Previous studies on curricular noticing have investigated the establishment of similarities and differences between tasks (Amador et al., 2017). These authors concluded that pre-service secondary school teachers noted that tasks, even when sharing the same goal and context, resulted in different students' solution pathways and mathematical elements. Amador and Earnest (2019) showed that pre-service teachers noticed discrepancies in the presentation of fraction content in an inquiry-oriented textbook compared to how they had initially learned that content. McDuffie et al. (2018) reported findings on teachers' noticing of features in the teacher resources of mathematics curriculum programmes. These authors found that the interpretation and decisions varied based on teachers' orientations and curriculum type.

Our study is part of a larger research project that aims to characterise the development of pre-service primary school teachers' curricular noticing. This paper is focused on curricular interpreting, particularised, in this study, as the ability to use mathematical and pedagogical content knowledge to recognise limitations in the curricular materials. To support pre-service teachers in developing curricular interpreting, they were provided with theoretical lenses since they have been shown as potential tools to support their noticing (Fernández & Choy, 2020). In a previous study, Zorrilla et al. (2024) have examined the coherence between how pre-service teachers interpret a sequence of activities from a textbook about fractions and how they complete the sequence using a hypothetical learning trajectory as a theoretical lens. The results showed that more than half of the pre-service teachers were able to complete the sequence of activities considering the limitations interpreted.

Our objective is to examine how pre-service teachers analyse a sequence of activities from a textbook about three-dimensional geometry to recognise limitations. Particularly, the paper examines whether pre-service teachers recognise limitations regarding the attributes of geometric solids (e.g., convex/concave), geometric processes (e.g., classifying) and modes of representation (e.g., concrete).

Method

Participants and context

Participants were 85 pre-service primary school teachers (PTs) from the University of Alicante (Spain). When conducting the study, participants were in their third year of the degree to become primary school teachers. They were enrolled in the course 'Learning and Teaching of Mathematics in Primary Education'. The main objective of this course is to develop professional competencies for mathematics teaching, such as interpreting students' mathematical thinking, analysing curricular materials or planning lessons in different mathematical domains (e.g. geometry). Participants had already completed two mathematics courses related to number sense and geometric sense in previous years.

Instrument: Professional task

PTs were asked to analyse a sequence of five activities from a 5^{th}-grade (aged 10-11) mathematics textbook (Figure 1, Ferrero de Pablo et al., 2018, pp. 178–179) related to 3D geometry. The activities address the concepts of polyhedron, prism and pyramid.

1. Answer the following questions:

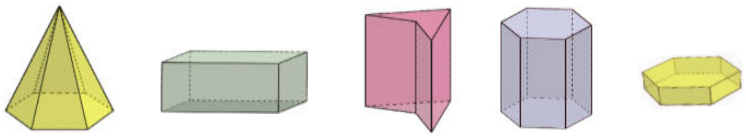
a) What kind of polyhedron is a shoebox?

b) What do the faces of a polyhedron look like?

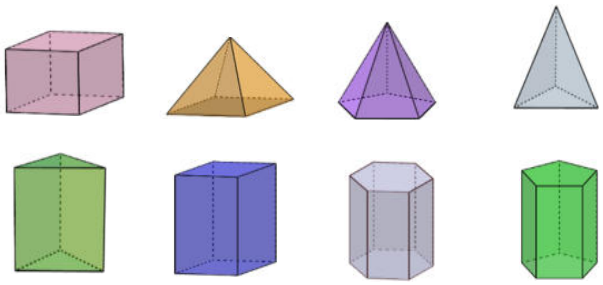
c) How many bases does a prism have? and a pyramid?

d) What do the side faces of a pyramid look like? What do the side faces of a prism look like?

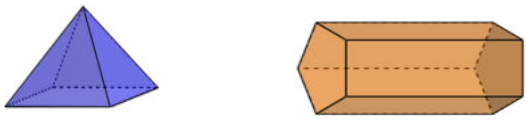
2. Classify the following polyhedra:



3. Indicate which of the following polyhedra are prisms and which are pyramids.



4. How many faces, vertices and edges do the following polyhedra have?



5. This is the flat development of a prism. Draw the flat development of the pyramid on the right.

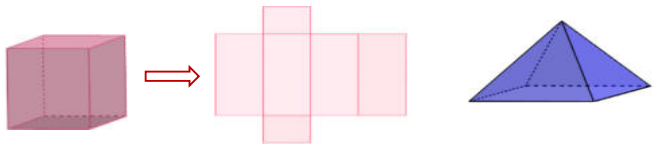


Figure 1: Activities from the mathematics textbook (translated into English from Ferrero de Pablo et al., 2018, pp. 178–179)

To analyse the activities, PTs had to answer some guide questions related to the curricular noticing. The guide questions related to curricular interpreting: (1) what other attributes of geometric solids could be incorporated to promote the understanding of the polyhedron, pyramid and prism concepts? (2) what other geometric processes could be introduced to promote the understanding of the

polyhedron, prism and pyramid concepts? And, (3) what other modes of representations and connections between them would help to promote the understanding of polyhedron, prism and pyramid concepts? PTs answered the guide questions related to the three skills individually in a 100-minute lesson of the course. The sequence of activities from the textbook was selected since PTs could identify some limitations, such as they could add oblique pyramids or prism as other attributes of geometric solids. Furthermore, they could add non-examples of polyhedra. They could add the process of defining or measuring and, regarding the modes of representation, the use of concrete materials.

PTs were provided with a theoretical document (theoretical lens) containing information related to the teaching and learning of geometrical contents in primary education. This document was designed considering previous research on mathematics education in this area (Battista, 2012; Bernabeu et al., 2021). For instance, the document encompasses information about the geometrical processes (recognising, analysing, classifying, defining, constructing, or proving), modes of representation (verbal, symbolic, concrete or graphic) and the importance of using a great variety of examples with different attributes of geometric solids (e.g., convex, concave, oblique, and right) and non-examples.

Data analysis

Data were the answers of the PTs to the three guide questions of curricular interpreting. Since the objective is to examine how pre-service teachers analyse a sequence of activities from a textbook about three-dimensional geometry, the four researchers performed an inductive analysis (Strauss & Corbin, 1994), identifying categories about the attributes of geometric solids, processes or modes of representations that PTs would incorporate in the sequence of activities to promote the understanding of the polyhedron, prism and pyramid concepts. First, a set of 30 PTs' answers were analysed individually, emerging initial categories. The four authors discussed agreements and disagreements until they reached a complete consensus. Second, the other set of answers was analysed, discussing and refining the categories, again achieving full agreement on the final categories. In table 1, two examples of the data analysis are presented.

Table 1: Examples of data analysis

Pre-service teacher's answer	Attributes categories	Processes categories	Modes of representation categories
"As for other attributes of pyramids, polyhedra and prisms, we could work on the following. In order to understand the concept of polyhedra, we could propose activities to work on convexity and concavity. These attributes can also be worked with prisms and pyramids. […] Regarding geometric processes, we could propose activities to define figures in different ways. […]	Concavity Convexity	Defining	Concrete materials

In order to support understanding, we could make use of concrete materials such as Meccano and Polydron". (PT1)			
"We can include oblique geometric bodies, bodies of revolution such as spheres, cylinders or cones to reinforce the concept of polyhedron and figures with different bases such as the truncated pyramid. To make other classifications, i.e. with other criteria; tasks of constructing and defining. To promote understanding it would help to use concrete materials that allow them to manipulate the figures". (PT3)	Oblique Non-examples	Classifying Constructing Defining	Concrete materials

Results

Our results show that 88% (75 PTs) would add attributes that can support understanding the concepts of polyhedron, pyramid and prism. They proposed including 3D shapes with the attributes of convex/concave (46 PTs, 54.2%), oblique/right (45 PTs, 52.9%), regular/irregular (39 PTs, 45.8%), or different 3D shapes according to the polygon of the base (18 PTs, 21.2%). These participants perceived that these attributes were not explicitly targeted in the sequence of activities of the textbook. However, it is noteworthy that the 3D shape representations in the sequence of activities considered some of these attributes (convex/concave; regular/irregular and 3D shapes according to the polygon of the base). However, oblique prisms or pyramids were absent, highlighting the concerns raised by 52.9% of the PTs who pointed out this attribute. Furthermore, other PTs reported the need to integrate non-prototypical figures (13 PTs, 15.3%) and non-examples (11 PTs, 12.9%). In this sense, PT30 alluded to both, expressing, "I would include the same figures in an oblique position, as well as solids of revolution such as sphere, cone and cylinder to consolidate the concept of polyhedron".

96.5% of the PTs (82 PTs) proposed some geometric processes to support students' understanding. These processes were constructing (49 PTs, 57.6%), measuring (32 PTs, 37.6%), analysing (26 PTs, 30.6%), classifying (26 PTs, 30.6%), defining (25 PTs, 29.4%), recognising (12 PTs, 14.1%), and proving (5 PTs, 5.8%). The majority of PTs recommended construction activities that should enable primary school students to not only obtain a flat development from its polyhedron but also reverse this process or combine a collection of polyhedra to obtain a new one. For instance, PT60 explained: "The sequence of activities works the geometric process of constructing but in the form of decomposition; therefore, some composition activities [with polyhedra] could be introduced". Furthermore, a relevant number of PTs noted the absence of measurement activities (e.g. obtaining the volume of a prism or measuring elements of polyhedra such as the height).

The number of PTs who identified modes of representation that can support students' understanding decreased compared to the other two aspects (attributes and geometric processes). 76.5% of PTs (65) proposed a different mode of representation or connections between them. The concrete mode of representation was the most frequently mentioned (62 PTs, 72.9%), followed by the verbal (27 PTs,

31.7%), graphic (8 PTs, 9.4%) and symbolic (3 PTs, 3.5%). Many PTs realised that the textbook does not support the use of physical objects (manipulative materials) and suggested the inclusion of structured (e.g., polydron, or Meccano) and unstructured (e.g., real-life objects and toothpick) materials. Additionally, some PTs suggested strengthening the verbal mode, highlighting the need for oral communication. For instance, PT4 would foster teacher-student interactions throughout the activity-solving process, whereas PT27 would encourage students to verbalise the solutions they obtained.

All PTs were able to identify at least limitations with regard to one of the aspects (attributes, geometric processes or modes of representation) in the sequence of activities to support the understanding of the concepts. As illustrated in Figure 2, 55 PTs (64.7%) identified some limitations in the three aspects, 27 (31.8%) in two aspects, and 3 (3.5%) in one aspect. Table 1 shows the answers of two PTs who identified limitations in the three aspects (PT1 and PT3).

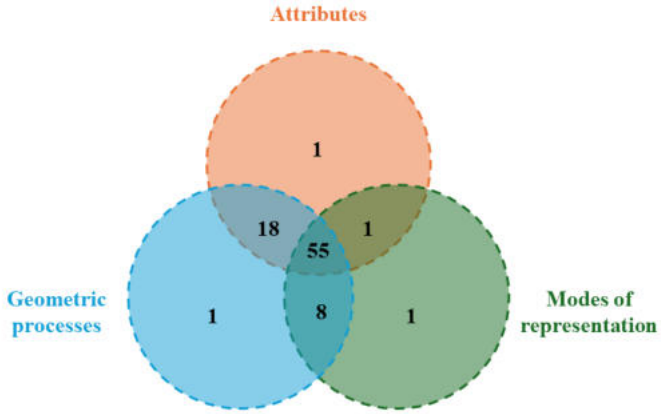

Figure 2: Aspects considered by pre-service teachers when interpreting

In the group of 27 PTs who identified some limitations with regard to two aspects, 18 focused on attributes and geometric processes, 8 on geometric processes and modes of representation, and 1 on attributes and modes of representation. For instance, PT10 successfully identified some attributes and geometric processes that could support the understanding of the concepts.

> We can introduce different types of pyramids considering the polygon of the base and regular polyhedra. With regard to geometric processes, activities of defining, constructing and classifying (PT10).

PT69 suggested some attributes that could support the understanding of the concepts and the use of non-examples. This PT did not propose any geometric process or mode of representation.

> In order to support understanding, bodies of revolution such as the cone, cylinder or sphere could be incorporated. Non-regular polyhedra or concave polyhedra could be introduced. Also, oblique polyhedral (PT69).

Discussion and conclusions

All PTs were able to find limitations in the sequence of activities at least in one of the aspects (attributes, geometric processes or modes of representations) and 64.7% in the three aspects.

Therefore, this result seems to indicate that the professional task and the theoretical lens provided (Fernández & Choy, 2020), could focus PTs' attention on these aspects (Zorrilla et al., 2024). The task and the theoretical lens used in this study can be considered in teacher education programmes as tools that can enhance PTs' curricular interpreting.

The number of PTs who identified modes of representation that can support students' understanding was lower compared to the other two aspects (attributes and geometric processes). It was expected that PTs identified the concrete materials (manipulatives) as a mode of representation that is rarely promoted by text (Díaz-Levicoy et al., 2019). This result suggests that PTs try to foster an approach similar to the one promoted by the curricular material and, as Blanco et al. (2021) indicate, the curricular material often outlines the teaching practice. In view of this result, teacher training programmes should emphasise professional tasks aimed at recognising the significance of incorporating manipulatives into primary school classrooms. With regard to the attributes, most pre-service teachers would add convex and concave polyhedra, and oblique prisms and pyramids. Therefore, these PTs were able to recognise the importance to work non-relevant attributes and a variety of non-prototypical examples. Considering the geometric processes, most of them proposed construction or measurement activities since the sequence of activities focused more on recognising, classifying and analysing.

This paper focuses on examining one of the three curricular noticing skills: curricular interpreting. The next objective is to investigate the relationships between the three skills to gain a deeper understanding of PTs' curricular noticing.

Acknowledgment

This research was supported by the project CIAICO/2021/279 funded by the Generalitat Valenciana (Conselleria d'Educació, Cultura i Sport, Spain).

Using textbook analysis in teachers' professional development

Marte Krohg Østby

OsloMet – Oslo Metropolitan University, Norway; marthekr@oslomet.no

This study investigates how ten elementary school in-service teachers reflect and conclude after using a theoretical framework to conduct a textbook analysis as a part of a professional development course. By using Duval's system of representations, the teachers did a textbook analysis of all tasks in a part of a textbook in use at their school. The teachers presented and discussed their analyses with each other. Audio recordings of presentations, discussions and a group interview were subject to a thematic analysis. The findings indicate that the textbook analysis stimulated the teachers' reflections in task selection, and they concluded that it is important to let go of the textbook and to be aware and critical in task selection. Further research is needed to explore this practice of professional development.

Keywords: Professional development, mathematics teaching, task analysis.

Introduction

It is widely accepted that professional development (PD) can improve teaching (Kennedy, 2016). A core part of a teacher's planning involves selecting, modifying, and formulating tasks as they prepare for lessons. This requires awareness and reflection around the choices made, and it is important to investigate practices that train teachers to meet this challenge. However, despite its significance, planning lessons is difficult to teachers. Cevikbas et al. (2024) presented the results of a systematic review of 20 empirical research studies on teacher competence in mathematics lesson planning and showed that teachers face difficulties in planning lessons. They call for courses in teacher education and PD that can provide teachers with a reflective experience to become proficient in lesson planning.

In Norway, educational policy grants teachers a high level of autonomy (Eriksen et al., 2022), which means that they are given pedagogical freedom to select methods, tasks and content they evaluate to be the most beneficial to their students' learning. Nevertheless, this autonomy is juxtaposed with a challenge: the current national curriculum offers limited directives about content and how it should be taught (Sundby & Karseth, 2021), so that the content and teaching methods depend on the individual teacher. This means that it is important to train teachers to fulfil this responsibility.

In situations where teachers do not find sufficient guidance from the curriculum, they may seek content information from the textbook (Bolstad, 2019). Fan et al. (2013) summarized 111 studies related to textbook research in mathematics the past six decades. The study revealed that researchers generally agree that textbooks have a significant influence in modern teaching of mathematics (Fan et al., 2013). Recent studies from a Norwegian context indicated that although teachers use different resources, they still use textbooks as their main source in their mathematics teaching (Bjørnset et al., 2020). These results are similar to those reported by Bolstad (2019) who reported that mathematics teachers seem to be aware that relying solely textbooks is not the best way to plan teaching, but the lack of specific guidance and objectives in the curriculum makes it difficult for them to disregard the textbooks. Together, these studies indicate that textbooks are widely used, so it is important to discover methods for teacher education and PD to train teachers in using textbooks wisely.

Mathematics textbooks consists of more than just tasks, but in this study I have investigated teachers' reflections after analysing textbook tasks. Riard and Kaur (2022) have investigated which and how teachers' resources influence their choices during mathematics task selection and modification. Their findings showed that the teachers' beliefs on the teaching and learning of mathematics, and the teachers' impressions of students' capacities and capabilities are dominant when choosing tasks. This aligns with Gustafsson et al. (2024) who investigated resource use in upper secondary school in Sweden and reported that when the structure of the textbook does not align with teachers' ideas of mathematics lessons, they use tasks from other resources. Siedel and Stylianides (2018) studied what kind of instructional resources teachers choose. Their findings showed that resource selection is complex, and teachers' reasons for selecting tasks are influenced by, among other things, resources at hand, collegiality, own beliefs of mathematics, students, and teaching mathematics. Taken together, these studies support the notion that beside curriculum resources, teachers' own beliefs of mathematics teaching are important when preparing tasks.

Remillard and Kim (2017) proposes that the knowledge activated by teachers when using curriculum resources is a central part of knowledge for teaching mathematics that needs comprehension and development. Reading, interpreting, and reflecting about mathematical concepts in curriculum resources represent an important aspect of teachers' work which directly affects lesson planning (Remillard & Kim, 2017). In this study, the aim is to understand how in-service teachers reflect after using a theoretical framework to do a textbook analysis. The present study seeks to answer the following question: *How do teachers reflect and conclude after conducting a textbook analysis with a theoretical framework as a pedagogical development practice?*

Context: systems of representations

In this study, the teachers were assigned to do an analysis of representations from a part of their textbook that contained fractions. The Norwegian curriculum states that pupils should use mathematical representations in various contexts through their own experiences and in mathematical conversations (Kunnskapsdepartementet, 2020). According to Duval (2006) "a representation is something that stands for something else" (Duval, 2006, p. 103). He points out that the difference between mathematics and other sciences is that mathematics does not have objects to observe directly. The only way to do mathematics, is by using symbols or other representations. Representations can be different, while representing the same mathematical object. Pupils' learning in mathematics is influenced by how they manage to understand and use representations, but also by how they learn to see connections between them (Duval, 2006).

Duval (2006, p. 111) has grouped representations based on the properties and proposes four systems: natural language, illustrations, symbolic language, and graphs/diagrams. Natural language contains both oral and written language and can, among other things, be a written text or an oral expression. Illustrations are referred to as visual figures and involve everything from simple sketches to geometric figures with very specific properties. Symbolic languages are all kinds of mathematical notation, both arithmetic and algebraic. Graphs and diagrams are usually presented in a coordinate system (Duval, 2006). This includes coordinate systems with one dimension, like a number line. Each system offers very specific and unique possibilities.

Method

A total of ten in-service elementary teachers participated in this study, teaching at ten different schools in the southeastern part of Norway. They had 2 to 27 years of teaching experience. At the time of the data collection, all participants were enrolled in a one-year part-time credit-bearing course (30 ECTS) for in-service teachers at Oslo Metropolitan University. Using in-service teachers in this study provided an opportunity to see how their teaching experience influenced their reflections and conclusions of their analysis.

Prior to this study, the in-service teachers had been introduced to Duval's systems of representations, and they were given the following assignment (translated from Norwegian and slightly shortened): "You are going to do a textbook analysis, based on fraction tasks in the 5th grade mathematics textbook used at your school. Look at all the tasks in that section of the book and use Duval's framework to decide whether students have to use language, illustrations, symbols, or diagrams to understand and solve the task. Create a table of the representations used in the textbook and present the result in an appropriate diagram." A quantitative approach to analyse the tasks provided the teachers with an opportunity to compare the use of representations in their textbooks. It also forced them to look at each task with new eyes, only looking for representations. The teachers' experience of doing a textbook analysis is the focus of this study, and a qualitative approach allowed me to explore their meaning and understanding.

The participants were divided into three groups of three or four teachers which had studied different textbooks. The group members compared their individual findings and together prepared a presentation, which ended with a discussion about their findings with all ten teachers. Following the discussions, a semi-structured group interview was conducted with the whole class. The intention of the interview was to explore the teachers' reflections, and frequent questions asked were "What have you learned from doing this?" and "What do you think about the results you found?" There were follow up questions, asking them to explain more carefully or elaborate. The intention was to let the teachers' ideas be the focus of the interview. The presentations, discussions and the interview were recorded with an audio recorder and transcribed in entirety in their original language (Norwegian), lasting totally for about 120 minutes. The teachers handed in documents from the textbook analysis, including results, written reflections, and presentations. Notes were also taken during data collection.

To answer the research question, the transcribed presentations, discussions and interview were subject to a thematic analysis, which offered the possibility for an inductively developed analysis, capturing the experiences of the teachers. Thematic analysis is a method for identifying, analysing and reporting stories about specific patterns (themes) of shared meanings within the data (Braun & Clarke, 2006, 2019). To acquire an overview of the data collected, all statements of potential interest to the research question were organized into a table and coded as clearly as possible. As one can see in Table 1, the words chosen when coding the statements were close to the original.

Table 1: Example of naming teachers' statements

00:41:02 Speaker 10 That is true. […] So definitely use multiple textbooks or try to find tasks and be much more aware of tasks.	Use multiple textbooks Be aware of tasks

The coding produced multiple codes, but these codes often captured small differences. For example, "Use multiple textbooks" and "find tasks from different places" was two statements with almost similar meaning. Clustering reduced codes to a more workable number, and the analysis went into a phase of generating, reviewing, defining, and naming themes. It initially ended up with three broad patterns of meanings: reflections upon task selection; reflections upon task implementation; and comparisons of textbooks. For this paper, I focused on developing the analysis of the data connecting to the reflections upon task selection. After reviewing relation to the codes, the coded data, and the full dataset, a structure with two themes appeared, with each theme describing an aspects of task selection. These are "let go of the textbook in task selection" and "to be aware and critical in task selection". For maintaining the teachers' anonymity, all names presented below are pseudonyms. Although every step of the analysis has been object of discussion with colleagues, it is important for me as a researcher to be aware of how my own subjectivity influences the analysis and interpretation of the data material. It will not be possible to capture all the reflections made by the teachers during this experience, and the analysis is based on teachers' own words, the presentations they made and written notes. I present my findings as possible tendencies, without making general conclusions.

Findings

Let go of the textbook in task selection

Examples of the codes included in this theme are "pick tasks from different places", "let go of the textbook" and "being tied to one book". When the teachers did their textbook analysis, it became clear to them that there were great differences between the textbooks, both in their use of representations, but also in content. The teachers' reactions can be exemplified in Figure 1, which shows digital messages sent between two teachers, Emma and Hedda, in an early stage of their analysis. The teachers shared these messages in their presentation. They asked question to their own textbook's use of representations and if it is true to the curriculum.

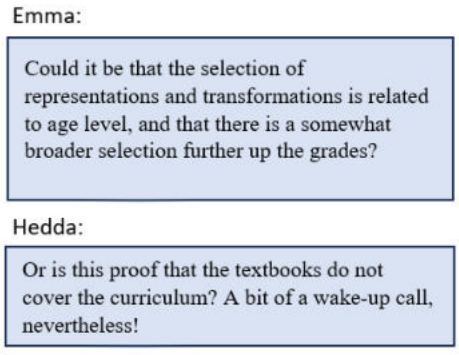

Figure 1: Messages

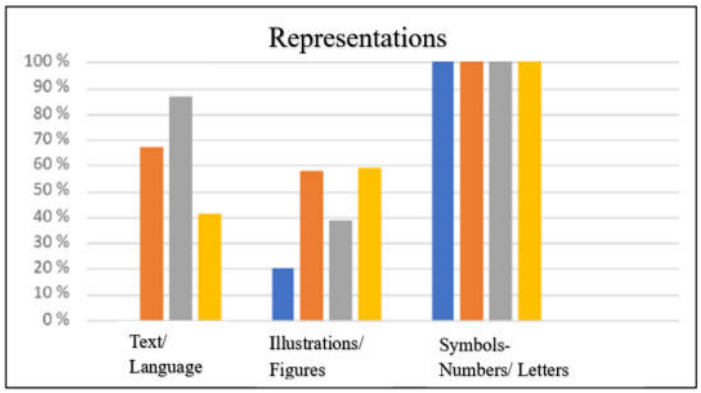

Figure 2: One slide from the teachers' presentations

Several quotes similar to “teachers really prefer following the textbook and the teacher’s guide” and “there are so many teachers that are bound to the book” made it look like the participants thought that following the textbook is a widespread practice among teachers. This align with recent studies of teachers’ use of resources (Bjørnset et al., 2020). It was also clear that they seemed not to approve of this way of teaching. When presenting their textbook analysis, the teachers emphasized the differences they found between the books, and they compared the textbooks with the curriculum, pointing out mismatches between the curriculum and the textbooks. After having presented their results, last slide shown in Figure 2, Lisa answered the question “what have you learned?” like this:

Lisa: So, we have learned a lot from working with this and gained awareness about what kind of task we use and also that the textbooks have a bit different approaches, and then of course when the students encounter different representations, they must also be encouraged by us to transform between them. So, it's our responsibility and not just the book's. Mostly our responsibility actually.
Tutor: What do you think these books require from a teacher?
Hedda: Ability to let go of the book.

These statements are examples of how the teachers both during the presentations and interview emphasized that the textbook analysis had illustrated for them the importance of avoiding a scenario where the textbook dictates the lesson planning. Instead, they advocated for using the textbook as a source as one of several sources to find the right task for each lesson. Eva commented on the textbook represented in blue in Figure 2, in which had illustrations in 20% of the representations, and the rest of the tasks were just represented with symbols. She said:

Eva: Focus on what you want the children to learn; if you want them to only be able to solve tasks and have quantity training, then you can use this book, but if you want them to have a deeper understanding, if you want them to explore mathematics, then you may have to use other tasks. Perhaps you must create your own tasks that are not in any textbook.

The teachers did not conclude with one book being the best or even better than the others. They stated strengths and weaknesses and compared the books. The importance of finding tasks from different sources, make their own tasks, and not rely solely on a textbook was clearly stated.

To be aware and critical in task selection

During the interview, the teachers emphasized the need to be critical and aware when choosing tasks for their lessons. Some of the codes included in this theme are “be aware of textbook being different”, “be aware of tasks” and “be critical while choosing tasks”. When asked about her findings, Eva said:

Eva: It appears that what we have actually found is the need to be aware in the selection of tasks, because all reflection is absent; no tasks facilitate collaborative learning or discussions, and none prompts reflection or exploring, like "What were you thinking?" Those aspects that, in a way, the new curriculum emphasizes, and the purpose of the subject are significantly missing in these tasks.

In this case, Eva stressed the importance of being critical in task selection. Although she did an analysis about representations of fractions, her argument shows that she has discovered other deficiencies in the textbooks as well. When discussing the need of being critical in task selection, the teachers stressed the importance of selecting tasks based on the goal of the lesson. Teachers must be aware of the qualities of the tasks and be critical when choosing which one to use. Hedda explained

this by asking “What does this task offer the students? Is it useful or not? How does this task differ from others? Which one should we choose?” These questions reflect a thinking process in selecting the right task to achieve a lesson’s goal. At the same time, the teachers refer to their experience of classes being different, asserting that a teacher needs to be critical in selecting tasks, tailored to their specific class. For instance, Ole explained what he had learned in these words:

> Ole: This means that you as a teacher must be critical to everything in the book, you must be critical to how to use it. And then I think that the book ... it is a book, and it is intended to be suitable for all students throughout Norway, but at the same time I know that each class and each group is different, so it is important to keep that in mind too. It is not certain that your book or those examples are exactly right. Perhaps you must present it in a different way for that particular group of students. […] So, I think no matter how you use the book, you must be critical of what you use and how.

Ole underscores the importance of being critical in choosing tasks that will both work for the class and the lesson’s purpose. He emphasizes the need to choose tasks critically, while recognizing that different tasks can be presented and exemplified in various ways. After having presented the differences between the books regarding their use of representations, Lisa highlighted how the experience from the textbook analysis shows how conversations about tasks should become integral to teachers’ discourse among colleagues:

> Lisa: But I think it really shows the importance of emphasizing that we are critical of the tasks we choose, and at my school there has always been discussions when purchasing a textbook; […] perhaps there needs to be more focus on the tasks we select ourselves than on which textbook we use; that is a discussion that might need to be brought to the table, then.

There is no clear distinction between the themes. When the teachers suggested letting go of the textbook, they didn't mean to stop using it altogether; instead, they advocated for its critical use. Being aware and critical in choosing tasks is necessary to let go of the textbook. At the same time, it is possible to be critical to tasks and still rely solely on a textbook. When asked about what they learned, Hedda said: “You become more aware yourself, I think. About what you choose. With the textbook, it's about letting go a bit and instead select tasks with care. In other words, thinking more about what you want.”

Discussion

The findings indicate that the textbook analysis stimulated the teachers’ reflections in task selection, concluding that it is important to let go of the textbook and to be aware and critical in task selection. This is important because we need to find ways to develop teachers’ professional knowledge in planning lessons (Cevikbas et al., 2024), and this might be a possible way to support teachers with a high level of autonomy (Eriksen et al., 2022) and a curriculum with limited directives (Sundby & Karseth, 2021). Mathematics teachers are influenced by their textbook (Bjørnset et al., 2020; Fan et al., 2013), and this study might offer a practice to train teachers to be more reflective in the process of selecting tasks for their lessons. If the teachers become more reflective in their selecting of tasks, it will make them more proficient in lesson planning. In the long term, this might lead to better instructions in mathematics classes and better opportunities to learn for students.

Getting to know a theoretical framework and use it for a textbook analysis seems to have transferability for these teachers. Using Duval's (2006) systems of representations as a framework for analysing textbook tasks appears to have started thought processes and reflections aside from the topics. The teachers did not only talk about representations of fractions, but selecting tasks and quality of lessons in a more general manner. Just by analysing a small part of their textbooks, the teachers experienced that the authors had made different decisions and that the textbooks differed from what the teachers perceive the curriculum to address. Although Duval's system of representations worked as lenses to see their textbook tasks in a different way in this research, other theoretical framework might also work to evoke similar reflections. More research need to be done on such designs to find out if similar practices of PD will support teachers' knowledge when using curriculum resources (Remillard & Kim, 2017).

This is an example of a practice that can train teachers' reflections upon task selection. Research indicate that teachers' belief of teaching has an impact when choosing tasks for a lesson (Gustafsson et al., 2024; Riard & Kaur, 2022; Siedel & Stylianides, 2018), and this knowledge activated by teachers when using curriculum resources needs development and comprehension (Remillard & Kim, 2017). The findings indicate that using a theoretical framework to do a textbook analysis can be an effective practice for PD to develop such knowledge, making the teachers reflect upon task selection and support their knowledge for lesson planning (Cevikbas et al., 2024).

In the interviews, the teachers were given open questions about what they have learned through this experience. This might have been important in catching the teachers' own experience doing the analysis. The teachers themselves kept coming back to task selection as an important eye opening when doing the analysis. It is a limitation that this study has only been with ten teachers who have attended a PD program voluntarily. Furthermore, it is not certain that doing a textbook analysis with pre-service teacher will show a similar result, since they do not have the same experience to reflect upon. More research needs to be done with other teachers and pre-service teachers as well. This study is an example of how PD can support and train teachers in choosing tasks when planning lessons.

Inquiry-based learning through problem posing in pre-service teachers' teaching practice: a study of discursive manifestations of contradictions

Gresa Pozhegu-Ermeni[1], Svein Arne Sikko[1] and Benedikte Grimeland[1]

[1] Norwegian University of Science and Technology (NTNU), Department of Teacher Education, Trondheim, Norway; gresa.p.ermeni@ntnu.no

Inquiry-based learning and problem posing in mathematics education are often seen as two different learning approaches. In this study we combined these two approaches and examined them as integrated in pre-service teachers' field practice in order to explore how problem posing could simplify the inquiry-based learning implementation. We used discursive manifestations of contradictions from Engeström's Cultural Historical Activity Theory to discuss the themes of challenges and attitudes of pre-service teachers' practice. Data is interpreted using content analysis. We found that the understanding of contradictions increases the possibility to develop inquiry-based learning through problem posing in mathematics education, and they can be interpreted as opportunities for future professional development programs.

Keywords: Inquiry-based learning, problem posing, pre-service teachers, activity theory, manifestations of contradictions.

Introduction

Our research aimed to investigate the use of problem posing (PP) activities in inquiry-based learning (IBL) and explore how PP could simplify IBL implementation. By PP, we mean activities where the student is given opportunities to engage in reformulating, extending, or creating new problems. By IBL, we mean a student-centered teaching strategy in which the students' role is to engage in their own learning, explore situations, inquire, pose questions, and seek explanations in a collaborative setting (Artigue & Blomhøj, 2013). We do this by encouraging pre-service teachers (PSTs) to support IBL lesson plans with PP activities and see how these lesson plans change with the inclusion of PP. Research has shown that there is an interest in integrating PP into classroom practice (Li et al., 2020). The same applies to IBL, but studies indicate that there is a need for professional development programs for integrating IBL in teaching because teachers find it difficult to implement it in the classroom (Sikko et al., 2012). PRIMAS (2011) identified IBL as crucial for successful education, introducing five aspects and their features, including students posing questions. Therefore, we focused on PP to help PSTs engage students in IBL, simplifying IBL implementation and fostering a student-centered environment. While researchers have extensively studied IBL features (PRIMAS, 2011), the key to easy implementation lies within these features. Therefore, our research addressed PSTs' practical challenges and attitudes, to make IBL more accessible and effective by emphasising PP, and to explore how IBL can be developed through PP in mathematics education as an integrated approach. PP is the process of creating new problems for investigating a situation or reformulating existing problems (Silver, 1994). Research (e.g., Zhang & Cai, 2021) has highlighted a lack of studies analysing the content and features of teaching through PP. Studying how PP can be integrated into IBL to facilitate learning and understanding the challenges in this process can inform research to

support mathematics teachers in teaching through IBL. Thus, it is important to explore IBL and PP as integrated parts, not separately, and to clarify the challenges and attitudes of joining the two approaches.

IBL is a multifaceted activity that may guide students to pose meaningful questions and generate relevant answers. PP activities may result in an increased use of IBL. Whether PSTs tend to incorporate IBL and PP in their teaching depends on their attitude towards what they learned from their own experiences, their education and instruction experiences, and their formal knowledge experiences (Richardson, 1996). Attitude is commonly defined as "a predisposition or tendency to respond positively or negatively" to things, people, places, events, or ideas (Vargas-Sánchez et al., 2016). PSTs' attitudes are a key element in understanding classroom practices. Changes in teachers' attitudes are also closely related to changes in teachers' practices, which may result in improved student learning (PRIMAS, 2011). It is therefore essential that we gain a deeper understanding of the attitudes of PSTs toward IBL approaches through PP activities during their school practice periods.

Using PP as a tool, IBL may influence the development of preservice teachers' experience. Studying this connection contributes to the research field by investigating PSTs' challenges and attitudes while they use IBL through PP lesson plans in their teaching practice. This study used the framework of Cultural-Historical Activity Theory (CHAT), based on the discursive manifestations on contradictions (Engeström & Sannino, 2011). In accordance with Engeström and Sannino (2011), contradictions are manifested in people's actions and speeches, and they cannot be directly observed. The aim of this paper, is to identify the discursive manifestations of contradictions as PSTs pursued their practice period where they would implement IBL through PP. Thus, we look at challenges and attitudes as contradictions, and contradictions as opportunities for future professional development programs of teaching IBL through PP. Our research question is: "What contradictions were manifested by problem posing in pre-service teachers' school practice within inquiry-based learning?"

Theoretical framework

In CHAT, contradictions are seen as opportunities for learning and development (Engeström, 2001). Contradictions cannot be directly studied empirically but must be approached through their manifestations (Engeström & Sannino, 2011). The manifestations of the contradictions can be detected from the actions and speeches of people, and four types of manifestations of contradictions have been identified by Engeström and Sannino (2011):

Double binds "arise when requirements and conditions are incompatible, often expressed as helplessness or desperate rhetorical questions" (Harvey & Nilsson, 2022, p. 7). They are manifested in expressions that reveal that individuals don't know what to do, feel under pressure, and would prefer alternatives to what they are doing. Double binds cannot be handled individually but need to be addressed collectively. Most commonly, this is expressed in a collective action such as "we need", "we have to" and as well as rhetorical questions such as "what can we do?".

Critical conflicts "are situations in which a person encounters inner doubts on contradictory but mutually dependent motives and meanings that are unsolvable by the person herself" (Harvey &

Nilsson, 2022, p. 7). During critical conflicts, individuals feel violated, guilty, silenced, paralysed and communication occurs using "I", and strong metaphors are often used.

Conflicts occur when participants oppose each other's opinions and actions; and there is resistance, disagreement, argumentation, and criticism involved. Conflicts are accompanied by phrases such as "no" and "I disagree" and are typically resolved by compromise or by taking the majority's side.

In a *dilemma*, incompatible evaluations are expressed or exchanged, either between individuals or within a single discourse, and are usually expressed as hedges and hesitations, such as "on the one hand[...] on the other hand" and "yes, but".

Methods

Our data was gathered from ten groups of three to four Norwegian PSTs for grades 5-10, with one participant from each group being selected for interview. PSTs were in their second semester of their first year, engaging in their teaching practice period in actual classroom settings. This involves supervised teaching experiences, allowing them to apply theoretical knowledge, develop teaching skills, and understand classroom dynamics. During a workshop about IBL through PP on campus, the participants were divided into ten field practice groups, so the participants for interviewing were selected on a purposive sampling approach, while each participant represents one group. The interview guide for the semi-structured interviews was based on themes of PSTs' challenges and attitudes related to IBL through PP revealed from prior campus workshops as well as literature. The themes of the interview were jointly discussed by the three authors. The first author of this paper conducted the interviews, and all interviews were conducted in English. It should be noted that English was not the first language of any of the participants. The interviews were audio-recorded and fully transcribed. The data were analysed using qualitative content analysis. We used the framework proposed by Engeström and Sannino (2011) to identify the discursive manifestations of contradictions. First, we identified segments relevant to our research question and we reduced our data in which PSTs mentioned challenges or attitudes (see Table 1). Second, we categorised each significant segment according to the four manifestation types (Engeström & Sannino, 2011). Additionally, key words for each manifestation were emphasised, along with arguments for categorisation. A better understanding of contradictions was provided by analysing their type and theme together.

Table 1: Examples of themes

Attitude	Challenge
I think the students enjoyed it very much because it was something different because maybe they thought that math wasn't their like favourite subject… like…I think it was fun to do something else that didn't feel like a normal mathematics lesson and so it helped their motivation a bit.	That was hard! That's what I think is the hardest thing: Those questions you ask, the students or the groups.... To make them... Ehhmm... work more or realise themselves what they can do without you telling them what to do.

Results

This study identified 80 discursive manifestations of contradictions. Table 2 gives an overview of manifestations of contradictions and their types. Based on the nature of the contradictions (Engeström, 1987), it is obvious that we have a higher frequency of contradictions in the challenges than in the attitudes of the PSTs. Most noticeable is the high frequency of "dilemma" and "double bind" manifestations, especially in the challenge theme and there was a much lower frequency of "conflict" manifestation.

