Movements must represent the content context appropriately at a normative level and support students in building fundamental concepts at a descriptive level (e.g., vom Hofe et al., 2021). Due to the abstract nature of mathematical content, the mathematical teaching-learning process is generally mediated through suitable visual aids. To enable movements as actions using the whole body and thus leverage the full potential of bodily and spatial

perception, traditional mathematical visual aids can be adapted for whole-body use in space, while maintaining general didactic principles. Mathematics educational orientations can be realized through so-called *movement-based learning environments* (see Radünz, 2025), where movement is considered and reflected from the planning stage, integrating the full potential of the body into lesson design. However, movement-based embodied learning in mathematics is much more than mere physical movement and only unfolds its potential for supporting mathematical understanding when integrated with classical mathematics didactic concepts.

Figure 2: Number carpet as a body- and space-oriented visual aid

A fundamental idea in mathematics is the decimal place value system, and thus, developing an understanding of place value and the related bundling principle is a central goal of primary school mathematics education. Despite extensive criticisms regarding the risks of counting-based arithmetic, the hundreds board has been a present visual aid for over 150 years for the number range up to 100. However, neuroscientifically, the spatial arrangement from top to bottom, according to reading direction (e.g., Dehaene, 1997), can be questioned, as well as the fact that the hundreds board omits the zero as a central element of the decimal system. Consequently, the *number carpet* has emerged as a *body- and space-oriented visual aid* that systematically and consistently sorts numbers from zero to 99 according to place values (see Figure 2). Thus, the number carpet offers opportunities for implementing a movement-based learning environment by making the decimal place value system physically tangible and enhancing understanding through whole-body engagement. The movement-based learning environments on the number carpet integrate physical movements to develop fundamental mathematical concepts and make abstract content tangible.

Methods: Case studies as exploratory investigations

To investigate movement-based embodied learning, a qualitative and hypothesis-generating research design was employed through exploratory case studies. Given the limited implementation in practice, a suitable setting was first developed. Movement-based embodied learning environments on the number carpet were designed based on the theoretical-analytical framework, and the teaching-learning lab MATHletics was established. This lab provided an authentic setting for capturing the case studies. Over two weeks, student teachers worked with an after-school program at a primary school in Wuppertal, Germany, creating and scientifically documenting comprehensive movement-based embodied learning experiences on the number carpet.

The methodology involved ten complex case studies with third-grade students, focusing on arithmetic and place value understanding. A multi-method approach was used to holistically examine the interplay of various factors in mathematical learning through movement and to derive implications for educational practice (for more details see Radünz, 2025). This article provides partial insights into the primary data consisting of video recordings collected during the learning activities. Video recordings, observation forms, and student documents were analyzed using qualitative content analysis (Kuckartz & Rädiker, 2023). The coding system was developed both deductively, based on theoretical understanding, and inductively from the data. This analysis aimed to distill essential aspects from the data and identify key features.

Based on the coding, seven main categories were identified, each further refined through additional subcategories. In relation to the case study presented below, this section will focus on illustrating the main category 7 – reactivating movements (see Radünz, 2025). The subcategories in this instance were primarily developed deductively, grounded in the conceptual framework. For example, the subcategory *Gestures* is coded when a child uses their hands to indicate direction or position. For example, Mostafa looks at the number carpet and moves his hands diagonally (see Figure 4). Gestures involve pointing to specific positions or spatial structures, while raising hands is not considered a gesture and is coded differently. The structuring coding process identifies central scenes in which learners use gestures in the context of the moving learning unit to access mathematical content. By interpreting and combining the results from the other instruments in the sense of method triangulation, the contribution of gestures as reactivating movements of movement-based embodied learning for learning mathematics can be worked out.

Results: Insights of a case study

Figure 3: Idris's self-directed gestures while describing neighboring numbers

The case studies revealed that students used movement in various ways to comprehend mathematical content, with the contribution of movement-based embodied learning to mathematics varying significantly from an epistemological perspective. With the special focus on the contribution of gestures, two exciting functions can be highlighted: First, students employed both active and reactivating movements to accompany and support their verbal communication, indicating that movement also served a *communicative function*. Notably, students with language difficulties attributed a self-directed meaning to their movements, using gestures in various directions to guide their own speech. For example, in Figure 3, the student Idris is shown standing on the number 46 on

the number carpet, describing the neighboring numbers. The other students are seated with their backs to the mat, attempting to identify the number based solely on his descriptions. Since his peers cannot see him, Idris uses gestures in different directions while describing the neighboring numbers, which serve as a form of *self-guidance* rather than communicative gestures.

Figure 4: Mostafa's discovery and gestural representation of repdigits on the number carpet

Furthermore, the epistemological function of gestures is illustrated by a striking scene involving the student Mostafa. While two classmates are representing the various positions of repdigits on the number carpet to address the challenge of number word reversals commonly observed in German, Mostafa, simply by observing his classmates, identifies the diagonal connection between the repdigits. He examines and represents this insight through self-directed gestures (see Figure 4; left and center). He then tests this realization through active movements on the number carpet, repeatedly tracing the diagonal connection between the repdigits and communicating this discovery to his peers through movements along the diagonal and gestures (see Figure 4, right), by repeatedly stating: "Look, they are connected too". It is important to emphasize at this point that the diagonal connection of repdigits on the number carpet holds significant potential for mathematical discoveries, although this was not the focus of the intervention in the context of the support unit at that time. Thus, Mostafa independently recognized this connection by observing his classmates and using gestures, highlighting the potential of reactivating movements for the learning value of active learning.

Discussion

The case studies presented highlight the potential of movement in mathematics education, particularly the significance of reactivating movements for learning mathematical content. While the role of active movements through space remains central for understanding and discovering mathematical concepts, the observations indicate that reactivating movements – such as gestures and the mental tracking of others' movements – also play a crucial role. Mostafa's case illustrates this impressively: through observing the active movements of his classmates and subsequently representing these insights through gestures and his own active movements, he was able to gain a deeper understanding of the mathematical concept of reciprocal numbers. This shows that the various forms of movement in their active and reactivating forms are mutually dependent and closely interlinked, although the question of the concrete connection between active and reactivating forms of movement and the various forms of reactivating movement among themselves still needs to be the subject of further research. Although these results are promising, the overall research on the potential of movement for learning mathematics remains underdeveloped. The scope of the present case studies is limited as they include only a small sample, in addition to the specific German socio-cultural context, and focus on specific

scenarios. Nonetheless, the insights gained provide valuable stimuli for future research, which should further explore the interplay between active and reactivating movements in mathematics education. Particularly noteworthy is the importance of a holistic and differentiated understanding of embodied learning in mathematics education. The study has demonstrated that a clearly defined and interdisciplinary-congruent understanding of *movement-based embodied learning* is necessary to effectively advance research in this area. Such a conceptual framework can not only help relate existing studies to one another but also establish clear distinctions and connections between different approaches. Therefore, it is essential that future research pays special attention to this aspect and builds on a coherent theoretical foundation.

Thus, it is important to further explore the connection to gestures. While gestures were primarily examined here in their self-directed function as reactivations of movement experiences, the question arises as to whether gestures might hold additional significance in the context of movement-based embodied learning. Given that full-body movements can also serve communicative functions, it remains to be seen whether movement-based embodied learning could benefit more substantially from research in the specific domain of gestures, and whether the boundaries and interconnections between these areas could be more thoroughly elaborated. Overall, this study emphasizes the immense potential of integrating movement – both active and reactivating – into mathematics instruction. The insights gained lay the groundwork for further investigations aimed at understanding the conditions and mechanisms under which movement most effectively supports mathematical learning.

Towards a theoretical framework for analysing block play constructions through the lens of crystallographic symmetry-breaking

Michael Rumbelow

School of Education, University of Bristol, Bristol, UK; cc18401@bristol.ac.uk

In this theoretical paper, I explore the possibility of using crystallographic theory as a framework for analysing young children's block play as crystallisation. Friedrich Froebel (1782-1852), the inventor of Kindergarten, made block play central to his play-based pedagogy. He was inspired by his time as an assistant to professor of crystallography Christian Samuel Weiss in Berlin, who was developing a novel system of categorising crystals according to their symmetries. While studying these crystal symmetries, Froebel experienced an epiphanic insight that the same basic symmetrical forms were key to children's understanding of Nature, and that by playing with blocks, children could imitate Nature's process of crystallisation. The crystallographic influences on Froebelian pedagogy have largely been lost in practice. As a thought experiment I attempt to analyse two early snapshots of block constructions from my doctoral study, through a crystallographic, symmetry-breaking lens.

Keywords: Kindergarten; block play; crystallography; symmetry-breaking; mathematics education.

Introduction

In my doctoral study I am analysing videos of 4-7-year-olds' free block play for evidence of proto-mathematical thinking. There is a long history of educational research into children's block play, dating back to Friedrich Froebel's invention of Kindergarten block play in the 1820s, including Froebel's own pedagogical experiments and development of blocks and block-based activities for young children and their carers, carried out by him and his colleagues at the schools he founded in Keilhau, Bad Blankenburg and elsewhere (Gura et al., 1992). Recently there has been renewed academic interest, from a historical perspective, in the profound, metaphysical inspiration Froebel drew on for his block-play pedagogy from crystallography, while working as an assistant to professor of crystallography Christian Samuel Weiss in Berlin from 1814-1816 (Friedman & Muñoz Alvis, 2023). For example, in Froebel's seminal 1826 work on Kindergarten pedagogy, *The Education of Man* (Froebel, 2005), he devotes over 20 pages to the metaphysical significance of the cubic symmetries of crystals and their relationship with child development. However, the quasi-spiritual language of Froebel's writings on the subject can be arcane, and the science of crystallography has developed significantly since – for example, embracing Dalton's then-new theory that matter consisted of combinations of atoms (which Weiss abjured) – and, despite the global popularity of his play-based Kindergarten, crystallographic aspects of Froebel's pedagogy have tended to be ignored in practice.

In this theoretical paper, as a thought experiment, I revisit Froebel's crystallographic inspirations for his block play pedagogy, alongside more recent insights from mathematical crystallography, such as group theory, Noether's theorem, entropy and symmetry-breaking, in order to explore crystallography as a potential theoretical framework for analysing patterns of block play, such as those I am observing in 4-7-year-olds. By focusing on the emergence – or crystallisation – of observable material structures when bodies interact with blocks in open-ended, free-play environments, I aim to stimulate potential

theoretical dialogue between Kindergarten pedagogy, mathematics and socio-materialist philosophies which decentre the human child by highlighting relationships with and between material objects.

Froebel's crystallographic concepts

When Froebel worked for Weiss, the field of crystallography had recently been established by René-Just Haüy in France, with his 1801 *Treatise on Minerology,* in which he showed how crystal forms corresponding to those observed in nature could be built up from unit cubes, which he could demonstrate using homemade wooden blocks (Figure 1).

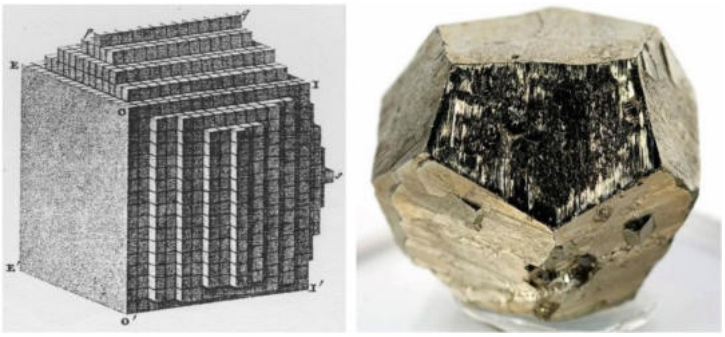

Figure 1: Haüy showed how symmetrical crystal forms, e.g., pyrite, can be built up from cubes

Weiss, rejecting the idea of atomic particles (in line with the contemporary *Naturphilosophie* idealism of his German intellectual milieu), developed a way of classifying crystals into seven 'systems' purely according to their symmetries, based on transformations of the symmetries of a cube, stretching or shearing its axes (see Figure 2).

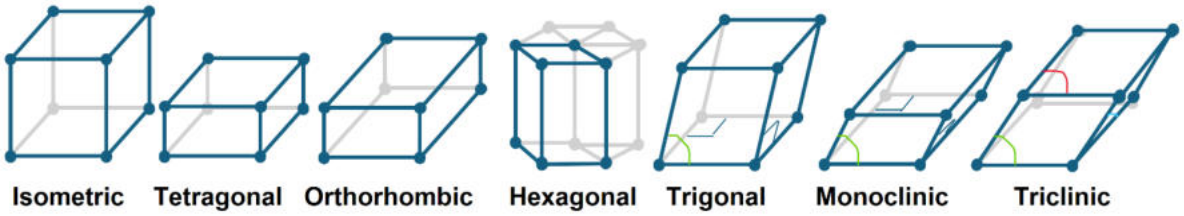

Figure 2: Weiss's seven crystal systems, each a transformation of a cube, by stretching or shearing

For example, the structure of a crystal such as diamond is based on a cubic (i.e., 'isometric') system, which has rotational symmetries. One can imagine, say, a cube of diced apple, and putting a cocktail stick in through the centre of the front face and out through the centre of the back face. If one twisted the stick a quarter turn clockwise the cube would rotate and end up looking identical. Thus, it has rotational symmetry (of order 4) about the axis of the cocktail stick. In total, the cube has 13 axes of rotational symmetry: 3 through its face-centres, 6 through its edge-centres, and 4 through its corners. Stretching a cube in one dimension to make a square-based cuboid gives the tetragonal system (e.g., apophyllite crystals), which has only 3 axes of (all face-centred) rotational symmetry. Stretching in another dimension, and shearing so that no axes are perpendicular, gives the triclinic system (e.g., turquoise crystals), which has no axes of rotational symmetry. In studying these crystal symmetries Froebel experienced an epiphanic insight, that these forms were also fundamental to our own minds:

"The simplest forms, which lie at the foundation of the fabric of the world, lay also the foundation in the minds of children for the understanding of the world" (Marenholtz-Bulow, 1876, p.1).

Turning down the offer of an academic professorship, Froebel would dedicate the rest of his life to teaching and developing his play-based Kindergarten pedagogy, centred on block play, in the belief that a child "follows the course of Nature … He likes to build and to imitate the structuring of form which we find in Nature's first activity, in the formation of crystals" (Lilley, 1967, p.38).

Froebel saw that, just as Nature generates a myriad of forms from simple basic forms such as cubes, so can a child, using simple wooden blocks. Froebel designed a sequence of manipulatives, or, 'Gifts', for children to play with as they grew: from Gift 1, a soft knitted ball meant to be reminiscent of the mother's breast, to Gift 2, a wooden ball, cylinder and cube, to Gift 3, a similar cube halved in each dimension to make eight smaller cubes, from which a vast variety of forms could be constructed in play (Figure 3). Further gifts consisted of similar cubes halved or doubled in length to make lower-symmetry bricks – e.g., tetragonal or orthorhombic cuboids – enabling more elaborate constructions.

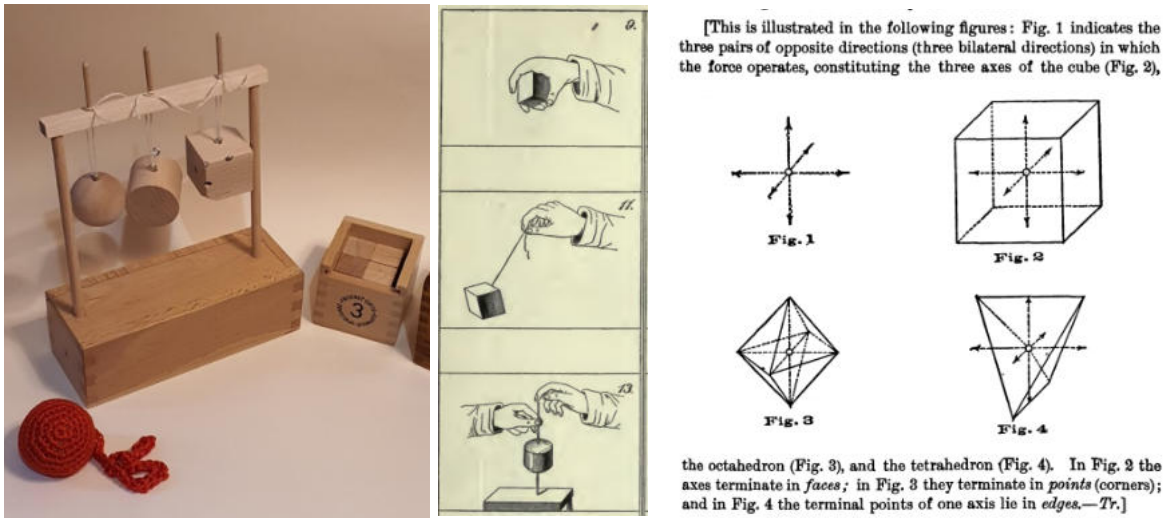

Figure 3: (Left) Froebel's Gifts 1, 2 and 3. (Centre) Froebel's illustrations of how Gift 2's cube could be spun on its axes using a string or stick. (Right) An image relating the octahedron and tetrahedron to the cube, from Froebel's *The Education of Man*.

From a crystallographic perspective Froebel added several features to highlight the symmetries of the wooden forms in Gift 2, for example drilling holes through their axes of symmetry, and fixing small eyelets to the ends of the axes. Thus, a stick could be pushed through the axis or a string through the eyelet, so the object could be spun showing the rotational symmetries. This motion added the fourth dimension of time to three dimensional shapes. For example, if the cube is spun rapidly about a face-centred axis, it appears transformed into a cylinder, revealing its invariant volume under rotation, which has its own symmetries. If the cylinder is spun rapidly about an axis perpendicular to its own axis it appears transformed into a ball. Play with Gift 2 can thus be understood as designed to support understanding of crystal symmetries and variances under rotational transformations. The smooth rolling of the spherical ball is a manifestation of infinite rotational symmetries, invariant over time.

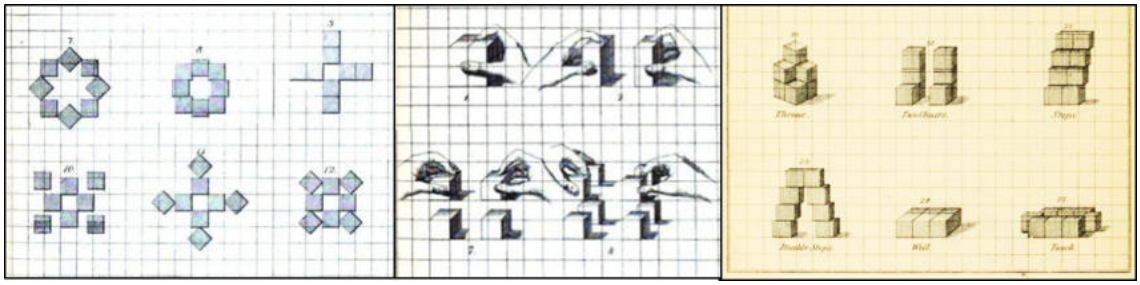

Figure 4: Gift 3, (Left) forms of beauty; (Centre) forms of knowledge; (Right) forms of life.

It is Froebel's Gift 3 of eight, one-inch wooden cubes that has become perhaps most emblematic of Kindergarten block play. For Froebel, time spent contemplating and playing with Gifts 1 and 2 was important preparation, as was storing the eight cubes together as a cube in their box, and using all eight (and no more) in constructions, maintaining a unifying, self-similar relationship with the larger cube, and via Gift 2, with the sphere. In modern Kindergarten such practices tend to be lost.

Froebel categorises block play activities into three forms: 'forms of beauty' – aesthetically pleasing symmetrical shapes, which could be made to 'dance' by transforming one into another; 'forms of knowledge' (or 'recognition') – shapes embodying abstract concepts such as numbers or fractions, as well as symbolic forms such as alphabetic letters; and 'forms of life' (or 'use') – models of people and objects familiar to the child, constructed from the eight cubes, which could be narrated and dramatised in stories, being rebuilt into new constructions as the story progressed (Figure 4).

Of these forms, the form of beauty is the most obviously crystalline in its dancing symmetries. However, with the form of knowledge, too, Froebel illustrated exploration of halving, then quartering the cube, and the new lower-symmetry cuboid forms these create, before halving quarters again into eighths returns to the cube form, pointing to an infinitely scaling crystalline symmetry of enlargement.

There are clearly many other aspects to Froebel's pedagogy, including further specific Gifts and activities (sometimes known as 'Occupations') such as weaving, painting, modelling with clay and 'peas-work' – the modelling of highly crystalline forms with toothpicks and peas – as well as singing, dancing, games, growing plants and spending time playing in Nature. Though there is not space to detail these here, I would highlight that for Froebel they were all designed to be a coherent whole, so all might in some way be related to block play and crystallisation, for example, and vice versa.

I have briefly outlined how Froebel's ideas of underlying crystallographic symmetries, gleaned from Weiss, were manifest in his block play pedagogy. Given that both block play and crystallography have evolved significantly since then I would now like to consider whether more recent, post-Weiss, crystallographic theory may also help inform crystallographic analysis of block play.

Additional crystallographic concepts: symmetry-breaking

In the decades following Froebel's time with Weiss, crystallography quickly developed from a branch of minerology to become a branch of mathematics. Galois's group theory in the 1830s enabled seeing Weiss's symmetrical analysis of crystals as more generalisable symmetry groups and began to offer ways of understanding wider physical phenomena in terms of symmetries. In 1894, Pierre Curie's dissymmetry principle theorised that any symmetry observable in an effect in a physical system can

be found in its cause. So, for example a smooth layer of iron filings scattered on a plate may have infinite rotational symmetries. That is, if one turns the plate by any angle, the iron filings look the same. But when a bar magnet is brought near the bottom of the plate, this infinite symmetry 'breaks' into a polarised pattern along the lines of the magnetic field, reflecting the field's lower, two-fold bipolar symmetry. Thus, observing and analysing the 'breaking' or lowering of the symmetry – here from infinite to two-fold symmetry – may offer a way of understanding the phenomenon:

> the occurrence of a phenomenon in a medium requires the original symmetry group of the medium to be lowered (broken) to the symmetry group of the phenomenon (or to a subgroup of the phenomenon's symmetry group). In such sense, symmetry breaking is what "creates the phenomenon" as claimed by [Pierre] Curie. (Castellani & Dardashti, 2021, p.633)

At other times the symmetry of physical systems may spontaneously break, such as when a crystal with 2- or 3-fold symmetry forms from the medium of an infinitely symmetrical gas or liquid. The final symmetry of the crystal may be highly sensitive to small variations in the medium. For example, the common crystal calcium carbonate (the main constituent of chalk and eggshells) has two symmetrically distinct forms, calcite and aragonite, both present in the shells of molluscs, which can finely control the chemical composition of the seawater their shells crystallise from. By analogy small adjustments in the block play environment may result in distinct symmetries in block constructions.

In the early twentieth century Emmy Noether's theorems made the connection between the physical laws of conservation (of mass/energy, momentum, charge etc.) and the conservation of the symmetries of a system, making symmetry – and symmetry-breaking – derived from crystallographic mathematics fundamental to understanding much of modern particle physics.

If subsequent developments in crystallography have arguably validated Froebel's focus on their importance in understanding Nature, they may also offer opportunities to reintegrate crystallographic thinking into the pedagogical analysis of Froebelian block play. For example, a tub of randomly mixed cubes may be seen as a medium with effectively infinite symmetry (i.e., by eye its symmetries are indistinguishable when the tub is rotated, mixed up etc.), analogous to scattered iron filings, or atoms in a hot gas, or a liquid solution. It may be that children's interactions with blocks break these infinite symmetries. For example, by picking up one cube, already the focus switches to a lower-symmetry object – the cube – albeit itself highly symmetrical. Connecting this cube with another to build a tower can again be seen as another symmetry-breaking – reducing the highly symmetrical cube to a lower-symmetry cuboid (or 'tetragonal' system crystal). And adding symmetrical 'arms' to either side of the tower breaks the symmetry further. While adding asymmetrical features, like a flower at the end of one arm, may break the overall symmetry to none. In theory, this offers a potential crystallographic lens for analysing block constructions observed over time as symmetry-breaking.

Experimental application

Traditionally ethnographic studies of block play have tended to categorise block constructions into types, or stages. For example two schemas introduced in the 1930s are both still commonly used (Tian, Luo & Cheung, 2020) – Johnson's seven stages (carrying blocks around, making rows or piles, bridging, enclosures, decorative patterns with symmetry, naming of block constructions, and dramatic

play with block constructions), and Guanella's five stages (nonstructural or pre-organized use of blocks, stacks or rows of blocks, bidimensional construction, tridimensional e.g., enclosures, and representational play with blocks). Though these schemas recognise the presence of symmetry occasionally, for example in repeating patterns (echoing Froebel's 'forms of beauty'), no schema I am aware of to date has used crystallographic symmetry as an organising principle for analysis.

Though any crystallographic schema would require thorough trials, and my gathering of video data of 4-7-year-olds' block play is still at an early stage, as a thought experiment I consider two snapshots of block constructions I have observed as examples for experimental crystallographic analysis.

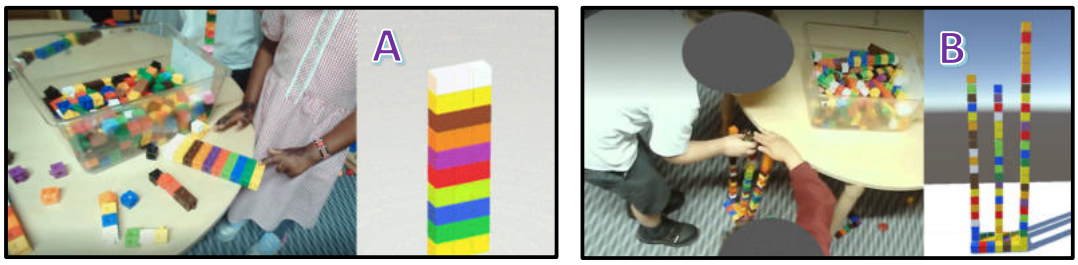

Figure 5: (Left) Model A: a rectangular form with orthorhombic symmetry. (Right) Model B: a form consisting of three tetragonal towers of different heights on a horizontal orthorhombic base.

In Figure 5 two snapshots of 5-year-olds' block constructions are presented, alongside 3D models of the constructions, re-created in 3D modelling software (with the aim of eventually being able to, e.g., view them as looping animations from various angles, and compare them side-by-side in virtual space, as well as extract coordinate data on block positions for potential symmetrical analysis). Both were taken from video clips of naturalistic, unguided free play with multilink cubes, to which the children were accustomed. Crystal system labels are applied to key phases of the construction, along with crude levelling of the symmetries – for example the cube is categorised as the isometric system (high-symmetry), and the tower, tetragonal (mid-symmetry) – to trace effects of actions on symmetry.

Model A was built up by one child, from a starting cube, made into a row of three of the same colour. This was then repeated methodically and carefully row by row upwards, with each row a different colour, with no discernible pattern to the colours.

Model B was made by two children playing together, with one creating the initial structure of three towers, and the other assisting with adding and taking away blocks over time. The towers changed rapidly, in playful conversation, both through deliberate changes to the construction, and accidents where a tower would break and fall and have to be resurrected.

Crystallographically, Model A can be seen as developing from the tub of cubes (~infinite symmetry), to a cube (isometric crystal system – high symmetry), to a row of three (tetragonal – mid symmetry), to two rows of three (orthorhombic – low symmetry), to three rows of three (tetragonal – mid symmetry), to four and then further rows (orthorhombic – low symmetry). Model B develops from the tub (~infinite symmetry), to a cube (isometric – high symmetry), to which a cube was added to start building a tower (tetragonal – mid symmetry). Three towers of different heights were added to a rectangular base (orthorhombic – low symmetry). The whole system thus became asymmetric (in crystal terms 'amorphous'), although spacing of the three tetragonal towers was approximately even.

Discussion

This theoretical paper describes a thought experiment in the possibility of developing a crystallographic theoretical framework for analysing block play constructions as symmetry-breaking. It is intended to raise questions for further theoretical development rather than draw any conclusions on limited block play data, and minimal formal method.

However, within these limited terms the thought experiment has demonstrated that block constructions may be analysed in terms of symmetries. And for constructions starting with a tub of mixed blocks (i.e., ~infinite symmetry), and then a single cube (high symmetry), constructions did tend to break these symmetries, forming lower-symmetry shapes. Thus, symmetry-breaking may offer a crystallographic basis for analysing at least one aspect of block play constructions.

As evidenced by previous studies and schemas, young children's early block constructions often tend to be 'abstract' – not recognisably models of everyday objects, which added to the fact they may be constructed with minimal if any verbal narrative, can make analysis challenging. Hence traditional schemas have often focused on observable topological features such as enclosures or bridging, or levels of dimensionality. Interpretations through a crystallographic theoretical lens may offer a supplementary framework, with the potential benefit of relating to well-defined mathematical models of symmetry, enabling, for example, computer-aided identification of symmetries across instances.

In addition, this thought experiment has highlighted some implications of the newer types of blocks, for example, interlocking cubes, or *Lego* (as well as virtual blocks such as *Minecraft, Roblox* etc.), compared with wooden blocks that rely on gravity to stay in place, on which earlier schemas are often based. Johnson's concept of balancing a 'bridge' between two stacks, for example, makes less sense if block constructions are snapped securely together. This touches on Curie's dissymmetry principle and to what extent the constructions reflect the symmetry of the force of gravity. And also suggests entropy as a phenomenon in building balanced block constructions as it is in crystallisation, – since in physics changes of state whether crystallisation or melting ultimately increase overall entropy – vividly illustrated by block towers noisily collapsing into an unordered state.