Table 2: Types and the themes of discursive manifestations of contradictions

	Double bind	Critical conflict	Conflict	Dilemma
Attitude	9	3	0	17
Challenge	12	17	2	20

Double binds

Double binds were less frequent in PSTs' attitudes than in challenges. PSTs were unwilling to use IBL through PP without prior instruction. PSTs declared that they need more help to implement these approaches in their teaching. They pointed out that it is important to practice it and not just being told about it. Thus, PSTs identified the developmental needs in their mathematics teaching with IBL through PP with the help of experts in the field:

> PST: I wouldn't wish that I knew more about PP and IBL, but I think by just reading or someone telling you about it, I don't think for myself, I don't learn more from that than actually doing it with the students because.... For me, seeing it in person… seeing it…come to life.

Time resulted in a double bind in the following way: during the practice, students had to abide by the schools' regular time schedule, which restricted their implementation of IBL through PP as they felt this required more time:

> PST: We have planned this, you know, so you only have like 45 minutes that it's just way too little time… That was stressful, and I also think the kids also got a little stressed because I think 2 minutes to write is way too.... It's not good at all, and they probably should have had way more time, I think, to write the problems. And also, I think you should have much time they like compared to like writing the equations and writing the text, you know...

Examples of double bind manifestations include rhetorical questions, the use of the pronoun "we," and confirms that contradictions need a collective action to get solved. Despite these seemingly insurmountable obstacles, PSTs managed teaching IBL through PP in their practice. Thus, manifestations of the double bind were characterised by an urgent need for action thinking that something must be done to improve the situation.

Critical conflicts

We found situations where PSTs felt guilty for asking students to work on tasks where they did not have sufficient prior knowledge, like using equations to solve word problems:

PST: I'm not sure, I think…and maybe not all of them really understood what an equation was or like they.... But at the same time all of them could be solved as equations, but they were kind of big task. I think maybe a little bit of we hadn't had like these types of problems that they had to solve beforehand because they only had like.... Just like solve this equation and not like text.... Yeah, so I think maybe we should have had like a lesson before where they solved these types of problems before they had to like to make them. But I don't, I don't know.... We got to know what could have made it clearer.

Another contradiction manifested as a critical conflict of PSTs was when PSTs were unsure how to guide the students without just telling them what to do. The following example illustrates PSTs' feeling of powerlessness:

PST: That was hard! That's what I think is the hardest thing: Those questions you ask, the students or the groups.... To make them... Ehhmm... work more or realise themselves what they can do without you telling them what to do.

Conflicts

Conflicts were the rarest type of manifestation of contradictions. The next example shows a challenge of a disagreement between a PST and a practice teacher:

PST: And I also think.... Time is also, can be a little challenging, time because…. Yeah, time was very challenging. We only have 45 which is way.... We were actually having 90 and then 45 minutes.... But then, like...Class like the week before she was like ...our practice teacher was like "yeah, we can't do that those minutes because we have to go do something else" or whatever they were.... And I was like, oh....

Another example is when there were also many different points of view about the contexts of the posed problems, resulting in a high incidence of conflicts between students:

PST: At least we had young students, and they also thought it was really cool to make a difficult task like "look, I made the most difficult task you can solve this", and then I asked, "can you solve it?", and then they're like "Oh no, I can't.". So yeah, that could be a problem as well. And also, how those students were because there was a class with many difficulties outside of the lesson itself because they yeah, as soon as they met a challenge, they were like jumping around and running around then yeah. So, they weren't dealing well with like meeting a task they didn't feel like they managed, yeah.

Dilemmas

Dilemmas were the most frequent type of manifestations of contradictions. Most of the dilemmas were about PSTs' expectations and responsibilities during their practice. One dilemma manifested when PSTs reflected on whether they could use IBL through PP in all lessons or whether this method should only be reserved for special lessons:

PST: I think it's… it could kind of explore things because I think you get a lot of a much deeper understanding too; you know solving the problems when you actually have to make them. It's often difficult to know how-to take-out information, but if you actually make them, you kind of know how they're built up, but I don't think we can like only have problem posing in IBL in like every lesson.... Because I think a lot of students need to have some structure and needs to be kind of guided in some ways as well.... hmmm…Important to have that habit in mind when you may....

Researcher: And listen to students that maybe sometimes it' s good to use problem posing into IBL....

PST: Yeah, yeah, and problem posing, because I think problem posing is kind of helps with IBL because IBL is very big and you don't know where to start, is like OK, you're going to be exploring things, but what do you do? Where do you... where do you begin ...?!

When IBL through PP teaching method is used in PSTs' practice, as new and more advanced than their previously used teaching methods, they become contradictory to PSTs' expectations of how the students understand the problem context and how this context has sense in real life. This contradicts the norms of creating mathematical problems that have sense in the real-life context. This contradiction is manifested as dilemma because PSTs were confused between the different ways in which students conceptualise the context of tasks:

PST: Choose harder [PST probably meant longer, not harder] length on the pool because...a pool that's 2 centimeters?! And yes, you can't swim in that, so you kind of get them to understand the logic that a swimming pool isn't just 2 centimeters, but it should be....

PST: Not everyone, I remember there was one girl that had this problem like oh, it didn't make sense, but it was so interesting to see how she came up with that problem. We also have one of these where like: Uh..., one half of a boyfriend and 1/4 of another boyfriend. How many boyfriends did you have like?

PST: Yeah, it didn't make any sense so but yeah, but some of them didn't understand it really good, then made this happened.

Researcher: Yeah, and why do you think this happened?

PST: It isn't a misunderstanding. Maybe they don't understand what the numbers mean or. Yeah, that is pieces of the whole enough that you can take one 3/5 of a person. And yeah, so these tasks are good to figure out and maybe things like this that the students don't know what it means or…. Yeah, yeah, common misunderstandings maybe!

Discussion and Conclusions

We show in the present study how activity theory with a contradiction's perspective contributes to understanding and shed light on the underlying structures for establishing PP in inquiry teaching. Our study implies that many PSTs are open to teach IBL through PP in their teaching. PSTs were ambiguous about IBL implementation, and this resonates with other findings from DiBiase and McDonald (2015). In our study PSTs were not confident regarding their own knowledge and skills. Blomhøj et al. (2022) emphasise the importance of supporting teachers in planning inquiry-based mathematic teaching, especially for students' independent inquiry. Our analysis of discursive manifestations of contradictions support Blomhøj et al. (2022). In our study, the PSTs felt that they needed more prior knowledge of IBL and PP before being able to implement it in schools in a way that enhances student learning. This points towards the need for professional development, at both pre- and in-service level, which is consistent with Sikko et al. (2012), who suggested that continuous professional development courses which promote improvements in mathematics and science teaching and classroom practice are needed.

We found that time constraints are an obstacle when trying to implement IBL through PP lesson in practice, and this turned up in different manifestations. Calleja et al. (2023) found that teaching through inquiry requires teachers to balance integrating inquiry with contextual challenges within sufficient time. It's typical for teachers to calculate their decisions in terms of time, but in this study, we also see time as an opportunity for PSTs to learn and develop their teaching. Firstly, in our study

the PSTs realised that lessons need to be organised so that students have sufficient time for posing problems and solving tasks. This means that lessons should be concentrated around a few carefully selected tasks/problems. PSTs saw this as important for their future work as teachers, and this was manifested as a double bind in our results. Secondly, a conflict about time occurred between a PST and a practice teacher. In line with Ruthven (2009), we see our results as an opportunity for PSTs to measure didactic time in terms of student learning progress and not just as a requirement to cover a curriculum. Ruthven (2009) calls this "time economy", which is a coordinating resource system consisting of a working environment, activity format, and curriculum script to support classroom activities. In our study, the PSTs felt guilty for not developing students' knowledge of textual problems with equations beforehand. Therefore, in this way they express their willingness to invest time in familiarising students with equations so that IBL teaching with PP activities is as practical as possible for students. This finding resonates with what Ruthven (2009) called "instrumental investment". The understanding of discursive manifestations of contradictions found in our study increases the possibility to develop IBL through PP in mathematics education as an integrated approach. We see potential for further study how IBL through PP approaches may improve teaching and learning. The results of the present study concerning PSTs challenges and attitudes, provide critical information about how teachers will implement teaching IBL through PP. Contradictions identified in this study could be interpreted as opportunities for professional development in the future. Also, this study could provide further insights into the relationship between contradictions and inquiry in mathematics education.

Utilizing a three-phased didactical model in a continuous professional development program for the implementation of inquiry-based mathematics teaching

Ida Redder Honoré[1] and Louise Laursen Falkenberg[2]

[1]University College Copenhagen, Denmark; idre@kp.dk

[2]University College Copenhagen, Denmark

Inquiry-based mathematics teaching (IBMT) has a potential to motivate and develop students' mathematical competencies but proves challenging for teachers to implement. This paper presents results from a continuing professional development (CPD) project focusing on implementing IBMT through lesson study cycles centered around a three-phased model for IBMT. A framework of essential IBMT-ingredients was used to identify essential IBMT-ingredients and challenges related to this. Our analysis shows teachers adopting IBMT-values and implementing the structure from the three-phased model. They succeed in initiating and engaging students in inquiry, thus creating opportunities for dialogue, justification and shared reflections. However, the latter rarely happens. This highlights the need to find ways to consistently support teachers in managing student responses through dialogue and facilitating whole-class discussions based on students' mathematical thinking.

Keywords: Inquiry based learning, professional development, mathematics teachers.

Introduction

Inquiry-based teaching has had a significant focus within the field of mathematics education during the last decades. Although there is no simple definition of inquiry-based mathematics, there is broad agreement that it is a student-centered approach that provides opportunities for problem-solving, reasoning, and communication, and has the potential to motivate students (Artigue & Blomhøj, 2013). The Danish curriculum is oriented towards developing students' mathematical competencies and it highlights the importance of students' engaging in mathematics through dialogue and in collaboration with others. It is therefore clear that the curriculum, in both goals and form, emphasize inquiry-based mathematics teaching (Ministry of Children and Education, 2019). Many mathematics teachers in Denmark find the inquiry-based and competency-oriented approach to teaching both inspiring and meaningful. However, they find it difficult to translate these ideas into their own teaching practice (Højgaard & Sølberg, 2023). In a large national survey, teachers highlighted several perceived challenges. They encountered difficulties generating inquiry-based problems to pose to students and finding time for planning. Furthermore, the teachers have an experience of "loss of control" when they cannot predict the direction of students' inquiry-based activities (Dreyøe et al., 2017).

In 2020 University College Copenhagen (KP) together with 10 primary and lower secondary schools in the Municipality of Copenhagen, developed a CPD-program aimed at enhancing motivation and student learning through inquiry-based mathematics teaching allowing students to engage in problem-solving, communication, and reasoning. For two years, mathematics teachers participated in a CPD collaboratively developing didactic strategies to facilitate inquiry-based mathematics teaching in their classrooms. They were supported by researchers and the school's mathematics supervisor.

In a similar project from Norway teachers highlighted a three-phased didactical model for IBMT as a crucial enabler for successful implementation of IBMT in school (Haavold & Blomhøj, 2019; Blomhøj et al., 2022). The three-phased model therefore became a central element in the CPD-program. In this paper, we will investigate if and how a CPD-program centered around the three-phased model can enhance the implementation of IBMT. The research questions are: *How can a continuing professional development program focusing on a three-phase model for Inquiry-based mathematics teaching strengthen its implementation? What challenges and successes do teachers encounter in each of the three phases?*

The framework of the CPD

Professional learning communities where teachers discuss instructional decisions based on shared goals and educational values, have shown promising in improving both teaching practices and student learning outcomes (Cobb et al., 2018; Akiba et al., 2019). Especially lesson studies have gained significant attention worldwide, inspired by how Japanese teachers collaboratively explore and investigate curriculum, teaching practices, and student learning through live classroom lessons (Lewis et al., 2006). The strength of lesson studies as a professional learning process lies in its strong focus on student learning and the enactment of teaching. This involves collaborative planning, observation and reflection, all centered around understanding how students learn and how teaching practices affect learning. It is well documented that this is crucial to promote mathematical knowledge for teaching and embed knowledge into daily teaching practice (Akiba et al., 2019). Lewis et al. (2006) illustrate two alternative ideas about how lesson study improves instruction: 1. by refining lesson plans and 2. by strengthening three pathways to instructional improvement – teacher knowledge, teacher communities and learning resources. While the first is easily recognized by teachers, it is the second idea our CPD program aims to promote.

In the project, a teacher learning community was established by teachers collaborating through lesson study-inspired learning loops. Mathematics teachers and supervisors participated in four loops. A learning loop consists of Shared Planning, Teaching/Observation and Joint Reflection (Figure 1).

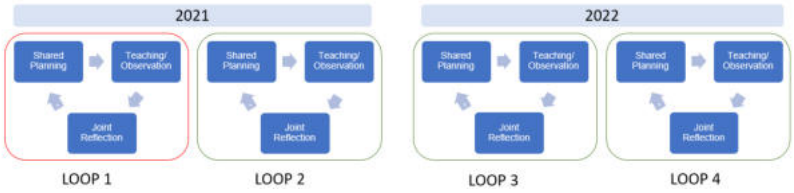

Figure 1: The framework of the continuous professional development program

The *shared planning* was led by both a researcher and a mathematics supervisor and was integrated into a course on current research in IBMT. It involved collaborative planning within smaller teacher teams. The *teaching and observation* followed a format of a research lesson. It was conducted in the classroom where one teacher teaches the lesson while the team, along with researcher and the mathematics supervisor, observe the lesson. The *joint reflection* was divided into two parts, Joint Reflection 1 being similar to a traditional lesson study post lesson reflection where observations are shared and reflected upon. This session is summarized by either the researcher or the mathematics supervisor. In Joint Reflection 2 all mathematics teachers and supervisor(s) at school gather to share

findings from their research lessons and to identify successful instructional approaches to IBMT. Research presented during their *shared planning* was revisited and connected to the experiences from the research lesson, ensuring that theoretical insights informed practical outcomes.

The content of the CPD

The content of the CPD focused primarily on operationalizing the ambitions of IBMT. The three-phased model for IBMT has proven to be an effective planning tool for teachers, and it also offers the potential to explore the instructional challenges inherent in each phase (Haavold & Blomhøj, 2019). The first phase involves setting the scene for students' activities. This includes creating engaging and clear inquiry questions, challenges or amazement to spark their curiosity. In the second phase, students engage in independent, inquiry-oriented activities. The third phase is a whole class discussion where results, and reflections from the activities are systematically organized and shared among students. Mathematical insights are extracted from these shared results and reflections, and these insights are linked to institutionalized knowledge, such as the curriculum. The model is illustrated in figure 2. The model served as a framework for sequencing the IBMT lessons and for discussing and reflecting on the teacher's role and challenges in IBMT.

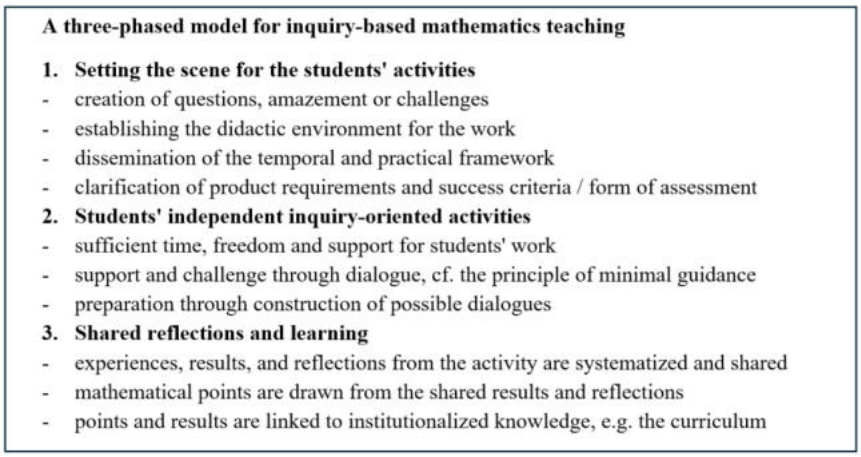

Figure 2: Three-phased didactical model for IBMT

To support teachers in noticing and enacting the classroom practices embedded in each of the three phases we found it useful to integrate the Five Practices framework into the three-phased model. Five Practices for Orchestrating Productive Mathematical Discussions is a framework designed to help teachers use student responses to advance the mathematical understanding of the class by providing teachers with some control over what might happen during the lesson. The five practices are *anticipating, monitoring, selecting, sequencing and connecting student responses* (Smith & Stein, 2018).

Each learning loop focused on one of the three phases and provided the teachers with research, examples, videos, and discussions addressing central elements within each phase. The teachers planned the entire lesson in each loop, but with particular emphasis on one of the phases. In loop 1 we focused on Phase 1 *setting the scene for the student activities*. Beside selecting tasks and setting goals, the teachers were engaged in how to launch a task in a way that motivates students to

investigative problems and provide all students with opportunities for participation. In loop 2 the central focus was Phase 2, *Students' independent inquiry-oriented activities***.** We addressed two central issues: to anticipate student response and support and challenge through dialogue. In loop 3 the central focus was Phase 3*, Shared reflections and learning*. Building on the teachers' anticipation of student responses, teachers engaged in how to organize a whole-class discussion where students ideas and results are shared, and the mathematical point stands clear. In loop 4 we addressed special issues the teachers identified as most difficult, e.g., the shared reflection (Phase 3) and how to identify the central mathematical idea or point in a task. We encouraged the teachers to base their lesson planning on IBMT activities that we introduced and worked on thoroughly during the course.

Methods

Our analysis focusses on the implementation of IBMT and the associated challenges encountered during the CPD-project. Two primary schools (grades 1–6) were selected as critical cases to obtain information that allows logical deductions of the type, "If this is (not) valid for this case, then it applies to all (no) cases." (Flyvbjerg, 2006, p. 230). These schools are considered critical cases because all mathematics teachers at both schools were actively involved in the project, each school had a highly experienced and dedicated mathematics supervisor and both schools received strong support from the head of school, which, as noted by Cobb et al. (2018), is a key factor in the success of a CDP. Our data consists of video observations from six IBMT lessons (1st grade (1), 2nd grade (2), 3rd grade (1) and 6th grade (2)) conducted during loop 2–4, as well as interviews with one teacher and three supervisors (who are also teachers). The video observations were partially transcribed, while the interviews were fully transcribed. The analysis and findings in this paper rely on data from both video observations and interviews. To identify the presence or absence of successful implementation of IBMT, we used the framework of five categories of essential ingredients in inquiry-based education shown in Figure 3: *valued outcomes, teacher guidance, classroom culture, type of questions* and *what student do* (Artigue & Blomhøj, 2013). The analysis followed a deductive approach, specifically looking for these essential ingredients. For instance, we coded the following statement from a teacher to his class "Just try. No one gets angry when you try. And if we make mistakes, we learn from them." (2nd grade) as *Valued outcomes, inquiring minds*. Like Figure 3 indicates, the five categories overlap, and this example could also be coded as *classroom culture, value mistakes*. Examples of coding of the remaining four categories. *Type of questions, open, multiple solution strategies*: Teacher: "It's about subtracting a one-digit number from a two-digit number. If I tell you the result [difference] must be three, which two-digit and one-digit numbers can I use?" (1st grade). *Teacher guidance, values and builds upon students' reasoning/scaffolding*: Teacher: "You've come to a standstill over here. Sander, tell us what you said before and how you arrived at that conclusion" (6th grade). *What students do, explain*: Student: "We started by giving 10. Then we found out that everyone could get 3 more, so everyone could get 13. Then there were 4 lefts." (3rd grade). *Classroom culture, dialogic*: Teacher: "Now we've been searching for rules. What have you come up with?" Student: "We've found a system." Teacher: "What's happening?" (1st grade)

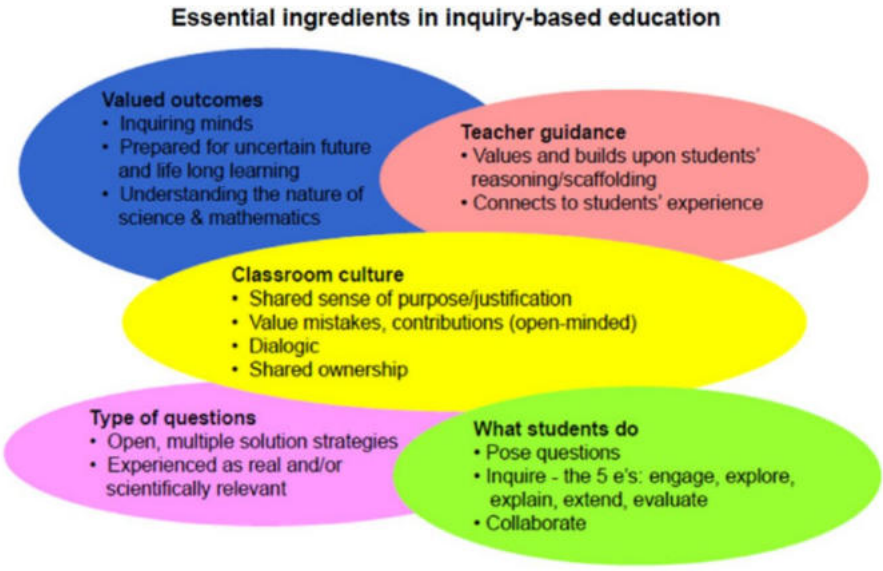

Figure 3: Essential ingredients in inquiry-based education

This coding was followed up by an examination of where these findings emerged during the phases of the lessons. Finally, we searched for elements of the three-phased model (Figure 2) to see what parts of the model was present (or absent) in the lessons and to identify possible challenges related to these. For example, "Is there a shared reflection and if so, does it contain sharing of results and systematization?"

Results

The analysis shows that all teachers adopt IBMT-values. In the interviews the teachers express the potential of IBMT in cultivating a *classroom culture* where students' contributions are seen as *valued outcomes.* One teacher emphasizes the affective potentials of IBMT: "…working together on something and feeling like one is contributing is significant for the students" (teacher 1). Another teacher highlights potentials regarding student participation "both high-achieving and low-achieving students can participate" (teacher 2). This teacher also emphasizes the potential of the *type of questions* in IBMT: "I like the idea that there are many ways to arrive at a solution" (teacher 2). The teachers' perceptions are also reflected in the IBMT lessons. They are being explicit with students about inquiry values by telling students mistakes are productive and welcome, that there are multiple paths to the answer, and encouraging them to experiment. Like in a 2nd grade class, where the teacher encourages students to take risks and again at the end of the lesson emphasizes this as a valued outcome: "Wow, you were so great. You must trust yourselves when you do something like this." (2nd grade)

The teachers use the terminology from the three-phased model when discussing teaching. For example, "We have opened our approach to setting the scene and shared reflections, and how we provide support along the way" (teacher 4). This indicates teachers having adopted the model and finding the concepts derived from it meaningful for describing teaching practice. The lessons are

clearly structured according to the three-phased model. However, in the following sections, it will become clear that some phases are easier for teachers to implement than others.

In phase one, we can identify a high amount of essential IBMT-ingredients, especially in terms of *type of questions* posed by teachers, *classroom culture* and *teacher guidance*. The teachers were exemplary in posing imaginative initial problems with multiple possible solution strategies. They received numerous positive reactions like laughter, smiles and students generally paying attention and listening to the teachers' initial question. This show that the problems are *experienced as real and relevant.* The teachers establish a *classroom culture* with a *shared sense of purpose and shared ownership* and are attempting to connect the mathematical problems to student's experiences for clear *teacher guidance*. Like in the following sequence from a 3rd grade, where the teacher introduces the class to a problem related to division with remainders through the context of Grandma Olga and her sausage-shaped dog. The teacher draws Grandma Olga on the board and tells the students she wants to distribute 95 gingerbread cookies equally among her 7 grandchildren. Olga has a dog named Sausage. Students are attentive as the teacher draws the dog. They laugh shortly and calm returns quickly. "Sausage will get the leftover cookies after a fair distribution… Sausage should keep his shape", the teacher says. (3rd grade) The teacher uses a familiar and fun context and uses drawings to capture students' attention, making the problem relevant and creating a shared sense of purpose. In the interviews the teachers also emphasize the first phase (setting the scene) as valuable. For instance, one teacher says, "…I think the idea of tying a story to an investigation really captures the students' interest" (teacher 4) thus telling us that this approach to starting an investigation is somewhat new to him. After a successful introduction of the problem to the students, the lesson progresses to the second phase - students' independent inquiry-oriented activities. Most of the children are actively participating in the task and *collaborate* with classmates. The teachers attempt to support and challenge students through dialogue, but maintaining a dialogic approach proves difficult. We observe teachers creating a *Classroom Culture* that is partly *dialogic.* For example, from video observation, 3rd grade:

Teacher:	Could you manage it [the method] with [distributing] 14 [gingerbread cookies to each]? how did you actually do it?
Student:	We just wrote 10 under each and then tried to write 4 under each, then we found…
Teacher:	…found out you were missing some gingerbread cookies.

Here we see an initially open question ("how did you actually do it?") which leads to the student explaining his method. However, the teacher interrupts the student and takes over his explanation taking away the possibility for the student to validate his solution. We see some elements of *teacher guidance* in trying to value and build upon student reasoning: "Okay, you find pairs of numbers. Aha. How do you know that 16 and 12 are a pair?" (2nd grade) But the questions are posed quickly and only partially answered by the students before the next question is introduced. Although the questions have the potential to enhance students' reasoning, insufficient time is provided for a genuine dialogue to develop. In phase three, all teachers gather students for shared reflections and learning at the end of the lesson. But it is mostly carried out as an arbitrary round of individual presentations of methods shortly validated by the teacher, e.g., "Great, good solution." (6th grade) without a need to justify.

Although focusing on the practices of anticipating and sequencing in the CPD we see few signs of teachers sequencing student solutions. On the contrary, one teacher opens the shared reflections by asking the student who found the task most easy to explain her most complex solution for the class: "Julia, you have solved all the tasks. Which part did you find the most difficult?" (2nd grade) This left the rest of the class losing focus and appearing disengaged in Julias explanation. Moreover, students' results are rarely connected to one another, and the lesson's mathematical points are seldom clear and linked to institutionalized knowledge.

However, in the 1st and 2nd grade we see students being able to identify and describe the mathematical system in the task (e.g., "It's a number pattern – you keep adding 1 each time." (1st grade student)), and a teacher who systematically guides students in this direction. Unlike the other lessons, this lesson was derived straight from a Japanese lesson study introduced at the CPD. Here the mathematical system and idea in the lesson was described in detail as well as the teachers' organization of the shared reflection. This could imply a need for more robust scaffolding for the teachers.

Discussion and conclusion

We have examined how a CPD program focusing on a three-phased model for IBMT can strengthen its implementation, and what challenges can be identified. Aligned with Højgaard and Sølberg (2023) we find teachers adopting IBMT-values. And as Blomhøj et al. (2022), we show that the elementary teachers adopt the three-phased model as a didactical tool for planning, conducting, and reflecting on their IBMT lessons. In this paper we show what kind of challenges the elementary teachers face translating IBMT ideas into their own teaching practice. The nature of these challenges appears to differ from the secondary teachers in the study from Blomhøj et al. (2022). Our analysis shows that the elementary teachers in phase one, clearly set the scene and hand over the problem to students in a way that allows all of them to engage in phase two with a shared sense of purpose. This result contrasts with the findings of Blomhøj et al. (2022), who report that secondary teachers face challenges in phase one, particularly in establishing a shared sense of purpose, where a mismatch between students' and teachers' perceptions of clarity is a key difficulty. We show how the elementary teachers struggle to sustain a dialogic approach to teaching that promotes students' reasoning, sequencing and connecting the class's solutions to the lesson's mathematical goals. The secondary teachers in the study of Blomhøj et al. (2022) have a clearer understanding of the mathematical purpose of the given task and focus on linking the task to the mathematical content. This suggests that the teachers in the two projects focus their efforts on different phases of the IBMT lessons.

Our study is based on two critical cases, defined by the fact that the teachers in our study have optimal conditions for implementing IBMT. These conditions include strong, supportive mathematics supervisors and a school leadership that prioritizes and facilitates teachers' time for professional development. Despite these favorable conditions and the strong three-phase framework for implementation, fundamental IBMT values such as creating opportunities for students' reasoning remains challenging. This suggests that even under favorable conditions, a CPD-program demands persistence to embed IBMT values into daily teaching practices.

However, our study also suggests that a CPD structured around well-developed IBMT lessons (e.g., from Japanese lesson studies) proves more successful for the implementation of IBMT than teachers

developing their own IBMT lessons. This is especially true when it comes to the shared reflection (Phase 3). While this finding is not surprising, it is to some extent still a rather provocative result in a Danish context, where we highly value teacher autonomy (Højgaard & Sølberg, 2023).

Fostering the perception of ambiguity and the processing of information in complex diagnostic situations

Andreas Rieu, Katharina Loibl and Timo Leuders

University of Education Freiburg, Institute for Mathematics Education, Freiburg, Germany;
andreas.rieu@ph-freiburg.de

Human perception and information processing is not always rational. For instance, it has been shown that teachers' judgment processes are subject to cognitive biases: Teachers sometimes fail to perceive the ambiguity of diagnostic situations, or they process irrelevant information in order to make their final diagnosis. Both biases may result in inaccurate judgments. Since accurate judgments are a basis for adaptive teaching, it is a concern of teacher training to improve the diagnostic competence of teachers. The present study describes two structurally comparable one-shot debiasing interventions designed to improve either situational awareness or the processing of information during decision-making in a simulated pedagogical situation. To this end, we randomly assigned prospective teachers (N = 73) to two experimental or one sensitization group and had them diagnose misconceptions in the area of decimal fractions using vignettes of virtual learners. The results demonstrate a significant effect of a debiasing training in the area of information processing, but no effect of a debiasing training on the perception of the ambiguous diagnostic situation. These results are discussed with regard to the necessary cognitive processes and their possible consequences for teacher training.

Keywords: Teacher training, Diagnostic competence, Information processing

Diagnostic competence and adaptive learning

Brühwiler and Vogt (2020) show that teachers' adaptive teaching skills effect significantly the learning success of students, because it increases the quality of teaching. In addition to general didactic skills, i.e. the use of suitable classroom methods, diagnostic competence is an important component of this adaptive teaching competence. Diagnostic competence is defined as the ability to assess the requirements of tasks or learning settings in the classroom on the one hand and the learners' prerequisites on the other hand (Artelt & Gräsel 2009; Rieu et al., 2022; Schrader, 2013). The quality of this assessment can be measured via judgment accuracy and thus expresses the teacher's ability to make personal (teacher's knowledge of different learners), task-related (task difficulty) and person-specific (personal characteristics or behaviours of individual learners) judgments (Urhahne & Wijnia, 2021).

Judgment accuracy

Meta-analyses show that teachers' judgment accuracy varies in different diagnostic situations and report moderate to high correlations between teacher ratings on students' individual abilities and students' individual performance on a standardized test (Urhahne and Wijnia, 2021). Various moderators could be identified such as characteristics of the teachers, the tests or tasks or the learners (Funder, 2012). These results categorize and systematize the influencing factors on judgment accuracy, but they do not provide more specific theoretical assumptions about the genesis or the

underlying cognitive processes of teachers' judgment. In recent years, studies have therefore focused on the genesis of diagnostic judgments and have shown, for example, the influence of situational characteristics such as time pressure or stress (Rieu et al., 2022) and personal characteristics such as subject-specific didactic knowledge (PCK) on the judgment processes. PCK was identified as a necessary prerequisite for the complex judgment processes and thus influences the teachers' judgment accuracy (Rieu et al., 2022).

Judgment biases

Another factor influencing judgment accuracy can be cognitive biases, such as the confirmation bias. Due to the confirmation bias people tend to select and interpret information in such a way that it confirms their own expectations and opinions. Cognitive biases are usually unconscious and often occur in complex diagnostic situations, e.g. where a lot of information are to be processed, the elements are interconnected, etc. (Marewski et al., 2010). Such complex diagnostic situations also arise in the area of pedagogical judgments. For instance, systematic occurring errors can have its origine in different misconceptions of the learner. Thus, in order to determine the existing misconception, further information must be obtained to generate an accurate final diagnosis.

More concretely, an incorrect solution to a task often cannot be clearly attributed to a misconception but can be the result of various causes. Therefore, the teacher should first consider all possible causes (misconceptions) for the occurrence of the error as hypotheses. Then the teacher needs further information to diagnose the existing misconception. By selecting relevant tasks, the teacher can obtain the necessary information for an unambiguous final diagnosis on the basis of the solutions obtained or by observing the solution process. In the described situation, a cognitive bias can be assumed both 1) in the perception of the ambiguous (multi-causal) situation and 2) in the complex processing of information (Rieu et al., 2024). That is, the teacher may fail to perceive the ambiguity of the situation (possibly because he or she already has a hypothesis regarding the underlying misconception in mind) or the teacher may fail to select relevant tasks or misinterpret the information obtained from these tasks and their solution (process).

Consequences for teacher training

Based on the state of research, the question arises as to what extent teachers can be prepared during their university training for the professional challenges in the field of diagnostic judgments. Various studies (Morewedge et al., 2015; Sellier et al, 2019) indicate that debiasing interventions have a positive influence on judgment processes, e.g. in forensic psychiatry or economics. However, a transfer of this approach to teachers has not yet been documented.

In the present study, two brief debiasing interventions to foster teacher diagnostic judgments were conducted. One debiasing intervention focused on the perception of ambiguous diagnostic situations, the other on deductive information processing (see van Brussel et al., 2020, Sellier et al., 2020, etc.).

1. Intervention concerning the perception of the ambiguity (multi-causality) of the diagnostic situation

In general, it can be assumed that systematic errors or occurring problems of learners in different mathematical learning topics can have different causes. It is therefore necessary to recognize and

carefully analyse all possible causes before making a final diagnosis. Also in the school context, diagnostic situations are often characterized by ambiguity (multi-causality). An intervention in this area should therefore first impart knowledge about the multi-causality of learners' behaviour and then select formats in which this knowledge can be applied in concrete situations. Specifically, this means that a school-related topic (e.g. school anxiety) is presented and explained as a phenomenon with various causes. The participants are then confronted with case description in which they are asked to recognise the multi-causality and also receive feedback on their answers (multi-causality recognised vs. not recognised, correct cause(s) named vs. not named).

2. Intervention concerning the information processing (selection of relevant information)

An intervention in the area of unbiased and deductive information processing aims that persons select and process relevant information with rational conclusions. The *Wason Task* can serve as an application example, in order to train human information processing with conditional statements. Four cards are presented, and the participants are told that each of the cards contains a letter on one side and a number on the other. From a formal point of view, the following logically valid conclusions arise: *if p then q and if not-q then not-p*.

Studies that applied the *Wason Task* as an intervention have shown that the unbiased and deductive information processing is reached much more frequently when the content is presented realistically, i.e. less abstractly (Beller, 2012). In the school context, the *Wason Task* has never been applied in teacher training situation but can be conceptualised with school references.

Research questions

The perception of the situation and the information processing of teachers in diagnostic situations, which are often multi-causal, are subject to cognitive distortions such as confirmation bias. This means, for example, that teachers do not perceive the ambiguity of the diagnostic situation, or they process irrelevant information in order to make a final diagnosis. The present study investigates the influence of two structurally comparable one-shot debiasing interventions that are designed to improve either situation perception or information processing during decision-making in a simulated practice situation.

The following research question arises:

To what extent

(1) a multi-causality intervention and
(2) an intervention for undistorted and deductive information processing

improve the judgment process and the judgment accuracy.

It is assumed that (1) leads to an increase in the number of alternative hypotheses formulated and that (2) leads to an increase in the proportion of processed relevant diagnostic tasks and that both interventions (1) and (2) lead to a higher judgment accuracy compared to a sensitization group.

Method

To investigate the research questions, a design was chosen in which vignettes are presented to prospective teachers, each with an incorrectly solved task by a pupil in the area of decimal fraction comparison. The context is based on an everyday diagnostic situation in the classroom or in group work, when the teacher identifies a systematic error and uses other tasks from the textbook or a test sheet to diagnostic purposes. The diagnostic goal was to determine the underlying misconception. In all vignettes, the presented incorrect solution to the solved task can be the result of several misconceptions. The participants were asked to formulate initial hypotheses regarding the misconceptions of the learners. Afterwards, they could select further tasks in order to determine the underlying misconceptions of each pupil. The participants were informed that the diagnostic cases shown to them were attributable to virtual learners and that they always solve the tasks using the same misconception. In the case of real students, random solutions would also have to be considered, which was ruled out here for methodological reasons.

Sample

The survey was conducted with student teachers for primary schools (81% identified as female) at the University of Education Freiburg. All participants were studying mathematics, were on average 22.6 years (SD = 3.13) old and were completing a practical semester at the time of the survey. This group of students was deliberately selected as diagnostic judgments was the main topic of the course that accompanied the practical semester. An overview of misconceptions (i.e. the specific, necessary PCK) was always present to the participants at any moment of the survey to ensure that all participants had access to the same specific didactic knowledge base during the intervention.

Implementation of the study

The data collection was computer-based. First, socio-demographic data (age, gender, course of study, tutoring and practical experience) of the participants were collected. The second part was constituted by the intervention, in which the participants were randomly assigned to the sensitization group or one of the interventions (multi-causality or Wason task). The sensitization took place via a short, written statement concerning the question of whether logical human thinking always represents rational thinking and addresses the occurrence of cognitive illusions. The two interventions took place as described above.

Finally, standardized cases (N = 5) were presented and had to be diagnosed. In these cases, virtual learners had solved a decimal fraction comparison incorrectly. By clicking on further tasks, the participants obtained a solution to these further tasks by the virtual student. The required PCK (Rieu et al., 2022) about the typical misconceptions in decimal fractions was shown permanently to the participants by means of a text. In all diagnostic situations, the initial incorrect solution cannot be clearly traced back to a single misconception. It therefore is an ambiguous diagnostic situation.

Data collection

The prospective teachers first formulated an initial hypothesis on the existing misconception based on the request *Which of the misconceptions could be present in the following case?*, whereby a free

text field allowed one or more hypotheses to be named. Participants were then able to select further tasks and received the students' solutions to these tasks in coherence with their misconception.

The tasks offered for selection were presented in groups of four and differed in terms of the relevance of their information for the final diagnosis. In a block of four tasks to be selected, there were always two tasks that provided evidence for a possible misconception and contradicted another possible misconception (relevant tasks). Two other given tasks did not carry any additional relevant information: These tasks can either be solved correctly with every misconception in the present study setting or the tasks correspond in structure and thus in information content to the task already shown at the beginning of the vignette. The order and placement of the relevant and irrelevant tasks changed from block to block.

The participants were free to decide on the number of further tasks to be completed by selecting any number of tasks from a block of four and by deciding to obtain further tasks in further blocks of four after viewing the solutions of the learner to the selected tasks. At any time, they could proceed to submit their final diagnosis. If the individuals opted for a further block of four tasks, a new block was displayed, which again contained two tasks with diagnostic potential and two tasks without additional diagnostic information. No time restrictions were formulated; the participants were simply asked to make an accurate final diagnosis. In summary, to answer the research questions, the type of initial hypothesis (single or multiple hypothesis), the amount and the type of tasks (diagnostically relevant or irrelevant), and the final diagnosis was recorded.

Data analysis

The overarching research question refers to the effects of two structurally comparable one-shot debiasing interventions that focus either on situational awareness or on information processing during decision making in a simulated practice situation. For this purpose, case-related descriptive statistics are reported, and hypothesis test were calculated to compare the influence of the interventions on diagnostic activities and information processing based on the initial hypothesis of the participants as indicator for the recognition of the ambiguity of the situation, the information search processes with regard to the relevance of the additional information, and the accuracy of the final diagnosis. All participants who completed the survey tool were included in the analysis.