Similarly, with multi-coloured blocks now common, there may be patterns of colour, co-existing with patterns of formal construction. In virtual worlds blocks may have many other properties. This 'sticky' connectivity of multilink or virtual cubes may in fact reflect more closely the way crystals form in nature, from layers of almost weightless atoms or molecules attracted to earlier layers.

Thirdly, focusing on symmetries has opened the possibility of connection with Froebel's largely neglected original crystallographic ideas, which may help make sense of his pedagogy more generally. For example, it is hard to contemplate a rationale for the holes along the axes of symmetry of the cube in Gift 2, without reference to Froebel's knowledge of crystallographic symmetries. And the 2- and 3-symmetries of crystals may offer resonances with 2- and 3-rhythms of Kindergarten dances and songs, woven or drawn imagery, and clay models, as well as the small-number symmetries of family structures, conversational dialogue and language grammar children are learning.

In addition, the mathematical nature of symmetrical analysis may offer bridges to more formal, post-Kindergarten mathematics, where crystalline tetragonal rows of interlocking cubes are often used to

model algebra and counting, symmetrical parallel rows modelling equality, orthorhombic rectangles modelling area and multiplication, or cubes modelling volume, and so on.

In future research, these early ideas of a crystallographic theoretical framework may be developed further, iteratively, through testing on video data of children's block play, and on 3D animated models of their constructions. In addition, Froebel saw deep philosophical significance in crystals, and there may be opportunities to explore potential links with philosophers who draw on metaphysical ideas of crystallisation, immanence and virtuality, such as Simondon, Deleuze and Guattari, and newer socio-materialist philosophers such as de Freitas and Sinclair, who might assign agency to the crystal forms.

As a final reflection, one early graduate of Froebel's pedagogy, who attributed much of his creative success to his time spent at Kindergarten playing with Froebelian blocks, was renowned architect Frank Lloyd Wright, a pioneer of the modernist architecture that has influenced much of the current urban built environment. He hints at the deeper pedagogical value of Froebel's focus on the mathematical symmetries of crystals, which a crystallographic lens might elicit:

> The virtue of all this [Froebelian Kindergarten activity] lay in the awakening of the child-mind to rhythmic structure in Nature - giving the child a sense of innate cause-and-effect otherwise far beyond child-comprehension. I soon became susceptible to constructive pattern *evolving in everything I saw* [Wright's emphasis]. (Rubin, 1989, p.30)

A plea for participatory/transformative methodologies in embodied and material studies of mathematics education

Anna Shvarts[1] and Karel Boonstra[2]

[1]Utrecht University, Utrecht, The Netherlands; a.y.shvarts@uu.nl

[2]Utrecht University of Applied Sciences, Utrecht, The Netherlands

In this paper, we reflect on methodological aspects of material and embodied studies of mathematics learning and teaching as derived from a paradigmatic shift in social science. Within (post)positivist/cognitivist and constructivist paradigms, we see a coherence across theoretical visions on cognition, main teaching practices, and core research methodologies as they all share core ontological and epistemological assumptions. Searching for a paradigmatic coherence, we resonate onto-epistemological assumptions of radical embodied and new materialist studies with those of transformative and participatory paradigms and their methodologies. An illustration from a study on embodied teaching and learning of reflection symmetry shows how the emergence of new onto-epistemological structures, iterative non-central regulation, intercorporeality, and warm participation are present in the practices of students, teachers, and also researchers.

Keywords: *radical embodiment, new materialism, participatory methodology, transformative methodology, paradigm.*

Introduction

When discussing embodied and material forms of learning mathematics, we often get a question: "Ah, it is clear that there is such a nice process going on, but how do I make a research study out of it?" The questions of assessing (Kolovou, 2022) and reporting (Sinclair, 2024) outcomes and processes of embodied learning without reducing their complexity to traditional pre-posttests and dryness of transcripts call for a methodological reflection. The situation becomes even more complicated once we bring affective processes and teachers into the research-practice landscape. If affectivity is "the fundamental 'responsivity' of life" (p. 3, Freitas et al., 2019) that flows across participants and unfolding sympathy determines the dynamics of the learning process, shall we perhaps assess affective engagement rather than cognitive outcomes? Yet, how can we do so if affect is fluid and mostly stays beneath consciousness? At the same time, even assessing the entire complexity of embodied learning might not contribute much to the future education unless teachers feel enthusiastic about new forms of learning. This is challenging as embodied approaches imply fundamental transformation of teaching habits (e.g., Macrine & Fugate, 2021). This paper aims to provide a reflection on methodological consequences of the paradigmatic shift that embodied and material focus in studying mathematics teaching and learning entails.

Classical views

In the current moment of cultural development, a traditional classroom is imagined as rows of desks oriented towards a teacher who transmits information to the students sitting still and attentive to the message. This intuitive image of students passively receiving and storing information in their heads perfectly matches cognitive science that developed in the 1950s as a response to behaviourism

(Miller, 2003). Classical cognitive science has assumed that cognition is an information-processing machine. It receives sensory signals, sophisticatedly processes them into mental representations of the outside reality, and reacts according to the received and previously stored information.

The general image of cognition—aiming to best represent reality as it is—is well aligned with the so-called positivist (or post-positivist) science paradigm. Ontologically, classical research assumes the existence of an objective universal reality that becomes an object of scientific investigation (Guba & Lincoln, 1994). Epistemologically, a subject separated from this reality conducts research aiming to cognize and represent the reality as well as possible, thus creating "knowledge of the "way things are" [that] is conventionally summarized in the form of time and context-free generalizations," (p. 109). Methodologically, this paradigm, as well as classical cognitive science, is reductionist: it tries to split the information about the world into independent variables and uncover causal or relational effects through empirical tests and interventions that do not alter the nature of the studied phenomena.

While a traditional classroom might seem outdated to a large part of the mathematics education research community, the theories and methodologies that are grounded in cognitivist assumptions are widespread. For example, Duval's popular idea of mathematical concepts existing in multiple semiotic registers builds exactly on cognitivist models of mental representations of reality (Duval, 2006). Experimental quantitative paradigms criticized in the early days of mathematics education research (e.g., Freudenthal, 1982) are now living through a partial revival due to new research technologies (e.g., Strohmaier et al., 2020). Moreover, some theories of embodied cognition (e.g., Barsalou, 2003) are in line with the information processing and representationalist paradigm.

Constructivist view

Alternative image of students' groups engaged in solving problems using manipulatives, followed by classroom negotiations on arising in problem-solving mental constructions, sounds attractive to many researchers and innovative to teachers. Such a vision of children constructing their own mathematical realities grounded many influential theories in the 1980s and 1990s, such as, for example, the theory of conceptual fields (Vergnaud, 2009). Bringing the image of students who shape their mental constructions from a mathematical classroom to broader society, we notice that this picture matches the constructivist paradigm of research in social science. This paradigm fundamentally abandons the universal ontological existence of independent reality. Instead, "Realities are apprehendable in the form of multiple, intangible mental constructions" (Guba & Lincoln, 1994, p. 110). While radical constructivism insists on the solipsistic individuality of those mental constructions and, consequently, realities (von Glasersfeld, 1991), social constructivism notices constant discursive negotiation of those intangible realities within community. Consequently, constructivist research methodologically leans on dialogic/dialectical discursive methodologies (Guba & Lincoln, 1994): researchers explore realities of the participants through interviews and negotiate the theories among each other.

Radical embodied and new materialist views and the transformative-participatory paradigm

An image of teaching/learning situation that radical embodied and new materialist studies develop is rather drastically different from the previous two images. Students are engaged in physically creating

the objects of their mathematical inquiry or discovering mathematical relations through movement (de Freitas et al., 2018; Sinclair, 2024; Shvarts & Abrahamson, 2023). Their teachers do not just discursively question students' mental constructions. Instead, they engage in co-creating new perceptual and physical objects and ways of talking about them (Flood et al., 2020).

Radical embodied and new materialist views: onto-epistemology

First of all, radical embodied and new materialist studies are *non-dualist* and, similarly to the constructivist paradigm, assert *relational* and *dynamic* ontology. This means that objects and cognizing subjects are fundamentally entangled. Ecological ontology, developed within the radical embodied approach, assumes that affordances—relational possibilities for an organism to act in the environment—are primary qualities of the world (Turvey, 2019, p. 334). It means that the environment is immediately structured for an organism along potential actions that it might wish to perform. New materialism prioritizes matter, yet not in its universal objective form, but in its performative becoming through forming new cuts and relations (assemblages) (Barad, 2007).

This entanglement defines how (material) objects and subjects are revealed to each other, thus mixing ontological and epistemological considerations. Instead of representing pre-structured reality, the world and its inhabitants constantly co-shape each other in the process of *becoming*. "There are only changing things" (Turvey, 2019, p. 329) states the nature of ecological ontology, highlighting the constant flow of transformation. The transformation includes the *emergence* of "non-decompositable" entities in complex system processes (Tompson et al., 2001, p. 420). This ability to form holistic synergetic units is, apparently, universal to quantum particles, brain networks, and bodily muscles. Karen Barad offers a notion of intra-action to capture this activity that precedes the separation of a phenomena and a cognizing subject: "It is through specific agential intra-actions that the boundaries and properties of the components of phenomena become determinate" (Barad, 2007, p.139). Both, in new materialist and in radical embodied approaches this emergence of new units is not a one-stroke but a *cyclic* and *iterative* process leading to new (relatively) stable forms: As for new materialism, "matter is a stabilizing and destabilizing process of iterative intra-activity" (p. 151), for radical embodied approaches, cognition emerges as it finds stable patterns in "cycles of operation" in interaction with environment and others (Varela et al., 1991).

In application to mathematics education, the interaction between students, teachers, and objects is seen as fundamentally embodied and pre-discursive—thus contrasting with the constructivist view. In cyclic processes of becoming, humans (and non-humans) encounter each other through *intercorporeal* coupling of sensory-motor processes across bodies (Shvarts & Abrahamson, 2023) and through *affectivity* that drives the entire interaction (Freitas et al., 2018).

Finally, the fundamental aspect of new-materialist and radical embodied onto-epistemology is *non-centralized* regulation of its future unfolding. Asserting transformations in body-brain-world system to emergent self-organization (Varela et al., 1991), the radical embodied approach to cognition rejects the central regulation of behaviour (see Shvarts & Abrahamson, 2023 for application to mathematics education). New materialism goes even further as they "decenter the human subject as the willful agent, and <…> animate the mathematical concept" (de Freitas & Sinclair, 2013, p. 460). From a

new materialist perspective, not only humans, but also non-human material entities, such as artifacts, agentically contribute to the unfolding future and possible transformation.

Transformative/participatory paradigm: onto-epistemology

In this section, we propose that the onto-epistemological assumptions of new materialism and the radical embodied approach match the onto-epistemological assumptions of the emerging transformative-participatory paradigm of research in social science. Participatory studies assume that "There is a given cosmos, a primordial reality, in which the mind actively participates. Mind and the given cosmos are engaged in a co-creative dance" (Heron & Reason, 1997, p. 279). Mind and cosmos co-shape each other, so "this ontology is thus subjective-objective" and the *emergent* reality "the fruit of an interaction of the given cosmos and the way mind engages with it." The transformative paradigm also sees reality as *emerging* and highlights the analysis of power relations in shaping the reality: "How is reality defined? By whom? Whose reality is given privilege?" (Mertens, 2007, p. 2016).

Critically, participants are engaged with the world in pre-discursive way: "Experiential knowing thus articulates reality through inner resonance with what there is and through perceptually enacting" (Heron & Reason, 1997, p. 281); only later, "this grasp is symbolized in graphic, plastic, musical, vocal, and verbal art forms." The other humans are present in this space of *affective warm participation*, forming *intercorporeality*: "when we open ourselves to meeting the given we are arrested by the presence of Other; <…> the Other declares itself to us so that we resonate with its presence in the world." (p. 281). An assumption that reality and its continuous *becoming* emerge in interaction leads "to a *cyclical* model of research that includes the establishment of partnerships between researchers and community members, including the recognition of power differences and building trust" (Mertens, 2007, p. 2018).

We claim that transformative approaches (e.g., in sustainability science) and participatory approaches (e.g., participatory action research, participatory design) form a unified participatory/transformative paradigm. They share fundamental onto-epistemological assumptions of *becoming*, *emergence*, *intercorporeality*, and *affectivity*, which are also inherent to radical embodied and new materialist studies. Those assumptions call for research methodologies that encourage *warm participation* of different stakeholders in *non-centralized iterative* processes of creating educational transformations.

Empirical illustration

We use materials from the second author's doctoral dissertation to illustrate how the qualities of *emergence*, *intercorporeality and warm participation*, and *non-central iterative regulation* are fundamental in research on embodied education at the levels of students, teachers, and researchers as the main stakeholders within such research. In a design research study of a professional development (PD) program, the teachers were invited to explore action-based embodied design activities for reflection symmetry within a low-tech environment. A fragment of an activity is as follows: There is a see-through mirror and two chess towers standing on a drawn line, orthogonal to a see-through mirror (see Figure 1). The students are invited to move two towers in a way that a mirror reflection of one tower coincides with another tower. As in all action-based embodied designs, students need to solve this motor problem and then reflect and describe the rule when the towers coincide. As

designers, we expect that students come to see that the towers need to be positioned at equal distances from the mirror to coincide. The role of a teacher is non-traditional yet critical: Teachers engage students in a reflection on their sensory-motor interaction with the environment and gradual transition from naïve to mathematical discourse in describing target relations (Flood et al., 2020).

In three iterations of designing PD program, 2 to 3 teachers were engaged in a workshop activity where we gave them a chance to experience learning environment and explained embodied teaching practices previously shown as effective in embodied teaching, such as multimodal revoicing, collaborative gesturing, and others (e.g., Flood et al., 2020). Further, each teacher went through two cycles of trying out activities with students and reflecting on them with the researcher.

Transformative aspect: Emergent structures in cyclic interactions

Level of students. After creating the target learning environment (Figure 1a), Mark moves two towers on the line from the mirror. All bodies are organized around the action field, and the perceptions of three students and the teacher are coupled to Mark's actions (Figure 1b). Moreover, Maja joins the actions by physically adjusting the position of one of the towers (Figure 1c).

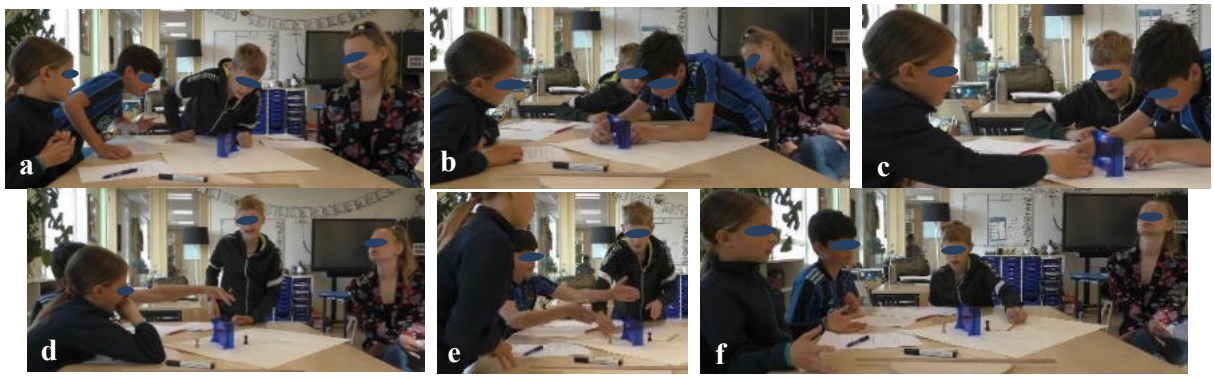

Figure l: Emergent structure of symmetry and students-teacher intercorporeal processes

Once smooth movement is achieved through *iterative attempts*, the teacher asks: "What do you see happening?" Simultaneously, very many voices and half-phrases manifest an intensive process of formulating the emerging perceptual structure: "We see that they are on each other"; "They move in the same way". Teacher asks for more specification: "When do they fall on each other?" Mark (*gesturing two sides from the mirror*, Figure 1d): "They go equally far… against the mirror". The teacher narrows the discussion even more: "And when are they precisely together"? All students together, alternating half-phrases between them, express the core idea of equidistance: "When you precisely" "same distance" "from the mirror" "the same distance" "from the mirror" (different colors mark different voices). Remarkably, their co-speech gestures gradually move away from the action space (Figure 1e,f), abstracting the *emergent perceptual structure* into a new property of symmetry.

Level of a teacher. Caty starts steering the lesson from sitting directly at the table, watching closely the children (Figure 2a); however, during the lesson, she gradually moves away from the table (Figure 2b,c), intervening only at what she calls later "critical moments". When asked at the reflection session about what she was aware of during the session, she immediately said: "I do know that what I really did consciously is to stay a little in the background (*gestures as if pushing herself back*), that I thought of 'hey, I don't want to be too much above it' (*gestures with two hands forward, above the table*), but

rather to let kids go their way and then watch also precisely what happens with the three of them." After conducting the lesson with the half-class she again recalls her emergent strategy of *sitting in the background:* "last time I was really sitting [in the background] so much (*gestures as if she is pushing herself back from the scene,* Figure 2d)." Caty did not deliberately enact the prescribed strategy in a top-down manner. Instead, the strategy *emerged* for her as an onto-epistemological entity through *iteratively* trying and adjusting her behavior to the feedback from the students, and further describing this emergent behaviour.

Figure 2: A sitting at the background strategy emerges

Level of a researcher. Equipped with the knowledge about embodied teaching practices (Flood et al., 2020), we hoped that teachers would follow our explanations in their lessons. Although exhibiting those practices from time to time, teachers barely used them as deliberate ways of acting. Instead, as we showed above, they developed their embodied ways of teaching and named them in their own ways. For us as researchers, a meta-level conceptualization *emerged*: the need for *non-linear pedagogy for teachers*. Just like we create special environments for students—*fields of promoted actions*—in which they discover in action and then describe in reflection new emergent onto-epistemological (mathematical) structures, we need to create action-reflection spaces for teachers so that embodied teaching practices emerge and reify through teachers' reflections. Although we knew principles of non-linear pedagogy ahead of the study, applying them to the case of the teacher was not straightforward. Instead, this realization *emerged in iterative attempts* to talk about embodied practices with teachers and reflect within the researchers' team on teachers' actions and reflections.

Participatory aspect: Incorporeality and affectivity in non-centralized warm participation

Level students–teacher. Fundamental co-presence of the teacher and the students is visible in our previous example (Figure 1a). Participants are coupled in an *intercorporeal functional dynamic system* (Shvarts & Abrahamson, 2023): their perception and action are directly interwoven in solving the sensory-motor problem. It is only through *warm participation* and contingent adaptivity to the bodies of the students and artifacts that Caty could distinguish "critical moments" for intervention and support. She does not just negotiate students' mental constructions, as a constructivist teacher would. Instead, she is present in the here-and-now of the students' sensory-motor discoveries.

Level teacher–researcher. Just like the co-presence of the teacher and the students is critical for the emergence of new geometrical constructions for the students, *warm participation* of the researcher is critical for the flow of the lesson and for the research discoveries. There were multiple moments when the teacher shared her *affective states* with the researcher: her laugh at students' naïve yet smart descriptions; indecisiveness in addressing unexpected situations. On Figure 1a, the students are expected to put a mirror on the line so that they "see only one line", thus orthogonally. Instead, they put the mirror directly on the line. Cathy is uncertain about how to progress and looks at a researcher

with a half-smile-half-question about what to do. The researcher makes a rotating gesture. Cathy immediately says, "Try to put the mirror in another way", which resolves the situation.

Where the direct *affective and intercorporeal presence* of the researcher and the teacher enabled enthusiastic flow of learning in a small group, in a later classroom situation, we, researchers, felt that such positive affectivity was lacking. Cathy felt the same: "in that [half-class] group <…> they were like 'how long will all of it last'". Theoretically, we could also understand what was going on: the students lacked the physical intercorporeal co-presence of a teacher in each group who would catch micro-zones of proximal development or struggles. A possible theory-based conclusion that this form of teaching is inappropriate for a classroom was interrupted by a suggestion from the next cohort of teachers, who iterated small-group lessons twice: They wanted to ask students from the small groups to become future teacher assistants, thus spreading the activity in the class. This idea would never come to us as researchers and marks *decentralization of expertise* in our research: Our researchers' theoretical expertise needs to be constantly advanced by the practical expertise of teachers.

Conclusions

In this brief overview, we show that, within each paradigm, theoretical and pedagogical visions on mathematics education are coherent with the involved research methodologies. For radical embodied and new materialist studies, we are still in the process of establishing suitable methodologies. We submit that the methodologies within the participatory/transformative paradigm might fit best: just like radical embodied and new materialist approaches, they see acquiring knowledge (in both research and education) as the process of *becoming* that leads to new onto-epistemological cuts. Research strategies of design research, lesson study, participatory action research might make a step towards new methodological standards suitable for radical embodied and new materialist studies. Such future methodologies would see (mathematics) education research as part of *transformative becoming* through *warm participatory* co-creation of *emergent* structures of future education.

[3]Department of Education, University of Oxford, UK

We explore the intersection of "experimental epistemology" in mathematics education and theoretical biology, by highlighting the disruptive work of Guy Brousseau in France and Humberto Maturana and Francisco Varela in Chile, initiated in the 1960s and 70s. We discuss the key notions of situation, structural coupling, embodiment and metaphorising and their influence on the understanding of mathematical objects. We argue that while French mathematics education has downplayed embodiment, Brousseau's approach inherently incorporates embodied cognition. Furthermore, we show how the Chilean School of Enactivism in Mathematics Education Research is in this vein actively bridging connections between mathematics education and theoretical biology.

Keywords: Experimental epistemology, mathematics, metaphor, autopoiesis, structural coupling.

Introduction

We explore the intriguing parallel disruptive emergence of "experimental epistemology" in two seemingly disparate fields: mathematics education and theoretical biology. Focusing on the 1960s and 70s, we compare the groundbreaking work of Guy Brousseau in mathematics education with that of Humberto Maturana and Francisco Varela in theoretical biology. By tracing each approach's origins, development, and core insights, we aim to illuminate their convergences and divergences. Specifically, we examine how their perspectives address the ontological status of mathematical objects and the role of embodiment and metaphor in mathematics. Key concepts such as Brousseau's "a-didactic situation," Maturana's "structural coupling," and Varela's "enaction" provide focal points for our analysis. While French mathematics education may have temporarily downplayed the importance of embodiment, we argue that Brousseau's work implicitly incorporates it, anticipating contemporary trends in mathematics and science education[1], including the burgeoning Chilean Enactivist School (Palatnik et al., 2023, p. 161; Videla-Reyes et al., 2023). We further explore the parallels between Brousseau's a-didactic approaches and enactivist perspectives, while acknowledging key differences. These include the emphasis on creating a safe learning environment within experimental epistemology of mathematics and the distinct dynamics of object creation within each framework. Ultimately, this comparative analysis reveals valuable insights with implications for both fields, opening new avenues for mathematics education research and pedagogical innovation.

[1] See https://embodiment-steam.sciencesconf.org for a recent example.

French experimental epistemology in mathematics education

In the 1960s, after a decade teaching elementary mathematics in France, Guy Brousseau (1933-2024) became outraged by the prevailing pedagogical approach, which he found abusive, punitive and segregative towards students. He later pointed out that his concern about this critical issue, which we fully shared, fuelled his research on "experimental epistemology of mathematics" beginning in the 1960s (letter, June 20, 2023). The "cognitive abuse" inherent in such teaching practices wasn't explicitly recognized in the literature until much later, though (Watson, 2021). Brousseau, influenced by Piaget, Sartre[2] and Makarenko (1951) tried to counter this cognitive abuse by making mathematical concepts exist, before formally defining them, allowing their meaning and purpose ("raison d'être") to emerge organically (Soto-Andrade and Diaz-Rojas, 2023). He designed engaging problematic *situations,* which made sense for the students and fostered their autonomous, collaborative learning. He carefully studied the *conditions* under which such situations would trigger, or not, the construction of the mathematical concepts the teacher was aiming at. This was the start of his "Experimental Epistemology of Mathematics" (EEM), a provocative terminology, later dropped in favour of the more mainstream denomination of "Didactics of Mathematics" (Brousseau, 2002). EEM later evolved into his theory of *a-didactic situations*, where the teacher steps aside, hides her didactic intent, and lets the students explore and discover on their own. In our view, his approach foreshadows von Glasersfeld's Radical Constructivism and Varela's Enaction.

A fundamental a-didactic situation for statistical inference: "Brousseau's bottle"

Designed for 4th graders ignorant of stochastics, this situation involves an embodied, interactive "mise-en-scène" going beyond typical data-driven exercises (Warfield, 2014). It was implemented at COREM[3] in collaboration with Nadine Brousseau, and later with prospective and in-service teachers. ***The teacher fills a small opaque bottle with five marbles drawn randomly from a bag with equal numbers of blue and red marbles. A small window in the bottle's cap allows students to peek at one marble at a time. She hands such a bottle over to each small group of students (typically five) in the class and asks about the number of blue and red marbles in it.*** Students, working in small groups, explore the bottle by peeking, shaking, and recording marble colours. The teacher observes their *statistical thinking* emerging in their self-organized sampling strategies. Interestingly, French kids tend to analyse data in sets of five, favouring the most frequent composition, while older Chilean students and prospective teachers track the accumulated proportion of blue marbles with each observation. Some of our groups, working with 20 series of 5 and 100 single marble observations, were bewildered to find that the mode of the series of 5 and the accumulated frequencies contradicted each other. We prompted them to look for an embodied, enactive explanation of this phenomenon, by handling concrete objects (e.g., 100 coins on a table), since a series of observations is not so tangible and concrete after all. The learners discuss how many

[2] Particularly by his motto: "L'existence prime sur l'essence" [Existence precedes essence].

[3] Centre pour l'Observation et la Recherche sur l'Enseignement des Mathématiques, in Talence, France (1972-1999).

samplings “are enough” to be able to “guess” the composition of the bottle. Eventually, they realise that there is no magic number of observations but that this is a matter of tendency, which becomes visible when they plot, say, the accumulated frequency of blue in *n* observations as a function of *n*. Crucially, the opaque bottle cannot*, and must not,* be opened. The teacher resists pleas from students to verify their guesses. When they think they have figured out the bottle’s composition, the teacher quickly empties the bottle back into the bag, so that nobody sees the colours of the marbles inside. This mimics real-world statistical scenarios where complete observation is impossible. Students eventually grapple with the possibility of a 3-2 (blue-red) bottle masquerading as a 2-3 bottle. This sparks a crucial insight: *to create a transparent 3-2 bottle and observe its behaviour under repeated sampling*: a transition from *statistical thinking* (inferring composition) to *probabilistic thinking* (predicting behaviour)! Students are encouraged to visualize their sampling process. They eventually see it as a 2D random walk: one step right for a blue marble, one step up for red. This walk, after some wild initial fluctuations, tends to settle within a wedge-shaped area, with the slope of the line from the origin to the walker's position indicating the current red-to-blue ratio.

Experimental Epistemology and Theoretical Biology from the South

Humberto Maturana (1928-2021) left Chile in 1953 to study at University College London, before completing his M.D. Lacking a formal degree, he faced obstacles enrolling in a doctoral program due to UK university regulations. He eventually found his way to Harvard, where he completed a Ph.D. in neuroanatomy and later a postdoc at MIT under Warren McCulloch, a pioneer of cybernetics. Through experiments on the visual system of frogs, Maturana proved wrong the prevailing view that vision was simply a pixel-based light detection mechanism. His research demonstrated that neurons respond to specific features of the visual world (like edges, movement, bugs, ...) Thus, the brain, instead of analysing a set of values in a matrix of intensities, does something radically different as it filters the visual stream according to predetermined patterns generated by evolution and ecology. Thus “to view” is isomorphic to “existing in a concrete manner” (Uexküll, 1926). This contradicted the prevailing "one-way street" metaphor of perception, where the brain computes an objective reality from sensory data. In 1963, Maturana met Heinz von Foerster, who invited him to his famous *Biological Computing Laboratory* (BCL), where he wrote his seminal report “*Biology of Cognition”* (BC) (Maturana, 1969). Maturana claimed that the brain is *not* a computer decoding “reality”, instead it constructs it, in an endless helix of sensory-motor *correlations* that *become* the objects populating the Umwelt of each organism. A still novel idea today, but nonsensical in 1969. After returning to Chile in 1969, Maturana and his former student, Francisco Varela (1946-2001), created the theory of *Autopoietic Systems* by translating the idea of sensory-motor correlations to metabolic networks. This theory (Maturana & Varela, 1973/1980) posits that the main property of living systems is that they continuously *self-fabricate* themselves and that this *self-fabrication entails autonomy*. The impact of these ideas is still swelling: more than half a million web references and over 5,000 technical articles use the notion of autopoiesis, which is central to many theories about the origin and nature of living systems (Cornish-Bowden & Cárdenas, 2020). Furthermore, by blending autonomy and the creation of sensory-motor correlations, Maturana and Varela created competing visions on how this construction happens: *structural coupling* and *enaction*. In retrospect, BC opened avenues for ideas

like sensory-motor correlations, metabolic closure, enaction, structural coupling, epigenetic niche, and language as a tool to recursively generate coupled behaviour (Meyer & Brancazio, 2023).