Results

The randomization into sensitization, multi-causality, and Wason groups was carried out using the online tool and generated comparable groups with regard to the socio-demographic data recorded (see Tab 1). Only in the case of tutoring experience, a few outlier data in one group (multi-causality) distort the mean value.

Table 1: Mean values (and standard deviation) of all participants in the Sensitization, Multi-causality and Wason intervention Groups

collected data	Sensitization Group	Multi-causality Group	Wason task Group

main subject mathematics	0.90 (0.30)	0.95 (0.21)	1.00 (0.00)
teaching experience	68.65 (59.31)	73.57 (41.42)	66.33 (58.05)
tutoring experience	10.52 (21.12)	77.90 (192.33)	23.33 (108.57)

In order to investigate the effect of the intervention on situation perception and information processing, the mean values of the persons participating in an intervention are calculated across all 5 cases and then compared with all other persons using t-tests. Due to this new point of observation, the number of analysed cases changes to 105 (5x21). The underlying hypothesis of this procedure is that one intervention has an exclusive effect on perception and the other exclusively on information processing and it can therefore be assumed that the multicausality intervention has no effect on information processing (and conversely the Wason intervention has no effect on perception).

The comparisons show a hypothesis-compliant result for the Wason intervention, after which the information processing (based on the proportion of relevant tasks processed (T(2,363) = -2.027, p = .022, d = . 0.33) and judgment accuracy (T(2,363) = -1.674, p = .047, d = .47) of the participants improved significantly (Table 2). However, the results of the multi-causality group are not as expected: an effect of the intervention on the perception of the situation (based on the formulation of multiple hypotheses) could not be proven (Table 3).

Table 2: Mean values of participants in the Wason intervention (Wason) in comparison to the other participants

Information processed in 5 cases	Control groups (n = 260)	Wason (n = 105)	Group comparison
Perception of situation	0.28 (0.45)	0.30 (0.46)	T(2,363) = -0.383, p = .351, d = -.45
Information processing	0.46 (0.20)	0.50 (0.18)	T(2,363) = -2.027, p = .022, d = -.33
Judgment accuracy	0.64 (0.48)	0.73 (0.44)	T(2,363) = -1.674, p = .047, d = -.47

Table 3: Mean values of participants of the multi-causality intervention (multi-causality) in comparison to the other participants

Information processed in 5 cases	Control groups (n = 260)	Multi-causality (n = 105)	Group comparison
Perception of situation	0.32 (0.47)	0.22 (0.42)	T(2,363) = -1.913, p = .028, d = -.34
Information processing	0.48 (0.20)	0.44 (0.16)	T(2,363) = -1.878, p = .031, d = -.21
Judgment accuracy	0.68 (0.47)	0.64 (0.48)	T(2,363) = -0.782, p = .217, d = -.47

Discussion

It was shown that an intervention for information processing based on the Wason task achieved an improvement in the proportion of relevant tasks processed by pre-service teachers, which also increased judgment accuracy. In contrast, a further, structurally comparable intervention to improve the perception of ambiguity in diagnostic situations did not achieve any effects. The question therefore arises as to whether the cognitive process of perceiving the ambiguity of a situation is more complex than information processing and therefore requires a special intervention. Müsseler and Rieger (2019) describe perception as a phase of early visual processing, which is characterized by a high proportion of stimulus-driven bottom-up processes (automated) without reference to more cognitive functions. However, when perceiving the ambiguity of a diagnostic situation, a process of identification and categorization, i.e. information processing of task features with regard to the depicted PCK, is expected. The perception of ambiguity required in diagnostic situations therefore requires top-down processing of the given information, which only a few participants achieved in our study.

A successful intervention in the area of situational awareness (in the sense of identification and categorization) must be cognitively more profound than that of information processing, since here both the complex situation (here: with the available information) and personal characteristics (here: the necessary PCK) are the necessary basis for recognizing the ambiguity (see Rauthmann, Sherman & Funder, 2015). One answer to this challenge can be found in the instructional design of the training curses: initial studies in the area of sensitisation to multicausal diagnostic situations show the expected effects (Özel et al., subm.) using the 4C/ID model (van Merrienboer, 2020) and thus point to a possible form of successful teacher training.

Using scriptwriting to examine how pre-service mathematics teachers anticipate and respond to students' productive struggle

Sigal-Hava Rotem[1] and Adi Eraky [2]

[1]Freudenthal Institute, Utrecht University, The Netherlands; s.h.rotem@uu.nl

[2]Achva Academic College, Israel

This study is a part of a larger research project that seeks to characterise scripts written by pre-service mathematics teachers (PSTs) in terms of student productive struggle and to understand how this characterisation helps reveal their perceptions in managing this type of struggle. We analysed 17 scripts written by PSTs around one problematised classroom situation involving fraction representation. Using the productive struggle framework (Warshauer, 2015), the analysis reveals that PSTs often do not expect struggle in the problematised situation, and any struggle they do anticipate focuses mainly on students' uncertainty in explaining their work. The PSTs usually use two teaching strategies to respond to struggle: direct telling and affording opportunities to continue thinking about the task. These two strategies are somewhat contradictory in terms of the way they preserve the task's cognitive demand. Implications are discussed.

Keywords: pre-service mathematics teachers, teacher education, scriptwriting, productive struggle.

Introduction and Literature Background

Responsive teaching, a core practice in mathematics education, posits that for teachers to be able to develop students' mathematical understanding beyond current knowledge they must first be attuned to their students (e.g., Barnhart et al., 2024). Warshauer (2015) proposed a framework of productive struggle through which responsive teachers can attend to and respond productively to their students' struggles. This framework offers three lenses to examine how teachers respond to their students: 1) how the task's cognitive demand is preserved; 2) how the students' struggle is addressed; and 3) how the students' mathematical thinking is supported.

Accordingly, teacher preparation programmes include responsive teaching strategies to prepare pre-service mathematics teachers (PSTs) to use these strategies in their future professional lives (e.g., Barnhart et al., 2024; Grossman et al., 2009). One approach to imparting responsive teaching strategies involves the use of simulation-based tools that enable PSTs to engage with their students' struggles and to consider various ways to respond. This paper focuses on one such tool—scriptwriting tasks (Zazkis et al., 2009).

Using scriptwriting, teachers and PSTs write dialogues that outline the progression of a lesson centred on a mathematical task (Zazkis et al., 2009). As a simulation-based tool, scriptwriting tasks offer several affordances: they enable teachers to envision their role in the classroom, including their actions and reactions, without the need for extensive resources in teacher education programmes. Indeed, scriptwriting enables PSTs to create representations of how they anticipate they will enact their teaching practices (Grossman et al., 2009). Moreover, these scripts provide valuable data for teacher educators to learn how PSTs perceive their future teaching. Recent research has examined

mathematical knowledge (e.g., Marmur et al., 2020), particularly mathematical knowledge for teaching among PSTs and teachers (e.g., Shure & Liljedahl, 2023), across various domains, as reflected in the teachers' turns in these scripts.

Scriptwriting tasks were developed to overcome the frequent oversimplifications and overgeneralisations in the lesson plans PSTs write in teacher education programmes (Zazkis et al., 2009). These tasks reveal how PSTs plan to teach content in the classroom, and how the PSTs take into consideration what both teachers and students contribute to the lesson. Further, these tasks are designed to problematise teaching and highlight classroom complexity by beginning with a complex classroom situation, to which a teacher can respond in multiple ways to advance students' understanding. Problematising teaching does not necessarily refer to students' difficulties but rather can include any type of struggle (e.g., how to begin working on a task, address misconceptions, or explain work). In responding to such struggles, teachers can continue the struggle and use it to foster further mathematical learning, or they can diminish it with direct instructions that decrease the task's cognitive demand. Framing these problematised teaching situations in terms of productive struggle (Warshauer, 2015) helps characterise both student and teacher turns in the discussion script, potentially facilitating an exploration of the dialogic relationship between teacher and student turns.

Current research often analyses teacher and student turns in scripted discussions separately (e.g., Shure & Liljedahl, 2023), overlooking the dialogic communication between teachers and students. Yet responsive teaching necessitates the interplay between student struggles and teacher responses. Indeed, a student's struggle influences the teacher's response, which in turn affects whether the struggle remains productive for the student's learning. Scriptwriting gives PSTs the opportunity to experiment with this dynamic interplay. Through scriptwriting, PSTs can imagine how students will handle struggles, how they as teachers will respond, and how they can preserve the cognitive demand of the task while addressing the struggle in a supportive manner. Hence, we build on studies that used written scriptwriting tasks to learn how PSTs planned to enact their teaching practices (e.g., Shure & Liljedahl, 2023), with specific focus on how PSTs managed their students' productive struggle (Warshauer, 2015). Moreover, here we adopt a different approach: Not only do we focus on the teacher's moves but rather we simultaneously focus on the students' contributions and the teacher's responses. We begin with a problematised classroom situation (Markovits, 2003) that introduces a non-traditional representation of a fraction that may potentially trigger misconceptions among students and teachers (described in detail in the Methods section).

This study makes several contributions. Its analysis of the interplay between student and teacher turns in the scripts expands the research knowledge about how PSTs perceive student struggles and how they will use these struggles to advance students' learning. This knowledge also has practical implications for teacher preparation programmes in that it can help teacher educators plan teaching preparation programmes. Lastly, the methods described here can be used to examine scriptwriting tasks written for different classrooms situations and other mathematical topics. We examine these contributions by exploring the following research question: *What does analysis of PSTs' scriptwriting tasks in terms of productive struggle reveal about how PSTs plan to manage future student struggle involving student's suggestion for representing a fraction?*

Methods

Task starting point –problematised classroom situation

The task in this study consisted of 1) a short, problematised classroom situation that served as a starting point (Figure 1); 2) several prompts aimed at facilitating the PSTs' understanding of the problematised classroom situation; 3) instructing the PSTs to write a script; and 4) prompts aimed at encouraging the PSTs to reflect on their script. Due to space limitations, here we focus only on part 3 of the task in which the PSTs were asked to imagine that they were the teacher, respond to the student mentioned in the short situation (part 1), and continue the dialogue between the teacher and the student(s).

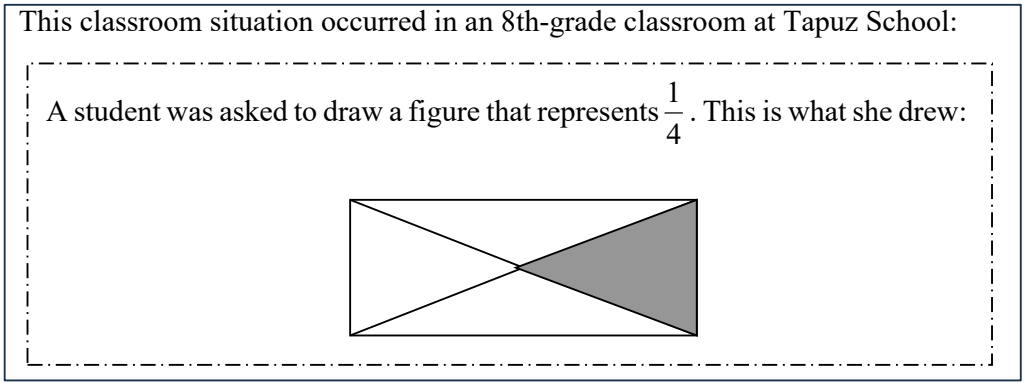

Figure 1: Starting point for scriptwriting task (Borrowed from Markovits, 2003)

The task was designed to problematise the classroom situation by showing a correct fraction representation that might potentially evoke misconceptions both about fractions and about geometry. In the case of fractions, a possible misconception is that students might claim that the triangles formed by the rectangle's diagonals are not equal because they might think about the congruence of the triangles rather than considering the areas of these triangles. A possible geometric misconception is that students might claim that the triangles do not appear to be equal in area. To address this misconception, a teacher or a student might suggest proving that the triangles are equal in area, showing that triangles that are equal in area are not necessarily congruent. In writing the scripts, the PSTs were instructed to imagine themselves in the 8th grade. We expected they would engage with the problem at a more advanced level than the simple part-whole relationship typically taught in 4th grade. Thus, we anticipated the PSTs would analyse it from an 8th-grade perspective, focusing on the geometric properties of the triangles formed by the rectangle's diagonals. By using this design, we aimed to reveal how PSTs navigate between different mathematical domains and grade-level expectations when confronted with a seemingly straightforward yet potentially complex situation.

Data collection and analysis

We collected 17 scripts written by 17 third-year undergraduate students (three male, 14 female) enrolled in a semester-long course about cognitive aspects in mathematics education. The course was part of a bachelor's degree programme (B.Ed), and the scripts were part of their final course assignment.

The scripts were coded according to the theoretical framework proposed by Warshauer (2015) (Tables 1 and 2) that incorporates the students' productive struggle and the teacher's responses to this struggle. As noted, we analysed only part 3 of the task (PSTs' scripts). Each turn in the script served as an analysis unit and was coded according to Tables 1 and 2. The scripts ranged from 14 to 98 turns. We coded a total of 467 talk-turns: 209 student turns and 258 teacher turns. The numbers in the square brackets appearing before the sub-categories in each category are used later in the examples in the Findings section.

Table 1: Coding scheme for students' struggle

Category name	Definition
Getting started	This type of struggle occurs when students have difficulty starting to work on a task. It includes [1-1] confusion about what the task is asking, [1-2] claims of forgetting how to approach this type of problem, [1-3] gestures of uncertainty and resignation, or [1-4] doing no work on paper.
Carry out a process	This type of struggle arises when students reach an impasse while trying to implement a mathematical process. It can involve [2-1] inability to implement a method from a formulated representation, [2-2] difficulty carrying out algebraic procedures, [2-3] forgetting facts or formulas, or [2-4] executing an algorithm.
Uncertainty in explaining and sense-making	This type of struggle is characterised by difficulty explaining work or solutions, such as [3-1] expressing uncertainty, [3-2] being unclear about reasons for strategy choice, or [3-3] being unable to make sense of their work.
Express misconceptions and errors	This struggle reflects fundamental misunderstandings about mathematical concepts, particularly misconceptions related to [4-1] probability, [4-2] fractions, [4-3] proportions or [4-4] geometry.

Table 2: Coding scheme for teacher responses

Teacher responses	
Telling	In this type of response, the teacher directly provides the needed information or instruction to the student by: [5-1] supplying information, [5-2] suggesting a strategy, [5-3] correcting an error, [5-4] evaluating student work, [5-5] relating the problem to a simpler one to decrease processing time.
Directed guidance	In this type of response, the teacher guides the student more explicitly towards a solution path by: [6-1] redirecting student thinking, [6-2] narrowing down possibilities for action, [6-3] directing an action, [6-4] breaking down the problem into smaller parts, or [6-5] converting the situation to an analogy.
Probing guidance	In this type of response, the teacher encourages students to elaborate on their thinking and reasoning by: [7-1] asking for reasons and justification, [7-2] offering ideas based on student thinking, [7-3] seeking explanations that could

	reveal an error or misconception, or [7-4] asking for written explanations of student thinking.
Affordance	In this type of response, the teacher provides opportunities for students to extend their thinking by: [8-1] asking for a detailed explanation, [8-2] building on student thinking, [8-3] pressing for justification and sense-making with a group or individually, or [8-4] affording time for students to work.

Because not all of the conversations revolved around struggles, we also used specific codes for other types of talk-turns. Here are some examples: student explains correct approach or reasoning (without any struggle); teacher asks an open question to promote classroom discussion (usually at the beginning of the lesson); teacher asks a student to share or explain answers.

To ensure the validity and reliability of the analysis, (Lincoln, 1995), both authors independently coded 15% of the data. After this individual coding, the authors compared their coding, reaching more than 80% agreement. We deliberated all discrepancies until reaching consensus and refined the codes accordingly. Then, the second author completed the rest of the coding process.

After all the analysis units were coded, we sought patterns within the data set. We calculated the frequencies for each student struggle and each teacher response. Then we sought patterns showing which type of student struggle is followed by which type of teacher response to reveal the interrelationships between them.

Findings

Our systematic data analysis of the PSTs' scripts detected some sort of struggle in 57% of the student turns, whereas the remaining 43% of the student turns did not exhibit any difficulty. Of the 57% that expressed some struggle, 39% were characterised as student uncertainty in explaining or sense-making, 9% expressed misconceptions, 7% were struggles in carrying out a process, and 2% were struggles in beginning to work on the task. Additionally, 10% of the teacher turns were coded as open invitations or requests by a specific student to share solutions or reasoning. The remaining teacher turns were aimed at responding to the students' struggles. Thirty-two percent of these teacher's responses were coded as affordances and 32% as telling. Eighteen percent of the teacher responses entailed probing guidance and 21% direct guidance. The diagram in Figure 2 describes these results. The arrow between the students' struggle and the teacher's response points to the dialogic relationship between the student turns and the teacher turns, as elaborated in the example below.

Two examples (Rana and Sarai) exemplify how this relationship is expressed in the script. Rana's script demonstrates the students' uncertainty in explaining their work, followed by teacher affordances. Sarai's script demonstrates the students' uncertainty in explaining their work, followed by teacher telling.

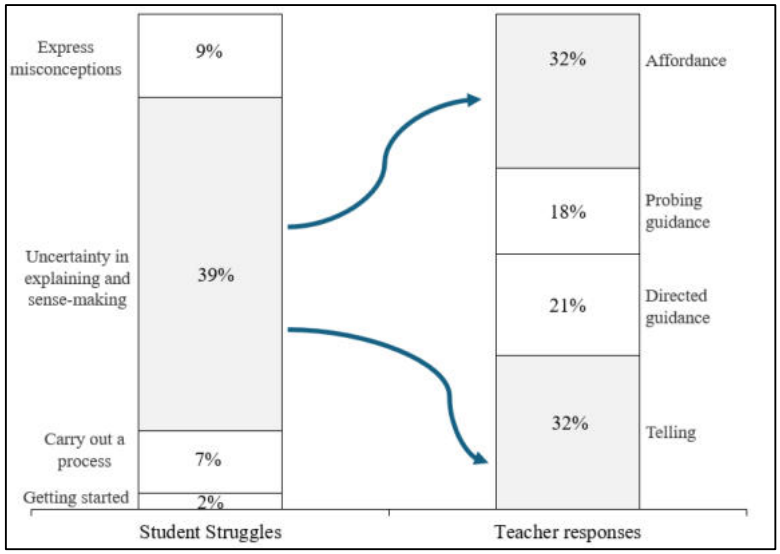

Figure 2: Students' struggles and teacher's responses in the PSTs' scripts

Rana's script. Rana's script included 32 talk-turns: 11 student turns and 21 teacher turns. In the script, Student 1 suggests a representation based on the starting-point situation. The numbers in the square brackets refer to the sub-categories delineated in Tables 1 and 2. The excerpt is followed by a full explanation.

Student 1: I divided the rectangle into four parts and coloured one part to represent a fourth.
Teacher: Dividing the rectangle into four parts is excellent work. However, it seems that the parts are not the same size. To accurately represent a fourth, the four parts need to be equal in area. Can you explain whether the areas of the triangles in your drawing are equal? [6-2] [8-1]
Student 1: Umm, I didn't really think about the areas of the triangles. I just divided the rectangle into four parts and coloured one part [3-1].
Teacher: That's a good start, Student 1. Let's explore the idea of equal areas together. Class, what do you think about the areas of the triangles in Student 1's drawing? [8-3]

The above student's turn, taken from the full script, suggests the student knows how to represent a fourth. The student's understanding appears to be somewhat intuitive as she does not know how to explain her reasoning. The teacher first responds by saying that this is the correct answer. Then, she *narrows down possibilities for action* [6-2] by saying the triangles need have equal area. Lastly the teacher *asks the student for a detailed explanation* [8-1], giving the student an opportunity to articulate her thinking. The student's struggle specifically emerges when she admits that she did not really think about how to reason this. Indeed, *uncertainty in explaining her work*, marked as [3-3] in the script, is her main struggle. The teacher then suggests that the whole class should explore why the areas of the triangles are equal. She *presses for justification and sense-making with a group* [8-3].

Figure 2 included two arrows. The first goes from *uncertainty in explaining their work* to *affordance,* as demonstrated using Rana's script. The second arrow goes from *uncertainty in explaining their work* to *telling*, which we now demonstrate using Sarai's script.

Sarai's script. Sarai's script included 48 talk-turns (17 student turns and 31 teacher turns). Here also, the student was uncertain when explaining the reasoning behind her response to the starting-point situation.

Teacher:	For the triangles to be equal, their areas must be the same. Let's think about the area of each triangle… calculate [its] area… [5-1] First, let's mark some points on the diagram. Before we calculate the area of the triangle, what do we know about a rectangle? [5-2]
Student 4:	It has 4 right angles.
Student 5:	Each pair of opposite sides is parallel and equal in length.
Teacher:	What else? Do you know anything about the diagonals? [5-2]
Student 1:	The diagonals bisect each other.
Teacher:	Very good. What about the point where the diagonals intersect? Is it a random point? [5-1] [5-2]
Student 1:	No, the diagonals meet at the midpoint of the rectangle.

As seen in the script above, the teacher provides a great deal of information (marked as *supply information* [5-1]) to help the students work towards the correct explanation. Then the teacher *supplies a specific strategy* [5-2] for marking some points on the diagram and thinking about what is known about the rectangle. After Students 4 and 5 stated what they now know (without exhibiting any struggle), the teacher directs the students' thinking even further by *supplying the strategy* [5-2] of focusing on the rectangle's diagonals. In the last teacher turn in the above excerpt (only a part of Sarai's script), the teacher *supplies information* in the form of *supplying strategy* – the teacher directs the students' focus towards discussing the diagonals' intersection point. Consequently, the teacher in Sarai's script focuses on *telling* the students what to do to reason about the starting point situation.

Discussion

The goal of this study was to characterise scripts written by PSTs in terms of productive struggle and to understand how this characterisation helps reveal PSTs' perceptions in managing this type of struggle. We systematically analysed 17 scripts written by PSTs that described classroom discussions around a problematised starting-point situation in which a student suggests an unusual representation for a fourth (Markovits, 2003). Analysis of the students' talk-turns in those scripts revealed that 57% of the turns reflected some sort of struggle, whereas in 43% of the turns the students did not express any kind of struggle.

Furthermore, in the PSTs' scripts identification of the students' struggle suggests that the struggle mainly revolves around expressing *uncertainty in explaining in sense-making*. This result surprised us. The problematised starting-point situation was designed to elicit various misconceptions, both in fractions and in geometry. Yet only 9% of the scripts perceived the students' struggle as connected to misconceptions. This finding has several possible explanations. First, talking about equal parts without emphasizing that the parts are also equal in area is a common misconception in fractions, and PSTs may also hold this misconception. Yet this explanation should be viewed with some skepticism in that the statements about equal parts in the PSTs' scripts may be somewhat inaccurate and they may actually mean equal in area. Second, with respect to the geometric misconception that triangles that are equal in area must be congruent, the PSTs may not perceive this in terms of student struggle. Nevertheless, one challenge for 8th-grade geometry students lies in recognizing the need to prove claims. The PSTs' lack of experience may have prevented them from seeing this as a possible struggle

for the students. Another possible explanation could be that the scriptwriting task format is challenging for the PSTs as they are not used to such a task, which in turn inhibits them from articulating their ideas; thus pinpointing some of the study's limitations.

Nevertheless, we are encouraged by these results exemplified by the scripts written by Rana and Sari. Rana and Sari's scripts were representative of the majority of the scripts while also pinpointing their variations, in which a similar starting-point situation and a similar struggle yielded two different teacher responses — *telling* and *affordance* — echoing what might happen in the classroom. Indeed, as both strategies are important and promote students' understanding (e.g., Warshauer, 2015), one of the contributions of this study is that it provides a nuanced understanding of how PSTs perceive and respond to student struggles. This in turn offers valuable insights for expanding teacher education programmes to include exploration of the dialogic relationship between student and teacher turns in the context of student struggle. Further, the small number of scripts addressing misconceptions highlights PSTs' "blind spots" in thinking about student struggle in this context, thus underscoring the affordances emerging from using scripts in teacher education. Further research can continue exploring the use of PSTs' scripts to examine teacher competencies, such as the flexibility inherent in moving back and forth between two the teaching strategies - telling and affording opportunities to think about the task. Another possible interesting line of future research would be to examine the PSTs' growth reflected in the scripts they write at different stages of their preparation program.

Shifting from on-site to on-line: How can key design criteria for effective PD be transferred to online, asynchronous programs?

Gil Schwarts[1] and Marita Friesen[2]

[1]Weizmann Institute of Science, Israel; gil.schwarts@weizmann.ac.il

[2]Heidelberg University of Education, Germany

We review recent developments and future opportunities in the realm of online, asynchronous professional development (PD) for mathematics in-service teachers, focusing on key design criteria. While teachers' asynchronous learning has gained traction in other educational fields, it has received limited and fragmented attention in mathematics education. We lay the foundation for a scoping review by examining how key design principles for on-site, practice-based PD programs can be used and adapted for the design of self-paced, online formats, emphasizing four key criteria: centering mathematical content, using representations of practice, facilitating collaboration, and being adaptive to participants' needs. In line with TWG18's focus, we discuss how on-site PD models, frameworks, and research methods can evolve in asynchronous spaces, expanding possibilities for teacher learning and related research.

Keywords: Asynchronous *online PD, mathematics teacher learning, teacher collaboration, adaptivity, representations of practice.*

Introduction

In recent years, accelerated by the COVID-19 pandemic, online platforms have become powerful learning environments — not only for students but also for teachers. In mathematics education, online professional development (PD) programs are increasingly popular (Koellner et al., 2023), whether conducted synchronously or asynchronously. Previous research on in-service teachers' professional learning has identified several key design principles for effective in-service PD, such as *centering content*, using *representations of practice* or facilitating *collaboration* amongst participants (e.g., Desimone, 2009). However, most of this research has been conducted in face-to-face settings. With the rise of asynchronous online PD, it is essential to explore how these elements can be effectively implemented in digital spaces and whether they require adaptation, especially since "It is still unclear whether online PD in general is as effective as face-to-face options" (Koellner et al., 2023, p. 554). Although several studies in the broader educational literature address this issue (e.g., Meyer et al., 2023), it has received scant attention in mathematics education research. Since mathematics teaching have unique characteristics, it is key to examine the particularities of shifting from on-site to on-line within mathematics PD. We focus on asynchronous PD — often referred to as "self-paced" or "on-demand", though each term carries nuanced distinctions — because these formats highlight the transition from on-site to on-line. In asynchronous settings, where participants engage with content independently, the impact of digital tools in prompting and directing becomes more evident, emphasizing the importance of their thoughtful design. Furthermore, it is important to distinguish fully asynchronous PD from synchronous online PD: While the latter shares key design features with on-site PD, such as duration, structure, and human infrastructure (Meyer et al., 2023), fully asynchronous PD may differ significantly in these aspects. Recognizing this distinction is crucial for

understanding the unique mechanisms at play in asynchronous environments. While the literature on massive open online courses (MOOCs) offers some valuable insights — such as principles of self-directed learning, peer support, and job-connected learning (Hollebrands & Lee, 2020) — MOOCs' focus on large, diverse groups and content delivery highlights the need for more research to understand the unique features of asynchronous online PD.

Following calls to improve the accessibility of PD and recognizing the potential for scaling-up PD programs, we anticipate a growth in the popularity of digitally mediated, asynchronous PD courses. However, we must not simply follow technological trends; while embracing innovations, we must examine whether key elements such as focus on content-specific practices, practice-based approaches, collaborative learning, and adaptivity to participants' needs (see Desimone, 2009) remain central to the design of asynchronous mathematics PD. For these reasons, we ask:

How can key design criteria for effective PD be transferred to asynchronous online mathematics PD programs? What challenges and opportunities are associated with designing asynchronous online PD in mathematics education, in particular with regard to centering mathematical content, using representations of practice, facilitating collaboration, and being adaptive to participants?

Modes of inquiry

Our aim in this paper is to take a first step in mapping the landscape of asynchronous online PD for mathematics teachers. To achieve this, we identified relevant papers published since 2020 in international journals or in proceedings of CERME and PME. Guided by the principles of scoping reviews, we sought to identify key themes, gaps, and trends in the literature, synthesizing the current state and highlighting future directions for research and design about asynchronous online PD. We focused on research papers describing projects that are fully asynchronous or have a particular focus on asynchronous design elements in their research and that are targeted to mathematics teachers. During this process, we faced challenges in selecting papers for review due to the broad (and ambiguous) definition of PD in asynchronous contexts. For example, we questioned whether a website offering resources for mathematics teachers qualifies as PD (see Copur-Gencturk & Orrill, 2023). Additionally, when a PD format resembles a lengthy survey, distinguishing between a PD project aimed at supporting teachers, and a research initiative primarily focused on collecting data, becomes complex. Ultimately, we decided to adopt an inclusive approach, to cover a wider range of PD formats and activities – realizing this is not noise, but signal: asynchronous spaces allow for innovative contexts that do not directly map to existing models and definitions.

Mapping the terrain: Key design criteria implemented in asynchronous PD

In the following, we review how four key design criteria identified in the literature for effective PD (e.g., Desimone, 2009) are addressed within asynchronous online PD. To do so, within each criterion, we first draw on the literature about on-site PD, and then compare the contexts.

Centering mathematical content

There is broad consensus on the importance of content-focused PD for mathematics teachers in enhancing their content knowledge (CK), pedagogical content knowledge (PCK), mathematical discourse practices, or teaching expertise. This emphasis is evident in PD designs targeting specific

content areas (e.g., statistics, Hollebrands & Lee, 2020), as well as in process-oriented programs not confined to a single topic, but aiming at fostering teaching practices or professional discourse (e.g., Schwarts et al., 2024). What is often not unpacked is *how* mathematical content is engaged within these PDs and how the PD structure shapes specific types of content engagement.

Engagement with mathematical content in synchronous versus asynchronous PD settings can differ significantly. In synchronous PD, real-time discussions allow for immediate feedback, clarification, and co-constructions of new meanings. Moreover, in terms of collaborative group work, the structure of synchronous PD often mirrors that of a mathematics classroom, enabling facilitators to plan activities where teachers engage in collective problem-solving. This live format fosters spontaneous mathematical reasoning that can go beyond the planned activities, and provides facilitators with opportunities to be responsive to participants' emerging needs. For instance, if facilitators observe that the mathematics at hand is too difficult, they can revisit key concepts.

Some of the elements described above can be addressed in an asynchronous format by drawing on asynchronous collaboration (see below). Matranga and Silverman (2024) provide evidence of such design in an asynchronous online course that was proven useful in fostering shifts in teachers' collective mathematical discourse, moving from focusing on visual features of function graphs to explaining function behavior. Another way to emulate the benefits of synchronous mathematical collaboration is through the careful design of prompts and feedback given by the system, for example by using avatars (AI-based or pre-programmed) to represent facilitators, peers, or students. For example, Copur-Gencturk and Orrill (2023) built on their research on common misunderstandings about proportional relationships to design an AI-based facilitator (based on an intelligent tutoring system) that offers targeted feedback to foster teachers' CK and PCK.

Asynchronous PD provides several distinct advantages over synchronous PD, including enhanced flexibility and interactivity in exploring mathematical content, as well as a convenient platform for experimenting with the integration of technological tools in lessons. In terms of flexibility, asynchronous PD allows teachers to engage with mathematical content at their own pace and revisit complex ideas based on their individual needs. This contrasts with synchronous PD, where teachers and facilitators may avoid challenging mathematics to protect their professional image. Moreover, a versatile design enables teachers to choose the level of complexity they prefer to engage with. In terms of interactivity, a major advantage is embedding mathematical applets as 'pop-up' activities directly within the course (Hollebrands & Lee, 2020), which enhances engagement by maintaining immersiveness and flow. Some asynchronous environments provide multilayered resources related to mathematics lessons (Hollebrands & Lee, 2020; Polly & Martin, 2020), enabling participants to swiftly switch between student and teacher roles. For example, teachers can use mathematical applets to solve problems (a student perspective) and then watch videotaped lessons around these problems, analyse student work, or access lesson plans (a teacher perspective). Finally, if the PD goal is to enhance technology use in the classroom, the online nature of asynchronous PD supports this aim by providing a space for experimentation. This is reflected in Polly and Martin's (2020) design of formative assessment digital tools, and the asynchronous PD framework built around them, providing a setting where teachers can examine these tools easily.

Using representations and approximations of practice

A practice-based approach to teacher learning emphasizes that teachers should gain insights from actual practice rather than relying solely on theoretical knowledge. Grossman et al. (2009) identify three different ways in which practice is taken up in teacher education: Representations of practice (e.g., videotaped lessons, storyboards of lessons), Approximations of practice (e.g., rehearsals, teaching simulations), and Decompositions of practice. These pedagogies demonstrate aspects of practice to allow teachers to enhance their repertoires, and to provide a public point of reference in teachers' discussions and imitations of practice. A wealth of research highlights the affordances of representations and approximations of practice for synchronous online teacher learning. However, only a few studies have explicitly examined their use in online, asynchronous PD. In particular, it is crucial to explore which approximations of practice can be enacted without the need for human infrastructure, as is required by synchronous approximations like rehearsals or micro-teachings.

Asynchronous PD includes some affordances compared to synchronous PD. For example, it enables smooth transition between different representations of practice, and easy scrutinization. In terms of the former aspect, Hollebrands and Lee's (2020) design uses several representations: videos of students working on a digital mathematics task (the video shows both the students and their shared screen), animations of students' reasoning, and videos of teacher launching a statistical investigation. Overall, similar to the literature about on-site PD, we found evidence for a wide use of video cases (Copur-Gencturk & Orrill, 2023; Polly & Martin, 2020; Seago et al., 2022) as well as student work and other classroom artifacts (Copur-Gencturk & Orrill, 2023; Schwarts et al., 2024). There are also uses of cartoons and storyboards of practice (Friesen & Knox, 2022; Schwarts et al., 2024). We also reviewed genres which are less common in the on-site PD literature, such as videos of experts explaining concepts (Hollebrands & Lee, 2020; Wischgoll & Prediger, 2024).

Returning to the second affordance mentioned above, the nature of asynchronous PD allows teachers to control the pace of going through the course, including engaging deeply with representations of practice. Teachers can review videos, artifacts, or storyboards at their own speed, pausing and replaying as needed to reflect on specific aspects of the practice, and decide with agency where they want to focus their attention within the representation. This flexibility allows for a more personalized experience, where participants choose the elements most relevant for them.

The lack of real-time discussion may limit opportunities for reflection on representations. To address this, asynchronous PD often integrates structured reflection activities, ensuring that participants can critically engage with the representations of practice in a meaningful way that aligns with the PD goals. Another option is the integration of AI-based facilitators or peers to scaffold engagement with the representation. For approximations of practice, such as digital simulations, interacting with non-human avatars (e.g., simulated students) replaces the need for costly and logistically challenging human infrastructure (e.g., as required for simulations with actors), providing a controlled environment to refine teaching (Schwarts et al., 2024).

Fostering collaboration

Collaborative settings provide teachers with the opportunity to form interactive learning communities and play therefore a crucial role for effective PD (e.g., Desimone, 2009). It can be assumed that collaborative activities, such as group discussions, enable teachers to make connections between practice and theory, provide opportunities to learn from peers and create alternative approaches to instructional practice (Meyer et al., 2023). For this reason, many PD programs support the collective participation of groups of teachers from the same school or grade and provide ample opportunities for participants to engage in collaborative tasks and reflection. Prominent settings highlighting collaboration in mathematics PD programs are, for example, lesson study approaches engaging teachers in co-planning and co-reflection, or video clubs engaging participants in peer discussions and joint reflections on critical incidents in teaching to develop teacher noticing (e.g., Amador et al., 2021). Recent studies have highlighted the key role of participants' collaboration also for the successful design and delivery of online PD formats: In a systematic review of the literature, Bragg and colleagues (2021) found that opportunities for collaboration positively affected learner satisfaction. Meyer and colleagues (2023) reported that collaboration in online PD did not only predict participants' satisfaction, but was the only quality characteristic besides cognitive activation that could also predict changes in teachers' professional practices. However, there was also evidence that in many of the PD online programs under investigation, collaboration was fostered to an only moderate degree and PD activities often lacked sufficient opportunities for teachers to collaborate (ibid). Since asynchronous online PD programs differ significantly from traditional face-to-face PD formats, the question of how collaboration among participants can be supported has to be reconsidered in a fundamental way.

Consequently, there is not yet a large enough body of research on how to design and implement effective collaborative settings in online PD (Koellner et al., 2023). Whereas synchronous online formats can still implement collaborative activities comparable to face-to-face PD programs (e.g., group discussions), asynchronous PD programs require the careful design of specific opportunities to allow for collaboration among the participants. A recent study in this context reported promising practices for online professional learning focusing on mathematics and coding, using a maker-pedagogies approach to teaching and learning (Morrison & Hughes, 2024). In the online PD, asynchronous collaboration was, for example, fostered by the use of a virtual platform hosting threaded discussions and an instant chat feature where teachers could share links, videos, and other resources. Teachers appreciated that they could post questions any time and received responses and feedback from their peers and the PD facilitator. Although online discussion forums as asynchronous communication tools are already widely used and researchers have tried to identify effective design elements, research-based applications in the context of online PD in mathematics are still rare (a notable exception is Matranga & Silverman, 2024) and will benefit from more investigation.

Being adaptive to participants' needs

Whereas adaptive teaching and differentiated instruction have become prominent research topics in mathematics education research on the classroom level (e.g., Gallagher et al. 2022), adaptivity in the PD level for in-service teachers has so far received much less attention. On one hand, there is a

consensus that what teachers learn in PD should be consistent with their knowledge and beliefs and connect to their prior experience to initiate cognitive activation and active learning (Desimone, 2009; Meyer et al., 2023). On the other hand, providing participants in face-to-face PD programs with learning opportunities that are tailored to individual needs is complex and challenging for teacher educators. Asynchronous online formats provide new possibilities in this context, since they can provide self-paced, on-going and work-embedded support for in-service teachers while also fitting better with teachers' busy schedules. Research shows that providing opportunities for teachers to engage in self-directed learning according to their own pace does not only affect their satisfaction with the related PD program, but can also lead to increased content knowledge as positive outcome (Bragg et al., 2021). However, adaptivity can not only be considered in the light of making choices about *when and how long* to learn, but also *what* and *in which format*: Friesen and colleagues (2023) designed an asynchronous online module on the teaching of algebra where the participants could follow individual learning trajectories. These were a combination of recommendations received by the online platform (based on responses to vignettes about typical demands when teaching variables, terms, and equations) and the self-paced engagement in corresponding instructional videos and interactive quizzes. Demmler and colleagues (2022) developed and investigated an asynchronous PD course in the context of problem-solving, where the participants could choose to study each of the presented topics (e.g., how to engage students in different problem-solving strategies) in different representation formats, namely as instructional video, collection of problem-solving tasks with students' solutions highlighting different strategies, or as classroom video, showing the teaching and use of different strategies in practice. PD which is not designed to be taken linearly also address the need for adaptivity (Copur-Gencturk & Orrill, 2023).

Concluding remarks and future directions

We join others in emphasizing that the quality of a PD program depends on its instructional design, not on whether it is online, in-person, or hybrid (Dede et al., 2016). We extend this argument by examining how shifts in context and structure — or, in PD space and time — are reflected in the PD instructional design. In this concluding section, we also touch upon the implications for research.