How Biology of Cognition informs Mathematics and Mathematics Education

The core idea of Biology of Cognition (BC), sketched in Maturana (1969) and further developed in Valdes-Zorrilla et al. (2023), is that all "objects" (a cat, Pythagoras theorem, HIV…) arise from our coupling with an external medium that continuously shapes our metabolism. Objects are not properties of the medium but properties of the Perception-Action trajectories every living being engages in with respect to its medium. Mathematical structures are not ideal entities independent of human observers, they arise as *invariants* of some particular flow of interactions with our medium**,** which *is not* a property of the world. Every object is a sensorimotor correlation constructed as we interact with our medium. Mathematical learning should prioritise human experience. Instead of watching properties of pre-defined entities, learners should experience how those properties arise from basic distinctions that they spontaneously make all the time. This echoes Sartre's "existence precedes essence, " which inspired Brousseau. According to BC, every distinction is *relational* and based on the complex properties of self-fabricating metabolisms, echoing Barad (2007): "There are no pre-existing individual entities at all, including us; the world is composed of *relations* between beings." We tend, though, to focus on *binary* relations and operations, very likely because we have two hands[4]. We may see binary relations as connecting edges between not yet existing points (Paton & Sinclair, 2024). But many meaningful relations are not *binary*, but *n-ary,* so a broader visualisation emerges: *higher-dimensional relational domains*, whose *boundaries* consist of points, segments, and so on. The familiar individual objects in our Umwelt (Uexküll, 1926) are then just the *0-dimensional skeleton* (vertices) of the boundary of those higher-dimensional relational domains we are ill-equipped to fathom. BC reminds us that the way we relate with our medium is shaped by our embodiment as vertebrates, limited by our relatively small nervous systems. Other life forms, like Hoyle's Black Cloud, would construct their Umwelten in ways we can scarcely imagine. Ultimately, BC emphasizes that two fundamental properties of living systems (metabolic closure and their existence as cognitive machines) are fundamentally linked. *It is thus impossible to disentangle the biological from the cognitive aspects, as cognition and living are two inseparable facets of organisms.* We develop theories by using *experience* to explain *experience*. For instance, we use our experience of unsupported objects falling to the ground to explain why some points of light in the night sky change position. Ptolemaic astronomy, based on perfect circular motion, even with adjustments couldn't explain the observed orbits. Galileo, Kepler, and Newton introduced a new metaphor: undisturbed masses move in straight lines, and the force ruling planetary motion is the same force that causes an apple to fall. This idea, that *experience explains experience*, can be extended from physics to mathematics by broadening the notion of experience to include theoretical experiences. Non-Euclidean geometries, like Lobachevsky's, redefine lines as the shortest paths (*geodesics*) between two points. In the Euclidean plane, these are just straight lines, but in the hyperbolic plane, modelled by the unit disk with a specific metric, "lines" are arcs of circles perpendicular to the disk's

[4] Indeed our bodies shape our cognition. Interviewing octopii or slime moulds would be most commendable…

boundary. The concept of a line as a *geodesic* is experiential and depends on the ambient metric. This experiential approach allows us to understand lines in other spaces, starting from lines in the Euclidean plane. For example, on a sphere, “lines” are maximal circles, like the Equator.

A-didactic situations from the viewpoint of Biology of Cognition.

We set up a fundamental a-didactic situation based on a *random walk* (a baby avatar of *Brownian motion*), where probabilities may emerge idiosyncratically metaphorised as *portions* of the walker, enabling an embodied approach to probability. Specifically, we consider the following 2D version of the 1D random walk of a frog in Soto-Andrade and Diaz-Rojas (2023), which has been worked out with various learners at the University of Chile (first-year humanistic students, prospective mathematicians, prospective mathematics-physics teachers, in-service primary school teachers). ***A puppy, fittingly called Brownie, with a nose for trouble, escapes from home to avoid a bath. Disoriented by the city traffic’s cacophony and smells, she randomly chooses one of the four cardinal directions at each intersection, sprinting for four blocks before collapsing in exhaustion. Her worried owner needs help finding Brownie and estimating how far she might have travelled.*** Students, working in small random groups, discover that Brownie can reach some corners but not others. Roughly half of them initially believe all reachable corners are equally likely; others disagree, noting that some corners are reached by multiple paths. Statistical simulations help most students rank corners by likelihood. To quantify these likelihoods, some students analyse simulation frequencies, while others try counting paths à la Laplace. The latter notice they would have $4^4 = 256$ possible paths, from which the favourable ones need to be extracted! There are, however, more intuitive and efficient *metaphorical approaches* to this quantifying. Under some minimal prompting like: *What else, more concretely, could you imagine instead of this (rather abstract) fair random choice between the 4 cardinal directions?* Some metaphors emerge idiosyncratically: The *Solomonic Metaphor* (Brownie splits into four at each corner, with each part taking a different direction); the *Hydraulic Metaphor* (Brownie flows like water, dividing itself equally among the four streets at each intersection); the *Splitting Pack Metaphor* (unleash a pack of puppies from home, fittingly 256 in this case, which split evenly into fourths at each corner). After prompting, typically, one or two out of thirty “see” Brownie splitting into fourths. In-service teachers are not so prone to metaphorising - didactical contract obliges (Brousseau, 2012). These metaphors allow quantifying corner likelihoods.

Embodiment in Experimental Epistemology

While embodied cognition isn't as explicit in EEM as in BC, Brousseau's approach is far more embodied than traditional Cartesian French mathematics education (Soto-Andrade & Diaz-Rojas, 2023). It rejects the "conduit metaphor" of teaching as transmitting knowledge and challenges the notion of mathematical objects as revealed pre-existing truths, “parachuted from Olympus”, whose definitions are to be recited, transmitted and applied to execute tasks. This parallels Maturana's simultaneous rejection of the well-entrenched metaphor of perception as a “one-way street” in cognitive science. Brousseau saw instead mathematical objects and processes as emerging from the embodied actions of learners in *situations*. EEM in our research even connects with embodied *non-human* cognition. Indeed, in Videla-Reyes et al. (2023, pp. 259–276) we showed how in *stochastic*

dance dancers simultaneously enact all possible unfoldings of a random walk, mirroring the maze-solving behaviour of slime moulds (Nakagaki et al., 2000) and in *flow of motion dance*, all possible orbits of a *deterministic* dynamical system in a finite cyclic universe. Structural Coupling sheds new light on "Brousseau's bottle", where both sampling strategies embody the *ergodic principle:* the "universe average" equals the "long time average". Ergodicity is indeed a powerful metaphor relating space (universe) to time, which needs to be enacted to have meaning. The amazing equivalence between *ensemble sampling* and *time sampling* and the equality "ensemble mean = time series mean" need a continuous confrontation between perception (experience) and the result of some actions promoted by this experience, i. e. engaging in a perception-action loop. Lived experience allows us to check the proportion of blue balls without "opening the box": students could engage in a betting game, trying to predict the percentage of blue balls in the next 100 observations, plus minus 5%, say.

Metaphorising in Experimental Epistemology

We prefer "metaphorising" (an active process) to "metaphor" (an object "out there"), to avoid abusive *reification* (Sfard, 1997). Rather than Lakoff and Nuñez's (2000) *metaphorising* of metaphor as an inference-preserving mapping from a concrete source domain into a more abstract target domain, we favour Sfard's (1997, p. 355) view of metaphor as a dynamic, back-and-forth exchange between source and target in a circular, *autopoietic* way. In enactivist perspectives, metaphorising is just "the tip of the iceberg" of a fundamental embodied *biological process* enabled by *structural coupling* (Maturana & Varela, 1980). Aristotle, limited by his time, only partially grasped metaphorising as renaming. Nowadays, we metaphorically say that metaphorising is *looking* at something and *seeing* something else, a sort of controlled *hallucinating* in the sense of Seth (2021), as exemplified in Brownie's random walk. Metaphor is not just a rhetorical device, but a powerful *poietic* cognitive mechanism, enabling us to *construct* new concepts and theories (recall Darwin's "tree of life" metaphor). See Abrahamson et al. (2012); Lakoff and Nuñez (2000), Sfard (1997, 2009), Soto-Andrade (2020). We promote learners' spontaneous, bottom-up generation of metaphors over prescriptive, top-down uses by teachers. Metaphors emerge from a learner's active engagement with a situation, not in the void. This is mirrored in Chaplin's "The Circus" (used by Brousseau as a start-up for his didactics courses), where Charlot struggles to be funny on command, yet effortlessly elicits laughter through spontaneous action. Moreover, "the fish is the last one to see the water"… or "the metaphor", as in the case of the second nature metaphor "teaching is transmitting knowledge."

Conclusion

We have explored the convergence of disruptive parallel "experimental epistemologies" in mathematics education and theoretical biology. We highlight how both emphasise a relational and metaphorical construction of knowledge, exemplified by our stochastic examples. Connecting Biology of Cognition (BC) and Experimental Epistemology in Mathematics (EEM), we see that BC focuses on how a living being constructs the objects within its Umwelt, while EEM aims to trigger a similar object construction in a learner's Umwelt through "a-didactic situations", which challenge them to discover mathematical concepts as necessary tools for navigating problems, much like organisms adapt for survival. These situations amount to "pushing a non-swimmer into a pool with a

safety pole nearby", since they should be genuinely problematic, requiring exploration and experimentation. We should not believe, though, that learners construct in their Umwelten the object we have in mind. We glimpse the variety of constructed objects when we let the learners "do anything they like" with a bunch of sticks, for example. Some build structures, others throw them in the air… Indeed, traditional math education ignores the notion of Umwelt. Now, while both approaches share core principles, EEM operates within the constraints of a classroom, a unique environment that must balance challenge with safety, needing careful consideration of time, space, and the emotional needs of learners, to provide a safe haven for them. Mathematical education, like life itself, is less about solving problems and more about experiencing reality. By blending insights from mathematics and biology, we explore how new ideas emerge—through confronting our existence or translating concepts across contexts. This challenges traditional mathematical thinking by proposing that understanding the creation of mathematical ideas requires considering mathematics and biology as equal partners. However, this approach's future remains uncertain, as our understanding of structural coupling is still limited, and preconceptions about the *a priori* existence of concrete or ideal objects must be replaced by intuitions that need to mature for a while before becoming helpful techniques.

Spatial perspective switching in group embodied activities

Jennifer Way

University of Sydney, Australia; jennifer.way@sydney.edu.au

Although evidence for the value of embodied approaches to representing mathematics concepts continues to accumulate, limited attention has been given to the complexities of children's engagement in group embodied representational tasks. This paper explores the observable responses of 5-to-7-year-old Australian children to group tasks requiring cooperation in the creation of large-scale mathematical representations using their bodies. It is argued that this type of task requires perspective-switching by at least some of the participants and involves the emergence of shared coordinated action. Given the rarity of research that draws together these task characteristics, this study provides a starting point for further investigation of the significance of spatial perspective switching in group embodied activities for children's learning.

Keywords: Mathematics, embodied representation, spatial perspectives.

Introduction

The current study focuses on the type of teaching/learning task that engages each student in using their body as a component of a large-scale mathematical representation, thereby evoking spatial awareness and reasoning, including perspective-taking. A social dimension is added to such tasks when forming the representation relies on the interaction and cooperation of more than one child. The aim of this paper is to provide an initial exploration of the role that spatial perspective switching might play in cooperative group activities involving the body movement of children around age 6 years. The study itself is focused by the question, *what can be inferred about the role of 'spatial perspective switching' from observing children's actions during the creation of group embodied representations?*

Spatial perspectives

Drawing on embodied cognition theory, the learning process can be described as involving multidirectional loops of perception, action and cognitive processing, with emphasis on the essential role of 'action' (Kiefer & Trumpp, 2012; Kim & Sankey, 2022). Integral to many aspects of learning is the development of spatial awareness, flexible spatial reasoning, spatial memory and associated spatial language (Bruce et al., 2017). It has been well argued that embodied experiences are fundamental to learning and memory, including the development of spatial reasoning (de Freitas & Sinclair, 2013; Kiefer & Trumpp, 2012). The term 'spatial reasoning' refers to "the ability to recognize and (mentally) manipulate the spatial properties of objects and the spatial relations among objects" (Bruce et al., 2017, p. 147). An aspect of 'spatial relations' that is of particular interest in this study is the phenomenon of switching spatial perspectives. In this paper, the term 'switching spatial perspectives' is used to encompass a range of changes in position, orientation and viewpoint by the learner (physically or through visualisation), in the context of physical engagement with an environment.

One way that switching spatial perspectives occurs is shifting between an egocentric frame of reference and an allocentric frame of reference (Avraamides & Kelly, 2008; Dackermann et. al., 2017). In an egocentric spatial perspective, a person thinks and acts in relation to the current positioning of their own body, giving particular meaning to concepts like forward, right, and up. An allocentric spatial frame of reference requires perceiving objects in the environment in relation to other objects and allows a person to create mental maps to navigate the three-dimensional environment, and also to create and interpret two-dimensional representations, such as maps (Shusterman, & Li, 2016). Different parts of the brain are activated during egocentric processing and allocentric processing (Galati et al., 2010), and spatial information is stored in memory according to the spatial frame of reference through which the spatial representation was formed (Galati et al., 2010; Ruggiero et al. 2016). Egocentric-based spatial representations are easier to retrieve from memory than allocentric-based representations (Ruggiero et al. 2016).

From a child developmental stance, the classic view is that egocentric spatial memory precedes allocentric representations (Acredolo, 1978; Piaget & Inhelder, 1967), although evidence of the ability of 3-to-5-year-olds to work with allocentric frames reference has been found (Vasilyeva & Lourenco, 2012). The key transition point appears to be development of a child's capacity to efficiently integrate egocentric and allocentric perceptions and experiences of an environment, which seems to emerge around age 6 years (Nardini et al., 2006; Vasilyeva & Lourenco, 2012).

Triggering spatial perspective switching

Linked to ego/allocentric switching is the ability to move between an on-ground visual-spatial perspective (from one's own perspective) and a from-above visual-spatial perspective (looking down on the scene), either through actual physical reorientation or through visualisation and mental imagery. For example, Ferrari and Soldano (2023) noted that when third-grade students were explaining, using words and gestures, the movements that two small robots (bee-bots) must perform to create symmetrical paths, one child seemed to switch between a bee-bot's view and bird's eye view, and at one point perhaps integrated the two perspectives to conceptualise the mirrored paths in a holistic way.

Dackermann et al. (2017) identified the role of interactions between different regions of personal space, and the integration of egocentric and allocentric frames of reference as mechanisms in achieving positive learning outcomes across several studies with 4-to-8-year-olds engaged in embodied spatial-numerical representations. For example, when interacting with a large-scale number line on the floor, a child might stand on a starting point and step forward to reach the next number. This is essentially an egocentric experience with the child's actions within their near space (one step). However, a task requiring the enactment of an addition or subtraction would require consideration of a greater portion of the number line, thereby triggering an allocentric perspective and an extension of the action space beyond their near space. More complex switching back and forth between (or integration of) frames of reference would be required by a task such as estimating the location of 63 between the marked locations of 0 and 100 (with no other markings present). Dackermann et al. (2017) advocate that participation in embodied tasks such as these enable the mapping of number concepts to spatial representations and build relational knowledge about

numbers. These examples of tasks with robots and floor number lines refer to perspective switching in individual actions, rather than in a group situation with social interaction.

Socio-kinesthetic interaction

It is generally assumed that the egocentric perspective comes naturally to humans and would have primacy in most situations. This notion is challenged by Tversky and Hard (2009) who found that the "mere presence of another person in a position to act on the objects" induced adult participants in their study to "describe the spatial relations from that person's point of view" without prompting (p. 124). Furthermore, "When the query about the spatial relations was phrased in terms of action, more respondents took the other's perspective than their own" (Tversky & Hard, 2009, p.124). Much of the embodied learning research with children has focused on the individual, but perhaps more attention should be given to the influence of the presence of other children in the embodied learning situations if we are to understand social contexts of classrooms.

Cooperative group tasks impose different demands on the creation of embodied representation of mathematical concepts than individual tasks. Shoval (2011) studied the behaviours and achievement of 158 second and third-grade children who engaged in learning about angles through body movement in cooperative groups using a length of rope as a representational object. Two of the five types of learning activities were "socio-kinesthetic interaction" and "sustaining the movement-aided learning activity" (Shoval, 2011 p.453). The most significant predictor of improvement in achievement was the *sustained movement-aided learning* activity, which is a combination of all the studied behaviours, including individual movement, cooperative movement, contact with an object, observing, speaking and listening (Shoval, 2011). Of particular interest in the present study is the activity of *socio-kinesthetic interaction*, which is characterised by two behaviours, cooperative movement with others and cooperative contact with physical objects pertinent to the learning activity (Shoval, 2011). *Socio-kinesthetic interaction* was positively correlated with learning, but with lower significance in comparison to other activity-types in Shoval's study. It is possible that the impact may have been moderated by the fact that social skills are still developing in young children (Slavin et al., 2003). It is also possible that attending to their own individual movement as well as coordinating with movement of other group members, challenged the capacity of some children to switch between or integrate egocentric and allocentric frames of reference. De Freitas et al. (2019) discuss the emergence of "embodied shared response-ability" in 15/16-year-old mathematics students collaborating to produce a graph via movements using WiiGraph software. The successful creation of the complex representation necessitated the development of "transindividual sympathy" that reflected the dynamic nature of the mathematical concepts (de Freitas et al., 2019). Perhaps younger students can also achieve the social connections needed for cooperative action.

Method

The context for this study is the *Embodied Learning in Early Mathematics and Science* project (2022-2024). The goal of Phase 1 (held in 2022) of the project was to investigate ways in which teachers could translate the findings of research on embodied learning from the fields of psychology, neuroscience and education (see Way & Ginns, 2024) into their mathematics teaching practice with 4-to-8-year-old children. The researchers worked collaboratively with teachers in one school in a

socio-educationally disadvantaged suburb of a major city. The school had just reopened to external visitors after the COVID-19 'lock downs', and the participating children had experienced limited social interaction with their peers for about a year. As part of the investigation, videos were made to record some of the embodied activities that were perceived by the teachers to be productive learning experiences. The current study returns to these videos as a data source for exploring a new question about the role of spatial perspective switching. Two video-recorded episodes sourced from two lessons were selected for this paper using the following criteria.

a) The focus of the tasks is the creation of a mathematical representation involving whole-body movement with the intention of promoting conceptual understanding.
b) The representational space has been 'scaled up' so that students can step into a frame of reference and become movable parts within the emerging representation.
c) Social interaction and some level of co-operation and/or collaboration to align the parts of the representation in an appropriate configuration is required for successful completion.

The data are presented as images from the videos and descriptions of the main actions of both individuals and the group as the task evolves. In all the activities, the teachers gave minimal instructions and allowed the children time to make their own decisions before deciding to intervene with suggestions for actions.

Analysis and interpretation of episodes, through repeated viewing of the videos, was guided by the following key ideas identified by previous research:

a) Embodied tasks may involve egocentric and/or allocentric spatial perspectives (e.g., Avraamides & Kelly, 2008; Dackermann et al., 2017)
b) Flexible switching between spatial perspectives may aid conceptual development and successful task completion (e.g., Dackermann et al., 2017; Ferrari & Soldano, 2023)
c) Thinking about one's 'far space' rather than only 'near space' may be a trigger for shifting from ego- to allo-centric spatial referencing (Dackermann et al., 2017)
d) The presence of others in a task may trigger perspective switching (Tversky & Hard, 2009)
e) Cooperative movement with others and cooperative contact with physical objects are pertinent to learning (Shoval, 2011)
f) Some 6-year-olds may not have sufficiently developed social/collaborative skills to co-ordinate their movement and positioning in group representation tasks. (e.g., Nardini et al., 2006; Vasilyeva & Lourenco, 2012)

These key ideas provided the basis for interpreting the actions of the children during their shared creation of a mathematical representation and for inferring the meaning of those actions.

Episode 1: Be a dot

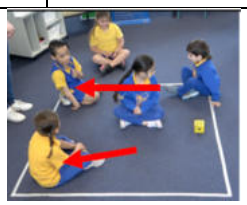
In this task 5/6-year-olds were expected to cooperate to recreate the dot pattern on a dice by positioning their bodies. When this task was first attempted, there was no square marked on the floor. When the children were asked to arrange themselves to 'be the dots on the dice' they were confused. The researcher and teacher quickly used masking tape to mark a large square on the floor to represent the face of a dice and restarted the activity.

Table 1: Episode 1 data, incorporating Figures 1A, B, C, D, E

A. The teacher rolls a 5 on the dice and asks the children to look at the number and pattern of dots.

B. Teacher invites the children to each become a dot on the dice. Three children sit inside the square but do not appear to be representing a particular dot.

C. One child leaves the square and another comes in. The teacher suggests they look at the pattern on the dice and they turn to look at the dice then glance around the square frame.



D. Without discussion about exactly which dice-dot they will 'be', two children move decisively from their original positions into two corners of the square, and a fourth child enters the square to sit in a third corner. The child who sat near the centre at the beginning remains there, turning her head and watching the other children moving around her.

E. The girl who previously left the square, returns to sit in the fourth corner to complete the pattern of five dots. The task was completed in under one minute.

Interpretation

The square marked on the floor provided a necessary environmental 'object' with which the children could interact. At first the children acted individually and presumably were perceiving an egocentric spatial frame. The prompt from the teacher appeared to help the children connect self to a dot and a significant shift to an allocentric (or 'from above') viewpoint seems to have occurred for the two children who relocated themselves to two corners of the square. This action seemed to trigger action in the remaining two children who positioned themselves appropriately in relation to others and to the square. Notably, all this occurred without the children giving verbal instructions to each other.

Episode 2: Numeral sequencing

This task captured the 6/7-year-old children's first attempt at sequencing consecutive counting numbers by physically forming a line. The teacher handed each child a numeral card (1 to 15) and asked them to organise themselves in order from smallest (teacher points near the wall) to largest (teacher gestures along a line painted on the playground). See Table 2.

Table 2: Episode 2 data, incorporating Figures 2A, B, C, D, E

A. The children mill about in a cluster next to the wall, looking at their own numeral card and not speaking much. The children holding 1, 2 and 3 position themselves next to the wall and do not move thereafter.

B. The teacher and two of the girls (holding 4 and 15) begin urging everyone to spread out. The children begin looking at each other's numerals and some children begin moving away from the cluster to stand beside a numeral consecutive to their own.

C. A few children begin pointing and giving instructions, "You have to go down there", "Find number 9"

D

E

D. The girl holding 10, moves further along the line on the ground and stands alone. Many of the children now stand facing the same direction, shoulder to shoulder along the line on the ground and turn their heads to the left and right looking up and down the line. Three children have stepped out of the line and face the other children while checking the sequence of numerals. The girl (holding 15) begins counting out loud, pointing to each child along the line to check the sequence and pauses while 10,11 and 12 get into position.
E. Everyone seems satisfied the task is complete.

Interpretation

At first the children lacked a strategy as they only had control of one numeral and perhaps could not visualise what the line would look like, suggesting egocentric operation. A few individuals began to influence the others through their own relative positioning or verbal and gestural instructions. A shared understanding of which direction to face appeared quite suddenly. Number-10-girl seems to have envisaged the whole length of the 'line' to estimate a proportional distance of 10 from 1 – thus thinking beyond 'near space'. The encouragement to spread out and find numbers before or after their own, appeared to trigger comprehension of the configuration required and the children moved into position, though children focusing only on the number before/after their own may have been thinking about 'near space', hence taking an egocentric perspective. The children providing some leadership seemed to be the ones who could take an allocentric perspective quickly, to imagine the entire number sequence along the line.

Discussion

Analysis of the two episodes indicates that 'spatial perspective switching' was integral to the creation of group embodied representations. The socio-kinesthetic interaction (Shoval, 2011) necessitated by the cooperative group task was anchored in spatial relationships between individuals, objects and the whole group. In Episode 1, the children needed the square on the floor to anchor their spatial representation and had to coordinate the arrangement of the dots on the dice with both their own position in the square and their position relative to each other. In Episode 2, the floor-line anchored the representation, and the children had to co-ordinate their position on the line in relation to the number before/after their own (egocentric perspective, near space) (Dackermann et al., 2017). Some

of the children also needed to take an allocentric perspective in the creation of the representation. This enabled "sustaining the movement-aided learning activity", which Shoval (2011) found to be a significant predictor of learning. Interestingly, children's co-operative actions were mostly triggered by observing the actions of others, rather than verbal communication. Both tasks challenged the children's capacity to translate their number knowledge into a spatial representational, yet, collectively, they succeeded with minimal teacher direction.

This study appears to be unique in that it draws together embodied mathematical representation, scaled-up representational space and social interaction with young children, to raise the idea that shifting between egocentric and allocentric spatial perspectives may play an important role in the dynamics of embodied learning and the development of mathematics concepts. The argument is currently tentative, but this study provides a starting point for further research into the role of spatial-perspective-switching in group embodied activities.

Developing functional thinking through bimanual movements

Hang Wei, Rogier Bos and Paul Drijvers

Freudenthal Institute, Utrecht University, Utrecht, The Netherlands; h.wei@uu.nl

This study investigates the role of bimanual movements in developing functional thinking (FT) through digital-embodied nomogram tasks. Two teaching experiments, conducted in the Netherlands and China, involved a total of 76 ninth-grade students. Using a mixed-methods approach, the research combines quantitative correlation analyses with qualitative examples and mini-interviews. The findings reveal that initial FT levels, as measured by pretest scores, are significant predictors of student performance in bimanual tasks. Higher pretest scores were associated with shorter times to achieve fluency and less time spent in the fluency phase, whereas students with lower pretest scores required longer time in the fluency phase for extended exploration. Mini-interviews further showed that students with different FT levels used different strategies. Overall, our results suggest that bimanual tasks effectively support the development of FT across different student groups.

Keywords: Bimanual movements, functional thinking, digital-embodied tasks, mathematics education, nomogram.

Bimanual movement in functional thinking

The development of functional thinking (FT) is an important learning goal in mathematics education, involving a fundamental understanding of functions and continuous variation and covariation of quantities. Developing FT poses a significant challenge due to its abstract nature, especially the covariation aspect. As noted by Thompson and Carlson (2017), fostering covariational reasoning is crucial not only for FT but also for broader mathematical development. Studies have shown that students often struggle to grasp the dynamic nature of covariation, especially when required to visualize or mentally manipulate relationships between quantities (Castillo-Garsow et al., 2013; Thompson & Carlson, 2017). A taxonomy of covariational reasoning levels proposed by Thompson and Carlson (2017) provides a framework to understand these challenges, describing a progression in reasoning about covariation. At the lowest levels, students either fail to coordinate quantities (L0) or simply observe that changes in one quantity correspond to changes in another (L1). Intermediate levels involve describing general patterns of change (L2) or coordinating specific increments between quantities (L3). Higher levels require envisioning simultaneous changes over fixed intervals (L4) or, at the highest level, perceiving smooth, continuous covariation (L5). Many students struggle with the cognitive demands of transitioning from discrete reasoning to continuous, dynamic thinking, particularly in reaching the advanced understanding required at L4 and L5.

To support students' development of covariational reasoning within FT, researchers and educators have turned to embodied learning, an approach that emphasizes the connection between physical experiences and cognition. This approach is based on the idea that learning is deeply rooted in the body's interactions with the environment. According to Lakoff and Núñez (2000), mathematical thinking itself is inherently embodied, meaning that our understanding of abstract concepts is grounded in our sensorimotor experiences. Bimanual movements—coordinated actions involving both hands—can offer promising opportunities in this context. Research has shown that such

movements can help students grasp mathematical concepts by providing a concrete, physical experience of abstract ideas (Abrahamson et al., 2014; Jaber et al., 2024; Walkington et al., 2014). For instance, Abrahamson et al. (2016) demonstrated how primary school students' understanding of proportions improved through bimanual tasks that involved physically manipulating objects to represent proportional relationships. This finding aligns with broader research on embodied cognition, which suggests that engaging the body in learning activities can enhance understanding and retention of abstract concepts (Alibali & Nathan, 2012).

The potential of bimanual movements in supporting covariational aspects of FT has also been explored in multi-representational learning environments (Pittalis et al., 2024). These environments integrate different forms of function representation, such as graphs and tables, to help students develop qualitative FT, which includes interpreting covariation through visual elements like the shapes of graphs. Rolfes et al. (2022) found that learning with graphs provided richer insights into covariation, supporting the idea that graphs, by visually presenting how quantities vary simultaneously, facilitate a deeper understanding of covariation (Carlson et al., 2002).

Building on this, the purpose of this study is to explore how bimanual movements on a nomogram—a representation consisting of two parallel number lines connected by arrows—can foster FT by providing a tactile, kinesthetic learning experience. Specifically, we address the research question of how students' bimanual activity in digital-embodied tasks relates to the development of their FT.

Method

Participants

This study involved 76 grade-nine students with comparable prior education from two international schools in the Netherlands (37) and China (39). These students were assessed through a pre and posttest and did tasks from three learning modules. To ensure uniformity in the research conditions, all participants received the same instruction and engaged in identical tasks.

Instrument

This study focused on the second of a series of three learning modules designed within the Numworx platform (https://bit.ly/bimanual2). Numworx is equipped with multi-touch and real-time feedback capabilities, making it an ideal tool for supporting the understanding of functional relationships through bodily interactions. Students were invited to work on tablets, using bimanual dragging motions to explore seven different function nomograms.

Data processing

Bimanual data

The bimanual movement data was collected from the Numworx log files, which captured every millisecond location of the two draggable points (representing two hand positions) on the nomograms. This data enabled the classification of student bimanual movements into two phases: the *Exploration* phase and the *Fluency* phase (Tancredi et al., 2021). In the *Exploration* phase, students initially explored the movement rule and made trial attempts to understand it. This phase reflects their early efforts to grasp the task and experiment with the hand movements. In the *Fluency* phase, students'

movements became more consistent and smoother, which could indicate that they had developed a better practice of the bimanual coordination and better understanding of covariation aspect of FT.