We demonstrated that all four key design criteria (mathematics, representations and approximations, collaboration, and adaptivity) are altered to varying degrees in the shift to online PD. Collaboration, in particular, undergoes a significant change, as asynchronous collaboration relies on different structures compared to synchronous collaboration. These shifts are mirrored in research, which gradually focuses more on system feedback than on skillful facilitation. Additionally, in online self-paced settings, teachers can choose the depth of their engagement with representations of practice and mathematical content, with additional resources (like mathematical applets) available at a click.

The shifts described above have implications for the frameworks and methodologies used to study teacher learning, calling for adopting methods from Learning Analytics, such as researching teachers' log data. Future research should also explore cultural differences in compliance with asynchronous format, as most current studies come from Europe and the US, and more is needed from countries with different norms around teacher learning and collaboration. Furthermore, we join other researchers who suggest that the study of asynchronous PD can advance the field by "disentangling

the contribution of specific design elements" (Wischgoll & Prediger, 2024, p. 734), by using controlled randomized trials and assigning teachers to different conditions that assess particular design components.

To conclude, we return to the point made earlier about the need to broaden and increase the flexibility of PD definitions in digital spaces. We see this as a crucial next step for research on mathematics teachers' professional learning, as it opens up new possibilities for designing adaptive and scalable PD experiences that better meet teachers' diverse needs.

This article presents an exploratory study involving 1st year undergraduate students in Basic Education from public and private higher education institutions, which aims to identify and discuss the aspects they value in teaching and learning mathematics. The study adopted a qualitative methodology and used content analysis to categorize the responses of the 125 participants who could become kindergarten or elementary school mathematics teachers. In two open-ended questions, the respondents were asked to indicate three aspects they consider the most important in teaching and learning mathematics. With regard to learning, these students prioritize the values 'Process', 'Mathematics in Context' and 'Motivation and dedication'. With regard to teaching, these students prioritize the values 'Motivation and dedication', 'Exposition' and 'Process'.

Keywords: Values in mathematics education, future elementary school teachers, teaching and learning mathematics.

Introduction

Values in mathematics education are the principles that individuals consider fundamental to the learning and teaching mathematics, functioning as a "window" that reveals what is prioritized by students, teachers, parents, principals, and society in general about these processes (Barkatsas & Seah, 2015). Since attitudes, preferences, choices and actions related to the teaching and learning of mathematics reflect what students and teachers value, but also what is valued by society (Fan, 2021), identifying these values and knowing how some are prioritized more than others can be a key component to improving the teaching and learning of mathematics (Barkatsas & Seah, 2015; Seah & Andersson, 2015). Knowing the values that future teachers defend allows them to be discussed and questioned during their teaching education course, thus helping them to become better teachers in the future. So, this paper intends to respond to the question: What aspects do 1st year undergraduate students who will become kindergarten or teachers who will teach mathematics in elementary school up to the age of 12 value in the learning and teaching of mathematics?

Theoretical Framework

From a cultural perspective, the idea of "value" gained prominence in mathematics education at the end of the 1980s, introduced by Bishop (1988). In this century, Seah (2008) broadened its scope, proposing that values are influenced by the sociocultural environment in which the individual finds themselves, stating that values and the process of valuing them are not exclusively cognitive or affective since they do not represent only mental processing, nor do affections exclusively guide them. According to Seah (2018), the process and act of valuing invariably involves reasoning and thinking. It is sociocultural in nature, as it reflects years of learning and the influence of our experiences, histories and social interactions as members of the cultures to which we belong.

In the context of mathematics education research, Bishop et al. (1999) consider three categories of values, specified by Seah (2016) as: (i) values through mathematics education in which teachers defend and teach their students to develop values that structure their personality, such as justice and human rights, through the way they plan or integrate collective discussions in the classroom; (ii) values of mathematics education that represent sociopolitical and cultural values, are incorporated into mathematics through educational policies and social norms, and that may, for example, value the ability to calculate as opposed to visualization; and, (iii) values for mathematics education where what teachers and students value can be taken into account to optimize mathematical understanding and competence, for example, when teachers recognize that if students value 'play' they can take advantage of this appreciation to optimize student learning by using exploratory activities with manipulative materials. For Seah and Andersson (2015), attitudes, preferences, choices and actions related to the teaching and learning of mathematics reflect what students and teachers value and what is valued by society. Kinone and Seah (2015) mentioned there is a huge range of attributes in mathematics pedagogy, which are the mathematics educational values and adopts seven pairs of mathematics educational values that were used in the formulation of the WIFI questionnaire[1]. These seven pairs of mathematics educational values can be seen to exist in complementary ways. We would likely value one value more than the other.

A study involving teachers and future teachers in South Korea identified the following as values related to teaching and learning: fun lessons, problem-solving, representations, calculation, aptitude and explanation, being problem-solving the most valued by teachers and future teachers (Yim et al., 2020). More recently, in a study in Malaysia regarding the alignment between teachers' values and those of their students in relation to learning mathematics, Chia and Zhang (2023) concluded that teachers prioritize process over product, hardship over well-being, effort over aptitude, application of knowledge over calculation, ideas and practice over facts and theories, exploration over exposition, and memorization over creation. Studying what 7th and 10th grade mathematics teachers in Portugal value in teaching and learning mathematics, Silvestre et al. (2023) state that teachers prioritize motivation and dedication, well-being, and curriculum and school organization.

[1] A large-scale questionnaire study which maps out what students' value in their mathematics learning experiences, developed by the Third Wave Lab, an international consortium researching values and valuing in mathematics education. https://thirdwavelab.education.unimelb.edu.au.

Research specifically focusing on pre-service teachers' values seems scarce. The existing literature has been carried out in contexts very different from Portugal (and most European countries), which requires some caution in their interpretation. Among these studies, Haciömeroğlu (2020) found that the future teachers' experiences obtained while they were students influence their values of about teaching and learning mathematics. Osman et al. (2024) argue that future teachers need to be aware of their values regarding the teaching of mathematics before they begin teaching as these can influence the way their teaching practices are shaped. It is also recommended that educators of future teachers identify their students' values regarding mathematics and its teaching, to align their practices and provide opportunities for them to become aware of their own values, how they affect teaching, mathematical learning and the construction of their students' values. This exploratory study is a first contribution to this field that is still so little explored, especially with potential future teachers who will teach mathematics in the first years of schooling.

Methods

Students attending the 1st year of LEB[2], in January 2024, at different Higher Education Institutions (HEIs) in Portugal were invited to take part in the study "What do I consider important in the teaching and learning of mathematics?" through a link sent to their cell phones by the course leader at each institution. For this communication, we only analysed the data related to the responses of 1st year LEB students from the four participating HEIs in the Lisbon area. The students had started their course last September. As every HEIs defines its own curriculum, the majority had not yet taken any mathematics subject. The response rate was 54%.

Data was collected using an online questionnaire consisting of closed-response items (5-level Likert scale) and open-response items. The questionnaire is an adaptation to the Portuguese context of the questionnaire developed by The Third Wave Project consortium (Kinone & Seah, 2015), which was translated from English and adapted by the Portuguese team, namely by adding three more pairs of values (Silvestre et al., 2023). This paper focuses on the items that aimed to collect sociodemographic data about the participants, as well as the items where these future teachers were asked to indicate the three main aspects that influence, respectively, the students' learning and the teaching of mathematics. It focuses exclusively on the qualitative analysis of the participants' open answers of those items. It was assumed that the students, having to mention three aspects as the most important, would choose those they valued the most in learning and teaching mathematics.

In the invitation addressed to 1st year LEB students, participants were assured that their contribution would be anonymous and voluntary, and the data collected would be treated confidentially and would not interfere in any way with their academic performance. 129 students responded but four were not considered as they did not respond at all, or the answers given did not correspond to the questions. A

[2] The degree in Basic Education (LEB) refers to the 1st Bologna Cycle of Studies with a total of 180 ECTS - "the degree aims to train graduates in the various areas of knowledge, enabling them to intervene in the fields of educational action, namely kindergarten teachers, elementary teachers, ATL, Museums, Municipalities, Libraries, Pediatric Services, among others." To become a teacher they have to attend a master's degree after the LEB.

total of 125 LEB students' answers were analyzed. Most respondents were female (94%) and aged between 17 and 23. Around 57% (73) of the future teachers had no professional experience in the field of education. Of those who did, only eight (6.3%) had experience as a math tutor in the early years in tutoring centers.

As the answers to the two items were statements, a content analysis was carried out after the data cleaning process. The data was analysed using the codebook produced by the Portuguese team of The Third Wave Project consortium (Silvestre et al., 2023), with slight adaptations to analyse the two items aimed at potential future teachers. Some open codes included were "learning from mistakes", "critical thinking", "flexible thinking", "inclusion" and "mathematical communication". Figure 1 shows the pairs of values that make up the codebook, initially adapted from Kinone and Seah (2015), as well as a summary of their meaning in the teaching and learning of mathematics.

	Values	Content	Values (complementary way)	Content
1	Aptitude	Values talent, aptitude, ability, capacity in the teaching and learning of mathematics.	Motivation and dedication	Values effort, dedication and motivation in teaching and learning mathematics.
2	Well-being	Values situations of calm, well-being and enjoyment in the teaching and learning of mathematics.	Hardship	Values disciplined behavior, difficulty and a tense environment in the teaching and learning of mathematics.
3	Process	Values the carrying out of processes in the teaching and learning of mathematics.	Product	Values the achievement of products in the teaching and learning of mathematics.
4	Application of knowledge	Values the application of knowledge in solving exercises and problems in the teaching and learning of mathematics.	Calculation	Values the calculation and execution of algorithms in the teaching and learning of mathematics.
5	Mathematical facts and abstraction	Values mathematical facts and abstraction in the teaching and learning of mathematics.	Mathematics in context	Values the context of everyday life or the real world in the teaching and learning of mathematics.
6	Exposition	Values explanation by the teacher in the teaching and learning of mathematics.	Exploration	Values students' own exploration and discovery, including collaboration, in the teaching and learning of mathematics.
7	Memorization	Values memorization, the recall of mathematical knowledge as it has been transmitted, in the teaching and learning of mathematics.	Construction	Values the creation of ideas, processes and products by the student in the teaching and learning of mathematics.
8	Technological resources	Values the use of technology in the teaching and learning of mathematics.	Non-technological resources	Values the use of non-technological resources in the teaching and learning of mathematics
9	Curriculum and school organization	Values aspects related to the curriculum and school organization in the teaching and learning of mathematics.	Equipment and physical conditions of the school	Values aspects related to the equipment and physical space of the school in the teaching and learning of mathematics.
10	Teachers' professional education	Values teachers' initial and in-service education in the teaching of mathematics.	Teachers' knowledge and practice	Values aspects of teacher knowledge and practice in mathematics teaching.

Figure 1: Values framework for teaching and learning mathematics

Results

In this section, we present the results of the data analysis. The percentages always refer to the total number of valid responses and not the total number of participants in the study. It should be noted that any student gave three answers for each item (7 and 8). The graph in Figure 2 shows that these

students respond differently when referring to learning or teaching.

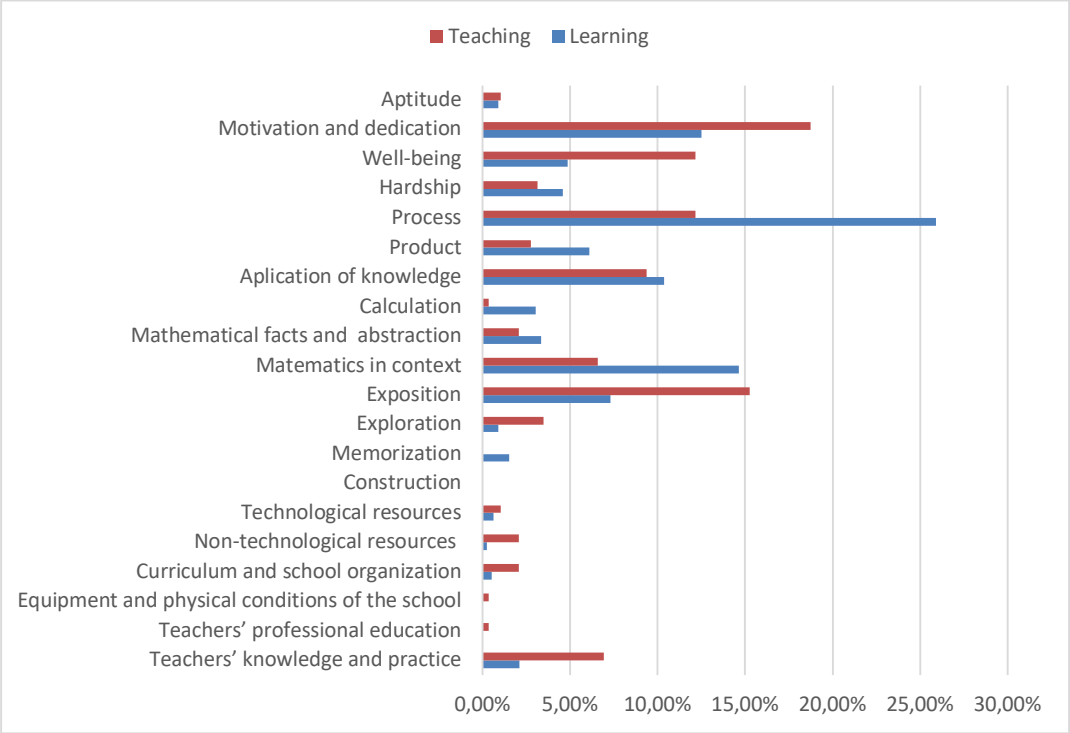

Figure 2: Percentages of the occurrence of values about learning and teaching mathematics expressed by the potential future teachers surveyed

From the graph, we identify the six aspects most valued by students in both teaching and learning. Four of them are common, but in a very different order. *Process* is the most mentioned value in learning, with 85 answers (25.91%), while in teaching it is in third place, with only 35 answers (12.15%). *Motivation and dedication* have the highest number of responses in teaching, 54 (18.75%), and are in third place in learning, with 41 (12.50%) responses. Still in teaching, *Exposition* has the second highest number of responses, 44 (15.28%), having 24 (7.32%) responses in learning (5th place). *Application of knowledge* has 34 responses in learning (4th place) and 27 responses in teaching (5th place). Also, among the six most valued are *Mathematics in context,* which is in second place in learning, with 48 answers (14.63%), *Well-being* in teaching (4th place), *Product* in learning (6th place) and *Teachers' knowledge and practice* in teaching (6th place).

To better understand the reason for the priorities set by LEB students, we analyzed the values corresponding to the top choices in learning and teaching. About *Process* (Table 1), the three most valued aspects coincide in learning and teaching, but not in the same order, with *Reasoning* being the most valued in learning and *Problem solving* in teaching. In learning, the three aspects identified are *Reasoning*, followed by *Understanding* and *Problem-solving*. It should be noted that the idea of *Reasoning* often mentioned is "logical reasoning". In teaching, the same three aspects are also prioritized, but in a different order and with a much smaller number of responses, *Reasoning* now appearing in third place, but not at a significant distance from *Problem solving* (1st place) and *Understanding* (2nd place).

Table 1: Aspects of valuing Process in learning (1st position) and in teaching (3rd position)

Learning		Teaching	
Reasoning	47 (56.63%)	Problem solving	12 (34.29%)
Understanding	27 (32.53%)	Understanding	11 (31.43%)
Problem solving	11 (13.05%)	Reasoning	10 (28.57%)

Related to *Motivation and dedication*, ranked first in teaching and third in learning (Table 2). A first analysis identifies a wide range of responses. *Dedication* has the highest number of responses in teaching, while in learning it is *Patience*, but with a number close to *Motivation* and *Dedication*. The data analyzed shows that, even in learning, students seem to be referring to the teacher with expressions such as "engaging students" or "students need to feel motivated to enjoy learning".

Table 2: Aspects of valuing Motivation and dedication in learning (3rd pos) and teaching (1st pos)

Learning		Teaching	
Patience	6 (14.63%)	Dedication	13 (24.07%)
Motivation	5 (12.20%)	Motivation	10 (18.52%)
Dedication	5 (12.20%)	Pactience	8 (14.81%)

These students seem to see learning as something they are still very much involved in, hence the value placed on *Reasoning*, *Understanding*, and *Problem-solving*. When they refer to teaching, they consider *Motivation and dedication* first, followed by *Exposition*. We, thus, conjecture that the values they attribute to teaching seem to be related to their experience as subjects who have been taught and not to their future role as a teacher, which is still a long way off.

Discussion and conclusion

This exploratory study sought to identify the aspects that 1st year students in LEB consider important in the teaching and learning of mathematics. The results show that these potential future teachers predominantly value the learning process, emphasising *Reasoning* and *Understanding*. This result aligns with the study by Chia and Zhang (2023), where *Process* is also highly valued. Still about the *Process* in learning, *Problem solving* appears relatively undervalued, contrary to what occurred in the study by Yim et al. (2020) also with future teachers, but, when refer to teaching is the most valued. These data suggest that it is important for these students to have opportunities to reflect on the meanings of the different terms involved. For instance, what *Reasoning* means to them when they associate it with logical reasoning, or what is for them Problem solving. This could be a way to expand the idea they have about the different terms and consequently the concepts involved.

Regarding teaching, they prioritize *Motivation and dedication* first, like the 7th and 10th grade teachers in the study by Silvestre at al. (2023). In contrast to this study, values such as *Curriculum*

and school organization are almost absent, which may be because participants are 1st-year LEB students and their values are marked by their experience as school students (Haciömeroğlu, 2020; Osman et al., 2024). In second place, they value *Exposition*, being *Quality of explanation* referred in a large number of responses, unlike the teachers studied by Chia and Zhang (2023), who value *Exploration*. It is worth noting that these students value *Teachers' knowledge and practice*, placing it in sixth place.

Given that teachers' values significantly influence their teaching (Bishop et al., 2006; Haciömeroğlu, 2020), and the values of future teachers may influence their future teaching (Osman et al., 2024), mathematics educators should be aware of the values prioritized by future teachers so that they can provide them with opportunities to reflect on those values. Thus, educators can align their practices by prioritizing the aspects they consider essential to be discussed. This alignment may challenge existing values and also facilitate the integration of these values with the principles of effective mathematics teaching as recommended in the literature and emphasized in curricular guidelines.

This exploratory study is a first approach to the topic with undergraduate students attending the 1st year of LEB. A first limitation of the study concerns the fact that we were only analysing responses from prospective 1st year LEB student teachers from four institutions in the Lisbon region. The fact that the data was collected through a questionnaire, answered by the students on their personal cell phones, constitutes another limitation of the study that should be completed following the students through their LEB course and/or collecting data using interviews. We consider it important to continue working on the topic and we propose to survey these students again at the end of the LEB.

Teaching Simulations as Formative Assessments: Generating Validity Evidence Related to the Test Content

Meghan Shaughnessy[1], Timothy Boerst[2] and Rosalie DeFino[3]

[1]Boston University, USA; mshaugh@bu.edu

[2]University of Michigan, USA

[3]University of Wisconsin-La Crosse, USA

In the context of a project to design, study, and use teaching simulations focused on eliciting and interpreting student thinking to formatively assess prospective teachers, we investigate questions focused on simulation validity. We investigated (a) the degree to which the student role protocol that guides a simulated student in the simulation covered the range of questions prospective teachers asked during the simulation, and (b) the degree to which simulated students were able to enact the role of the simulated student with fidelity. The results are promising and implications are addressed.

Keywords: Preservice teacher education, teacher educator, simulations, formative assessment.

Introduction

Formative assessment has been shown to impact learning significantly (Black & Wiliam, 1998) and it has been identified as a crucial component in teacher preparation (Darling-Hammond et al., 2005; Association of Mathematics Teacher Education [AMTE], 2017). Formative assessment provides prospective teachers with the type of feedback they need to improve their practice. As undeniably useful as it may be, providing formative feedback on most teaching requires seeing the teacher in action, and it can be challenging to facilitate such opportunities when field sites are limited in terms of in-person or video accessibility and/or opportunity to work on particular facets of teaching. In recent years, there has been an increased focus on using teaching simulations in teacher preparation (Mikeska et al., 2021). For over a decade, our research project has developed and studied the use of teaching simulations focused on the teaching practices of eliciting and interpreting student thinking as formative assessments to support prospective teachers' learning.

By teaching simulation, we mean an approximation of practice that places a prospective teacher in a situation that requires authentic engagement in the work of teaching while at the same time standardizing or controlling the context of that teaching in ways that support focus on a particular practice, element of content, or student interaction (Shaughnessy et al., 2025). As we have articulated elsewhere (Shaughnessy et al., 2019), simulations present several advantages for assessing prospective teachers in relation to the where, when, and what is assessed. They can focus on teaching without the need to be in a field context. Further, since simulations do not involve prospective teachers directly with students, simulations enable teacher educators to collect information about the knowledge, skills, commitments, and resources that prospective teachers bring to initial preparation and enable multiple collection points across a program. They can be constructed to embody particular teaching situations that might not be uniformly available. They position teacher educators close to the action (in terms of time and distance), which makes them amenable to providing feedback and gathering information useful for subsequent learning experiences.

While teaching simulations present important formative assessment opportunities, they also have limitations that must be carefully factored into studies of their use in teacher education. We focus on one such limitation. To enact teaching simulations requires resources that are not readily available and cannot simply be rechanneled from other assessment approaches. Special protocols and training are needed for those in the "student" role in a teaching simulation. These substantive limitations help define the nature of validation research needed to make teaching simulations a meaningful and usable mode of providing formative assessment.

The field would benefit from investigating the validity of teaching simulations, specifically when used to formatively assess teaching. As we noted earlier, an affordance of teaching simulations is that they can be designed to focus on a particular teaching situation. This stands in contrast to casually or informally observing teaching as a form of formative assessment where different aspects of teaching might be seen for different prospective teachers. To support the broader use of teaching simulations for formative assessment that present the same opportunities to demonstrate and appraise teaching, we need to design and then study the extent to which they make the situation repeatable across prospective teachers and doable by people beyond its developers. This is crucial because formative assessments are intended to support learning through appraisal of performance and actionable feedback (Cizek, 2010), and we need to ensure that all prospective teachers are encountering the same simulation so that it is possible to appraise their performance in that situation and provide feedback. Studies generating evidence for validity arguments (AERA et al., 2014; Kane, 2001; 2013) can support our understanding of how the simulation assessments are intended to work and what it takes to support effective use in varying contexts, including direction, preparation, support, and reassurance for those making an effort to use simulations as formative assessments. We report findings from a study that focuses on one source of validity evidence: test content.

Teaching Simulation

The teaching practice foci of our teaching simulation are eliciting and interpreting student thinking. By this, we refer to the fact that in teaching, teachers pose questions or tasks that encourage students to share their mathematical thinking. Teachers do this to assess student understanding and use what is learned for a variety of purposes, including instructional decision making. These teaching practices are central to everyday classroom teaching.

In the simulations we design, a prospective teacher interacts with a "standardized student" (a teacher educator taking on the role of a student using a well-defined set of decision rules for responding) around a specific piece of written work (see Shaughnessy & Boerst, 2018 for a more detailed description of how we design the simulation). Our live actor teaching simulations involve two teacher educators. One teacher educator takes on the role of the standardized student (referred to as the student or simulated student). The second teacher educator (referred to as the teacher educator) facilitates by appraising the performance and providing formative feedback.

Our simulations have four parts from the vantage point of a prospective teacher. First, the prospective teacher examines a piece of student work and plans questions to ask the student to learn about their process and understanding of the mathematics.

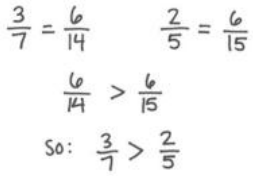

Figure 1: Sample student work

Second, the prospective teacher has five minutes to interact with the simulated student to elicit the student's thinking. In the data we feature in this paper, the student has used a procedure, sometimes known as "common numerators," to solve the fraction comparison problem shown in Figure 1. We train the "simulated student" to take on a particular student's way of reasoning about and understanding the mathematics task. To do this, we have developed a set of response guidelines that specify the student's process and the student's understanding of the ideas underlying the process (e.g., the student knows you have to multiply (or divide) the numerator and denominator by the same number to generate an equivalent fraction, but does not understand why that process works). These response guidelines (see Figure 2) include general guidance and specific responses to anticipated questions. As the prospective teacher interacts with the simulated student, the teacher educator uses an observational tool to capture key aspects of those interactions.

Third, the teacher educator interviews the prospective teacher to learn about their interpretations of the student's thinking. As the prospective teacher responds to questions about their interpretation of the student's process and understanding, the teacher educator uses an observational tool to capture key aspects of those interpretations.

Fourth, the teacher educator engages the prospective teachers in a feedback conversation about the performance in which they aim to support prospective teacher development through attention to considering when, how, why, and whether they might use particular eliciting moves.

Present Study

In this study, we explored two questions related to generating validating evidence for our teaching simulation as a formative assessment. We focused on the student role protocol (see Figure 2) that guides the simulated student's responses in the teaching simulations. First, we examined the match between the student role protocol design and the questions posed by prospective teachers. More specifically, we asked, "How well does the student role protocol cover the range of questions prospective teachers ask during the simulation?" This question is crucial to understand because simulated students will only be able to be standardized in their responses if the student role protocol supports responding to questions actually posed by prospective teachers. Second, we examined the match between the student role protocol design and the enacted student responses. We asked, "How standardized are "student" responses during the simulation?" In other words, when enacting the role of the "student," how closely were the "students" able to adhere to the student role protocol?

Characterization of the student's process: The student is using the common numerator method. To determine which numerator to use, the student finds the least common multiple of the numerators of the original fractions. The student generates equivalent fractions by multiplying the numerator and denominator of each fraction by the same number. Then the student compares the denominators to determine which fraction is larger.

Characterization of the student's understanding of the ideas involved in the problem/process: The student knows you have to multiply (or divide) the numerator and denominator by the same number to generate an equivalent fraction but does not understand why that process works. Once the student has common numerators, the student understands that when you have the same number of pieces, you can use the denominator to determine which fraction has larger pieces and therefore which fraction is larger.

Other information about the student's thinking, language, and orientation in this scenario: The student knows of other strategies for comparing fractions, but the student thinks that the common numerator methods works best with the given example.

The student's way of being: The standardized student gives the least amount of information that is still responsive to the prospective teacher's question.

Specific responses (a subset of them):

Prospective teacher prompt	Response
What did you do first?"	"I wanted to change the fractions so that there would be something in common."
Asks about how 6 was identified as the common numerator	"I wanted the numerator to be 6 because it was the least common multiple."
"Why can you compare fractions by comparing the denominators when the numerators are the same?"	"When you make the numerators the same it means you have the same number of parts so all you need to think about is how big the parts are."
"Why is 6/14 greater than 6/15?"	"Fourteenths are larger than fifteenths."

Figure 2: Excerpt of the student role protocol

Methods

Participants included both teacher educators and prospective teachers in the United States. Four teacher educators were recruited to take on the role of the "student" in the teaching simulation. These teacher educators, henceforth referred to as "simulated students," received the document containing the student role protocol (see excerpt in Figure 2) and engaged in a two-hour training in which they viewed and discussed video examples of simulations, discussed common questions, and practiced enacting the role of the "student" with coaching by project team member. Thirty-six prospective teachers enrolled in an undergraduate elementary teacher education program participated.

The assessment was administered at the mid-point of the teacher education program and prospective teachers consented to using this data for research purposes. Two teacher educators participated in two consecutive years and each served as the "student" in six teaching simulations each year. In addition, two teacher educators participated for one year, and each served as the "student" in six teaching

simulations. There was a total of 36 teaching simulations. The performances in teaching simulations were video recorded, and written artifacts were collected.

We used the software package Studiocode© to code the teaching simulation video. We began by parsing the video into talk turns. Then, we identified what we refer to as "instances," which contain a question posed by a prospective teacher and the "student" response to that question.

To address our first research question focused on the comprehensiveness of the student role protocol, for each instance, we characterized the question posed by the prospective teacher using one of three codes: (1) scripted response available, (2) no scripted response, but there is general guidance, and (3) guidance not available. *Scripted response available* means that a scripted response exists in the student role protocol and could be used to respond to the question posed. *No scripted response, but general guidance* means no scripted response exists in the student role protocol that could be directly used to respond to the question posed; however, the general guidance provides information that might be used in response. *Guidance not available* means there is no scripted response in the student role protocol that can be used to respond to the prospective teacher's question and no guidance for responding to the student was available in the general guidance section.

To address our second research question focused on the fidelity of the student, for each instance, we characterized the "student" response to the question posed by the prospective teacher using one of five codes. *Shares appropriate information* means that the "student" response was aligned with the student role protocol. In other words, the "student" used the scripted response or followed the general guidance in instances when a scripted response did not exist. *Omits important information* means that the "student" response left out important information. For example, the student role protocol includes a scripted response to "What did you do first?" The scripted response is, "I wanted to change the fractions so that there would be something in common." If the student said, "I wanted to change the fractions," and then stopped, we coded this response as "omits important information" because it did not include the fact that the student was changing the fraction because they wanted something to be in common. *Offers information that was not elicited* refers to instances where the response provided by the "student" shared information about the student's thinking that was beyond what was indicated in a scripted response. For example, if a prospective teacher asked, "What did you do next?" and the "student" responded with information about the next step and why the process works, it would be coded as "offers information that was not elicited." *Response was not aligned with the elicitation* refers to instances where the "student's" response did not address the prospective teacher's question. *Other* was used for instances that did not fall into the categories above, including instances where the question was unclear or there was no guidance in the student role protocol for responding.

Two coders independently coded each video. Discrepancies in scoring were examined by the full team, referencing the codebook as needed to reach consensus.

Results

First, we report the findings related to the comprehensiveness of the student role protocol. Specifically, we asked, "How well does the student role protocol cover the range of questions prospective teachers ask during the simulation?" Our analysis focused on the extent to which the

student role protocol provided guidance in responding to questions posed by prospective teachers. Across the 36 performances, there were 469 instances in which prospective teachers posed a question to the "student." In 69.5% of the instances (326 of the 469), a scripted response was available in the student role protocol. For example, one prospective teacher asked, "How did you pick 6 as the common numerator?" There is a scripted response for "asks about how 6 was identified as the common numerator." In another 25% of the instances (117 of the 469), there was no scripted response available, but the "student" could respond by drawing on other guidance provided in the student role protocol, such as information provided about the student's understanding of relevant mathematical concepts and general demeanor. For example, one prospective teacher posed an additional problem for the "student" to solve. In this problem, the "student" generated equivalent fractions with a common numerator of 12. The prospective teacher then asked the "student," "How did you use 12 as the numerator?" While the response to this exact question was not scripted, the "student" could reasonably use the general information available in the student role protocol and the scripted response for a common numerator of 6 to generate a response to the question. Another way of interpreting these findings is that for 94.5% of the questions posed, some guidance was available in the student role protocol for responding. These results suggest that the student role protocol is sufficient for providing guidance to the "student" for responding in standardized ways.

In the remaining 5.5% of the instances (26 of the 469), no guidance was available in the student role protocol for responding to the question. In these instances, the "student" had to improvise to construct a response to the question. We examined how these 26 instances were distributed across prospective teachers. Because the prospective teachers asked varying numbers of questions, we calculated the percentage of "no guidance" instances for each prospective teacher. We found that the percentage of instances where no guidance was available ranged from 0% to 29%, with a mean of 5% and a standard deviation of 10%. There were five prospective teachers for whom the percentage of instances with no guidance available was higher than 15%. This suggests that instances of "no guidance" were somewhat idiosyncratic and clustered around a small subset of prospective teachers.

Next, we report the findings related to the match between the student role protocol design and the enacted student responses. For this analysis, we looked across 24 teaching simulations. This was six teaching simulations for each teacher educator, and all were in their first year using the assessment. In 70% of the instances (229 of 327), the "student" shared an appropriate amount of information. In other words, the "student" responded in a way that matched the guidance in the student role protocol. This could have been responding with a scripted response or using the general guidance in the student role protocol. In another 12% of the instances (39 of 327), the "student" omitted important information in their response. In another 3% of the instances (10 of the 327), the student offered information that was not elicited by the prospective teacher's question. In 6% of the instances (20 of 327), the student response was not aligned with the question posed by the prospective teacher (e.g., the response answered a different question). The remaining 9% of instances were coded as other, and most of these cases were instances in which the question posed by the prospective teacher was not covered in the student role protocol, and thus, there was no guidance on how to respond.

Discussion

This study generated validity evidence related to the test content of a teaching simulation as a formative assessment. Our study results suggest that it is possible to design a "student role protocol" with scripted responses that address the vast majority of questions posed by prospective teachers and that it is important to include a general frame for how the student was thinking in addition to scripted responses to anticipated questions. Further, our results suggest that it is possible to train teacher educators to carry out the role of the student in a way that adheres to the student role protocol. In 82% of instances, the teacher educator carrying out the role of the student shared appropriate information or, in a small number of cases, omitted information, which created space for a prospective teacher to ask an additional question to learn about student thinking. We view these findings promising and we note that this is an exploratory study. The prospective teachers all came from one teacher preparation program and it is possible that a broader range of prospective teachers might pose different sorts of questions and that other teacher educators might need different supports to take on the role of the student. We and colleagues are investigating these and additional questions related to the validity of the teaching simulation as a formative assessment.

Taking a step back, as the field moves towards approaches for formatively assessing the teaching of prospective teachers beyond observations in the field, it is crucial to invest in conducting validity investigations into the approaches to ensure that the investment in such approaches is warranted. Formative assessment of prospective teachers demands the same level of attention to assessment quality given to high-stakes summative assessments while ensuring that we tailor validity investigations to the purposes that formative assessments serve. Specifically, formative assessments must provide information that educators can act on to support learning (Hopster-den Otter et al., 2019; Van Haneghan et al., 2009). In the context of our teaching simulation, it is crucial to ensure that all prospective teachers have opportunities to engage in a situation in which their eliciting of student thinking is being elicited by the test situation. We suggest that the field continue to explore both additional approaches to formative assessment and invest in such validity.

Teacher reflections in lesson study: Transition from external to internal support

Charlotte Krog Skott

University College Absalon, Denmark; chks@pha.dk

Though teacher reflection with colleagues obviously has potentials, it is often a complicated endeavour especially in countries unaccustomed with the new forms of teacher collaboration like lesson study. In Denmark, where this is the case, some schools have moved beyond the initial adaptation of Japanese lesson study and now use it consistently as an approach to professional development of their mathematics teachers without including external support. In the paper, I investigate the reflection phase at two such schools from a social-practice perspective. The aim is to identify how one group of teachers at each school improvises purposes and artefacts of lesson study in their local setting. Although the schools are alike on comparative school measures, the conclusions are that the two groups improvise these parts of lesson study very differently and that the differences are strongly influenced by cultural and social aspects of their local school settings.

Keywords: Teacher reflection, lesson study, mathematics teaching, social practice theory, figured worlds.

Introduction

Teachers' joint reflections on aspects closely related to their classroom teaching are at the heart of lesson study, a relatively new form of teacher professional development in Denmark based on collaboration. However, it is often complicated for teachers to reflect productively together (Horn & Kane, 2015). Research on teacher reflection in lesson study tends to focus on the characteristics of teachers' discourse, especially the presence or lack of productive speech acts (Suzuki, 2012; Vrikki et al., 2017). However, 'discourse' is generally used in two senses, one that focuses merely on speech, and another that includes broader perspectives (e.g., Gee, 2005), such as social and cultural aspects of the specific educational settings. As such contextual aspects seem to be crucial for teachers' ways of participating in lesson study, there is a growing tendency to include these aspects in lesson-study research (Clivaz & Miyakawa, 2020; Ebaeguin & Stephens, 2014; C. K. Skott, 2024).

It is well-known that teachers tend to return to their old routines, when professional development initiatives end or extern support withdraws from them (Hennessy, 2014). In this light, it appears important to explore what happens when schools outside East Asia use lesson study consistently as an approach to professional development without external support. Though important, this focus is only rarely studied (C. K. Skott, 2024). The present paper aims to contribute an exploration hereof with a specific focus on the reflection phase and viewed from a holistic, contextual perspective.

The paper reports a multiple case study, in which a group of teachers and their lesson study at each of two schools – Topas and Hilltop – in the Copenhagen area constitutes a case. Both Topas and Hilltop have moved beyond the initial adaptation of lesson study and now use it consistently as professional development of their mathematics teachers. Topas and Hilltop included initially external support (among other the author) for longer periods but are now continuing without. At both schools,

lesson study has been designed as consisting of three phases: planning a research lesson collaboratively; conducting and observing the lesson; jointly reflecting on the lesson based on observations of student activity. The teachers found particularly reflecting challenging as they often found themselves in situations for which they did not have a set of immediate responses. Using social practice theory, inspired by Holland et al. (1998), the paper focuses on the two groups' joint reflections and their negotiation of purposes and artefacts of lesson study in their local school setting. The paper addresses the research question: How do two teacher groups improvise the reflection phase when they engage together in lesson study in their local school setting without external support?

Teacher reflection in lesson study

Studies argue for the importance of building teacher reflection into professional development (Hennessy, 2014), as it is generally believed to have significant potential for supporting teacher learning (Horn & Kane, 2015). According to Myers (2013), lesson study is "ideal for nurturing reflectivity" (p.1), as it is collaborative, cyclic, and focuses on messy, challenging and real-life teaching situations. However, reflecting with colleagues can be challenging, and often it does not lead to the expected improvements in classroom teaching or teacher learning (Horn & Kane, 2015).

Research on teacher reflection in lesson study is scarce (Myers, 2013). Among the existing empirical studies, I have identified three strands. The first strand focuses on generic levels of reflection, such as descriptive, analytical and critical levels (e.g., Myers, 2013). Teachers' speech acts are taken at face value without regard to how the content can be interpreted in relation to classroom events, teachers' sense-making or contextual aspects. Although the highest level, critical reflection, is found to be most productive in terms of teacher learning, Myers (2013) shows that this level is rare in both in-service and pre-service teachers' reflections.

The second and third strands focus on identifying the most productive aspects of reflections for teacher learning. The second strand has a quantitative focus, while the third has a qualitative focus and a stronger focus on the mathematics. The second strand combines an analytical focus on speech acts with teachers' dialogic moves and learning processes. One aim of its research group (i.e., Vrikki et al., 2017; Warwick et al., 2016) is to develop a reliable coding protocol for quantitative analyses of teacher discussions. A second aim is to unpack the black box of teacher learning and investigate "the specific dialogic mechanisms that enable teacher learning to take place" in a lesson study context (Warwick et al., 2016). The group adopts a sociocultural perspective, and claims learning happens when teachers *interthink* together – a dialogic analogue to interact (Warwick et al., 2016).

The protocol comprises three coding dimensions: 1) dialogic moves (i.e., teacher contributions that move the dialogue forward, such as requesting information, building on ideas, providing evidence), 2) scope of discussion (i.e., the extent to which teachers address groups or selected case-study pupils), 3) learning processes (i.e., descriptive or interpretative). For instance, the code, 'interpretive learning process' is assigned when "teachers use words of evaluation [of teaching] such as: good, nice, […] fun, […] difficult" (Vrikki et al., 2017, p. 223).

The third strand interprets teachers' speech acts in relation to classroom events and teaching stances. Suzuki (2012) identifies six discourse modes that led to the self-declared learning of a Japanese

teacher participating in several lesson studies. Suzuki categorises the six modes as belonging to a teaching stance either a technical expert or a reflective practitioner. For example, the mode "Did the children learn what the teacher intended them to?" (p. 220) belongs to the technical expert, whereas the mode "Did the teacher teach what the children actually learned?" (p. 224) belongs to the reflective practitioner. Suzuki concludes that the latter mode best supports teachers' learning.

To summarise, the three strands focus on discursive characteristics of teachers' speech. The first focuses on generic levels of reflection, whereas the second presents a protocol for quantitative analyses of teacher discussions. In contrast, the third offers categories that directly address the purposes of lesson study, which is to inquire deeply into teaching/learning problems. However, none of the strands applies a holistic, contextual approach, which is called for by recent research on lesson study adaptations. This research emphasises the importance of contextual concerns, such as teachers' use of artefacts, the collaborative setting of their school (e.g., social norms, work relations), and wider social, cultural and power-related questions (e.g., the national teaching culture outlining general obligations and values for the teaching profession) (Clivaz & Miyakawa, 2020; Ebaeguin & Stephens, 2014; C. K. Skott, 2024). Aiming for a holistic, contextual approach, I draw on social practice theory.

Theoretical approach

I use Holland et al.'s (1998) framework, especially their concepts of *figured worlds* and *improvisations*, to conceptualize the Danish teachers' adaptation of lesson study into their local school setting. The framework is rooted in social practice theory that highlights the mutual and formative relationship between persons and their social world. By using the framework, I can capture how teachers' behaviour form and are formed by their cultural and social contexts, and how they orient and respond to the contexts' prevailing interpretations. A figured world is defined as "a socially and culturally constructed realm of interpretation in which particular characters and actors are recognized, significance is assigned to certain acts, and particular outcomes are valued over others" (Holland et al. 1998, p. 52).

For my present purpose, it is important how teachers learn to act and engage in a new world of lesson study and to (re)produce and assign meaning to the artefacts in this world. According to Holland et al. (1998), people can form such cultural knowledge heuristically by continual rehearsal of how to act and engage in figured worlds, as those "move through us as spoken discourses and embodied practices" (p. 251). However, in educational contexts such as the Danish, where the underlying cultural features of lesson study are largely unknown, it is not straight forward how teachers may learn this cultural knowledge heuristically. To conceptualise this challenge, I will draw on the concept of improvisation. A person improvises when confronted with a situation for which he/she has no set responses (e.g., chairing a reflection session for the first time) by reacting impromptu and drawing upon cultural artefacts (verbal, gestural and material) that are available in the moment. In addition to these artefacts, a person also improvises in relation to the sediments of his/her past experiences and the subject positions afforded him/her in the situation (Holland et al., 1998).

An artefact relates to a figured world as they are constructed as "parts of collectively formed systems of meaning [and as] products of social history" (Holland et al., 1998, p.35). Thus, people construct artefacts by engaging in social activities of a figured world and by negotiating and assigning meaning

to the artefact in this process. However, artefacts can also be constructed as emerging products of an improvisation and possibly "be taken up and become conventionalized or made into culture" (p. 17). Holland and her colleagues emphasize two aspects of an artefact: a material aspect as some kind of an instrument or reification and a conceptual aspect, as a collective memory of the artefact's substance and meaning as it is embedded in a figured world. When people improvise, the two aspects are constantly changing.

In this paper, I focus on the groups' improvisations of both the purposes and the artefacts of lesson study including their material and conceptual aspects, and on how these improvisations are related to each groups' dominant figured worlds. For this, I draw on J. Skott's (2013) perspective of how a teacher relates dynamically to a multitude of shifting prominent practices and figured worlds, when participating in social interactions, such as in the reflection phase. The teacher's participation may be inspired or transformed by figured worlds and practices, which the teacher has engaged in previously or by broader social and cultural practices and worlds at the school and beyond. This perspective allows me to conceptualize the part of the teachers' improvisation that relate to their experiences from past, present and new figured worlds, and practices at their school and beyond.

Methodological approach

The study is a multiple case study (Cohen et al., 2011) with a teacher group at each of Topas and Hilltop as a case. The schools are in the same middle-class neighbourhood of Copenhagen and are alike on comparative school measures. Acting as participant observers, my colleagues and I facilitated lesson study at Topas for 3 years (2014–17) and at Hilltop for 2½ years (2016–18). The designs of the lesson study were continuously adapted to each school's setting and the last year of our collaboration, all the mathematics teachers participated. Hereafter, the schools continued with lesson study without external support. They devoted two hours to each teacher group to plan the research lesson and the lesson was only taught in one class. A year after our collaboration, we selected data from three lesson studies at each school and for this paper, I draw primarily on one lesson study in grade 5 at Topas with 8 teachers (December 2017), and one lesson study in grade 8 at Hilltop with 5 teachers (March 2019). The data consists of two reflection sessions (2 times 60 min., audio-recorded, transcribed), two lesson plans and two research lessons (2 times 45 min., video-recorded).

As "it is not apparent at the outset what practices and figured worlds are significant for the teacher" (J. Skott, 2013, p. 552), my analytical objective was to deduce empirically what figured worlds and practices the teachers tended to draw on in their reflections and to investigate the fluctuating relations between these figured worlds and practices. Conducting a double analysis, I first constructed a set of possible dominant figured worlds and practices by analysing the teachers' acts and utterances and assembling these into 'as-if' realms using our previous analyses as a backdrop (C. K. Skott, 2024). Second, I re-analysed the data to confirm, possibly delete, or add new worlds, and to investigate shifts in their prominence for the groups, when they improvise the purposes and artefacts of lesson study. For Topas, the dominant figured world was *School*, which encompasses disciplinary issues, students' general behaviour and interactions (e.g., group dynamics), student mood and other general pedagogical concerns. For Hilltop, the most prominent worlds were: a new world of *Lesson study,* which comprises values and acts related to planning for, investigating and reflecting on student

learning, and a well-established world of *School mathematics*, that includes values and acts related to the teachers' ordinary mathematics teaching which tended to focus on students' mastery of skills and procedures. I will briefly describe each research lesson before I present the results of the analysis.

Mathematical communication in grade 5 at Topas: Teacher Bo began the lesson by presenting its learning goals: learn to communicate about addition, subtraction, multiplication, and division, and use these Latin terms rather than the Danish ones. There were three activities: 1) categorise 20 word-problems in relation to the involved operation, 2) match an operation with a word problem, 3) explain each operation individually and talk about them in groups. Bo tended not to listen to the students' mutual talk and in classroom discussions, he did not unpack their contributions nor provide mathematical explanations or ideas and the discussions regenerated into show-and-tell. The students struggled with the last activity, writing for example "Subtraction is when you minus". Finally, the students should indicate with smileys if Bo had communicated clearly and if they had been motivated.

Mathematical inquiry in grade 8 at Hilltop: Focusing on tessellation, teacher Jan began by showing a picture of a street paved with dragon-squares tiles. Then, he asked for properties of the pattern and for reasons why dragon-squares can tessellate. The students did not specify any properties, but one student suggested that dragon-squares can tessellate, because they can be divided into two triangles and all triangles can tessellate. Jan responded that he was unsure if it was correct. Another student suggested that all quadrilaterals can tessellate, and Jan then asked the class to investigate this conjecture using paper and scissors. After working half an hour, Jan asked about their investigations, but none of the students were able to confirm or reject the conjecture. Both Jan and the students were clearly frustrated as they wanted a valid argument for why all quadrilaterals can or cannot tessellate.

The two teacher groups' improvisations

The protocol is an important artefact for structuring teachers' joint reflections in Japanese lesson study. Both groups appointed a chair to lead the reflections and the chair used the protocol to structure them, encouraging first Bo/Jan to recount their experiences of the lesson and then the other teachers. The Hilltop-group had a stronger focus on the other parts of the protocol than the Topas-group, such as selecting themes for discussion, improving the plan, and summarising the reflection. Both groups thus improvised the protocol's material aspect, and the Hilltop-group also improvised its conceptual aspect to some extent. For example, when the chair specifically asked for observations that could inform the plan's research focus (i.e., how to guide students' inquiry without supporting them too much) thus encouraging the participants to analyse deeply this focus based on their observations.

When reflecting together at Topas, the teachers distinguished strongly between their ordinary classroom teaching and teaching a research lesson and repeatedly negotiated the purposes of the latter as compared to the former. Bo stressed that lesson study was "a tour de force in how you can DO some things". He had wanted to show how to organise student work with the three activities and to show a new assessment method. Though feeling stressed, he was concerned by "signalling [to the class] that I was not [stressed] (…) it should be clear to them what the goal was (…) and my expectations". Therefore, the lesson "became more shallowly that normally", and he "did not walk to each group of students (…) to get an impression of what they were talking about (…) I would get it when we reflect together". Here, Bo improvises the purpose of the lesson study as demonstrating new

teaching approaches and assessment tools, and deliberately without paying attention to the students' mutual talk, nor to a great extent to their mathematical contributions. These improvisations were supported by the chair: "You will get these [insights into student thinking] now". None of the teachers questioned these improvised purposes, although only a few learning opportunities emerged for the students in the research lesson. One reason may be the group's orientation towards *School.* In this world, a teacher's autonomy and own decision-making regarding teaching methods are highly valued.

Another important lesson-study artefact is observations. The chair asked for observations of "what you have experienced" and not for observations that could shed light on the plan's learning goals or other central aspects. The teachers provided observations about students' use of the Latin terms as asked for in the plan, but none of their observations concerned the students' mathematical learning. Rather, the observations were detailed descriptions of group dynamics and organization of the activities, which all relate to *School*. One teacher used her observations to argue that the last activity was not sufficiently challenging but added immediately after "we need to adjust it", taking it upon her and the others to fix it, not suggesting that Bo should have reacted differently or otherwise criticising him. To respect colleagues and not criticise each other is also part of *School,* and the group can be seen as drawing heavily on this world in their ways of improvising the purpose and artefacts of lesson study. The group thus used observations, but they did not use them to analyse students' learning nor other emerging issues in the research lesson. As this is part of the artefact's conceptual aspect, the group only improvised its material aspect.

At Hilltop, the group improvised a double explorative purpose of lesson study. The first was to explore how to guide students' mathematical inquiry without providing them the solutions. The second purpose was purely mathematical and was to explore themselves whether all quadrilaterals can tessellate. The group did not solve the problem before the research lesson, and during the reflection they repeatedly expressed uncertainty about it, as when Jan said, "Are you convinced that they [quadrilaterals] can [tessellate]? I do not know if you are, but I believe they can". Jan's uncertainty strongly influenced his participation in the research lesson as is evident in the above description of the research lesson. He also emphasised it in the reflection, "there were too many uncertainties for me (…) both the mirror figure and the concave figure (…) we should have made some specific choices" and "we had agreed that I should use the picture to talk about what to be attentive to (…) I forgot it and I think it had an influence". Despite this, the teachers did not question the appropriateness of their second improvised purpose. Certain aspects of the group's *Lesson study* world were inspired by the municipality's involvement, and the group's improvisation of the second purpose and how they dealt with it seemed to be influenced hereby. Also, the first purpose was inspired by their orientation towards *Lesson study*, but more in line with a general picture of the figured world and its practices.

The Hilltop-group linked their observations to the research focus and the focal points of the lesson plan, skilfully guided by the chair. They used their observations, which were more reflective and less descriptive than the Topas-group's, to analyse the focus and selected themes. One teacher observed for example "They had drawn one figure, but they did not dare to draw more. Then you came [Jan] and you drew more figures (…) and they realised that they needed not to see through the problem before drawing it". As such use of observations relates to the cultural model of lesson study, the

Hilltop-group improvised both the material aspect and the conceptual aspect of the artefact. Occasionally, the group judged students' answers superficially, such as "if she said the same to an outsider, it would be nonsense" not analysing the meaning of the utterance. Such practices relate to *School mathematics*. Compared to the Topas-group, the Hilltop-group primarily oriented itself towards *Lesson study* and their well-established *School mathematics,* and much less towards *School*.

Discussion and concluding remarks

This study contributes an exploration of teacher reflection in lesson study without external support from a holistic, contextual perspective. The two Danish schools, Topas and Hilltop, have both moved beyond the initial adaptation of lesson study and now use it to develop their mathematics teachers professionally. My analysis showed that the two groups improvised the purposes and artefacts of lesson study significantly differently in the reflection phase. The Hilltop-group improvised two explorative purposes, one didactical and one mathematical, and tended to use both the material and conceptual aspects of the artefacts, while the Topas-group improvised lesson study as a way to demonstrate new teaching approaches and methods and tended to use only the material aspects of the artefacts. The analysis suggests that these differences are primarily due to social and cultural aspects of the teachers' local school setting as indicated by their different dominant figured worlds and practices. The significance of these contextual aspects is supported by the fact that the schools are similar on comparative school measures, such as parents' socio-economic status and national ranking, and these measures can thus not account for the differences between the two groups.

The study's contextual perspective differs from the above-described three strands identified in research on teacher reflection in lesson study (Myers, 2013; Suzuki, 2012; Vrikki et al., 2017). If I had used the first strand's generic categories (Myers, 2013), it would probably have led to the same result: fewest critical reflections. However, as indicated in my analysis, it is often difficult to grasp the meaning of teachers' utterances based on their face value as there can be many layers of meanings and understandings beneath. The second strand's interthink-concept seems productive to describe how teachers learn together in lesson study (Vrikki et al., 2017). However, the strand's quantitative approach and in particular the protocol's learning part appears rather superficial. Using it on my data, most of the teachers would learn interpretively as they tended to evaluate the teaching by using the codes fun, motivating, etc. However, as the analysis showed, the teachers' observations, especially at Topas, were rarely connected to the students' learning nor the content. The third strand's discourse modes focus on the relationships between mathematics, student learning and teaching (Suzuki, 2012), but there are important aspects of teacher reflections that the modes do not capture such as teachers' use of artefacts. Concludingly, compared to these strands, this paper's holistic, contextual approach encompasses to a larger extent the complexity of teacher reflection, and includes further teachers' (re)productions of existing or new artefacts which seem to influence their reflections significantly. Therefore, it appears important to further explore teacher reflection in lesson study by using contextual approaches. This study also sheds light on the sustainability of lesson study as a continued teacher-led professional development without external support. Both groups have profoundly developed their ways of working together, especially the Hilltop-group. However, there are aspects of both groups' improvised ways of doing lesson study that from a student-learning perspective seem inappropriate, such as the explorative purpose in relation to mathematics at Hilltop. These aspects

should preferably not develop into stable practices. Thus, both schools might still benefit from external support, for instance from a teacher with lesson study experiences from another school, who is able to question such parts of the groups' reflections.

The impact of pre-service teachers' basic mathematical knowledge on their university mathematics grades: A case study from Norway

Morten Ugelid Søyland[1] and Arne Jakobsen[1]

[1]Department of Education and Sports Science, University of Stavanger, Norway;
morten.u.soyland@uis.no

In this paper, we investigate whether Norwegian pre-service teachers' (PSTs) basic mathematical knowledge and skills upon entering teacher education can predict their performance in mathematics and didactics courses at the university. To measure their basic mathematical knowledge, 127 PSTs were assessed using a test designed for grade 8 students. The PSTs' scores on this test were compared with their performance on two university-level mathematics examinations and a national test in algebraic thinking. The findings reveal a moderate but significant correlation between the PSTs' basic mathematical knowledge and their performance on both the university examinations and the national test. This paper contributes to the discussion on how well PSTs' basic mathematical knowledge at the start of teacher education predicts their future academic outcomes in university-level mathematics courses and how this insight can be used to improve the quality of teaching and learning for PSTs.

Keywords: Teacher education, pre-existing knowledge, mathematics achievement.

Introduction

In Norway, the debate over teacher quality and the entry requirements for teacher education has become a pressing issue. There is a shortage of qualified teachers, with 26 percent of primary school mathematics teachers not being qualified to teach the subject during the 2021–2022 academic year (Arnesen et al., 2023). Some attribute this shortage to the national entry requirements, which initially mandated that applicants to primary teacher education programs have a minimum of 35 school points from upper secondary school, along with a grade of 4 in mathematics and 3 in Norwegian (Forskrift om opptak til høgare utdanning, 2017, § 4-7). However, in 2022, the requirement was adjusted to 40 school points, while the minimum grades were reduced to 3 in both mathematics and Norwegian (Forskrift om opptak til høgare utdanning, 2017, § 4-7). Despite these changes, the number of applicants to teacher education remains low. In 2024, the requirements were further relaxed when the Norwegian Ministry of Education introduced legislation allowing universities to admit pre-service teachers (PSTs) with only a passing grade from upper secondary school (Forskrift om opptak til høgare utdanning, 2017, § 4-7A) after application to the ministry. Twelve universities applied, and 35 teacher education programs have accepted all applicants with minimum passing grades from upper secondary school to begin studying teacher education.

The opposition to lowering the requirements for entering teacher education argues that grades from upper secondary school are a good predictor of how well PSTs perform in teacher education. The argument is that quality teaching requires well-qualified teachers with a solid understanding of both content knowledge and pedagogical content knowledge. However, studies investigating how well students' grades from upper secondary school predict their performance in higher education show

mixed results. For instance, Cyrenne and Chan (2012) report that the average of students' high school[1] grades "is a strong predictor of their university GPA [grade point average]" (p. 541). Similarly, studies from the US have compared students' high school GPA with their ACT scores for college readiness, finding that GPA has a stronger relationship with students' college performance compared to the scores resulting from the ACT admission test (Allensworth & Clark, 2020).

In Norway, apart from a study investigating the relationship between engineering and calculus students' performance in mathematics at the university level and their basic mathematical knowledge at the start of their studies (Nortvedt et al., 2019), little is known about PSTs' readiness in terms of content knowledge. Except from a non-peer-reviewed report from Norwegian Council for Quality in Education (NOKUT) (Haakens & Bråten, 2017), we have found no research investigating the relationship between Norwegian PSTs' basic mathematical knowledge upon entering teacher education programs and their performance in mathematics and didactics courses at the university level. The report by Haakens and Bråten (2017) suggests a connection between prior formal knowledge in mathematics, such as grades and courses from upper secondary school, and PSTs' results on a national administrated mathematics examination. The report also suggests that the link between Norwegian PSTs' prior knowledge when entering university and their performance at university courses should be further explored.

This gap in knowledge motivated our study, which investigate the PSTs' mathematical knowledge using a standardized test designed for grade 8 learners. The study is limited to one university in Norway, where we aim to answer the following research question:

> What is the relationship between Norwegian PSTs pre-existing basic mathematical knowledge at the start of their teacher education and the grades they receive in university-level mathematics courses?

Previous research and context of the study

Common content knowledge is a component of Mathematical Knowledge for Teaching (MKT) (Ball et al., 2008). Good teaching skills and the ability to understand young children's mathematical thinking require that PSTs have a solid understanding of the content they are going to teach—referred to as basic mathematics. Several studies have shown that teachers with weak MKT provide lower-quality instruction, which also negatively affects their students' learning outcomes (Hill et al., 2008).

According to the Organization for Economic Cooperation and Development (OECD) and its 2022 Program for International Student Assessment (PISA) report, grades are "positively related to the expectation of completing a university degree in all participating countries and economies" (OECD, 2022, p. 11). However, the report does not provide information on students' performance or completion rates in specific study programs, nor does it explicitly address university mathematics courses.

[1]We use the term "upper secondary school" students except from when we refer to literature from the US that use the term "high school" students.

Research in the United States has examined both university entry examinations, such as the SAT, and grade point averages (GPA) from upper secondary school. These studies show that GPA is a better predictor of university mathematics performance than SAT scores (e.g., Allensworth & Clark, 2020). It's important to note that the SAT is a composite test, where basic mathematical knowledge from upper secondary schools in Norway contains only mathematics (Norwegian Centre for Mathematics Education, 2024). In Norway, it is only the grades from upper secondary school that are used as entry requirements to universities, and there are no national standardized tests regulating university admissions.

We therefore suggest that a test related to the content which the PSTs are going to teach is a minimum of what is expected as basic mathematical knowledge to succeed in the task of teaching mathematics. A test which is designed to unveil misconceptions related to mathematics for 8-graders will hence be suitable for PSTs that are training to teach 1–7-graders.

A project related to the mathematical pre-knowledge of economic students demonstrates how a diagnostic test at the beginning of their studies can be a useful tool to uncover frails in the students' mathematical knowledge (Landgärds, 2019; 2021). A pre-course related to the diagnostic test also seems to be an effective measure to help the students to succeed in university level mathematics courses (Landgärds, 2019; 2021).

The Norwegian context

In Norway, Initial Teacher Education (ITE) consists of four program types: (1) Primary ITE (1st–7th grade), (2) Lower-Secondary ITE (5th–10th grade), (3) Teacher Education Program (8th–13th grade), and (4) Post-Graduate Certificate in Education (Jakobsen & Munthe, 2020). This study focuses on PSTs enrolled in the first program—Primary ITE, grades 1–7—and in terms of the number of PSTs, it is one of the largest ITE programs in Norway. It is a five-year master's program that educates the vast majority of primary school teachers in Norway and is guided by national curriculum regulations (National Council for Teacher Education, 2016).

In this program, 30 out of 300 ECTS credits are in Mathematics, and it is compulsory. This study is situated at one Norwegian University where the 30 ECT mathematics course are divided into two: one course of 15 ECTS with an oral examination created locally by the ITE institution (LE-1), and one course of 10 ECTS with written examination, which is also locally made (LE-2). In addition, there is a written national examination worth 5 ECTS in algebraic thinking (NE), which is the same for all PSTs in all ITE programs in Norway. The content of all mathematics courses is a mix of mathematical and didactical content, preparing the PSTs to teach the subject.

Method

Sample

All PSTs enrolled in the ITE program for primary school teachers grade 1–7 from one Norwegian university were invited to participate in the study. 74 PSTs from the cohort that started August 2021 and 53 from the cohort that started August 2022, a total of 127 PSTs, opted to participate. The basic mathematics knowledge test (BMK-test) was given at the beginning of their first mathematics course (see Table 1 for an overview of the two first year of studies, including BMK test and examinations).

Table 1: Overview of the first two years of the ITE program, mathematics courses, BMK test, and examinations

Semester	Topic	Examination
1	Other ITE courses	
2	Mathematics (15 ECTS) + other ITE courses	BMK-test (at the beginning of the semester) + LE-1 (at the end of the semester)
3	Mathematics (10 ECTS) + national examination (5ECTS) + other ITE courses	LE-2 and NE (at the end of semester)
4	Other ITE courses	

Basic mathematical knowledge (BMK) test, locally and national made examinations

The BMK test was administered during the PSTs' first mathematics lesson. It consisted of tasks developed by Professor Alistair McIntosh (Norwegian Centre for Mathematics Education, 2024). The framework aims to assess Norwegian 8th graders' basic mathematical knowledge and identify common misconceptions, primarily related to number sense. Number sense is an essential part of the common content knowledge dimension of MKT, as it strengthens the teacher's ability to calculate numbers quickly and correctly. Therefore, it enhances their ability to "Evaluating the plausibility of students' claims (often quickly)" (Ball et al., 2008, p. 400). The test contained 35 questions in total, each graded as either "right" or "wrong," with a maximum score of 35. Eighteen of the questions were multiple-choice, each with only one correct answer, while the remaining seventeen were single-answer questions.

For both the locally administered and national examinations in algebraic thinking, the A–F grading scale was used. The grades were translated as follows for measurement purposes: A = 6, B = 5, C = 4, D = 3, E = 2, and F = 1.

The relationship between the PSTs' scores on each of the examinations and their results on the BMK test was analysed by calculation Pearson's correlation coefficient, calculated with SPSS Version 29.0.1. The correlation coefficient indicates the strength of the relationship between the pretest and examination results. The aim of the analysis was to either confirm or reject the hypothesis of a relationship between BMK test results and examination scores. Additionally, we calculated a weighted total score (WTS) for all three examinations (LE-1 + LE-2 + NE) and examined its relationship with the BMK score. It should be noted that we expect that WTS will be more influenced by, and probably more strongly correlated with the LE-1 test, while being less so with the LE-2 and NE. However, this aligns with the overall grades given to the students and will therefore be the most useful measure. We followed Cohen's (1988) guidelines for interpreting correlation strength: values

above 0.50 indicate a strong relationship, values between 0.30 and 0.50 indicate a medium relationship, and values between 0.10 and 0.30 indicate a weak relationship.

Results

The average scores and the standard deviation of BMK, LE-1, LE-2, NE and WTS are presented in Table 2, and shows that PSTs had around 77 % score in average at the BMK-test, and that that it was easier to get a good grade in the oral examination (LE-1), than the two written examinations (LE-2 and NE).

Table 2: The average scores and the standard deviation of BMK, LE-1, LE-2, NE and WTS

Test or examination	Point scale	Average score	Standard deviation
BMK	0–35	26.95	4.8
LE-1	1–6 (A–F)	3.75	1.52
LE-2	1–6 (A–F)	2.86	1.50
NE	1–6 (A–F)	3.00	1.48
WTS	1–6 (A–F)	3.28	1.31

The correlation between BMK and LE-1, LE-2, NE and WTS is respectively presented in table 3, and shows that there is strong relationship between BMK and both LE-2 and WTS, while there is a medium relationship between BMK and both LE-1 and NE. As predicted, there is a strong correlation between LE-1 and WTS, but also between LE-2 and WTS.

Table 3: Correlation matrix showing the relationship between the different examinations/test

		1	2	3	4	5
1	**BMK**	1				
2	**LE-1**	.44*	1			
3	**LE-2**	.56*	0.51*	1		
4	**NE**	.46*	0.40*	0.58*	1	
5	**WTS**	.57*	0.88*	0.82*	0.67*	1

* $p < .001$ (two tailed)

Discussion

The results indicate a medium to strong correlation between the PSTs' pretest scores and their examination grades (Cohen, 1988). While the correlation coefficient reveals a stronger relationship between the BMK test and the WTS score compared to the BMK test and any of LE-1, LE-2 or NE, it is also notable that the relationship between the BMK and LE-2 is stronger than that between the BMK and both LE-1 and NE. This may suggest that the BMK test is a better predictor of performance on the LE-2 examination than on the others. Further research is needed to get a better understanding of these relationships.

Although one should be cautious about establishing a direct connection between PSTs' basic mathematical knowledge and their performance in the mandatory mathematics course in teacher education, the scores suggest that PSTs with stronger prior knowledge tend to perform better in these courses. This is consistent with findings by Ball et al. (2008) and Hill et al. (2008), who argue that mathematics teachers need both a solid understanding of mathematics and specialized content knowledge to succeed.

The results of the BMK test indicate that several PSTs in this study struggled with basic primary school mathematics at the start of their teacher training. These PSTs were admitted based on their upper secondary school grades, which included a grade of 3 in both mathematics and Norwegian, and a total of 40 school points. However, as of fall 2024, twelve teacher education institutions in Norway have removed these admission requirements due to a shortage of qualified applicants (Forskrift om opptak til høgare utdanning, 2017, § 4-7A). After the previous intake requirements were introduced, the Norwegian Ministry of Education reported a higher completion rate among PSTs enrolled in teacher education program, with fewer PSTs dropping out (Ministry of Education, 2024). It is therefore likely that the reduction in admission requirements will have the opposite effect.

We also anticipate that PSTs enrolled at the teacher education institutions that have removed the intake requirements in 2024, may struggle with a lack of basic mathematical knowledge. In an environment where the formal requirements for admission to teacher education are lowered or even removed (Forskrift om opptak til høgare utdanning, 2017, § 4-7A), we foresee one of two outcomes: either PST success rates will decline (Allensworth & Clark, 2020), or the standards for passing teacher training will be lowered over time, as studies from other countries have documented (e.g., Nieswiadomy & Kim, 2024; Rojstaczer & Healy, 2012).

To address these challenges, we suggest that a pretest on PSTs basic mathematical knowledge—a test like the one presented in this paper—has the potential to serve as a tool for identifying mathematical difficulties among PSTs. Once these challenges are identified, targeted support should be provided to help PSTs begin their teacher training with a stronger foundation in mathematics, as Landgärds (2019; 2021) has had successfully implemented for the mathematics course for economics students.

Teacher professionalisation through the use of a digital diagnostic tool in settings with different forms of additional support

Anica Stemmer[1], Katrin Klingbeil[1] and Bärbel Barzel[1]

[1]University of Duisburg-Essen, Germany; anica.stemmer@uni-due.de

As teachers do not implement formative assessment practices frequently, there is a need for support. To understand how this may be realised, we investigated in which ways teachers show professionalisation in the work with a digital formative assessment tool in different support settings. In the analysis of six teacher interviews from three treatment groups, we found that all teachers show a form of professionalisation by applying and enlarging different facets of their professional knowledge leading to a reflection on or change in their teaching practices. Hereby, the attendance in a professional development session as well as an engagement with the test items and didactical explanations provided by the tool allow for similar forms of teachers' professionalisation.

Keywords: Digital formative assessment, professional development, algebraic thinking.

Introduction

Learning algebra, especially understanding the meaning of variables, is crucial for students to be successful in secondary mathematics education as algebraic competencies form the basis for many subsequent themes. However, students have great difficulties in this topic (e.g., Arcavi et al., 2017). Formative assessment (FA) is one possibility for teachers to address these problems as it might help to identify and respond to students' individual needs. Implementing FA can be complex and challenging for teachers, making the use of a digital FA tool a potentially valuable resource. This raises the question in which way such digital tools provide support for teachers and which forms of professionalisation they undergo when they are working with a digital FA tool.

Theoretical Background

FA is defined as an activity in which "evidence about student achievement is elicited, interpreted, and used by teachers, learners or their peers, to make decisions about the next steps in instruction" (Black & Wiliam, 2009, p. 9). Empirical studies show that, on the one hand, FA may have positive effects on students' learning, depending on the subject and the concrete form of implementation (McLaughlin & Yan, 2017). But on the other hand, it is rarely realised by teachers (Bennett, 2011). Research shows two main reasons why German teachers do not frequently practice FA: expenditure of time and a lack of expertise and experience (Bürgermeister & Saalbach, 2018). To overcome the lack of expertise, teachers could participate in a professional development (PD) program. But in Germany teachers rarely participate in such programs (Jude et al., 2024), so other options need to be considered. Cusi et al. (2024) point out that teachers might benefit from the use of digital FA tools. In their model of technology enhanced FA, they differentiate four areas of teachers' practices in FA which they combine with the three phases of preparing lessons as well as with three functionalities of technology in the process of FA.

The *digital tool SMART* (Specific Mathematics Assessments that Reveal Thinking), used in this study, was developed at the University of Melbourne and is currently being adapted for use in

German-speaking countries. It consists of about 130 multiple-choice-tests covering various mathematical topics. The tests elicit students' understanding of mathematical concepts by focusing on their conceptual knowledge. Based on response patterns, the tool carries out an advanced analysis shown in individual stages of understanding and possible misconceptions displayed in the automatic evaluation for the teacher. The tool provides teaching suggestions and additional materials for the teacher to support further instruction. Lastly, teachers decide whether and how to use the materials and teaching suggestions (Price et al., 2013).

In this process, the teacher as a decision maker plays an important role. Therefore, working with SMART requires a high level of teachers' professional competence. To define what we mean by *teacher professional competence*, we rely on two theoretical models. Blömeke et al. (2015) are modelling professional competence as a continuum, differentiating between dispositions, performance, and situation-specific skills. In the COACTIV model of teacher professional competence, Baumert and Kunter (2013) distinguish between four aspects of teacher professional competence: motivational orientations, beliefs/values/goals, self-regulation, and professional knowledge. In this paper, we focus on the professional knowledge which can be further divided into five domains: content knowledge, pedagogical content knowledge (PCK), pedagogical/psychological knowledge, organisational knowledge, and counselling knowledge. PCK is especially relevant when utilising a digital FA tool in a specific topic within a mathematics classroom. It can be realised in three facets: explanatory knowledge, knowledge of students' mathematical thinking, and knowledge of mathematical tasks. Combining these two models, we comprehend professional competence, and especially professionalisation, in this study as the application and enlargement of professional knowledge as a part of teachers' dispositions that leads to a reflection on or change in teachers' behaviour as performance.

While working with SMART demands teachers' professional competence, it can also contribute to teacher professionalisation. It offers didactical explanations on particular aspects of a topic (e. g. information on different roles of variables) supporting knowledge acquisition and reflection. Additionally, it offers matching teaching suggestions and material that may encourage teachers to reflect and adapt their teaching practices (Stacey et al., 2018).

Research Question and Methods

A first analysis of a few teacher interviews with the focus on tool elements used has shown that SMART contributes to teacher professionalisation (Eumann et al., 2024). But still little is known about the concrete forms of professionalisation that occur when using SMART. Therefore, this paper aims to explore the following research question: In which ways do teachers show professionalisation with regard to the application and enlargement of professional knowledge when they work with elements of SMART in different support settings?

To answer this question, we interviewed teachers after having used the tool in their lessons for the first time, implementing two tests on two different algebraic topics: substitution of values for letters in simple algebraic expressions and understanding the meaning of letters. The interviews are part of the project SMART[alpha] in which we investigate the algebraic thinking of students and the development of FA competencies of teachers while working with the tool. Teachers were randomly

assigned to three treatment groups, each receiving different forms of additional support: Group 1 (G1) received the fully automated evaluation of the SMART system, including the test items and their students' answers to each item, explanations about stages of understanding and misconceptions and teaching suggestions and material. After the implementation of the test, this group also took part in a PD program focusing on teaching algebra. In the first PD session, teachers were engaged in activities to learn about the different roles of variables and misconceptions that might occur during algebra lessons (PCK: knowledge of students' mathematical thinking). They also evaluated strategies and procedures for teaching algebra (PCK: explanatory knowledge) and tried different tasks related to algebra learning (PCK: knowledge of mathematical tasks). To investigate teachers' potential professionalisation using only the SMART tool, Group 2 (G2) received the fully automated evaluation of the SMART system, including the same elements as G1, but without an additional PD program. As a sort of control group, Group 3 (G3) received a reduced version of the SMART system with all the test items and their students' answers, but only feedback on the correctness of students' responses, without the fully automated evaluation, explanations, and material. Also, this group did not participate in any PD program. The interviews were conducted after the implementation of the two tests and for G1 after the attendance of the first PD session. In all interviews, we followed a guideline consisting of two main topics: teachers' interpretation of the test results and the consequences for their teaching drawn from it.

In the following, we present preliminary results, arising from an exemplary qualitative content-analysis of six teacher interviews, with two teachers from each treatment group[1]. These teachers worked in different regions in Germany at different secondary schools in grades 7 or 8. Before the test, all classes had worked on the meaning of variables and on how to formulate, manipulate, and substitute values for letters in an algebraic expression. Teachers worked with the SMART tool independently and autonomously in their classes and used the provided information at their discretion for lesson planning. Due to organisational issues, at the moment of the interview, some teachers had already taught some lessons after the SMART test, while others had not. Therefore, some teachers report on lessons they had already taught, while some describe only plans for their upcoming lessons.

Data analysis was conducted using qualitative content analysis. In a first step, we identified the central passages of the interviews, resulting from a previous analysis (Eumann et al., 2024). These passages were in a second step analysed in detail. Hereby, we used a deductive-inductive category system, where deductive categories arise from the material teachers had available (depending on their treatment group: items and students' answers, results, explanations on stages and misconceptions, teaching suggestions and material, insights from the PD session) as well as the facets of teachers' PCK (explanatory knowledge, knowledge of students' mathematical thinking, knowledge of mathematical tasks (Baumert & Kunter, 2013)). We inductively developed four categories indicating the different aspects of professionalisation, focusing on the form of reflection on or change in teachers' behaviour.

[1] The teachers are named by T, followed by the number of their treatment group and then numbered serially, e.g. T2.1 is the first teacher from G2.

Results

Results will be presented following the four aspects of professionalisation found during data analysis: explicit knowledge acquisition, reflection on tasks and learning activities, fostering diagnostic activities, and reflection on attitudes. Each aspect will be explained and illustrated with examples, hereby referring to the material mentioned by the teachers, the facets of PCK involved, and highlighting similarities and differences among the three treatment groups.

Explicit knowledge acquisition

The first aspect is realised only by teachers in G1 and G2 and predominantly, but not exclusively, in an unintended but conscious manner. All four teachers gained new PCK in the facet of *students' mathematical thinking*.

They state that they have gained new knowledge about possible misconceptions and students' ways of thinking referring to different material: While T1.2 and T2.1 draw this knowledge from the *explanations*, T2.2 relates to the *teaching suggestions* and T1.1 refers to the first *PD session*. As the teachers mentioned to be surprised by what they could learn from working with the tool, we concluded that they did not aim for gaining new knowledge, but noticed their own learning. Therefore, we name this an unintended but conscious knowledge acquisition.

Furthermore, the aspect of explicit knowledge acquisition also becomes apparent at the end of the interview with T2.2. He states that the *explanations* and the *teaching suggestions* were helpful for him and that he would use the tool again, but with constraints. For him, the decision to work with the tool depends on two factors: the subjective relevance and his own PCK of the concrete topic. This leads to the conclusion that he also actively and intentionally uses the tool to gain new knowledge.

Reflection on tasks and learning activities

The second aspect of professionalisation is shown in two forms: in a reflection on concrete situations and in general considerations on mathematics education practices. In both forms, teachers apply different facets of their PCK.

Both teachers from G2 apply *knowledge of mathematical tasks* when they report about the implementation of *teaching material* offered by SMART. T2.2 even adapted *explanations* of misconceptions and some questions of the *test items* for discussion in the classroom.

By reflecting on concrete classroom situations, teachers from all groups demonstrate a form of professionalisation in an expansion of their *explanatory knowledge*. T1.1 reports that at the beginning of the next lesson series on solving equations, he realised that particular students did not show the deep understanding of variables that is addressed by the SMART test. He takes this as an initial point to reflect on the conducted lesson, concluding that the introductory example might have been too complex. Relating to the first *PD session*, T1.1 reflects on the use of "fruit salad" algebra to explain simple algebraic transformations, concluding that it would improve his teaching to avoid this practice. T2.2 draws similar conclusions, reporting that he "felt caught" because he read about "fruit salad" algebra in the *teaching suggestions*. T1.2 reflects on his use of Cuisenaire rods for visualising algebraic expressions by areas and scopes of rectangles, concluding that this practice might encourage

misconceptions. Hereby, he draws on his own observations of the *test results*, as well as on the *explanations* and the discussion in the *PD session*: "and as the results were like this and as exactly this misconception was diagnosed for a lot of students, it came to my mind spontaneously in the last PD session that the Cuisenaire rods might not be meaningful." In addition, T2.2 describes that in future lessons he wants to emphasise more explicitly the different roles of variables. He sees a lack of students' understanding in this aspect as a probable reason for problems in the SMART test addressing the meaning of letters. Hereby, he relies primarily on the *teaching suggestions* provided by the tool.

Teachers in all groups also demonstrate an application of *knowledge of students' mathematical thinking*. T1.1 retraces a discussion about handling teaching material in the tool held in the *PD session*. He concludes that the main aspect of good mathematics teaching practice is not to provide students with opportunities for a lot of exercises and thus quickly develop procedural routines, but to initiate a deep understanding of mathematical concepts. Looking at the *results* of his student group, T3.2 comes to a similar consideration: "Now I recognise that in my own lesson, I introduced a procedure that maybe overloads them a bit. I have to take care that we focus on the meaning once again." T2.1 also relies on the general *results* of the group, using them as a source to prioritise ideas and concepts that he will focus on in future lessons. T2.1 also describes the reflections concerning his own language practice in classroom as an "aha-effect". He formulates the consequence that in future lessons he will pay more attention in the class to being a role model in the use of language and to pay more attention to the students' use of language as well.

Only T3.1 does not use his reflections on tasks and learning activities for his own professionalisation. He describes a similar situation as T1.2, using straws as Cuisenaire rods to visualise algebraic terms. But in contrast to T1.2, T3.1 does not reflect this practice as possibly promoting misconceptions. Instead, he states that this practice works well, showing that he is not aware of its underlying risk.