To distinguish between these two phases, we first calculated the moving average of the differences between the actual and target positions of the right hand, with the target position determined by the left hand's location. The target position varied depending on the specific task, reflecting the different functional relationships. For each task, we set a task-specific threshold to differentiate the phases based on the difficulty of each task. Movements where the difference fell below the threshold were classified as part of the *Fluency* phase, indicating that the student had achieved accuracy in coordinating the two variables.

However, to prevent mislabeling brief moments of fluency, any fluency period lasting less than three seconds was reassigned to the *Exploration* phase, differing from the method used by Tancredi et al. (2021). The variable Ly represents the left hand's movement, while Ry represents the right hand's movement. By plotting these hand positions over time, we were able to identify detailed trajectories of the student's bimanual movement process, specifically differentiating between the *Exploration* and *Fluency* phases.

Pretest and posttest data

The pretest and posttest were designed to measure student's FT level using a paper-pencil format. The validity of the assessment tool was established through a multifaceted approach, incorporating expert reviews from both experienced mathematics teachers and researchers. Each test comprised 15 items, scored on a 5-point scale, with a maximum total score of 75 points. The posttest mirrored the pretest in item structure and content focus but featured variations in numbers or data. The pilot of the pretest to 51 students allowed for a classical test analysis, including calculations of p-value, variance, item reliability index (Rir), and item-total correlation (Rit), culminating in a Cronbach's alpha (α) of 0.71. To ensure the reliability of scoring the pretest and posttest, two independent coders evaluated the work. Following their independent assessments, a consensus discussion was conducted to reconcile any differences. The inter-rater reliability for these assessments was quantified using Cohen's kappa, which yielded coefficients of 0.91 for the pretest-posttest comparisons.

Correlation test

We conducted a Spearman's Rank Correlation test to explore the relationship between bimanual task performance indicators—time to fluency (TTF) and fluency time sum (FTS)—and FT improvement (pretest to posttest). This non-parametric test was used due to the non-normal distribution of bimanual data, guided by two hypotheses: ***H*1**: advanced FT levels relate to shorter TTF; ***H*2**: advanced FT levels relate to a longer FTS.

For the correlation analysis, we excluded datasets from students who did not reach a fluency phase, as their TTF could not be measured. Additionally, we removed outliers to ensure the accuracy and reliability of the results. For TTF, we excluded data points greater than 150 seconds, and for FTS, we excluded data points shorter than 3 seconds and longer than 400 seconds. After these exclusions, approximately 250 valid samples across seven tasks remained for analysis.

Mini interviews

To capture students' learning progression along the HLT (Wei et al., 2024), we conducted brief, one-to-two-minute mini interviews during the teaching experiments. The aim was to encourage students to reflect on and expand upon their written responses in the answer boxes within the learning environment through open-ended questions and follow-up prompts, promoting deeper engagement with their learning processes (Drijvers, 2003). Conducted by the research team, these interviews were held individually or in pairs, allowing insight into students' problem-solving processes and reasoning.

Results

In this section, we present two cases to explain the bimanual task and to clarify the interpretation of the exploration and fluency phases. Next, we present the results of correlation analyses between bimanual movement indicators and pre and posttest outcomes.

Case study

Figure 1 presents a student's hands movement trace for function $f(x) = x - 3$. He moved the right point upward significantly without getting green feedback, causing a decrease in movement speed and a slight repositioning of the right point. Subsequently, he realized the necessity of moving both points in parallel, which led to the achievement of the *Fluency* phase. As the student approached the top of the screen, he paused and began exploring different directions, entering a second exploration phase. Finally, both points were moved downward simultaneously with green feedback.

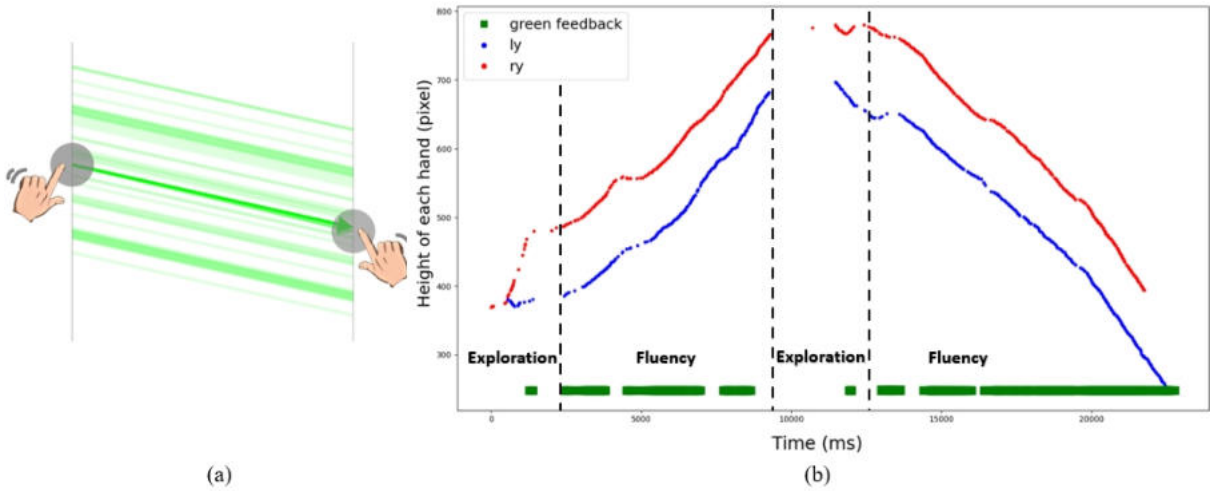

Figure 1 (a) Bimanual movement of $f(x) = x - 3$; (b) A student's hand movements across phases

For the task in Figure 2, students were assigned to first complete the nomogram of the function $f(x) = -x$. This student also went through multiple learning phases. Following the initial *Exploration* phase, his hand movements displayed a pattern: his right hand moved upwards while his left hand moved downward simultaneously. In the subsequent *Exploration* phase, he adopted an inverse approach, moving his right hand downward while moving his left hand upward, showing a geometrically symmetrical movement according to the properties of the target nomogram. After

navigating the entire screen, he described his findings in the answer box: 'To get the green line, I moved the two dots in opposite ways which created this pattern'. Many students also noted the intersection point on this nomogram and used it as a reference to adjust their movements.

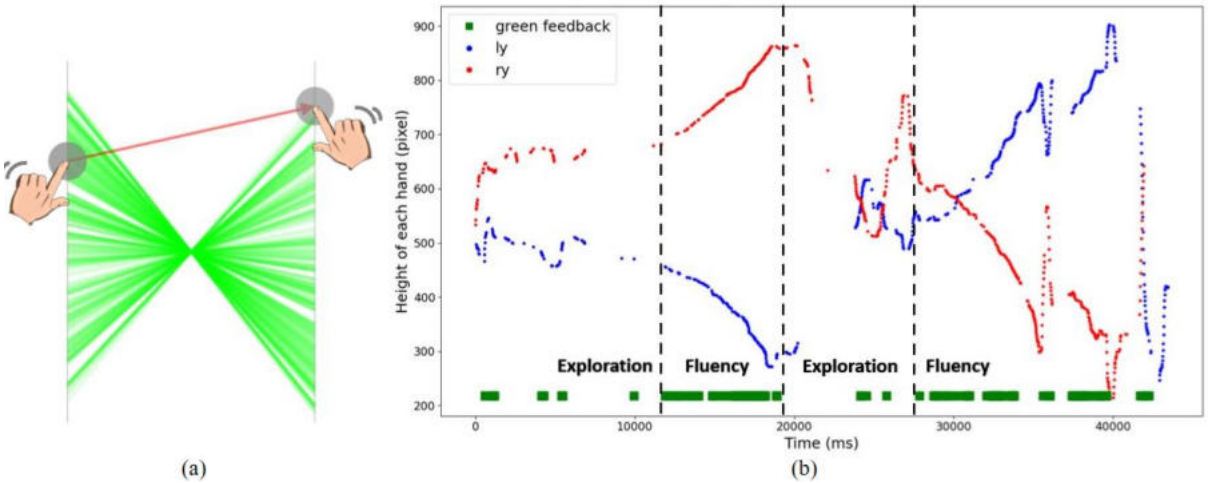

Figure 2 (a) Bimanual movement of $f(x) = -x$; (b) A student's hand movements across phases

Correlation analysis

This section presents the results of the correlation analysis between bimanual movement data and the pretest and posttest scores, which reveals students' FT levels.

Table 1: Correlation test between bimanual indicators and test scores

	Pretest	Posttest	Overall Improvement
Time to Fluency (TTF)	r = -.28, p= .02	r = -.25, p= .04	r = .11, p= .37
Fluency Time Sum (FTS)	r = -.45, p< .05	r = -.33, p< .05	r = .28, p= .05

Concerning TTF aspect, both pretest and posttest scores are negatively correlated with TTF. The stronger correlation with pretest scores indicates that initial FT levels are a more robust predictor of how quickly students reach fluency, supporting ***H1***. The positive but non-significant correlation between the overall improvement and TTF suggests that improvements in FT levels are not strongly related to how quickly students transition to fluency. This may indicate that the transition speed is more closely tied to students' initial FT levels rather than how much they improve.

For FTS aspect, a strong, significant negative correlation between FTS and pretest suggests that students who spend less time in the fluency phase have higher pretest scores. This could imply that students with better initial FT skills maintain fluency more efficiently, needing less time to stabilize their movements. The significant negative correlation between FTS and posttest indicates that higher posttest scores are associated with shorter fluency times. The positive correlation between FTS and improvements suggests that students who demonstrate greater improvements in their FT levels tend to spend more time in the fluency phase.

Discussion and conclusion

In this study, we addressed the research question of how students' bimanual activity in digital-embodied tasks relates to the development of their FT, with a focus on the covariation aspect. By analyzing movement patterns during the exploration and fluency phases and correlating these with pretest and posttest scores, we gained insights into how bimanual tasks help students understand and apply covariational relationships in the field of functions. The results from the case studies suggest that bimanual tasks support covariational reasoning by encouraging students to engage in hands-on activities that emphasize the dynamic and smooth continuous relationships between covaried quantities. The results also highlight how the transition from the initial exploratory phase to fluency enables students to progressively build a deeper and more nuanced understanding of covariation.

In the first case study, the student's movement patterns initially lacked coordination, reflecting an exploratory approach as they attempted to understand the relationship. Over time, the student learned to move both hands in parallel, indicating an emerging understanding of the relationship between the variables based on the bimanual experience. This shift from uncoordinated to coordinated movement marks a transition from exploration to fluency, demonstrating how bimanual tasks can potentially support the development of FT by allowing students to physically manipulate and observe the effects of changing variables on nomograms.

The second case study further supports this conclusion, showing how the student's movements mirrored the geometric properties of the function $f(x) = -x$. By adopting symmetrical bimanual movements that reflected the inverse relationship between the variables, the student demonstrated a deepening understanding of covariation. For example, the student connected the geometric properties of the nomogram with the type of function, stating, "I didn't mean that they (arrows in the nomogram) all pass through a single point (intersection point), then it must be a linear function. But if they pass through the point (0,0), then it's definitely a direct proportional relationship." The ability to visualize and manipulate these relationships through bimanual tasks suggests that such tasks can be potential tools for improving students' conceptual grasp of functions.

Correlations between movement indicators and FT

The correlation analyses on the whole group data provide additional evidence of the relationship between initial FT levels and performance in bimanual tasks. Higher pretest scores, indicative of stronger initial FT, were associated with shorter times to achieve fluency and less time spent in the fluency phase. Conversely, students with lower pretest scores spent more time in the fluency phase. This may suggest that students with lower initial FT need longer time to master the embodied task and mathematize their bimanual movements within the task's context: the two variables covary according to a functional relationship, which is mirrored by their bimanual movements.

The mini-interview data provide further insights into these correlations by showing the different strategies used by students based on their initial FT levels. Some students with lower pretest scores mentioned using a strategy that involved trying out multiple pairs of numbers on the nomogram and searching for patterns. This method, which likely contributed to their extended time in the fluency phase, aligns with the correlation results showing longer engagement times for these students. Their

need for more thorough exploration suggests that they require additional time to develop a robust understanding of covariational relationships. In contrast, students with higher pretest scores used a more direct approach, such as substituting values into $y = ax + b$ after identifying a few number pairs (normally less than three). This strategy facilitated a quicker transition to fluency, as these students could leverage their existing understanding of functional relationships or equations to efficiently solve the task. These strategies also suggest that prior knowledge of linear functions allows students to deliberately search for specific features during the learning process. This appears to diverge from the process often described in embodied design, where such functions are expected to emerge as mathematizations of students' verbal describing their solution of the embodied task.

Implications for educational practice

The findings have significant implications for educational practice in mathematics education. Bimanual tasks provide a dynamic, interactive means of developing FT by engaging students in hands-on exploration within a digital-embodied learning environment. Educators can use or redesign these bimanual tasks that cater to different levels of student. For students with lower initial FT levels, allowing enough time for exploration and providing structured opportunities for pattern recognition and hypothesis testing can help build a strong foundation for function learning. For students with higher initial FT levels, encouraging more targeted and efficient strategies can facilitate the transition to fluency and reinforce their understanding of covariational relationships.

In conclusion, this study investigates how bimanual task could foster FT within a digital-embodied learning environment. The examples and correlation analyses indicate that students' initial levels of FT significantly influence their learning processes and outcomes when engaging with bimanual tasks. Additionally, the strategies identified through mini interviews show that individual differences in FT shape how students approach problem-solving and the time they spend in different phases of the bimanual tasks. These findings suggest that bimanual tasks can be effective tools for fostering FT. Future research could explore the long-term impact of bimanual tasks on FT and investigate their adaptability across different educational settings and subjects.

Body and materiality from a perspective of visuality in mathematics education

Cláudia Regina Flores [1], Débora Regina Wagner[1] and Mônica Maria Kerscher-Franco[1]

[1]Federal University of Santa Catarina, Faculty of Education, Brazil; claureginaflores@gmail.com

Keywords: Embodied learning, visuality, eye movements.

Introduction

In Flores at al. (2023) we showed how mathematics and the body intertwine in encounters with arts-based activities in classrooms, providing a lived mathematical experience. This time, we want to highlight the notion of "visuality", which interrelates visual perception with sociocultural aspects, drawing attention to the active role of the gaze in the creation and invention of mathematical knowledge in the classroom. Through this poster[1], we aim to discuss how "visuality" can be a valuable concept, offering theoretical insights for research on the embodied nature of mathematical activity and learning[2].

The perspective of visuality

The term visuality, initially introduced in the book titled *Vision and Visuality* by Hall Foster (1988), was borrowed by us from American studies on visual culture to create a 'perspective of visuality in mathematics education.' (Flores, 2024). Visuality refers not only to the biological function of the eye but also, and more importantly, to the socio-cultural practices that shape the act of seeing.