Fostering diagnostic activities

The third aspect of professionalisation is demonstrated in two different ways: comparing the results of the automatic diagnosis to expectations based on their own classroom observations and trying to understand the diagnostic potential of SMART.

When comparing the results of the automatic diagnosis to the expected outcome, teachers essentially focus on divergences in the *results* of the whole group or of individual students. In most cases, they try to find explanations for the observed discrepancies, providing short insights into their *knowledge of students' mathematical thinking*. Concerning the sort of explanations for discrepancies, especially for individual student results that are worse than expected, there are clear differences between individual teachers. On the one hand, T1.1, T3.1 and T3.2 only give superficial explanations, such as an unfavourable point in time for mathematics lessons, copying the neighbours' answers, or even students' characteristic traits: "That's also inattentiveness. Wanting to finish quickly, not reading adequately. Well, that's what he is like." Similar kinds of explanations are also given for individual results that are better than expected, such as luck or coincidence. On the other hand, T3.2 also tries to find reasons that show deep insights into students' thinking: "For that person, I would say that she did not understand exactly what p and b stands for." In a similar way, T2.1 and T2.2 give profound

possible explanations. They search for reasons in their own lesson practices as well as in the fact that students "do not rely on their own correct thinking and thus are sometimes misdirected by different response options." (T2.1)

This last statement already leads to the second way of fostering diagnostic activities, as all teachers (except T1.2) are trying to understand the diagnostic potential of the *items*, thus applying and enlarging their *knowledge of students' mathematical thinking*. While T1.1 only claims that for him it was quite obvious what the test items aim at, the other four teachers go far deeper in the analysis of particular items. T2.1 tries to retrace the automatic evaluation by trying to find connections between different response options in the *items* and the *explanations* about the stages of understanding and misconceptions, hereby taking into account students' thinking: "Well, I found that very fascinating. […] that you can somehow understand what could be the way of thinking that a student had." T2.2 also looks at some individual answers given by students to comprehend the automatic analysis. He looks deeply into the content of the items and the didactic information, which allows him to understand that it is not the number of correct answers that leads to a certain stage of understanding but the type of answers given. Of course, teachers from G3 could not analyse the results as deeply since they did neither receive the diagnosis of the fully automated evaluation nor the explanations about stages of understanding and misconceptions. Nevertheless, they also gained new knowledge by analysing the *items* and students' responses. T3.1 gains very deep insights into his students' thinking by investigating individual students' answers over several items in the test. In this process, he describes his observations very closely to the explanations in the stages of the tool. T3.2 also states that he seems to understand what the items aim at. By analysing the items and response options, he identifies that different typical errors and possible misconceptions are addressed. On the basis of some of his findings, he concludes that he has to change his own practice, especially concerning exact use of language when defining variables, and the necessity to clearly work out the meaning of variables. As a consequence, he sees the necessity to analyse students' responses more deeply to get reliable findings.

Reflection on attitudes

The fourth and last aspect shows a form of professionalisation that occurs aside from concrete facets of professional knowledge and is identified only in G1 and G2. Apart from the fact that all teachers in these two groups find it interesting to see the *results* and possible misconceptions, and are curious to get new results from other tests, they also reflect on their own habits. T1.2 realises that sometimes teachers have difficulties in anticipating particular misconceptions as they are very familiar with the mathematical topics. Moreover, T1.2 reflects on his attitude concerning the work with the *teaching suggestions* in the tool. He explains that even though it might be feasible for teachers to read all the explanations and choose adequate teaching material by themselves, he wishes that the tool would assign concrete tasks to individual students. He admits that this wish might be due to the fact that he did not engage enough with the material. T2.2 expresses a similar wish, explaining that an individual distribution of the proposed teaching material to students might be too time-consuming. He also shows a process of reflection of his work with the *teaching suggestions* and the *explanations,* reporting that, first, he was a little bit annoyed by the length of the texts, but then admits: "I also took a lot from it." T1.1 comes to the same conclusion, acknowledging that it is worth the time spent on

reading the teaching suggestions even if it seems quite a lot. He explicitly explains: “But in fact, I mean, it is basically your own attitude how you deal with it then. And if you want to gain something from it, then it is worth investing the time.”

Discussion and Outlook

In the analysis of six teacher interviews from three treatment groups working with the SMART tool in different support settings, we found four different aspects of professionalisation. All teachers apply different facets of their PCK (Baumert & Kunter, 2013) and use their insights to reflect or change their performance in mathematics teaching. Thus, teachers demonstrate professionalisation in different parts of the underlying continuum model (Blömeke et al., 2015).

Teachers in G1 and G2 show widely similar forms of professionalisation in all four aspects. In both groups, the aspect of *reflection on tasks and learning activities* is predominant. But we see that teachers recapitulating an activity or a discussion in a *PD session* (G1) might draw the same conclusions for their teaching practices as teachers only accessing *teaching suggestions* from the SMART tool (G2). Only teachers from G2 show an application and enlargement of the facet of *knowledge of mathematical tasks*. The facets of *explanatory knowledge* and *knowledge of students' mathematical thinking* are shown by teachers from both groups, even though they refer to different material.

Meanwhile, teachers from G3, that do not receive the information from the tool, show very different forms of professionalisation. In this group, only the aspects of *reflection on tasks and learning activities* and *fostering diagnostic activities* could be found, with a predominance of the latter one. An intensive analysis of the *test items* allows these teachers to gain deep insights into students' thinking. Furthermore, conclusions about good mathematics teaching and the necessity to foster students' understanding of concepts instead of setting priority to procedures are drawn from interactions in the first *PD session* (G1) as well as from a deep analysis of the *items* of the SMART tool even without the automatic evaluation and the supplementary explanations (G3).

Therefore, we may conclude that an intensive investigation of well-designed and research-based items of a diagnostic tool allows for an application and enhancement of PCK, especially in the facet of *knowledge of students' mathematical thinking*. But for professionalisation that includes more facets of PCK and allows for different forms of reflection on and change in behaviour, more support is needed. The preliminary results of this study indicate that the additional elements in the SMART tool might have similar potential for such forms of professionalisation as the attendance in the accompanying PD session. In addition, the engagement with the *explanations* in the SMART tool allows for reflective processes that go beyond concrete practices. Therefore, the use of this tool might offer a low-threshold option for teachers' professionalisation beside PD sessions (cf. Cusi et al., 2024).

Due to the small number of interviews analysed per group, these results are preliminary. To confirm these findings, an analysis of further teacher interviews is needed. Moreover, further analyses could also focus on other aspects, such as teachers' lesson plannings or realisation of FA practices and their interconnections with professionalisation processes. As the results of this study are snapshots that are based on self-reported practices, there is also a need for further research investigating teachers'

application of professional knowledge by directly observing their work with SMART and the implementation of the practices in their classrooms.

Learning to assess and respond to children's mathematical thinking in early arithmetic education: a vignette-based study with pre-service teachers

Simone Wirth[1], Marita Friesen[2] Kathleen Philipp[3] and Christine Streit[3]

[1]University of Education Freiburg, Germany; simone.wirth@ph-freiburg.de

[2]University of Education Heidelberg, Germany

[3] University of Applied Sciences and Arts Northwestern Switzerland, School of Education Switzerland

A central goal in early arithmetic education is to develop a solid conceptual understanding of numbers and operations. For this, teachers face the challenging tasks of assessing children's mathematical thinking and of responding to it in an adaptive way. Essential prerequisites are the abilities to form precise diagnostic judgments about children's existing number and operation concepts and to make adaptive decisions for further instruction. With a vignette-based research instrument and N=172 participants, this study investigated the quality of pre-service teachers' diagnostic judgments about children's mathematical thinking, and how these judgments were related to subsequent instructional decision-making. The results for example show that pre-service teachers' tend to formulate general and imprecise statements in their diagnostic judgments about children's mathematical thinking leading to difficulties in choosing the next adaptive task for a child.

Keywords: Adaptive teaching, diagnostic judgment, early arithmetic education, teacher education, vignettes.

Introduction

Children's heterogeneous learning requirements are a central characteristic of primary school education (Liebers, 2023). Among other things, selecting and designing adaptive learning settings based on children's individual learning requirements is an essential prerequisite for successful learning (Beck, 2008). This also applies to understanding-oriented early arithmetic learning settings, which aim to ensure that every child acquires solid basic concepts of numbers and operations. Therefore, teachers first must precisely assess children's mathematical thinking to be able to offer adaptive learning settings in subsequent instruction. This emphasises the need for teachers' abilities to make diagnostic judgments and instructional decisions (Brandt, 2022; Schulz, 2014; Streit et al., 2019). However, supporting children in developing their mathematical understanding from counting to solid concepts of numbers and operations is a challenging task (Anghileri, 2006). Due to uncertainties in assessing children's concepts and making subsequent instructional decisions, German primary school mathematic teachers do not yet seem to be prepared to cope with this task to a satisfactory extent (Hagena & Besser, 2023). National surveys have repeatedly shown that a significant proportion of children in Germany do not have an adequate understanding of numbers and operations at the end of primary school (e.g., Stanat et al., 2022). Consequently, the question arises on how necessary changes can be brought about in early arithmetic education and how teacher education and related educational research can contribute. Since studies have shown that adaptive

teaching in early arithmetic education is characterized by an interplay between assessing children's mathematical thinking and designing adaptive, understanding-oriented learning settings (Moser Opitz, 2022), current efforts focus on future teachers' abilities to form diagnostic judgments and to make instructional decisions (e.g., Brandt, 2022).

Theoretical background

There is a variety of different terms and discussions around the abilities that teachers need to form precise diagnostic judgments and to make instructional decisions for adaptive teaching. Three interrelated but distinct abilities have emerged, on which there is widespread agreement: based on one's professional knowledge, important information must be perceived in a targeted and selective manner, then interpreted, and finally a decision must be made (Enenkiel et al., 2022; Jacobs et al., 2010; Loibl et al., 2020; von Aufschnaiter et al., 2018). The first two abilities are needed to form a diagnostic judgment, and the last ability is needed to make an instructional decision. Applied to the task of designing adaptive early arithmetic learning settings, teachers must use their professional knowledge to

- *precisely identify children's thinking as shown in their approaches* when solving an arithmetic task and *interpret the identified approach regarding specific underlying concepts* of numbers and operations (diagnostic judgment formation)

- *make an adaptive instructional decision* to build on children's existing concepts (instructional decision-making).

Regarding the connection between the processes of diagnostic judgment formation and instructional decision-making, Moser Opitz (2022) assumes that they are closely related, and, from an analytical point of view, the diagnostic judgment formation precedes the instructional decision-making. In favour of considering the two processes separately, she also argues that teachers need subject-specific didactic knowledge about learners to form precise diagnostic judgments and need additional knowledge about understanding-oriented instructional methods to make adaptive instructional decisions. However, van Ophuysen (2010) emphasises a reciprocal interplay between the formation of diagnostic judgments and instructional decision-making. She argues that knowledge about instructional methods does not only become relevant during instructional decision-making but also directs teachers' perception and interpretation during judgment formation.

Despite the high relevance of teachers' abilities to form diagnostic judgments in connection with instructional decision-making for adaptive teaching in early arithmetic education, studies in this field are still scarce. Especially the interplay between diagnostic judgment formation and instructional decision-making in early arithmetic education is not yet fully understood (Streit et al., 2019). As far as we know, only Brandt (2022), Jacobs et al. (2010), Schulz (2014) and Streit et al. (2019) have explicitly investigated this complex interplay. Regarding the abilities of pre-service teachers, the findings of these studies indicate that pre-service teachers often fail to precisely identify children's approaches, to interpret underlying, specific concepts and to make appropriate instructional decisions for adaptive learning settings. Moreover, comparisons of the three abilities mostly show a decrease in capability from identifying to interpreting and again to decision-making. Although all three abilities have been described as interrelated, the connections appear to be only weakly developed. In

particular, there seems to be a lack of coherence between pre-service teachers' diagnostic judgments and instructional decisions.

Due to the few and predominantly qualitative studies with a small sample or only one vignette as a research instrument, the results are still limited. In order to substantiate the findings, further studies with larger sample sizes are needed, which also enable quantitative evaluation methods such as correlation analyses. Therefore, in the present study we used a vignette-based research instrument with four vignettes and a sample of N=172 pre-service teachers to further investigate the quality of and interplay between pre-service teachers' diagnostic judgment formation and instructional decision-making. The main research questions guiding this work are:

1) How well do pre-service teachers succeed in forming diagnostic judgments about children's mathematical thinking in early arithmetic education? 2) How appropriate are their instructional decisions to build on children's existing concepts? 3) How are pre-service teachers' diagnostic judgments related to their subsequent instructional decisions?

Sample, design, and methods

For answering the research questions N=172 pre-service teachers at the beginning of their bachelor's degree studies were asked to analyse four purposefully designed and structurally identical text-image-vignettes in an online questionnaire, leading to n=688 data sets (see Wirth et al., 2023 for more details about the vignette design). For this study, vignettes as representations of practice with reduced complexity (compared to videos or even real classroom situations) where chosen to fit the beginning stage of pre-service teachers emerging expertise. In advance, all participants have attended a one-semester course covering the following topics: teaching and learning basic concepts of numbers and operations in early arithmetic education. They were provided with subject-specific didactic knowledge about learners and understanding-oriented instructional methods and had been given ample opportunities to apply this knowledge when analyzing vignettes, tasks, and textbook material. Each vignette started with a short introductory description of a classroom situation (Figure 1).

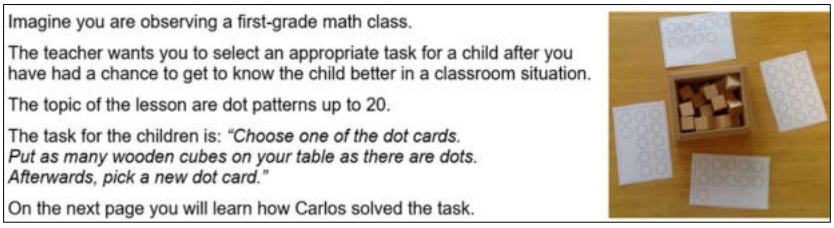

Figure 1: Introductory description of a classroom situation

The introduction was followed by information about one child's approach to solve an arithmetic task (Figure 2). The open-ended question for the participants as a stimulus to form a diagnostic judgment was: *Based on the information available, what can you say about Carlos's mathematical thinking related to his number concepts?*

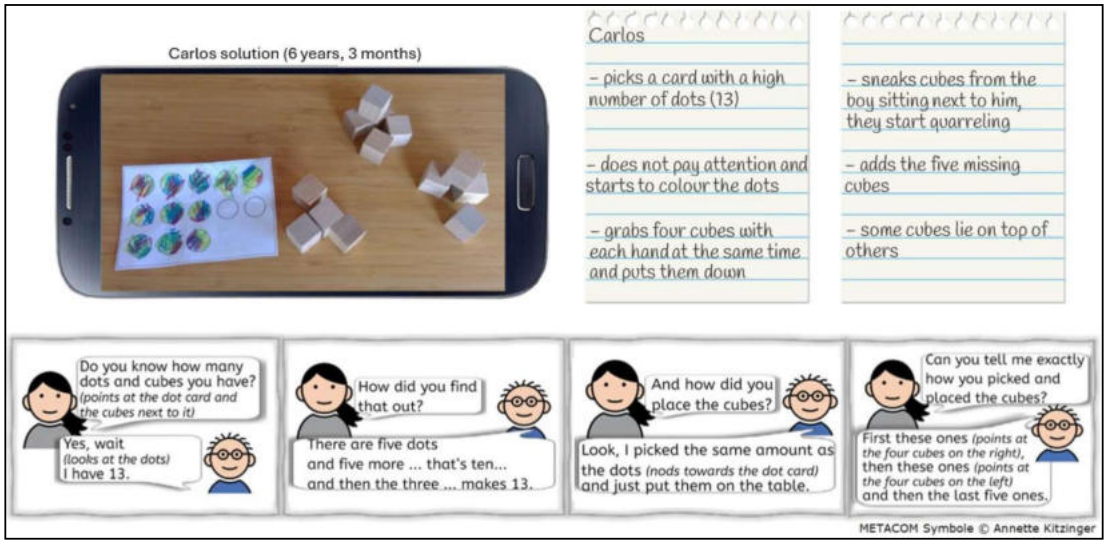

Figure 2: Information for diagnostic judgment

Finally, three suggestions for tasks were provided (Figure 3) and the partly open-ended stimulus for participants' instructional decision-making was: *Now please decide on a task that you would like Carlos to do next. Give reasons for your choice.*

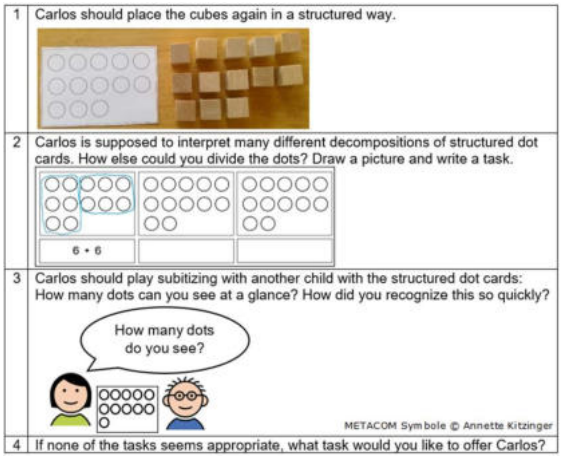

Figure 3: Task suggestions for instructional decision-making

While working on the vignettes, the two tasks: forming a diagnostic judgment and making an instructional decision could only be worked on one after the other, as it was not possible to go back to a previous page in the online questionnaire.

In order to develop an expert-rating for data analysis, all parts of the vignettes (here: Figures 1 to 3) were analysed by 14 researchers in the field of primary mathematics education regarding diagnosing and fostering children's basic concepts of numbers and operations. For example, the expert norm developed for the "Carlos vignette" was:

> Carlos recognised the structure of the dot pattern as 5+5+3 and captured the quantity without counting. He then used a different decomposition of the number 13 (4+4+5) to place the dice. Carlos can therefore recognise the structured amount of dots through conceptual subitizing and

has a solid part-whole concept. Task 2 would be an adequate choice for Carlos to work on next to strengthen his already existing understanding of part-whole relations.

Based on each expert norm deductive-inductive coding guidelines (Rädiker & Kuckartz, 2019) were created for the qualitative content analysis of pre-service teachers' 1) diagnostic judgments and 2) instructional decisions. 30% of the data was double coded by two independent raters and the interrater agreement according to Landis & Koch (1977) was at least substantial and more often almost perfect. Disagreements were systematically discussed regarding consequences for the coding guidelines. The coding was then used for a four-level categorical classification of the diagnostic judgment quality as well as the quality of the instructional decision (Figure 4).

To analyse the interplay between diagnostic judgment formation and instructional decision-making, chi-square tests according to Pearson were carried out in SPSS. The preconditions were met for all tests carried out, as the data originated from a random sample, the measurements were independent from each other and all expected frequencies per cell were greater than five. If a correlation was found, the effect size was calculated using Cramer's V and interpreted according to Cohen (1988).

Findings

Figure 4 presents an overview of the findings related to pre-service teachers' diagnostic judgment quality and the quality of their instructional decisions (related to research questions 1 and 2). The frequencies of diagnostic judgment quality indicate that pre-service teachers' judgments including precise statements about a child's approach and specific statements about underlying concepts are rather exceptions (code "4" in Figure 4 left). In a majority, pre-service teachers' judgments include only imprecise statements of a child's approach or unspecific statements of underlying concepts (code "2" in Figure 4 left). Here is a sample answer:

> "Carlos number concept could have improvements; he understands it to some extent as he is able to calculate the dots on the sheet by making 5+5+3."

In this judgment the statement about Carlos' approach is imprecise, because it is left unclear how Carlos captured the amount of dots and there is no statement about the way in which he placed the dice. Additionally, the statement of concepts he is capable of is rather general.

The frequencies of quality of instructional decision indicate that although follow-up tasks were suggested only in 55% of the cases an adaptive task was chosen. Moreover, only in 38% of cases the reason for the choice of an adaptive task was also adaptive regarding the children's existing concepts.

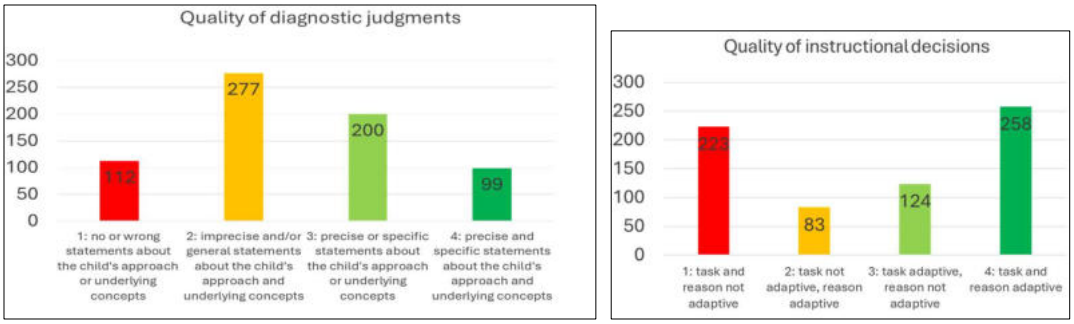

Figure 4: Frequencies of PSTs' diagnostic judgment quality and quality of instructional decisions

Figure 5 presents an overview of the findings related to the interplay of pre-service teachers' diagnostic judgment formation and instructional decision-making (research question 3). For example, in 47% (141) of judgments with higher quality and 30% (117) of the judgments of lower quality, an adaptive task with an adaptive reason for the choice was selected. A significant correlation was found between the diagnostic judgment quality and the quality of the instructional decision. The strength of the correlation lies between a small and medium range ($\chi^2(3, N=688)=29.430$, $p<.001$, $V=.207$).

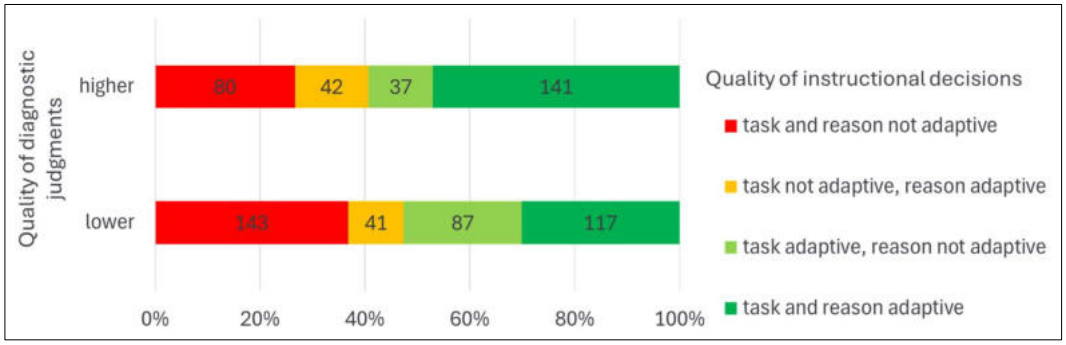

Figure 5: Frequencies of the interplay between pre-service teachers' judgment formation and instructional decision-making

Discussion and conclusions

Considering the limitations of the study (e.g., a limited representation of practice through a vignette-based instrument) the findings show that pre-service teachers' abilities to form precise diagnostic judgments about children's existing number and operation concepts and to make adaptive instructional decisions need to be fostered. Although a connection between pre-service teachers' abilities to form diagnostic judgments and to make an instructional decision could be found, the strength of the correlation was weak. The findings therefore strengthen the findings of Brandt (2022), Jacobs et al. (2010), Schulz (2014), and Streit et al. (2019) as well as the assumption of Moser Opitz (2022) that diagnostic judgment formation and instructional decision-making are separate processes.

Regarding the interplay between diagnostic judgment formation and instructional decision-making and the role of knowledge about understanding-oriented instructional methods the findings also strengthen van Ophuysen's (2010) assumption that it is reciprocal. For example, after being introduced to the task suggestions a considerable number of pre-service teachers were able to give an adaptive reason for their task choice although their diagnostic judgments were of lower quality. It can be assumed that these participants used the task suggestions as sources of information not only for the instructional decision but also for a final diagnostic decision. Maybe they noticed that no task was offered, which was adaptive to their previously formed diagnostic judgment. This may have triggered the diagnostic process again and even changed the diagnostic judgment. Due to the methodological design of the study, the participants had no opportunity to return to their previously formulated diagnostic judgments to adapt them during their instructional decision-making. They were only able to express their final diagnostic decision as the reason for their task choice. By this, the findings contribute to a better understanding of the interplay between pre-service teachers' diagnostic judgment formation and instructional decision-making in early arithmetic education and provide

important information for the education of future primary school mathematic teachers. Moreover, as the study is limited to the subgroup of pre-service teachers at an early stage of emerging expertise, the findings encourage further research about the interplay of diagnostic judgment formation and instructional decision-making of teachers in more advanced stages of expertise. To conclude, assessing and responding to children's mathematical thinking in an adaptive way is not an easy endeavor for pre-service teachers. Therefore, already in teacher education, future teachers should be provided with ample opportunities to develop diagnostic judgment abilities in connection with forming adaptive instructional decisions (Wirth et al., 2023) – an important prerequisite for all primary school children to be able to acquire a solid understanding of numbers and operations.

Examining the lesson plan designs and reflections of pre-service elementary teachers regarding mathematics teaching

Bilge Yilmaz Aslan[1] and Mehmet Fatih Ozmantar[1]

[1]Gaziantep University, Faculty of Education, Turkiye, bilgeyilmaz@gantep.edu.tr

Recognizing the importance of lesson planning in effective instruction, this study examines how pre-service elementary teachers design lesson plans and the challenges they face. The study involved 60 teacher candidates from a public university in Turkey and employed document analysis of lesson plans and reflective writings from a "Mathematics Teaching" course. Findings show that participants used varied strategies such as storytelling and real-life contexts to engage students. In the Explanation and Elaboration phases, they emphasized student-centered and collaborative activities. During evaluation, they incorporated both traditional and innovative tools including games and Web 2.0 applications. Participants also reported concerns related to classroom management, content transitions, and designing assessments. These reflections underscore the need for more structured support in teacher education programs.

Keywords: Lesson planning, pre-service elementary teachers, mathematics teaching.

Introduction

The quality of mathematics instruction is influenced by several factors, including teacher knowledge, instructional strategies, and the organization of the teaching process (Kahan et al., 2013). A critical yet often overlooked aspect of teaching is the preparation that occurs outside the classroom, specifically lesson planning. Lesson planning not only enhances instructional effectiveness (Rusznyak & Walton, 2011) but also plays a crucial role in the overall teaching-learning process, improving both time management and the efficiency of instruction (Krepf & König, 2022). The act of lesson planning is central to the teaching process, and research has shown that teachers face numerous challenges during this phase. These challenges, such as classroom management, transitioning between topics, and structuring complex mathematical concepts, can significantly influence the effectiveness of the lesson (Derri et al., 2014). These difficulties are particularly evident in the context of pre-service teachers, who are still developing their pedagogical skills. While many studies focus on the challenges teachers face during lesson planning, fewer have examined how structured instructional models, such as the 5E Model (Engagement, Exploration, Explanation, Elaboration, Evaluation), can help pre-service teachers navigate these challenges. The 5E Model has been widely recognized for its effectiveness in promoting student-centered teaching and providing a systematic approach to lesson planning. However, despite its potential, research on how pre-service teachers apply this model in real-world classroom settings remains limited. This study builds on the work of prior research by examining how pre-service elementary teachers design lesson plans for mathematics instruction using the 5E Model. The research also investigates the experiences and challenges they encounter during this process. By integrating findings from previous studies on lesson planning and instructional models, this research contributes to the growing body of literature on pre-service teacher preparation. Specifically, it aims to address gaps in understanding how structured instructional frameworks influence lesson design and how pre-service teachers manage the

complexities of lesson planning. The study is guided by two primary research questions: “How do pre-service elementary teachers design lesson plans for mathematics teaching according to the 5E Model?” and “What concerns and challenges do they face when designing these plans?” In this study, the 5E instructional model functioned not only as a pedagogical design tool but also as a framework for categorizing and interpreting the lesson planning practices of PSTs (Pre-Service Teachers). While its primary function was instructional, its structural stages provided an analytical lens through which reflections and lesson plan components could be examined systematically. This dual role of the model—as both a teaching scaffold and a methodological lens—offered deeper insight into the planning process, highlighting the multifaceted ways in which structured instructional models can support both practice and research. Theoretical frameworks such as the 5E Model provide a foundation for examining the intersection of pedagogical content knowledge, teacher anxiety, and the organizational aspects of lesson planning. By aligning this study with the broader literature on instructional design and teacher preparation, the research underscores the significance of supporting PSTs in overcoming the challenges they face during the lesson planning process. Furthermore, the study offers practical insights for teacher education programs, providing strategies for better equipping future educators to develop effective, student-centered lesson plans that align with evidence-based instructional models.

Methods

This study employs document analysis and was conducted with 60 PSTs enrolled in the third year of a primary education program at a public university in Turkey. Document analysis involves collecting, reviewing, questioning, and analyzing various written or electronic texts as the primary source of research data (Morgan, 2022). The data were collected from lesson plans prepared by the pre-service teachers, based on the 5E model, as part of the "Mathematics Teaching" course, prior to their sample teaching practices. The course was structured in two phases: theoretical and practical. During the first 8 weeks, pre-service teachers were provided with content related to elementary mathematics teaching (theoretical frameworks, lesson planning, teaching and learning approaches, etc.) by the mathematics teacher educator (MTE). Over the next eight weeks, during the first session of each week, the MTE presented an example of instructional design related to an elementary mathematics topic. In the second session, the teaching performance of the pre-service teachers was observed. Before conducting their teaching performance, each pre-service teacher submitted their prepared lesson plan electronically to the MTE. Additionally, the pre-service teachers also shared their reflective writings, in which they described their experiences while preparing the lesson plan, via electronic submission. All data were categorized according to the elementary mathematics learning domains (Numbers and Operations, Geometry, Data Analysis, Measurement). Lesson plans and reflective writings were randomly selected from each learning domain. This study includes the analysis of documents from 12 pre-service teachers. In the findings, each participant was assigned a number from 1 to 12. Pre-service teachers were coded as PSTx, where "x" represents the number assigned to each teacher candidate. The documents, including the lesson plans and reflective writings, were systematically examined and evaluated. The raw data were initially divided into meaningful units, then coded and categorized as explained by Patton (2002) to gain an understanding of the research problem. In this study, we analyzed the lesson plans of pre-service teachers by dividing them into three dimensions:

i) Engage, Explore, ii) Explain, Elaborate, and iii) Evaluate. Sub-codes related to the structure of each dimension were identified. Content analysis was conducted on the reflective writings of the pre-service teachers, and sub-codes were created for each category.

Findings

Structure of Pre-service Elementary Teachers' Lesson Plans

In this section, findings regarding the structure of the lesson plans designed by pre-service elementary teachers will be presented, organized by dimensions. The structure of each dimension is provided in Table 1 below.

Table 1: PSTs' lesson plans and their structure

Dimensions	Structure
Engagement and Exploration	Activating prior knowledge
	Relating to real life
	Gamification
	Storytelling
	Singing
	Exercises
	Assigning tasks
Explanation and Elaboration	Mathematical thinking activities (e.g., prediction, problem formulation, transformation, comparison)
	Student-centered activities
	Group work
	Alternative activities
Evaluation	Traditional assessment tools (e.g., tests, fill-in-the-blanks, matching)
	Game-based assessment
	Using Web 2.0 tools

Engagement and Exploration Dimension

At the beginning of the lesson, pre-service teachers aimed to activate prior knowledge by posing questions related to earlier topics. For example, PST1 described entering the class with a balance scale and a bathroom scale, asking students questions like: "What are these in my hands?" and "What do we use them for?" After briefly discussing the answers, PST1 would ask: "Do you remember? Last year, we measured our weights in class. Shall we see how much weight we've gained?" This approach aimed to engage students and refresh their previous knowledge about measurement before introducing new content, such as grams. Some prospective teachers used storytelling to explorate students for the lesson. PST6, for instance, entered the classroom with a basket of apples and asked the students to identify a picture (see Figure 1) from the story "Snow White and the Seven Dwarfs."

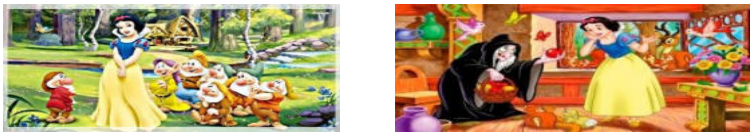

Figure 1: The image used in the story of PST 6

After recounting the story with the students, PST6 proposed changing the ending: "Let's say the witch is kind-hearted and gives Snow White a basket of apples." Each student was given an apple, and the teacher asked, "How many apples did everyone eat?" and "How many are left in the basket?" This led to a discussion about division, helping students recall a prior lesson while setting the stage for the new content.

Explanation and Elaboration Dimension

All pre-service teachers incorporated student-centered activities in the explanation and elaboration dimension of their lesson plans. While some activities were designed for individual work, group work was the predominant focus. Most lesson plans also included mathematical thinking activities such as estimation, problem formulation, transformation, and comparison. For example, PST 7 designed a lesson plan for a 4th-grade class on recognizing and modelling fractions (Ministry of Education, 2018). In this plan, students were given materials (Figure 2) and asked to complete a skeleton fish activity. Using three skewers labelled with the fractions 1/10, 1/2, and 1/5, students compared the fractions and arranged them from largest to smallest on a number line, represented by the skeleton fish. Additionally, the pre-service teacher included alternative activities for modelling fractions, such as group work using the puzzle technique. Students, divided into pairs (assuming a class size of 30), were tasked with assembling four puzzle pieces that corresponded to a specific fraction, its area model, its number line representation, and the type of fraction (Figure 2).

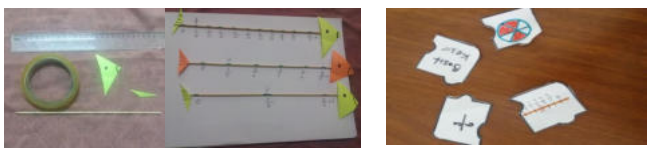

Figure 2: Example of task designed by PST 7 and Alternative task example designed by PST 7

Some pre-service teachers also designed activities to enhance students' problem-formulation skills. For instance, PST1's lesson plan for 3rd-grade students on measurement included an activity where

students, in pairs, were asked to create and solve two problems based on images (Figure 3) shown by the teacher. An example from PST1's plan is as follows:

Figure 3: Image of PST 1's problem-posing task

Problem: Aunt Hatice goes to the market and buys 550 grams of lentils, 300 grams of flour, and some red pepper. If she has a total of 1200 grams of goods, how much red pepper did she buy?

Solution: By adding the weight of the lentils and flour, and subtracting it from the total, we can find the weight of the red pepper. 550 + 300 = 850 grams. 1200 - 850 = 350 grams of red pepper.

Evaluation Dimension

Five of the pre-service teachers used traditional assessment tools in their lesson plans. They distributed individually prepared or pre-made worksheets to students, which included tools such as true/false, fill-in-the-blank, and multiple-choice questions. Some pre-service teachers, however, opted for game-based assessments. For example, in a lesson plan on place value for a 2nd-grade class, PST5 designed a BINGO game. Students picked a card (e.g., a pink one) and placed a LEGO piece on the corresponding number on their BINGO card if they correctly identified the number. The first student to correctly identify all the numbers and complete their BINGO card won the game (Figure 4 illustrates the BINGO setup).

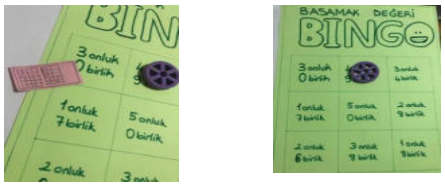

Figure 4: Game-based evaluation example of PST 5

Additionally, some pre-service teachers incorporated Web 2.0 tools in their assessments. For instance, in a 1st-grade lesson plan on geometric patterns, students were expected to distinguish between patterns and non-patterns, find the rule of the pattern, and complete missing parts of the pattern. PST12 used the LearningApps platform, where students took turns answering questions at the board. This interactive activity enabled the teacher to assess students' understanding of the topic (activity links: https://learningapps.org/watch?v=pzeji5qz524).

Experiences of Pre-service Elementary Teachers in Lesson Planning

Pre-service teachers who designed their lesson plans individually were asked to share their experiences alongside their plans. It was found that they faced several challenges and held certain concerns throughout the lesson planning process. These challenges and concerns are illustrated in Figures 6.

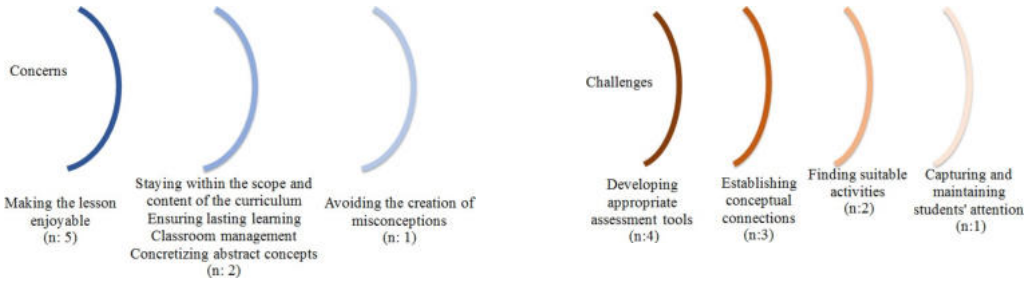

Figure 6: Concerns and challenges experienced by pre-service teacher during the lesson plan preparation process

When designing their lesson plans, pre-service teachers frequently expressed concerns about "how to make the lesson enjoyable." For example, PST6 shared: “I believe in learning through fun because my elementary years were filled with strict, sometimes threatening teachers. I never want to be like them. That’s why I aimed to create a plan where students aren’t afraid to speak up and are eager to share their ideas." Additionally, they mentioned concerns about staying within the scope of the curriculum, ensuring lasting learning, managing the classroom, and making abstract concepts concrete. Sample statements for these concerns are as follows. Staying within scope: “PST1: I noticed that many videos and activities I found online went beyond the learning objectives, so I did a lot of research to ensure I stayed on track.” Ensuring lasting learning: “PST7: I used multiple activities to explain fractions because I believe variety helps students retain information better.” Classroom management: “PST4: I might struggle with managing the class during my activities. The students could get too excited, and I’ll need to put extra effort into keeping them on track during group work.” Making abstract concepts concrete: “PST12: Since my target audience is 1st graders, I focused on using many visuals to make the lesson more concrete for them.” In addition to these concerns, the pre-service teachers also reflected on the challenges they faced while preparing their lesson plans. The most common difficulty was creating appropriate assessment tools. They also struggled with transitioning between mathematical concepts, finding suitable activities, and capturing students’ attention at the start of the lesson. Some examples include: Conceptual transitions: “PST10: After reviewing the frequency table and object graph, I struggled with how to introduce the bar graph. I wasn’t sure how to explain it, so I opted to transition through the object graph.”

Result & Discussion

This study offers significant insights into the lesson planning experiences of PSTs within the framework of the 5E Model, particularly in mathematics instruction. The findings reveal both the strategies employed by these PSTs and the challenges they encountered, each of which provides opportunities for deeper reflection on teacher education and professional growth. One of the key findings highlights the importance of the Engagement phase of the 5E Model, where PSTs used strategies such as storytelling and real-life connections to activate students’ prior knowledge and increase motivation. This aligns with the literature that emphasizes the role of engaging students early in the lesson to foster interest and a deeper understanding of the subject matter (Livy & Downton, 2018). By incorporating techniques that make lessons more relatable and enjoyable, PSTs aimed to create a positive learning environment, which is crucial for effective teaching. However, the

challenges faced during lesson planning—particularly in the areas of maintaining scope, ensuring conceptual transitions, and creating effective assessment tools—highlight areas where PSTs need more support. For instance, many PSTs expressed concerns about staying within the curriculum while still making the lesson enjoyable. As PST1 noted, the fear of going beyond the curriculum goals led to extensive research to ensure alignment with learning objectives. This finding is consistent with prior research, which suggests that staying within the curriculum while designing engaging activities is a common struggle for teacher candidates (Arias et al., 2017).

The findings also indicate that PSTs found it difficult to design assessments that accurately reflected student learning. While some relied on traditional methods, others explored more innovative approaches, such as game-based assessments and Web 2.0 tools. This diversity in assessment approaches reflects an ongoing shift in teaching practices, where traditional methods are complemented by interactive tools to engage students better and assess their learning in more dynamic ways (Matsumoto-Royo & Ramírez-Montoya, 2021). Teachers' ability to diversify their assessment strategies is crucial, as it allows them to meet the needs of students with different learning styles and preferences. Another critical challenge was the difficulty in making conceptual transitions between mathematical topics. As PST10 expressed, transitioning from one concept to another, such as moving from object graphs to bar graphs, requires thoughtful planning and creativity. This echoes the findings of Thompson (1984), who identified that teachers often struggle with creating smooth conceptual links between topics. Overcoming this challenge requires a deeper understanding of the interconnectedness of mathematical concepts and the ability to scaffold students' learning effectively. Importantly, these challenges should not be perceived solely as negative aspects; they also present opportunities for growth and improvement. Rather, they can be interpreted as reflective indicators of PTSs' active engagement in their professional development. The articulation of concerns and difficulties signifies a developmental process in which future teachers critically examine their practices, experiment with solutions, and cultivate pedagogical resilience. In several cases, participants were observed to spontaneously generate solutions to the challenges they identified, indicating not just awareness, but also adaptive professional behaviour.

As noted by Darling-Hammond and Bransford (2007), challenges in teaching often serve as catalysts for professional learning, pushing teachers to reflect on their practices and seek innovative solutions. Furthermore, the findings suggest that several pre-service teachers not only articulated concerns but also engaged in reflective practices that led them to devise their strategies and tentative solutions. For instance, while some participants voiced uncertainty about managing group dynamics or transitioning between abstract concepts, their reflective writings revealed subtle shifts in thinking that pointed toward practical adaptations. This duality reflects an important aspect of professional growth. It indicates that PSTs are not passive recipients of training but are actively shaping their learning through critical self-assessment and emergent problem-solving. This underscores the need for teacher education programs to recognize and build upon these spontaneous strategies as evidence of developing professional agency. Finally, the concerns and challenges expressed by pre-service teachers throughout the lesson planning process should not only be seen as developmental hurdles but also as valuable diagnostic tools for teacher education programs. These reflections, grounded in real-world classroom preparation experiences, offer genuine insight into areas where novice teachers

require support. Therefore, systematically collecting and analyzing such concerns can inform the development of more targeted, responsive, and context-specific professional development modules. Integrating PST's lived challenges into training designs ensures that these programs are aligned with the actual needs of future educators, enhancing both their preparedness and confidence.

The Reflective Gaze: A Case Study on Eye-Tracking Technology's Role in Shaping Mathematics Teacher's professional identity

Adi Eraky

Achva Academic College, Faculty of Leadership and Education, Israel

AdiE@live.achva.ac.il

Keywords: Eye tracking, mathematics education, teacher professional identity, reflective practice, professional development

Rationale

A teacher's professional identity development is a complex process influenced by various experiences and reflective practices. Teachers' professional identity comprises five interconnected components: knowledge, emotions, beliefs, confidence, and personal principles (Looney et al., 2017). Current research in mathematics education has established the value of eye-tracking methodology for understanding cognitive processes (Strohmaier et al., 2020). The relationship between visual attention and mathematical thinking has been well-documented (Schindler & Lilienthal, 2019), particularly in how eye movements reveal underlying cognitive strategies and problem-solving approaches. However, the potential role of eye-tracking in professional identity development still needs to be explored. This study takes a novel approach by integrating eye-tracking technology with reflective practices, offering a unique opportunity to make cognitive processes visible and concrete for teachers. This study, conducted as part of a master's program, combines these technological capabilities with Looney et al.'s teacher professional identity framework (2018) to create a unique method for supporting identity development through technology-enhanced reflection. This is especially important in mathematics education, where grasping cognitive processes is vital for effective teaching and assessment.

Research Aims and Methods

This case study examines how eye-tracking technology and stimulated recall interviews impact a mathematics teacher's professional identity development. The primary research question asks: How visualisation of and reflection on cognitive processes, captured through eye-tracking, influence various aspects of a teacher's identity. I analysed a single participant, Dana (pseudonym), an elementary mathematics teacher with eight years of experience, to examine the impact of eye-tracking on professional identity components as outlined by Looney et al. (2017). The eye-tracking session lasted 363 seconds and was part of a professional development framework. The research design used multiple methods: eye-tracking data during a geometric task with a Pupil Labs device, immediate recall interviews while watching recordings, written reflections on the experience's implications for teaching practice, and a follow-up interview after one week to assess sustained impact. Data analysis combined quantitative measures from eye-tracking data with thematic analysis of interviews and reflective writing. The interviews lasted approximately 45 minutes each, and analysis included both deductive categories based on Looney et al.'s (2017) framework and inductive coding to capture emergent themes, allowing exploration of how the experience impacted each.

Results

The eye-tracking data revealed complex patterns of problem-solving. During the 363-second solving period, Dana made a total of 1,493 fixations (4.11 fixations per second), with an overall entropy value of 4.178, indicating systematic exploration patterns. Though the active eye-tracking experience was relatively brief, the subsequent reflective processes—including stimulated recall, written reflection, and follow-up interviews—created an extended learning experience that facilitated deeper integration into professional practice. The initial 15 seconds 59 fixations (entropy of 3.21), suggesting intensive early problem space exploration. Dana's reflection demonstrated enhanced metacognitive awareness: "The experience sharpened all the theoretical knowledge we learned during the course", illustrating how abstract concepts became concrete through visualization. The data revealed an emotional trajectory throughout the experience. Initial anxiety was evident in statements such as "You are stressing me out", while later reflections showed professional growth: "Wow, amazing. You gave me therapy". Dana's beliefs about teaching and learning evolved through this experience. Her reflection, "It is important to remember the diversity in the classroom, that every brain is different", was supported by observed variations in her problem-solving approaches. Eye-tracking data evidenced strategic approaches and emphasized differentiated instruction. This objective data enhanced professional self-awareness. Dana stated, "I'm a planned person, always thinking ahead", reflecting her strategic planning patterns, a characteristic clearly visible in the sequential and organized patterns of eye movements observed during problem-solving, where she systematically scanned the problem space before focusing on solution paths. The follow-up interview showcased how Dana applied these insights in her classroom, illustrating that eye-tracking coupled with structured reflection, can foster changes in teaching strategies. The experience deepened core teaching principles, as shown in her statement, "The experience sharpened my need to adapt my teaching to each child". While a brief eye-tracking session alone will not transform professional identity, this study suggests that using such technology as a catalyst for reflection in a comprehensive professional development program can reveal cognitive processes usually invisible to teachers. These findings provide practical implications for educators, offering a new perspective on professional development and the benefits of technology-enhanced reflection in teaching and as a research method.

Identifying, monitoring and fostering conceptual understanding of the arithmetic mean

Laura Geldermann[1]

[1]Ruhr University Bochum; laura.geldermann@rub.de

Keywords: Conceptual focus, representations, conversions, arithmetic mean.

Theoretical background

Conceptual focus is a crucial aspect of learning mathematics. In terms of instructional practice, conceptual focus involves *identifying* learning content, *monitoring* pupils' learning progress, and *fostering* pupils' understanding (Prediger et al., 2022). For the arithmetic mean, which is the subject of this study, the following aspects of understanding can be identified (Strauss & Bichler, 1988). The *aspect of compensating* relates to the determination of the arithmetic mean through redistribution. The *fair-share-aspect* concerns the equal distribution of the sum of the integers to the number of the integers. Furthermore, in the context of conceptual focus, *conversions* (Duval, 2006) play an important role, as they develop and make visible conceptual understanding by linking various representational registers (e.g., symbolic, iconic, verbal). Against the background, this exploratory study investigates the following research question: How do pre-service teachers demonstrate conceptual focus with regard to the aspects of the arithmetic mean through a text vignette?

Method

In order to answer the research question, 60 secondary level pre-service teachers in their 5th Bachelor semester at a German university worked on a text vignette as part of a lecture on the didactics of mathematics. Figure 1 presents the vignette, which is based on a pupil task that includes conversions of representational registers and addresses the three practices *identifying* learning content (1), *monitoring* pupils' learning progress (2), and *fostering* pupils' understanding (3).

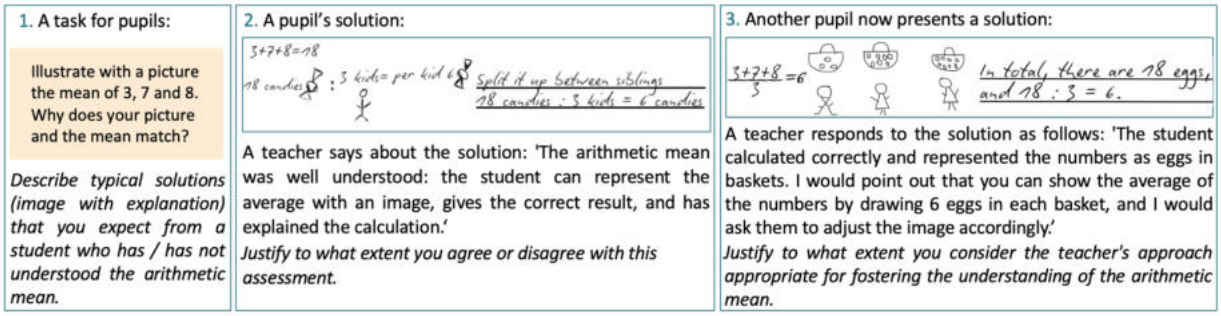

Figure 1: Vignette "Diagnosing and fostering conceptual understanding of the arithmetic mean"

Results

In the following, the answers of two pre-service teachers are quoted and analysed to contrast how conceptual focus can become visible through the vignette by referring to its three components:

Case 1

*Identifying: "*Aspect of compensation: Blocks are removed from the taller towers (larger numbers) until all towers are the same height." *Monitoring:* "The child understood the calculation but only decorated it with 'pictures.' It is not clear what exactly the quantity of 18 and the quantity of 3 mean and how the process leads to the result. […]" *Fostering:* "The pupil drew the initial situation correctly. […] The first drawing can be kept but should be supplemented by the teacher's suggested drawing" In this case, conceptual focus is demonstrated in the responses to *identifying* and *monitoring,* as they take into account both the conceptualisations of the arithmetic mean and the conversion of representational registers. In contrast, this is not reflected in the response related to *fostering*.

Case 2

*Identifying: "*I would draw the three numbers as stacks of building blocks with the number of blocks corresponding to the numbers, and then distribute the blocks so that the towers are of equal height*."* *Monitoring: "*I agree with the teacher. The arithmetic mean was only partially represented visually, but it was understood on a mathematical level." *Fostering: "*I also agree with the teacher here. The distribution of the eggs needs to be represented more clearly. However, the arithmetic mean was understood." In this case, the response to task 1 demonstrates conceptual focus based on the aspect of compensation. However, in the statements regarding *monitoring* and *fostering,* conceptual understanding is concluded from the correct calculation and the conversion of representational registers is not taken into account. Therefore, there is not conceptual focus here.

Conclusion and outlook

In summary, results from the analysis of the vignette suggest that identifying conceptualisations of the arithmetic mean does not imply monitoring and fostering conceptual understanding. Based on this, the poster introduces the vignette and illustrates the results to discuss the relationship between identifying, monitoring and fostering conceptualisations of the arithmetic mean.

Acknowledgment

Teachers' discussions used to explore students' mathematical writing

Jonas Jäder[1]

[1]Mid Sweden University, Dept. of Engineering, Mathematics and Science Education, Sundsvall, Sweden; jonas.jader@miun.se

Keywords: Teacher collaboration, professional learning communities, students' mathematical writing

Introduction

Teachers' collaboration can be a strong means for developing the teaching of mathematics (Garet et al., 2001; Kennedy, 2016). It has been shown that discussions on students' thinking and learning tend to have a greater impact than those directed toward teachers' behaviours (Kennedy, 2016; Timperley, 2006). Furthermore, it is essential for the participating teachers to be able to identify with the group and that there is a common norm for the discussions (Karsenty et al., 2024). Adding to this is the importance of a suitable topic for a professional development, both in terms of coherence, and in terms of its relevance (Prediger et al., 2015). One such topic is students' mathematical writing. For example, there is a need to address how good mathematical writing can be described (Teledahl et al., 2023). In an ongoing project teachers' collegial discussions are used to explore students' mathematical writing. The research question guiding this text is how teachers' discussions can be modified to enhance the opportunities to explore students' mathematical writing. Twenty teachers at two schools of similar size participate in the project. Both schools include all grades from pre-school up to grade 6 with a student age range from 6 to 12 years old. Ten two-hour meetings have been conducted with discussions focused on students' mathematical writing. The arrangements for the discussions are explorative in the sense that the organization develops over time. The role of the researcher in the discussions is primarily to direct attention to students' mathematical writing. During each of the meetings, notes have been taken, which have been used in a strive to enhance the discussions without the interaction of an external mediator. Suggestions are tried continuously and related to an idea of good teacher discussions as something with a clear focus that allows teachers to describe as well as interpret happenings related to students' mathematical writing, and to put teaching into practice to create opportunities for students to develop their mathematical writing skills.

Results and discussion

In summary, three modifications have improved the discussions:

- To divide the teachers into sub-groups consisting of 3-4 teachers, teaching the same or close grades. The discussions were conducted alternately with the whole group and the sub-groups.
- To collectively work with designing activities to be implemented in the classrooms.
- To focus on the same mathematical topic and concepts, with similar relatable goals for all grades, and to include the same or similar questions.

These modifications had to do with two themes: coherence and the integration of students' actions and learning with the discussions. Consciously formed sub-groups made it easier for teachers from different schools to relate to each other and to identify with the group. The importance of a common

point of departure (Karsenty et al., 2024) was taken into consideration as the teachers could use their understanding of students of a specific age, making it possible to also relate the discussion to classroom work. At the same time, the importance of building a norm and point of departure (Karsenty et al., 2024) for the whole group was taken into consideration as activities and learning goals were designed to fit students in pre-school as well as grade 6. The use of the same task, with slight variations for different grades has been applied successfully before (Jäder & Wedman, 2023). The designed activities also served as a basis for a more active learning. Basing part of a discussion on students' thinking has been found to be functional for collegial learning (Kennedy, 2016; Timperley, 2006). A focus on students' learning may possibly also reduce pressure on teachers in the professional learning situation. Making each one of the teachers involved in the overall theme, but at the same time making them the expert on their own classroom and their own students in relation to the specific design of the activity, strengthened the possibility for active participation in the discussions (Garet et al., 2001). Overall, a conclusion is that teachers' discussions can develop exploratively through collaboration and joint decisions and may take advantage of the above-mentioned ideas.

The interplay between mathematics teachers' professional development and classroom practice: A scoping review

Therese Carlsson

Linnaeus University, Department of Mathematics, Växjö, Sweden therese.karlsson@lnu.se

Keywords: Mathematics teachers' professional development, classroom practice, scoping review.

Introduction

In studies on mathematics teachers' professional development, effective principles for teachers' learning have been identified (Darling-Hammond et al., 2017; Desimone, 2009). However, other studies indicate that the impact of mathematics teachers' professional development on classroom practice is often limited (Pellegrini et al., 2021). This contradiction raises a query as to why mathematics teachers' professional development on the one hand is seen as promising for teachers' learning, but on the other hand, has a limited impact on classroom practice. To understand this contradiction, this study focuses on how and with what results previous studies have investigated the relationship between professional development and classroom practice. This is investigated through a scoping review guided by the following research questions: RQ1) How has the relationship between mathematics teachers' professional development and classroom practice been studied? RQ2) What are the results of studies on the interplay between mathematics teachers' professional development and classroom practice?

Method

This study was conducted as a scoping literature review (Peters et al., 2020). The databases used were ERIC and Web of Science. The search was structured around the following themes: professional development, classroom practice, impact, and mathematics (search string: "professional development" OR "teacher* learn*" OR "learning communit*" AND "classroom* practic*" OR "teach* practic*" OR "teach* prax*" OR "student outcome" OR "student* achiev*" OR "student* learn*" OR "chang* pra*" OR "teach* chang*" AND effect* OR implement* OR improv* OR innovation* AND mathematics). Only scientific, peer-reviewed articles published after 2009 in high-impact qualitative research journals were included. The articles were screened based on the following inclusion criteria: the study must involve some form of professional development, have a direct connection to the teacher's own classroom practice or impact on student learning, be focused on primary or secondary education, be empirical, and primarily focus on mathematics education. The screening process resulted in the inclusion of 150 articles. To answer RQ1, the articles were analyzed based on their research design, for example, experimental, longitudinal, comparative, or case study. To answer RQ2, and partially RQ1, the included articles were analyzed using coding in NVivo. An initial set of codes was established, while additional codes were developed during the analysis process. The codes were developed to capture key aspects such as the type of professional development program (e.g., lesson study, coaching, implementation of a tool or method), the study sample (large- or small-scale), the duration of the program (categorized as one year or less, one to three years, or more than four years), and the reported results. Results were coded as positive, none,

mixed or negative. Additionally, whether the results were reported from the student or teacher perspective was documented.

Results and discussion

Connected to RQ1, the results indicate that most studies included in this review are small-scale, involving fewer than a hundred participants, and that the majority have a timespan of one year or less. The results also show that experimental designs and case studies are the most common research designs. A notable gap in previous research appears to be the lack of longitudinal studies. To gain a deeper understanding of how changes in teachers' practices over time influence student learning, and how various forms of professional development for mathematics teachers impact teaching, longitudinal studies would be valuable. Regarding RQ2, the results from experimental and case studies reveal both positive and negative outcomes, but predominantly positive. Positive outcomes mean that the results show an improvement in student learning, or a development in the teacher's practice, and negative outcomes mean that no improvement was shown in either the students' results or the teacher's practice. Regarding study duration, studies with a longer duration report a higher proportion of negative results. This suggests that the effect of professional development diminishes over time. The results presented in the articles included in this review are primarily linked to teachers' practices. Fewer than half of the included studies report findings that directly measure student outcomes, and these measurements predominantly consist of pre-tests and post-tests. The interplay between mathematics teachers' professional development and classroom practices is rarely addressed in the reviewed literature. This lack of focus may contribute to the limited capacity of these studies to explain why professional development does not consistently yield the desired effects.

The poster will be organized into four sections. The first section will present the rationale for the study along with the research questions. The second section will outline the methods employed in the study. In the results section, diagrams will provide an overview of the distribution of various research designs, professional development approaches, and outcomes. By illustrating the interconnections between these aspects, the poster will then present a section highlighting identified gaps in the current research, providing implications and directions for future studies.

Teacher noticing framework to examine multiple teaching skills: Analysis of teaching and lesson planning

B. Sumeyye Kurutas

University of Delaware, Mathematics Education, Newark, DE; sumeyyek@udel.edu

Keywords: Teacher noticing, mathematics education, analysis of teaching, lesson planning.

This study proposes a framework to examine teachers' analysis of teaching and lesson-planning skills and how these skills might mutually be the indicators for the other. The framework builds on teachers' noticing construct (Sherin, 2017) and extends its boundaries by using it to examine what teachers notice not only during teaching but also before teaching. This is important because by using the same framework it may be possible to understand the relationships between different teaching skills.

Teacher noticing can be defined as distinctive approaches teachers use to observe and interpret classroom events and instructional details. Some may argue that teacher noticing primarily refers to what teachers notice during teaching (Weyers et al., 2023). However, Sherin (2017) explained the scope of teacher noticing as "we should think of noticing as something that occurs when teachers prepare for and reflect on their teaching experiences" (p. 405). Choy et al. (2017) supported and argued that teachers should pay close attention to student thinking by using classroom artifacts and interpreting these artifacts mathematically at all points of a lesson—before, during, and after.

Many studies unpacked teacher noticing dimensions somewhat differently but in parallel to one another (Santagata & Yeh, 2016; Scheiner, 2016). For example, Kaiser et al. (2015) proposed teacher noticing as "(a) perceiving particular events in an instructional setting, (b) interpreting the perceived activities in the classroom, and (c) decision-making, either as anticipating a response to students' activities or as proposing alternative instructional strategies" (p. 374). Even though there are different terms for teacher noticing dimensions, they can mainly be listed as (1) attending, (2) interpreting, and (3) responding (Amador et al., 2017; Santagata & Yeh, 2016). Therefore, this framework suggests these teacher noticing dimensions (purple column in Figure 1) can be applied to multiple teaching skills to understand the possible relationships between these teaching skills.

Figure 1 summarizes how the noticing framework can be applied to examine both teachers' analysis of teaching and lesson planning skills by presenting which elements can be used to analyse these teaching skills and how these elements correspond in terms of teacher noticing dimensions situated in the literature. One conjecture can be teachers who are better at providing suggestions for improvement in an enacted teaching video might be more successful at foreseeing key learning moments of the lesson prior to instruction and anticipating students' thinking before and after these moments, as both skills correspond to the responding level of teacher noticing dimensions which is considered to be the highest level of noticing (Kaiser et al., 2015). Elements to analyse these two forms of teacher noticing (orange column in Figure 1) have been previously in research studies. From the lesson planning perspective, Choy et al., (2017) used *noticing* as an analytic framework to identify the lesson's key mathematical concepts and anticipate students' thinking. Within the analysis of the teaching video context, Santagata and Yeh (2016) included mathematics content, student thinking, pedagogical teaching moves, and suggestions for improvement in their rubric.

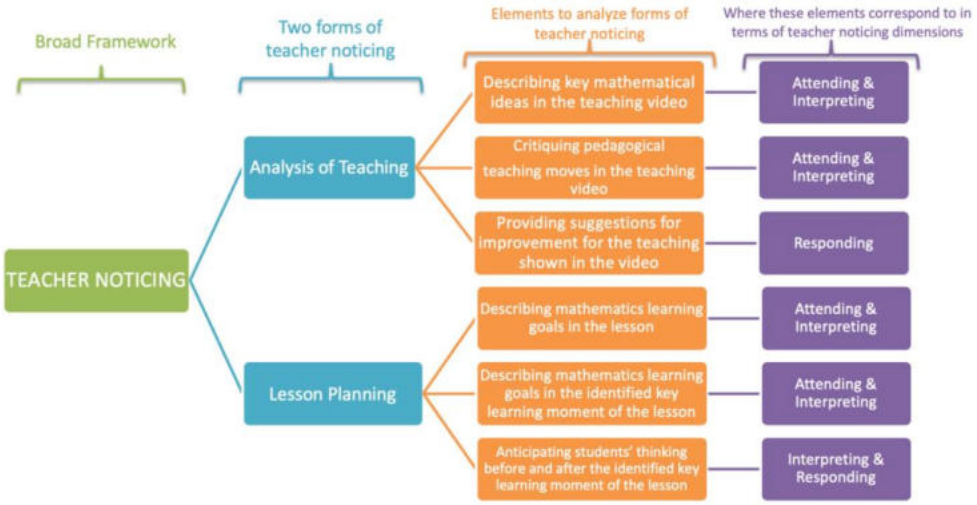

Figure 1: Teacher noticing framework to examine teachers' analysis of teaching and lesson planning skills

Learning to teach problem solving using a four-step lesson structure

Sabine Lit[1,2], Marjolein Kool[1] and Paul Drijvers[2]

[1]HU University of Applied Sciences Utrecht, The Netherlands; sabine.lit@hu.nl

[2]Utrecht University, The Netherlands

Keywords: Problem solving, teacher education, teaching practice.

Introduction

Mathematical problem solving has recently been established as a key objective in Dutch primary education. Consequently, teaching problem solving has become a new subject in teacher education. At our institution, a course on problem solving is implemented at the end of the second year. We have initiated an ongoing design study to gain insights into how preservice teachers (PSTs) can develop teaching skills for teaching problem solving.

Theoretical Framework

In a literature review on the knowledge and skills necessary for teaching problem solving (Lit et al., 2025), we found that one of the most challenging skills for teachers is leading whole-class discussions. To address this challenge, Stein et al. (2008) developed five practices for orchestrating productive mathematical discussions: anticipating, monitoring, selecting, sequencing and connecting. These five practices were incorporated into our course design, alongside the lesson structure for teaching through problem solving proposed by Takahashi (2021), which is itself based on the problem-solving steps outlined by Polya (1945). As a result, we developed a four-step lesson structure specifically for teaching problem solving (see Table 1). The research question guiding this study is: How and to what extent can a four-step lesson structure assist preservice teachers (PSTs) in implementing problem-solving lessons in primary education?

Methods

Twenty PSTs participated in the study. During the course on problem-solving, they taught three non-routine problems to students aged 8-12 years. The PSTs documented their use of the four-step lesson structure and submitted video-recordings of their teaching sessions. The video-recordings were utilized for cross-validation to ensure the completeness and accuracy of the reports.

Preliminary Results

The implementation of our four-step lesson procedure by PSTs is detailed in Table 1.

Table 1: Steps in teaching problem-solving

Four-step lesson structure for teaching problem-solving	Results
1. Understanding the problem	All PSTs focused with their students on identifying the given information and the question posed in the problem. PSTs were motivated when they saw that most students began tackling the

	problem, even if the students were unfamiliar with non-routine problems.
2. Students solve the problem, while PSTs monitor, select, and sequence their approaches	PSTs reported being able to understand the approaches of at least half of their students. PSTs applied selection-criteria in line with the findings of Dunning (2022).
3. Whole class discussion	Nearly all PSTs asked two or three students with diverse approaches to present in class. They assisted these students in presenting effectively and ensured that their peers comprehended the presented material.
4. Connecting and looking back	Most PSTs reported difficulties with the last step, consistent with the observations of Gil et al. (2019). PSTs noted that children often do not generate reflections independently and PSTs struggled to find adequate questions to maintain student engagement.

Conclusion

The four-step lesson-structure for teaching problem solving is applied and appreciated by all PSTs. It helps PSTs focus on their students' problem-solving approaches and effectively present these in class. However, the step of connecting and looking back is found to be challenging to implement. This study will further analyse the questioning and noticing skills of PSTs. As an implication, we suggest that greater emphasis should be placed on learning problem solving within teacher education.

Fostering argumentative dialogue in secondary math classrooms: Teacher development trajectories through task-based PD

Reut Parasha

Weizmann Institute of Science, Israel; reut.parasha@weizmann.ac.il

Keywords: Dialogic teaching, argumentative dialogue, task design, professional development.

Introduction, Methods, and Research Questions

Dialogic teaching, which encourages students to engage in collaborative problem-solving and critical discussions, is widely recognized as an effective approach in mathematics education. However, the systematic implementation of dialogic teaching in mathematics classrooms faces several challenges, including teacher-centered discourse dominance and lack of suitable tasks that invite discussion (Schwarz & Baker, 2017). While task-based professional development (PD) using expert-designed tasks has shown promise (Swan, 2007), pre-designed task sets may not always fit the specific needs of individual classrooms. Jones and Pepin (2016) suggest that teachers' active participation in selecting, adapting, or designing tasks can develop their agency in implementing new pedagogies. This study examines how a task-based PD program, focused on collaboratively adapting standard textbook tasks into more dialogic ones and enacting them, supports mathematics teachers in fostering argumentative dialogue in their classrooms. The study was conducted as part of DIALOGOS project, which aimed to foster dialogic teaching in mathematics, science and philosophy in Israel. Through multiple case study research (Stake, 2000), the study followed five mathematics teachers who participated in the DIALOGOS PD between 2018–2022. Data were collected through video recordings of PD meetings, documents (tasks, lesson plans, written reflections), personal communications, reflective interviews, observations, and audio recordings of dialogic lessons. The analysis was guided by Schoenfeld's (2011) ROG framework (Resources, Orientations, and Goals) for modeling teacher decision-making, extended to include Practices (P). Through iterative thematic analysis, 32 Professional Development Trajectories (PDTs) were identified — stories documenting specific changes in teachers' perspectives or practices related to dialogic teaching (averaging 6–7 PDTs per teacher). Each PDT captures a developmental shift from initial stance (e.g., "Upgrading dialogic tasks: from resistance to recognition of necessity") and is characterized by its area of development and dimension of change in PROG terms. The research questions are: (1) What areas of development and dimensions of change were observed in the PDTs of secondary school mathematics teachers who participated in a task-based PD aimed at encouraging argumentative dialogue in mathematics classrooms? (2) Which components of the PD program contributed to these PDTs?

Findings

Areas of Development and Dimensions of Change: Analysis revealed 32 PDTs, distributed among three main areas of development with inductively identified subgroups: Task Design (13 PDTs), including *Format selection and dialogic characterization of the task* (10), and *Independence in task design* (3); Approach to Dialogue (8 PDTs), including *Feasibility of independent dialogue among students* (1), *Developing distinction between dialogue types* (4), and *Defining new dialogic goals* (3); and Implementation of Dialogic Situations (11 PDTs), including *Small-group work* (4), *Dialogic*

instructions (2), *Teacher intervention* (3), and *Managing class discussion* (2). Changes occurred across all PROG dimensions, with Resources (50% of 32 PDTs) and Orientations (41%) being most frequent, followed by Practices (22%) and Goals (19%). However, the distribution of these changes varied across the three areas of development. Task Design showed dominant changes in Resources (77%) while Orientations influenced 38%. Approach to Dialogue had balanced changes across ROG dimensions (38% each). Implementation of Dialogic Situations emphasized Orientations and Practices equally (45% each), linking teachers' beliefs and actions in this area.

Key PD Components: Analysis revealed various PD activities' impact on teachers' PDTs: 1. Planning-implementation-reflection cycles were the most influential, affecting 23 PDTs across all areas; 2. Task Upgrade Workshop (influenced 6 PDTs): Provided teachers with strategies to transform standard tasks into dialogic ones by changing their formats; 3. Viewing classroom video recordings (9 PDTs): Encouraged reflection and sharing of practices among teachers; 4. A model for identifying dialogic triggers in tasks and potential dialogue types (8 PDTs): Offered a shared language and tools for selecting/designing tasks and planning/identify type of dialogue; 5. Personal support in designing dialogic lessons (7 PDTs): Provided tailored guidance in task adaptation and implementation.

Conclusion

This task-based PD, focusing on redesigning and implementing dialogic tasks, effectively promoted diverse PDTs across various areas of dialogic argumentation implementation. Identifying PDTs provides crucial insights into teachers' multifaceted growth, enabling more targeted PD design. The PD program combined well-established activities like video analysis and iterative planning-implementation-reflection cycles (Swan, 2007) with unique emphases on task formats and dialogue types. This approach revealed how different activities complemented each other by influencing various PROG dimensions. For instance, the Task Upgrade Workshop primarily affected Resources, while video viewing was more effective in changing Orientations. These findings highlight the importance of integrating diverse activities in PD programs to address different aspects of teacher development, contributing to more effective, tailored growth strategies in mathematics education.

Teachers in noticing courses, how are they noticing and what do their educators notice about their discussions?

Jop Schaap[1,2], Theo van den Bogaart[1] and Paul Drijvers[2]

[1]HU University of Applied Sciences Utrecht, The Netherlands; jop.schaap@hu.nl

[2]Utrecht University, The Netherlands

Keywords: Teacher noticing, educator noticing, in-service teacher education.

Introduction

This study presents the initial findings of two years of a course on teacher noticing and in particular the perspectives of mathematics teacher educators (MTEs) on the important moments in this course. As part of teacher education at HU University of Applied Sciences Utrecht, we piloted this course for master's students, who are currently in-service teachers with teaching experience ranging from 4 to 20 years, aiming to enhance their teacher noticing skills. The participants contributed video segments from their own classrooms, examined and discussed these clips with their peers through the lens of teacher noticing, guided by an MTE. The discussions were recorded and the proficiency of the participants regarding their noticing skills were analysed using a measuring instrument based on existing frameworks as outlined in the methods section. In a second round of analysis MTEs identified what they considered to be important moments for learning to notice in these discussions. We therefore address the question Amador (2022, p. 169) poses "... *how* those who teach noticing to teachers actually notice..." by answering our research question: What moments do MTEs consider to be pivotal when teaching noticing in relation to what teachers notice?

Theoretical Background

According to Amador (2019), research on teacher noticing conceptualizes it as a discipline, an analytical tool for research or a framework for teaching. Our study takes a combined approach, a common practice among researchers (Amador, 2019), and studies three well-established aspects of teacher noticing (Stahnke et al., 2016): perception, interpretation, and decision-making.

Intervention

Participants were asked to bring video fragments from their classrooms, which they jointly viewed two consecutive times. The participants were prompted to note their observations regarding perception, interpretation, and decision-making. MTEs facilitated a group discussion highlighting different perspectives and providing connections with didactical concepts. Key ingredients of the intervention are working with video from the participants' classrooms, and a direct prompt for the participants to write down the three aspects of teacher noticing.

Methods

The group discussions were recorded and coded in ATLAS.ti, assigning one of three levels of perception, interpretation, and decision-making to the remarks made by the participants. Research data consists of transcripts with labels, where two coders discussed their initial differences until a final label was agreed upon. The development of this measuring instrument, which was based on a

synthesis of frameworks of van Es's (2011) and Jacobs et al. (2010), was introduced and detailed by the authors at CERME13. A second round of analysis was conducted, where the MTEs identified key moments in the discussions they considered to be fruitful or showed evidence of learning by the participants. These moments were compared to the labels of teacher noticing.

Results

MTEs identified fruitful moments in the group discussions corresponding to moments where participants show a certain level of noticing.

Table 1: Fruitful moments in the group discussions as identified by MTEs

Why the moment was fruitful according to MTEs?	Level of noticing of participants
"Questions helped to specify thinking"	Level 1: general, nonspecific, unconnected
"Participant set great example by story"	Level 3: specific, detailed, connected
"The participants had different interpretations of the same facts, the discussion encouraged them to think about their assumptions"	Mixed levels

The poster elaborates on these moments with transcripts of discussions and considers how these findings can be used to strengthen the development of noticing. The results provide insights for MTEs to notice opportune moments for learning when moderating discussions, and pointers for how a discussion may proceed matching the level of noticing the participants display.

Contextualisation and complexity in online rehearsal of feedback: Insights from online mathematics teacher education

Kristofer Sidenvall

Dalarna University, School of Information and Engineering, Falun, Sweden; ksv@du.se

Keywords: Mathematics teacher education, online, approximation of practice, rehearsals, role-playing.

Introduction

This proposal addresses the challenges of contextualising classroom teaching when using approximations of teaching practices in online mathematics teacher education (MTE) to prepare preservice teachers for ambitious classroom teaching.

A practice-based MTE programme is centred around key core practices in the teaching profession. By approximating these practices in simulated teaching scenarios, preservice teachers can learn core practices in MTE even when access to real classrooms and pupils is unavailable (Grossman et al., 2009). These approximations also provide a safe and low-stress environment where preservice teachers can rehearse teaching principles and strategies within the core practices without the demands of real classroom teaching. Previous research has shown that a practice-based approach in campus-based MTE better prepares pre-service teachers for ambitious mathematics instruction than traditional teacher education (e.g., Mancenido et al., 2023). Further, research on practice-based MTE advocates that teaching practices should be rehearsed in an environment that preserves the complexity of teaching, rather than in situations that simplify and focus on isolated aspects of teaching practice (e.g., Lampert et al., 2013). Although the number of preservice teachers pursuing their education online continues to grow, studies on online practice-based MTE are very limited. This raises questions about how complexity can be maintained and how rehearsals can be contextualised when preservice teachers practice in an online environment. This poster aims to highlight findings that focus on enhancing contextualisation and preserving complexity during online rehearsals in MTE.

Method

Educational design research focuses on iteratively developing theory as well as practical solutions to problems. The study reported in this poster is based on a design study on rehearsals in online MTE with data generation from three cycles to date. The design process is guided by theoretical underpinnings derived from previous research relevant to the study and informed by insights gained from reflective analysis after each iteration (McKenney & Reeves, 2019). Participating preservice mathematics teachers were recruited from an online MTE university course about assessment and feedback in secondary school. Each semester, two to three participants met online with a teacher educator (the author) to rehearse the core practice of eliciting and responding to pupils' thinking. The rehearsals were organised as role-plays with participants assigned the roles of teacher and pupil, while non-acting participants actively observed and reflected. A mathematics task with an incorrect pupil solution was shared with the participants on the screen before each role-play. The role-plays and later follow-up group discussions were recorded and transcribed. The insights presented in this poster are

based on the results of a thematic analysis of the transcripts, examined in relation to relevant prior research.

Findings

To address the need for contextualisation and maintained complexity in online rehearsals, this poster presents three strategies based on the findings.

Enhance the use of non-verbal forms of expression: Role-play activities revealed limitations in the digital environment for supporting non-verbal feedback, (e.g., pen-and-paper drawings could enhance feedback). To address this, digital annotation tools were more clearly introduced and the slides with mathematical tasks were reorganised to allow more space for digital drawings, thereby improving the incorporation of written feedback in online learning.

Present the mathematical tasks in advance: In mathematics teaching, the tasks pupils work on are usually not unfamiliar to the teacher. Therefore, allow participants to review the mathematical tasks prior to the online role-playing session. This ensures that the tasks do not come as a surprise when presented to the participants on the screen at the start of each new role-play during the online meeting.

Facilitate deep and varying mathematical conversations: To deepen the focus on mathematical didactics during role-plays, encourage the pupil role-player to challenge the teacher's feedback, prompting the teacher to consider different responses. Additionally, increasing variation in role-play scenarios, such as assigning observing participants the task of devising alternative misunderstandings, allows the teacher to rehearse various instructional strategies. This also helps prevent participants from becoming passive in the online environment when not assigned a teacher or pupil role. The researcher can actively participate as a pupil by introducing new challenges, further enriching the learning experience.

These strategies address the challenges of contextualising and preserving the complexity of classroom teaching when using approximations of teaching practices in online MTE. Additional approaches to better simulate real teaching situations in online rehearsals will be explored in my future research.

Preservice teachers' awareness of their own developmental trajectories in primary mathematics teacher education

Michiel Veldhuis[1,2], Sonja Stuber[1] and Ronald Keijzer[1]

[1]IPABO University of Applied Sciences, Amsterdam, Netherlands; m.veldhuis@ipabo.nl

[2]Freudenthal Institute, Utrecht University, Netherlands

Keywords: Primary school, teacher education, learning trajectories, preservice teachers.

Introduction

In the mathematics meetings at primary school teacher education most attention is devoted to the learning and developmental trajectories of primary school students (e.g., Van den Heuvel-Panhuizen, 2008). Preservice teachers (PSTs) are taught to notice and interpret primary school students' mathematical behaviour and ideas and thus 'place' them on particular spots in such a teaching and learning trajectory. Using such an idea, on where students are in their mathematical development, can help PSTs to decide about suitable next steps in their mathematics lessons. A topic to which much less attention is devoted, is PSTs' awareness of their own learning and developmental trajectories in mathematics teacher education. Evidently, PSTs develop their knowledge and skills in teacher education, both at the teacher education institute and in their practice schools. We distinguish three separate, albeit connected, trajectories in our primary school teacher education program: mathematics didactics, professional numeracy, and mathematical attitude (cf. Carillo-Yañez et al., 2018). Mathematical attitude is a multi-faceted concept concerning broadly two approaches: an appreciative stance towards mathematics and awareness of the ubiquity of mathematics in the outside world (Oonk & De Goeij, 2008). In this study, we investigated the awareness PSTs exhibit of these trajectories with the research question: How aware are PSTs of their developmental trajectories in mathematics in primary school teacher education?