Therefore, we assume that visuality operates as one of the principles underpinning our visual activities in mathematics education. This means that visualization in mathematics is not based solely on the activity of reasoning to interpret and understand visual information. It means that the concept itself is implicated not only in the eye of the mind that sees cognitively but also in the eye that resonates with affection and affect, seeing in the image that which, socially, constitutes it. This involves the eye movement of the multiplicity that encompasses gesturing hands, the mouth that speaks and the emotions that circulate in the interaction between body, mathematics, and the arts.

As a method, visuality operates as both an analytical and experimental tool, implying a more relational and dynamic view of mathematics, in which mathematical abstraction and matter are not separated but rather interpenetrate, creating a living practice where the mind, body, objects, and mathematical tools are intertwined. Mathematical knowledge is not merely something mental or formal, but a material practice that involves the body and the objects of the physical world, both in teaching and in the practice of mathematics itself.

[1] The poster presented at the conference can be accessed at: https://gecem.ufsc.br/imagens-do-labirinto/poster/

[2] This aim is arised from the research project 'Powers of visuality in workshops with visual arts: About mathematical aesthetic practices', conducted by the first author and supported by CNPq-Brazil.

Visuality and embodied learning in experiments with art

In the last 10 years, our research group has been conducting studies[3] based on this perspective, mainly considering the arts, such as paintings, sculptures, and art installations. This involves putting the movement of looking into practice, operating different ways of producing, imagining, and inventing mathematical knowledge in the classroom. By doing this, we have focused on imagination and mathematical abstraction as socio-material practices, through sensorimotor processes, including gestures, drawings, touch, use of language, etc., within and between bodies. Therefore, these are research studies that engage in aesthetic experiences, providing access to embodied mathematical content: the body in its pulsation, in other words, in its immanent flow that characterizes life. In this direction, the body not only produces political relations but also constitutes potentials for learning.

Inviting questions

How can visuality, as a concept, change the way we understand mathematics learning and teaching? How does the idea of visuality challenge traditional approaches to mathematics, which often consider it an abstract and disembodied practice? How do emotions and affectivity influence the way we perceive and engage with mathematics visuality? What happens when the "vision" of mathematics involves the body, gestures and emotional expressions? How can this enrich or complicate mathematical learning? Can visuality be applied equally to all students, considering different learning ways? These questions can help to further deepen the debate on the implications of visuality in mathematics education, encouraging reflections on pedagogical practices, theory of knowledge and the relationship between body, affectivity and cognition in mathematical learning.

Re-presenting abstract and concrete in the diagrams of Al-Khwarizmi

Yassir Maknaoui[1], Vinay Kathotia[2] and Brigitte Stenhouse[2]

[1]Royal Holloway, University of London, [2]The Open University, UK; vinay.kathotia@open.ac.uk

Keywords: Al-Khwarizmi, algebra, area, diagrams, quadratic.

Introduction

This poster builds on a recent translation (Maknaoui et al., 2024) of sections on quadratic equations from Al-Khwarizmi's seminal algebra text (Al-Khwarizmi, 813/846). Using print, Al-Khwarizmi and other 8th–13th century Islamic scholars *re-presented* and clarified transient 'dust-board' based Indian mathematical algorithms (Al-Uqlidisi & Saidan, 1978). We read Al-Khwarizmi's original work to explore how his representations could inform working with present-day digital and material media, which allow for transient and rigid representations via reconfigurable visual and tactile interfaces. In exploring the diagrammatic (rectangular, area-based) representations used by Al-Khwarizmi to support his algorithms, we noticed that they disrupt the abstract-concrete dichotomy in mathematics, in ways similar to those advanced by Coles and Sinclair (2019) and Nemirovsky et al. (2025). Here we outline some of Al-Khwarizmi's approach, and how it provides an instance of a more unified and inclusive approach to abstract and concrete in the learning and teaching of mathematics.

Translating Al-Khwarizmi – roots, wealth, numbers, and areal representations

> And I have found that these three types, which are the roots and the wealth and the numbers, associate and from it there are three coupled associations; they are: wealth and roots equal a number, wealth and a number equal roots, and roots and a number equal wealth. (Al-Khwarizmi, as translated in Maknaoui et al., 2024, p. 3)

In Al-Khwarizmi's diagrams, unknown quadratic quantities (wealth) are represented as square areas, unknown roots are side lengths, and known numbers are given as money (dirhams). In associating (adding) them, Al-Khwarizmi admits an abstract notion of quantity encompassing wealth, roots and numbers, also represented as areas, while the three types of associations (equations) reflect the materiality of the different ways they come together (in the absence of negative amounts). This mixed use permeates his work, where the end goal of his 'doors' (algorithms) is not simply the determination of one unknown but engagement with the connected set of wealth, roots and numbers. The doors are presented in prose, and seem quite magical, with diagrams to make sense of and justify them.

> … like when you say, wealth and ten of its roots equal thirty-nine dirhams, … Its door is to halve the roots, and in this matter, it is five, so you multiply it by what is like it, which results in twenty-five. Then you add it to thirty-nine, resulting in sixty-four. Then take its root, which is eight, subtract from it half of the root, which is five, leaving three. This is the root of the wealth that you want, and the wealth is nine. (Al-Khwarizmi, as translated in Maknaoui et al., 2024, p. 3)

While diagrams in the text (rightmost diagram in Figure 1) are static representations of their final state, the text details the steps taken to create these diagrams, illuminating the algorithms (shown using present-day symbols, and with corresponding construction diagrams, in Figure 1).

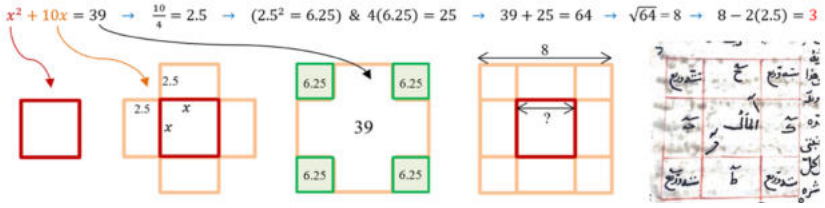

Figure 1: Algorithm and diagram for 'wealth and ten roots equal thirty-nine dirhams'

Discussion – doors to mathematics

Both Coles and Sinclair (2019) and Nemirovsky et al. (2025) counter the 'material equals concrete' and 'symbolic equals abstract' reductive approach to abstraction, and, quite differently, see concretising and abstracting as co-existing accessible experiences, offering a more inclusive approach to mathematics. Coles and Sinclair (2019, p. 467) see concretising as "productive shifts in attention … from relations to objects" while abstracting "moves from objects to relations". In Al-Khwarizmi's setting, these could correspond to solving and setting up equations respectively, with his diagrammatic environment corresponding to their 'symbolically structured environments', where learners can represent actions and be supported in making their own novel moves. Nemirovsky et al. (2025) on the other hand, see abstracting in terms of immersive "acts of as-if world-making", and concretising as being better oriented in, and having a more connected sense of, a mathematical domain. In this framing also, the setting up of equations can be seen as abstracting, playfully conjuring up worlds where wealth, lengths and money can be pooled and equated. Working with the areal diagrams can be concretising, connecting area with quadratic quantities and enabling learners to make sense of adding, multiplying and equating quantities, and clarifying algorithms.

Acknowledgment

We are immensely grateful to the Bodleian Library for access to Al-Khwarizmi's book, and to the UK's Engineering and Physical Sciences Research Council for research support for the first author.

Collaborative reflection on embodied abstraction for geometry: questioning the research-teaching interaction

Benjamin Nicolas-Noir[1] and Karel Boonstra[2]

Keywords: Embodied abstraction, teacher-researcher collaboration, geometry, primary school.

Introduction

A growing body of research supports the recognition of embodied processes in the learning and teaching of mathematics (Abrahamson et al., 2020). However, as stated in the call for contributions, sharing these insights with a broader community remains challenging. We aim here to investigate this methodological issue by problematising the interaction between research on embodied processes and teaching practices. Considering the development of embodied designs, Abrahamson et al. (2020) frame the relationship between research and teaching as a pedagogical one: "the time is ripe to educate prospective teachers, in-service teachers, and collegiate instructors regarding embodiment" (p. 17). While we recognise the importance of understanding how research can *inform* teaching, we aim to investigate how teaching practices can also *inform* research. Carrying the call to "cross traditional boundaries" (ibid., p. 20), we therefore consider in-service teachers' perspective on embodiment in teaching and learning mathematics and focus on how researchers' and teachers' perspectives *interact*. Thus, our research question reads: what knowledge arises when researchers and teachers commonly investigate the role of embodiment in teaching and learning mathematics?

Context and methods

We investigate the research-teaching interaction by focusing on a specific mathematical content and a localised teaching context. To do so, we build on research conducted by Boonstra et al. (2023) on the fostering of *embodied abstraction* in primary school geometry. This work recognized a tension between the embodied abstraction approach on geometry and the teaching of geometry at the primary level in the Netherlands. Then, a series of tasks was developed for teachers to experience and reflect on emerging embodied processes, focusing on reflectional symmetry. In the Vaud canton of Switzerland, recommendations for primary teachers also contrast with the approach of embodied abstraction. They focus on using manipulatives for building "mental images", on sensitive experiences of physical quantities (weight, length, area…) and on changes of spatial scales (the sheet of paper, the classroom or the building). Thus, the tasks developed by Boonstra et al. (2023) are likely to come into *tension* with the practices of local primary teachers, bringing the perspectives of research and teaching practices to interact. Using tasks on equidistance between reflective symmetric points, we investigate with Swiss primary teachers (also working as teacher educators) how the action-based design and its underlying principles (see Abrahamson, 2014) could relate to their teaching practices.

The methods (and, admittedly, the reasons) for conducting this investigation ground in the principles of *collaborative research* (Savoie-Zajc & Descamps-Bednarz, 2007). This approach frames the teacher-researcher relationship as *co-constructive* for knowledge about teaching practices. To co-

construct such knowledge, the setting of an activity that *reflects* teachers' practices and allows to reflect on them is required. Thus, we investigated the selected tasks in relation to the rationale of action-based design for mathematics (Abrahamson, 2014); then, we experienced the tasks and discussed their use in their respective classes; finally, teachers could try the tasks in class and reflect on the experience with the first author. Results from the first two phases are here presented, providing methodological insights on possible interactions of teachers' and researchers' perspectives.

Insights and opening question

Discussions display a research-teaching tension (resonances and divergences) on epistemological aspects of bodily experience in mathematics. In resonance with the tasks' rationale, teachers valued tasks which involve the body as a resource for solving a mathematical problem (Boonstra et al., 2023, p. 7), rather than as a medium for expressing the solution of a mathematical task. However, diverging with the tasks' rationale, teachers differentiated tasks depending on the "scale" of embodiment: they deemed important to involve the body beyond the hands and arms, asking pupils to reflect the displacements of a classmate standing on the other side of a line. This divergence can be related to their context of practice, which emphasises the variation of spatial scales in mathematics rather than sensorimotor challenges. However, varying spatial scales in geometry is also addressed in research on embodiment (Marchand et al., 2024). Thus, how to build on the epistemological diversity of "embodied research strands" (Gerofsky, 2014) to pursue this fragmented and nuanced interaction?

Body in between multinaturalism and mathematics education

Introduction

The aim of this text is to problematize the concept of the body from the perspective of Amerindian Multinaturalism and Perspectivism (Viveiros de Castro, 2018) as a potential framework for research and classroom practices in mathematics education. In our field, it is common to find investigations in which the body is seen merely as a biological delimitation. However, the body plays an active role in the production of mathematical knowledge, whether in its inclusion or exclusion, as well as in the desirable modulations within and arising from the project of modern schooling. Investigations such as those by Efron (2023) have explored the body's participation in acquiring mathematical knowledge, while Flores and colleagues (2023) highlight the interplay between seeing and speaking in observing the world, space, and works of art. In this poster, we introduce another point of view, Multinaturalism, in which the nature of bodies is entirely relative to perspective. We attempt to propose a different understanding of body concept in mathematics education research and classroom practices, emphasizing the contingent and relational aspects of nature, where bodies and knowledge emerge through interactions shaped by diverse perspectives and agencies.

Fixed epistemology and variable nature

In Amerindian cosmologies, the world is populated by agents: gods, spirits, animals, plants, rivers, the deads. For them, in their cosmologies, humans (in all their corporeal variations) inhabit and are constituted through exchanges, predations, rituals, among other relational dynamics. In the framework of our limited grammar and lexicon, all species (agents) are conceptualized as human, though understood through diverse mutations and corporealities, emphasizing relational perspectives rather than fixed identities. A subject is always constituted from a human perspective: the jaguar sees itself as human and sees us as non-human. Thus, unlike a Western cosmopolitics, agents have variable natures, that is, different ontologies, yet they operate and relate in the same manner, that is, within the same (human) epistemology. Particularly, regarding the concept of the body (whether animal, plant, or indigenous), its identity is established in terms of a perspective, a point of view, in relation to the one who perceives it. The body is not stable, fixed, nor does it occupy a singular position; its form is relative to the perspective of the other. As Taylor and Viveiros de Castro (2019) state:

> [...] the identity of the perceived body depends on the nature of the body of the 'person' from whom the gaze originates. The body, therefore, cannot be considered outside of its necessary relationship with an observer acting as a subject." (Taylor and Viveiros de Castro, 2019, p. 770)

If we operate with this concept of the body, perhaps a different mathematics classroom and new ways to research in mathematics education could emerge. In bodies that are always invented from perspectives, and in relationalities with other bodies, in a school territory inhabited by different agents (both human and non-human), discussions should not only focus on mathematics learning processes (in their cognitive aspects); it seems necessary to explore what kinds of belonging and commitments

could be entangled. A body only happens in the possibilities of encounters with another. A body changes (mutates) from the perspective of the other, from the one who sees it, and as a result, the effects and political project of mathematics education can also change. A body unfolds in dissonances, pauses, fissures, sparks, and suspensions, weaving possibilities in formal and informal contexts that are unlikely to be anticipated. Contingency emerges as a central point. These discussions can also be applied to research.

Some considerations (or some questions for future discussions)

To produce a classroom or research as a territory of suspensions, equivocations, and problematizations, where bodies affect one another, may initiate a political process of deconstructing (or decolonizing) discourses that imprison and inflict violence upon certain bodies, especially those that perceive the body as something fixed, possessing only a mind. If the body is not something given, but intrinsically depends on the gaze of the other and can be altered (modified) by agents (human and non-human), establishing itself in relation to the one who sees it, how can mathematics classrooms be spaces that not only produce mathematics but also create bodies, continuously nourished by others? What dynamics can be established in the classroom to enable the reading of this gaze of the other upon "my body" so that I may see myself through their eyes? If a body is constituted in dependence on the gaze of the other, what is the function of this other in a mathematics classroom? What kinds of agency would be possible with mathematics, instruments, and bodies in a mathematics classroom? How can we navigate the spaces between multinaturalism and mathematics education, particularly with this concept of variable body?