Methods

To investigate PSTs' ideas about their developmental trajectories in mathematics at primary school teacher education we used an online questionnaire. For this, 58 PSTs in their first (n = 39) and in their second year (n = 19) at IPABO University of Applied Sciences, Amsterdam, responded. In the questionnaire, PSTs were asked 10 questions: three on their general impression of the learning process of mathematics at teacher education (*what have you learned, what do you still have to learn, how competent do you feel*) and seven on the specific learning trajectories (*do you recognize the learning trajectory [didactics; professional numeracy; mathematical attitude], can you provide an example of a teacher education activity, how important do you consider each learning trajectory*). We analyzed these data and categorized the open-ended answers using a deductive framework based on evidence for the three aforementioned learning trajectories. This analytical process is underway.

Results

PSTs in general expressed feeling rather competent about mathematics ($M = 7.01$, $SD = 1.4$ [min-max: 1-10]). In their explanations they provided two types of evidence for their competence, experiential ("because I have taught many lessons at primary school already" [didactics]) or more

test-related ("I successfully completed the WISCAT [the entry test for mathematics at primary teacher education]" [numeracy]). PSTs remarked that they learned most about mathematics didactics, but also have most to learn in that trajectory. They report, for example, to have learned how to analyze student work in mathematics and how best to explain several mathematical topics. Many PSTs mention that they developed their numeracy but have somewhat to learn still. In classes at teacher education, they did mathematical exercises which were discussed in the classroom. By participating "in these discussions I developed my own numeracy." The mathematical attitude trajectory was least recognized, PSTs mentioned not having learned much and also not recognizing it as something to be further developed. They did recognize it as being present in one of their first assignments: *Mathematics in the news* (cf. Stuber et al., 2021).

When asked to rank the different trajectories in importance, the didactics trajectory was deemed most important (34 times 1st place), followed by professional numeracy (18 times 1st place) and finally by mathematical attitude (7 times 1st place). When asked to provide examples for teacher education activities related to the different trajectories the PSTs struggled; about half of them were not able to mention any activities. When they did provide examples, they mentioned for example "analysing student work and discovering mathematical errors" (didactics), or "calculating in different number systems" (numeracy) or "an introduction with a game or open question or mathematical puzzles" (attitude).

Preliminary conclusion

PSTs do not show much awareness of their own learning trajectories. They do mention still needing some more knowledge, but what that consists of remains difficult to pinpoint. They rarely exhibit understanding of how activities in teacher education are related to the three separate learning trajectories. Nonetheless, the first- and second-year PSTs express feeling rather competent in teaching mathematics in primary school.

[3]University of Michigan, Ann Arbor, USA

[4]University of Dublin, Trinity College, Dublin, Ireland

[5]Charles University, Prague, Czech Republic

Introduction

Research on teaching is central to mathematics education, and TWG19 traces its history to CERME1. After CERME8, the single TWG, *From a Study of Teaching Practices to Issues in Teacher Education,* split into TWGs 18, 19, and 20. TWG19 has since sought to define its focus, build a supportive community, and advance scholarship. At CERME10, participants reflected on challenges in talking across papers. Papers were organised topically, e.g., on assessment or on lesson planning, but papers within groups seemed idiosyncratic, like apples and oranges. Theoretical foundations differed, as did contexts of schooling, policy, culture, and language. Moreover, purposes varied, e.g., describing common practice, responding to a new curriculum, or arguing for a particular theoretical orientation. In response, participants proposed developing a pool of shared data, so that analyses carried out on the same data could support thinking across papers. They also proposed organising papers using an underlying framing for teaching instead of surface level topics. Research on teaching and teacher practice(s) must contend with multiple, key domains of the work, yet any study will likely foreground one, while maintaining attention to others. As organisers, we have used the following foundational domains to group papers and stimulate cross-paper discussion.

- Consideration of **mathematics** and the central endeavour of extending the subject to students.
- Becoming acquainted with, relating to, and responding to **students** as people and learners.
- Organisation and **enactment** of design, interaction, and discourse of teaching and learning.
- Attending to broader social, cultural, and political **issues** that matter for teaching and learning, including imperatives of social justice.

At CERME14, we explored additional ways to enhance the work of the group: (i) designing sessions to be more inclusive; (ii) taking stock of past scholarship; and (iii) developing shared understanding of foundational efforts to conceptualise teaching. This paper reports on these initiatives, then reviews papers presented at CERME14, and reflects on our collective experience at CERME14.

Designing sessions to be inclusive and productive

Mindful of CERME's three Cs (communication, cooperation and collaboration) and in keeping with the paper acceptance policies introduced for CERME14, we continue to include and support early career researchers. Over half of the participants of TWG19 at CERME14 identified as such. Two

forms of support are crucial: personal and emotional support and substantive support for conducting and reporting on research. We are committed to thoughtful, constructive reviews of all submissions at all stages. This requires time and energy but provides essential support – for individual and collective learning about the nature and conduct of research and for helping participants feel at home. To help participants feel welcomed, we started the week by learning each other's names and hearing what each participant is passionate about related to research on teaching. In asking for feedback daily, reporting on what the participants said, and adjusting accordingly, they sensed that that their input mattered. To support authors' work, we kept presentations short (5 minutes each, for groups of 4 papers), then each author met with 4–6 colleagues to discuss their paper and provide feedback. We encouraged authors to provide minimal opening remarks about the status of the paper and the feedback they sought but to spend most of their time listening to the discussion without intervening. An organiser then commented on each of the 4 papers. After two rounds, with 8 papers discussed, the 4 authors in each group met to discuss their related papers (similarities, differences, and shared insights), while 4 authors, those not presenting that day, discussed similarities and differences between their papers and the papers presented. For some discussions, people chose in which group to participate; for others, we assigned groups, attentive to mixing and balancing participation. We provided similar structuring of posters and small group discussion of themes for the week. These design choices were meant to honour each participant's contributions, both as author and colleague.

Review of papers from previous proceedings

To gain a picture of ongoing work, we reviewed papers from proceedings since CERME9. We revisited the introductory papers to consider trends, used quantitative text analysis to compare trends in word use, and identified commonly used references. TWG19 has averaged 24 accepted papers (from 18 to 27). The introductory paper from CERME9 highlighted connections between teaching and learning, described classroom interactions as complex, and called for more specific definitions of teaching. Comparison of word use indicated that papers in CERME9 emphasised assessment, textbooks, and textbook tasks more than papers since. At CERME10, the introductory paper again reported concern about the clarity of terms and a need to develop more common language. Word use indicated a shift from *teachers* to *teaching*, with words such as *critical* and *reflection* appearing more frequently.

At CERME11, an entire session was devoted to papers using shared data and participants reported that this was helpful for thinking across different lines of inquiry. Additionally, a distinction between teaching as *activity* versus *work* was proposed, reflecting a shift in research on teaching from investigating the actions or moves that teachers make and their effects, to attending to issues, situations or problems that make teaching challenging. At CERME12 (a virtual conference) several papers used shared data, and the meaning of teaching was explicitly discussed. Analytic domains were given in the call for papers and used to organise papers. In comparing word use, *learners* and the *Mathematics Discourse in Instruction* framework were more prominent. The use of domains continued at CERME13, and participants discussed the often-implicit purposes of studies, attending to how purposes might relate to conceptions of teaching. Papers gave increased attention to *students* and more invisible aspects of teaching, such as *listening* and *noticing*.

In examining references, we were surprised to find few common references. Shared references to specific research on teaching did not appear in more than five of the papers each year. Most frequent were references to Franke et al.'s (2007) handbook chapter, Stein et al.'s (2008) paper on five practices for orchestrating productive discussions, Yackel and Cobb's (1996) paper on socio-mathematical norms, Ball et al.'s (2008) paper on mathematical knowledge for teaching, and Cohen et al.'s (2003) paper on the resources for instruction. Yet, the overall impression was that references were scattered, and common theoretical foundations were few.

Conceptualising teaching

Given participants' call for better ways to talk across the different lines of inquiry, at CERME14 we presented and discussed foundational literature. Participants used presented ideas to consider the nature of their own work and how it sits in relation to others' work.

Teaching is an under-theorised construct. One basic challenge lies in its ubiquity. As Lortie (1975) pointed out, nearly everyone in society "sees" teaching. Everydayness renders it unremarkable and taken-for-granted. More than this, Lortie describes an *apprenticeship of observation* in which students' years in classrooms lead not just to over-familiarity but to false impressions – because they see teaching from a biased, student-oriented perspective that has little access to teachers' intentions, planning, and reflection, instead relying heavily on imagination and projection. Related challenges include uncertainty, unnaturalness, and intricacy. As Ball and Forzani (2009, p. 499) argue:

> To listen to and watch others as closely as is required to probe their ideas carefully and to identify key understandings and misunderstandings, for example, requires closer attention to others than most individuals routinely accord to colleagues, friends, or even family members. To provoke discordant thinking or errors in logic and argument intentionally would seem odd if not downright irritating in many situations. And, few adults seek to learn about others' experiences and perspectives as systematically as teachers must.

In the face of these challenges, researchers have proposed variants of an instructional/didactical "triangle of interactions" with which teaching must contend. Goodchild and Sriraman (2012, p. 581) state that this commonplace "triangle in which student, teacher, and content form the vertices (or nodes) of a triangle is the classical trivium." Figure 1 offers three such variants.

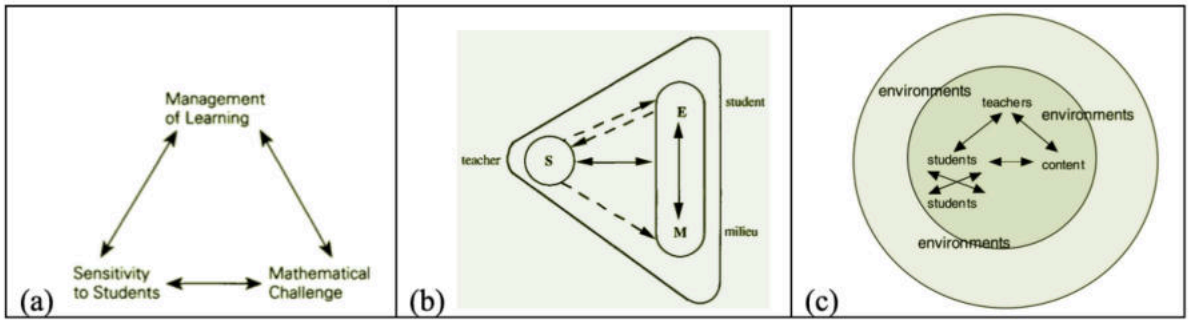

Figure 1: (a) Jaworski's (1994) teaching triad; (b) Brousseau's (1997) theory of didactical situations; (c) Cohen et al.'s (2003) visualisation of instruction as interaction

Cohen (2011) identifies teaching as a human improvement profession and intersects the three components, which he calls terrains of practice (acquaintance with students' knowledge, instructional discourse, and knowledge extension), with key social resources for doing the work (infrastructure of practice, mutual commitment to improvement, and work practitioners and clients do together).

Building on these ideas, scholars have sought to attend more fully to sociocultural complexity, oppression, and to the interplay of the micro and macro (Figure 2).

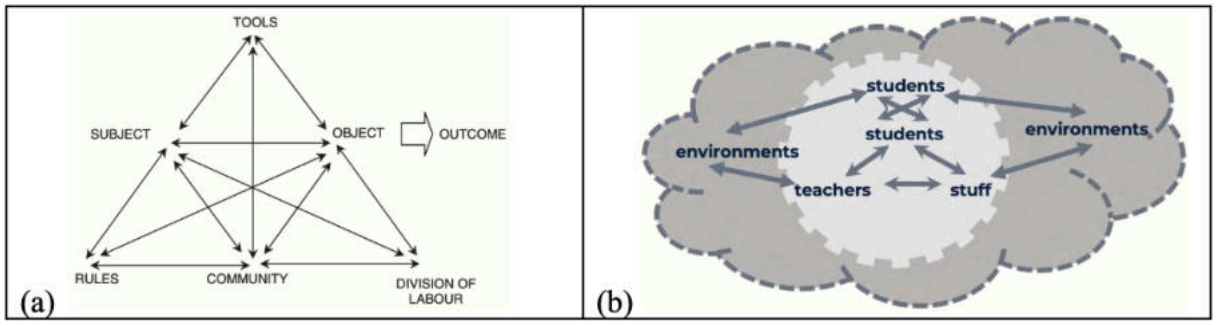

Figure 2: (a) Jaworski and Potari's (2009) expanded mediational triangle; (b) Ball's (2018) model of the discretionary spaces in teaching

Another important line of research on teaching has emerged from scholars from marginalised communities. They have approached the challenge of attending to sociocultural complexity and systemic oppression through a critical lens focused on academic success, asset-based attention to cultural competence, and advocacy for sociopolitical consciousness (e.g., Ladson-Billings, 2014).

In TWG19, as we investigate the layered, messy work of teaching, we continue to struggle to wrap our arms around it all and manage the challenges inherent in the work. At the same time, we find this to be an interesting and stimulating time to be involved in the study of teaching. The field continues to seek ways to disrupt long-standing patterns in which many students (in particular, women and racially and ethnically marginalized students) experience mathematics classrooms as unwelcoming, stressful, and exclusionary. It is also expanding awareness and approaches for addressing endemic challenges for doing, conceptualising, and studying teaching. As participants in TWG19, we find our interests and approaches vary widely, but we also find it useful to foster ways to talk across these and to see similarities and differences in our work more clearly.

Contributions of CERME14

Seventeen papers and four posters were accepted for presentation, with 26 participants from 15 countries. Germany had the largest representation, followed by Norway, Sweden, and Türkiye. Others were from Brazil, Czechia, Greece, Israel, Japan, Kosovo, Latvia, Netherlands, Spain, UK, and USA.

Table 1: Grouping of papers into domains

Domain	Paper	Count
Issues	Hartmann et al.	1
Mathematics	Chico et al.; France et al.; Lanting; Morina & Vondrova	4
Students	Hansen & Arnesen; Hoover & Ball; Mosvold et al.; Yasar et al.	4
Enactment	Häsel-Weide & Nührenbörger; McIvor et al.; Nama et al.; Öcal et al.; Ogawa & Miyakawa; Post & Sahin-Gür; Neufeld & Häsel-Weide; Wæge & Mosvold	8

The paper in the *Issues* domain explores the alignment of mathematics education teacher-researchers' attention to sustainability goals of the United Nations 2030 Agenda. Given the scope of the paper, it allowed participants to talk across their contexts during the introductory session.

Mathematics. Four papers foreground mathematics, highlighting the complexities of implementing student-centred and constructivist reforms aimed at developing students' understanding and problem-solving skills, and underscoring the need for effective teacher training and professional development. These studies emphasise the pivotal role of teachers' decision-making and the frequent divergence between planned interventions and actual classroom implementations. For instance, France et al. identify significant differences in Latvian teachers' performance when implementing a new mathematics curriculum, indicating varied professional development needs. Similarly, Morina and Vondrová found that while Kosovo teachers appreciate the SIMPLE approach for supporting word problem-solving, they face implementation challenges that require additional training. Lanting's theoretical paper proposes a variation of Polya's problem-solving method to foster analytical thinking in Dutch secondary students, emphasising mathematics as a language and highlighting the importance of structured group discussions and reflection. Finally, Öçal et al.'s study in Türkiye reveals that student teachers primarily select and sequence student-generated problems based on content and complexity, often overlooking incorrect or incomplete problems, further illustrating the complexities of effective pedagogical choices in practice.

Students. All four papers in this domain foreground the vital role of the teacher in attending to students' mathematical thinking across contexts. They collectively revealed the complexity involved in interpreting and building on student ideas to promote deeper mathematical reasoning, advocating a shift from deficit-based perspectives to valuing students' sense-making. Each study underscores the importance of reflective teaching practices and highlights the need for teacher education programmes to develop teachers' skills in attending, interpreting, and responding thoughtfully to a variety of student contributions. Hansen and Arnesen analyse a teacher's interactions with seventh graders solving a collaborative mathematics problem, showing that while the teacher aimed to foster generalised arguments, students struggled to follow the reasoning. Hoover and Ball focus on listening attentively to children's mathematical expressions through speech, gestures, and drawings, noting that traditional views of mathematics as solely correct or precise often obscure recognition of children's competence, especially among marginalised groups. Mosvold et al. propose a framework for monitoring student thinking, based on observing students' independent problem solving. Finally, Yasar et al. examine a preservice teacher's reflections on her noticing during one-on-one teaching, revealing emerging awareness and pedagogical decisions, though with some gaps in explanation. Together, these studies portray teaching as a complex, adaptive practice and call for enhanced preparation of teachers to effectively notice and respond to student thinking.

Enactment. Despite different foci in the papers foregrounding enactment, all explore opportunities to learn. Four of the papers examine the work of building inclusive environments. McIvor uses the concept of "status" from the theatre to discuss productive classroom discourses in which teachers work deliberately to minimise the status gap. Nama et al. focus on the tensions that teachers experience between challenging students mathematically and taking diverse learning needs into consideration. They underscore implications for teachers' professional development. Professional

development is also central in Neufeld and Häsel-Weide's paper, which argues that understanding of ways to support "struggling" children's learning of basic arithmetic skills is important for teacher development and professionalisation. In the context of professional development co-enactments, Wæge and Mosvold explore interaction between talk moves and other teaching moves. They find that the teacher they studied used different categories of teaching moves simultaneously and in interaction.

The other four enactment papers examine the complex role that teachers play in structuring classroom discourse, fostering inquiry, and adapting to diverse learner needs. Chico et al.'s study in Spain emphasises the importance of intra-mathematical connections, illustrating how teachers can support reasoning and communication by strategically utilising student contributions within a structured framework. Häsel-Weide and Nührenbörger explore inclusive classrooms in Germany, identifying discursive, content-related, and differentiated practices through long-term video-based research; their findings highlight the challenge of ensuring equitable participation, especially when certain students dominate interactions. Ogawa and Miyakawa's case study in Japan applies the *Anthropological Theory of the Didactic* to evaluate teacher preparation for inquiry-based learning, revealing the complexities of teacher decision-making and the need for training that fosters both teacher autonomy and structured collaboration. Lastly, Post and Şahin-Gür analyse teacher noticing within professional development contexts in Germany, indicating that although teachers often focus on moderation techniques, fewer attend to content-specific noticing, a gap that underscores the need for targeted professional development strategies. Collectively, these studies emphasise that while reforms encourage student-centred practices, their success hinges on teacher reflection, professional support, and thoughtful curriculum design.

Cross-paper themes. At CERME 14, several themes emerged from discussion across these papers. Hoover and Ball introduced the concept of *listening*, in ways that pay attention to students' mathematical productions with openness and curiosity, rather than evaluatively seeing whether students "get it". Other papers (e.g., Hansen's and Yasar's) use *noticing* for attending and reacting to students' contributions, and Mosvold et al. use *monitoring student responses* for the work of teaching that takes in and responds to student contributions. Although listening could be part of noticing and monitoring student responses, the specific focus on listening led to interesting reflections on a view of students as knowers or non-knowers and students' agency. For instance, listening and noticing might be thought of from preset ideas about mathematics and expected forms of behaviour or from an open stance that is attentive to alternatives.

Another theme discussed at the conference was *practice*. The name of the TWG includes practice, the concept is used in several papers and often heard in discussions. However, there is little uniform understanding. Some papers describe what they mean by practice, for example, Häsel-Weide and Nührenbörger state that a practice involves teachers' patterns of utterances and actions, as a shared phenomenon shaped by individual identity. Mosvold et al. examine the practice of monitoring student responses by unpacking the "work of monitoring". In the former, teaching is something teachers do; in the latter, it is core tasks to be done.

Teaching students who struggle to learn mathematics, as currently taught, was another theme of the discussions. A question that came up was how we can talk about this without labelling students.

Different ways of talking about these students, for example, students *with* difficulties, students *in* difficulties, or special educational *needs of* students, have consequences for mathematics teaching and for who owns and is responsible for the "problem". Participants expressed concern for equity and discussed how issues of language and clarity were implicated.

Reflections and conclusion

In the final session at CERME14, participants were invited to reflect on the week, identify insights, and look for themes. They recorded individual insights on a Padlet and then worked in groups to identify themes. They also responded to a survey. We discussed participants' reflections and identified three key ideas to consider in our ongoing support of TWG19.

Supportive atmosphere. During the week and at the end, participants expressed appreciation for the friendliness in the group, the design of the sessions, the structuring of discussions, the steady energy, and the overall sense of community. Several participants appreciated the attention given to pronouncing each other's names and opportunities to work in different groups with different people, some self-selected, some assigned. Looking to CERME15, participants suggested organising a dinner early in the week. They also suggested exploring ways to provide support between CERME conferences – meeting virtually in a small group to support writing, exploring potential paper collaborations for CERME15, sharing research artifacts and giving each other feedback, or discussing a professional practice, such as how to review a paper or read a foundational text.

Broadening perspectives. Participants in the group come with different perspectives and ideas about mathematics teaching and teacher practices. The group runs the risk of being too spread out for in-depth discussion, but this did not happen. With the added support, participants experienced the discussions as rewarding and the different perspectives as enriching. They found it helpful to hear and more deeply understand each other's thinking, perspectives, culture, and language and they appreciated how this contributed to a greater awareness of their own research. Reading papers, listening to presentations, and discussing research outside their immediate interest – but recognisably about mathematics teaching and teacher practices – helped to put their own research in a larger context and stimulate ideas for future studies.

Importance of wording. With so many different perspectives and studies situated in diverse literature, participants could see the need to clarify the meaning of central concepts. In addition to being more explicit about what we mean by *teaching*, we need to clarify what we mean by *listening*, *noticing*, and *practice*, and attend to ways language can be exclusionary. It is not an end in itself, and we do not need agreement on the meaning of core concepts, but we need to clarify, distinguish, and delineate our use of terms better as we communicate about our work.

In closing, we look forward to living into the three Cs and continuing to build a robust community engaged in crucial research on mathematics teaching, the heart and soul of mathematics education.

Sustainability and mathematics education considering the 2030 Agenda: Understandings and practices of university professors in Portugal

Andrei Luís Berres Hartmann[1], Marcus Vinicius Maltempi[1] and António Manuel Dias Domingos[2]

[1]São Paulo State University (Unesp), IGCE, Rio Claro, Brazil; andrei.luis@unesp.br

[2]Nova "New" University from Lisbon, Caparica, Portugal

This text discusses the understanding and sustainability practices of university professors in mathematics education working in Portugal, considering the United Nations (UN) 2030 Agenda. The 2030 Agenda proposes 17 sustainable development goals to be achieved globally, based on three aspects of sustainability: economic, social, and environmental. We conducted semi-structured interviews with ten professors from six Portuguese universities between January 16 and April 10, 2024. Data analysis using content analysis techniques indicates that the practices developed by the interviewees are aligned with the economic, social, and environmental aspects of sustainability. We conclude that the professional activities of these university professors in mathematics education have contributed to implementing the UN's 2030 Agenda.

Keywords: Mathematics education, sustainable development goals, practices of professors.

Initial considerations, with a synthesis of the literature

Problems related to economic, social, and environmental aspects have plagued different countries worldwide. For example, in Brazil, the Amazon has seen a significant increase in deforestation since 2013, exacerbated by the weakening of environmental legislation and the expansion of agriculture (Messias et al., 2021). The populations of Portugal and the Czech Republic have suffered from high levels of indebtedness (Opletalova, 2015; Santiago, 2016), and the African continent has a disparity in economic development associated with social factors such as high poverty rates, informal work and low school enrollment rates (Messy & Monticone, 2012).

Issues like these have been the target of global concerns and movements, especially since the beginning of the 21st century, when the millennium development goals (MDGs) were proposed, challenging countries to end hunger and poverty (MDG 1) and reduce child mortality (MDG 3), for example. Subsequently, a new movement emerged with the need to continue and improve these goals, culminating in the document "Transforming Our World: The 2030 Agenda for Sustainable Development" (ONU BR, 2016).

The United Nations' 2030 Agenda, approved by representatives of 193 countries in September 2015, highlights 17 new goals, the sustainable development goals (SDGs), to be achieved globally by 2030. These goals are: eradicate poverty (SDG 1); eradicate hunger (SDG 2); quality health (SDG 3); quality education (SDG 4); gender equality (SDG 5); clean water and sanitation (SDG 6); affordable and clean energy (SDG 7); decent work and economic growth (SDG 8); industry, innovation, and infrastructure (SDG 9); reduce inequalities (SDG 10); sustainable cities and communities (SDG 11); responsible consumption and production (SDG 12); climate action (SDG 13); life below water (SDG

14); life on land (SDG 15); peace, justice, and strong institutions (SDG 16); and partnerships for the goals (SDG 17) (ONU BR, 2016).

These goals support the MDGs in the vision of sustainability already adopted, affirming the need to think about sustainable development in three aspects: social, economic, and environmental (ONU BR, 2016). However, despite the 2030 Agenda discussing various necessary contemporary elements and challenges, one of its problems is the inseparability and interdependence between the SDGs. Campos (2020, p. 40) exemplifies this criticism by highlighting that SDG 8 "has positive interactions, allowing for the reduction of poverty (SDG 1) and hunger (SDG 2), but also negative interactions such as increased consumption (SDG 12) and increased emissions (SDG 13)." Developing one SDG can thus impact other SDGs – positively or negatively. Additionally, we need to be aware that the formulation of the SDGs was carried out and is maintained by an intellectual and social elite, while many people need to be made aware of these goals to problematize them.

Through our discussions, studies, and publications, we have recognized the importance of advocating for quality education (SDG 4). Quality education helps raise awareness and empower individuals and plays a vital role in achieving other sustainable development goals, ultimately leading to a more just and equitable world across social, economic, and environmental domains. For instance, in mathematics education, concepts from ethnomathematics, such as education for citizenship and peace (D'Ambrosio, 2012), contribute to these discussions. Furthermore, critical mathematics education emphasizes the necessity of addressing fundamental conditions for acquiring knowledge, being mindful of social issues, inequalities, and oppression, and striving to make education a proactive agent for social change (Skovsmose, 2001, p. 101).

Previous discussions at the Congress of the European Society for Research in Mathematics Education (CERME) related these aspects. For example, Vorhölter and Siller (2023) report a program developed in Germany aimed at education for sustainable development and the role of mathematical modeling in this context. Furthermore, Fuertes-Prieto et al. (2023) reflect on including discussions about the SDGs in teacher training and incorporating sustainability into the curriculum alongside mathematics.

In other words, this research shows us that sustainability has been the object of analysis in mathematics education, but that we need to move forward in this area. The problems highlighted in the SDGs require global action, and we understand that one way is through education, putting them into discussion and thinking about practices that support the achievement of the objectives. As pointed out by Fuertes-Prieto et al. (2023), sustainability has been included in curricula, combined with mathematics, and we need to reflect on whether university teachers are aware of these issues and discussed with future basic education teachers. Still, for example, in Brazil's curriculum (Ministério da Educação, 2018), themes related to the SDGs, such as the environment, food education, human rights, health, gender and consumption are considered contemporary themes, which should permeate the mathematics subject. Vásquez et al. (2023) indicate that education for sustainable development is one of the ways to face the current crises, with mathematics education being a possibility to achieve this, although teachers have limited knowledge on the subject.

In this set of ideas, aiming to expand the relationships between mathematics education, sustainability, and the SDGs, we conducted research driven by the question: what relationships can be established

between sustainability and mathematics education based on knowledge and practices of university professors? Based on idealized actions and the results of the study conducted, in this text, we aim to discuss the understanding and sustainability practices of university professors in Mathematics Education working in Portugal in light of the United Nations' 2030 Agenda.

Methods

We conducted qualitative semi-structured interviews with university professors in mathematics education who work at universities in Portugal. When conducting semi-structured interviews, it is essential to have a prior script to guide the dialogue (Fiorentini & Lorenzato, 2012; Creswell, 2014).

We guided the interviews based on eight themes: i) education; ii) work; iii) projects and research lines; iv) sustainability; v) SDGs; vi) mathematics; vii) partnerships; and viii) indication of other projects and researchers. The first group of questions (i-iii) aimed to get to know the professors, their knowledge and practices, based on the exposure of their trajectories and experiences. The second part (iv-vi) focused on practices and knowledge about sustainability and mathematics education. Finally, the last questions (vii-viii) sought to address SDG 17.

We proceeded with research in Portuguese repositories and university websites and recommendations from research colleagues to invite university professors for the interviews. From the contacts made and the recommendations of new professors from the interviews conducted (by question viii), we totaled ten acceptances, whose synthesis we present in Table 1.

Table 1: Interviews conducted

Nº	*Date*	*Interview time*	*University*
1	January 16, 2024	30min 45s	Universidade de Lisboa
2	January 23, 2024	26min 29s	Universidade NOVA de Lisboa
3	January 26, 2024	1h 08min 56s	Universidade NOVA de Lisboa
4	January 30, 2024	41min 19s	Universidade de Lisboa
5	February 7, 2024	1h 08min 57s	Universidade Lusófona
6	February 12, 2024	49min 23s	Universidade Algarve
7	February 16, 2024	52min 29s	Escola Superior de Educação de Lisboa
8	March 1, 2024	35min 27s	Escola Superior de Educação de Coimbra
9	March 22, 2024	1h 01min 26s	Universidade de Lisboa
10	April 10, 2024	48min 17s	Universidade de Lisboa

The data generated from the interviews presented in Table 1 were analyzed using content analysis techniques (Bardin, 2016), following three phases: pre-analysis, material exploration, and treatment of results and inferences. In the pre-analysis phase, we transcribed the interviews with the help of the *Good Tape* software and then read and textualized them. Textualization consisted of organizing the transcription in text form, cleaning up language defects and word repetition.

In the material exploration, we identified the context units (data excerpts) and the registration units (themes related to the context units for categorization purposes). For example, in the interview with Professor 5, it was mentioned that: "my dear because the title is social and educational inclusion as a

social justice project. This title is a vision of inclusion issues, even in social and social terms, right?" We observed that this context unit was related to the social aspects highlighted in the 2030 Agenda. Therefore, we associated ourselves with this registration unit that we called "social sustainability".

In this text, we aim to discuss the understanding of sustainability of university professors in mathematics education working in Portugal. Considering the United Nations (UN) 2030 Agenda, we chose the registration units a priori since the 2030 Agenda is based on economic, social, and environmental sustainability. Finally, in the treatment of results and inferences phase, we proceeded with categorization through the aggregation/convergence of the recording and context units. The following section presents interview data on the three aspects of sustainability.

Presentation and discussion of data

By analyzing the interview texts using content analysis techniques, we observed the discourses of the university professors related to the three aspects of sustainability. Below, we briefly present some examples of the interviewees' statements (as similar ideas were repeated at other interviews) associated with the economic, social, and environmental sustainability of the 2030 Agenda.

Economic sustainability

The first aspect we highlight concerns the economic sustainability presented by the 2030 Agenda, which makes us reflect on issues related to an economically efficient and balanced world with coherent investments that support the other pillars of sustainability. Among the goals of SDG 17 – partnerships and means of implementation, it states, "assist developing countries in achieving long-term debt sustainability through coordinated policies aimed at fostering financing, debt relief, and debt restructuring [...]" (ONU BR, 2016, p. 40). The teacher-researchers in the research addressed practices and ideas inherent to economic sustainability, for example, by professors 3 and 8.

Professor 3: I am granted this second postdoc in environmental sciences because my sustainability process involves practical work with fishermen. And rethinking the fishing practice itself, right? I also revisited the materials I use, the way they fish, the importance of artisanal fishing, and how they need to engage with what is nowadays called sustainability.

Professor 8: Well, sustainability is one of the themes connected with financial education. When I work on the theme with my students, when we address the theme besides the economic issue, we always refer to the sustainability issue because, naturally, associated with the consumption of a product, we are, in a way, consuming more products, or more material goods from our planet. Therefore, when we address water consumption, healthy eating, and all these very connected issues, we can work on financial education, economic education, consumer education, and consumption sustainability. Health education related to healthy eating also comes with sustainability issues. Therefore, this allows us to work with students more reflectively, escaping what I usually call escaping mathematics, where the goal is to solve an exercise and see if it is right or wrong. No, we are on a path to, and the goal is that mathematics is a tool to help us reflect and be critical and informed citizens in different areas because we are forming, not students, but citizens, and citizens who will be consumers and will be on this planet for many years. This reflection type is associated with financial education, consumer education, and sustainability.

From these data, we can observe public investment in financing sustainability-related projects, as reported by Professor 3. The 2030 Agenda (2016, p. 25) indicates that "by 2020, substantially increase globally the number of scholarships available to developing countries, particularly least developed countries, small island developing states, and African countries, for higher education." Furthermore, there is the potential for discussions in financial education associated with sustainability, such as those related to consumption. Additionally, Professor 8 indicates work beyond numerical mathematics, where only the exercise and the result matter, a factor associated with the ideas of critical mathematics education, such as scenarios for investigation (Skovsmose, 2001).

Social sustainability

The social sustainability advocated by the 2030 Agenda highlights the need for and importance of thinking about opportunities and rights for all, focusing on people and society in general, where human rights are preserved and the less privileged have more opportunities to ascend socioeconomically. The document emphasizes pursuing a "world with equitable and universal access to quality education at all levels, healthcare, and social protection, where physical, mental, and social well-being are ensured" (ONU BR, 2016, p. 4). Ideas associated with social sustainability were explicitly presented by the research participants, such as Professor 1 and Professor 5, as follows.

> Professor 1: I am mainly at the university, contributing to the sustainability, let us say, of the planet, particularly in the domain of social sustainability, as it contributes to making society more coherent. Indeed, its members are better educated, especially regarding their domain of mathematics, but also, in a broader sense, when learning mathematics, we develop more globally. And therefore, from this perspective, there is undoubtedly a contribution. I contribute strongly to social sustainability, more directly in Portugal and through my work, travels, and interactions with people from other countries, particularly in Brazil, which I have visited many times. Many periods in Brazil... In various universities, working with teachers and students, especially postgraduate students from these universities, on topics that significantly contribute to social sustainability.
>
> Professor 5: My areas of intervention are in the master's degree in special education, where I teach a curricular unit, which I think has my, as I usually say, my face because the title is social and educational inclusion as a social justice project. This title is a vision of inclusion issues, even in social and societal terms, right? The issue of human rights encompasses all these fields: human rights, discrimination, and participation. This is the issue that Hannah Arendt brought us: the right to have rights, right? Therefore, it is an important issue. And that human rights also start at home, right? How we relate to those closest to us, listen to them, and express ourselves. Well, this is a curricular unit.

From the above, as Professor 1 indicates, mathematics has the potential to provide people with a global understanding of different aspects. Furthermore, Professor 5 reports practices related to social justice, involving the inclusion of the entire population and human rights. In this context, we highlight that SDG 16 aims to promote justice for all, and the vision of the 2030 Agenda (2016, p. 4) is associated with "a world of universal respect for human rights and human dignity, the rule of law, justice, equality, and non-discrimination; respect for race, ethnicity, and cultural diversity." For a socially sustainable world, ethnomathematics supports the discussion of education for citizenship and a world of peace, primarily through the appreciation of different knowledge and cultures (D'Ambrosio, 2012).

Environmental sustainability

The third and final aspect of sustainability in the 2030 Agenda, which concerns the environment, calls for respect and appreciation of natural ecosystems, where social and economic elements prosper alongside nature. Mentioning goals associated with SDG 12 – responsible consumption and production, for example, the 2030 Agenda (2016, p. 34) states the need to "encourage companies, huge and transnational companies, to adopt sustainable practices and to integrate sustainability information into their reporting cycle." The interviewees, especially professors 3, 7, and 9, revealed practices associated with environmental sustainability.

Professor 3: When we write, we write, right? Since I got here, SDG 14, the ocean one, all of mine now. It has to be, dear, right? When I did Urban Frontiers, there was no SDG yet, so that should be in SDG 4 easily. And one easily. How ridiculous, right? I will not eradicate anything, but... Also, there are spaces and paths for improvement. So, if I look now and need to categorize, I categorize, right? But it is not just that; it is also the economy. The environment, in general, is also in the neighborhood, right? Sustainability: I have 15, right? Anyway... If I go through my projects, if you want a straightforward answer, it is SDG 14, Smartfishing, Party Bridge. Party Bridge and Urban Frontiers, Party Bridge, too, right? SDG 4... I don't put Smartfishing in 4 because four don't fit informal ocean literacy. I didn't have any formal process. Or informal, I only had a non-formal process. Now... The others didn't, the others did, right? Party Bridge had classes here at the college, and the fishermen came to teach. For the master's degree, we prepared a lot of things beforehand. And... So, these are the two SDGs that permeate the most, and that is, I don't know if I needed to place them as sustainable; they were these two, too.

Professor 7: Mathematics in schools, environmental themes, or environmental aspects. Therefore. Interdisciplinary practices are based on research in initial teacher training. We considered that this chapter contributed to 4, therefore, quality education. 7, renewable and accessible energies. 11, sustainable cities and communities. 13, climate action. And 15, life on land. This is because the chapter encompasses work not only in this curricular unit that I mentioned. But also, others and other projects, namely from other teachers. They are also co-authors of this chapter from natural sciences. Then, we focused on group work that our future teachers had planned for this curricular unit. Indeed, the groups focus on a wide variety of environmental problems. Therefore, they touch on different aspects, from energy consumption to other issues. Therefore, there is an excellent diversity of themes. Others are more focused on the preservation of plant species.

Professor 9: Yes, it was interesting because, in that project, I mentioned statistical literacy and statistical reasoning; I don't know if it was by mere chance, but we explored some issues related to the environment. It wasn't intentional, but in the search for themes, it came up because it is natural for statistics to be a tool for interpreting reality. So, it came a bit from there, and it was even later, based on those materials we had created, that we developed a small project with colleagues from the area of the sciences, where we sought it was a very significant project for us... The theme was related to global warming issues. It was the theme we chose, bringing perspectives from science people, their knowledge, and mathematics, in this case, with statistics. This was a very significant project because they had the opportunity to work together over a semester.

By reporting the practices and results of a research project (Professor 3) and a published article (Professor 7), the teachers related their experiences to SDGs 11, 13, 14, and 15, mainly referring to the environmental dimension of the 2030 Agenda. Ideas like those these teachers expose help us problematize "the threat posed by climate change and environmental degradation" (ONU BR, 2016,

p. 11). Furthermore, Professor 9 indicates the potential of working with statistics to discuss aspects related to environmental sustainability, such as global warming. One way to address these issues is through mathematical modeling, as highlighted by Vorhölter and Siller (2023).

Final considerations

In this text, we discussed the understandings and sustainability practices of university professors in mathematics education working in Portugal in light of the United Nations' 2030 Agenda. The interviews, conducted with ten university professors in mathematics education from Portugal, indicated relationships with the three aspects of sustainability advocated by the 2030 Agenda: economic, social, and environmental.

Although this relationship between teachers' practices and understandings with the three aspects of sustainability is one of the results of this study, the participants did not carry out in-depth studies on the 2030 Agenda and the SDGs. During the interviews, they revealed that, although universities had begun demanding inclusion of the SDGs in subject plans and publications, training and opportune moments to actually learn about the 2030 Agenda's propositions were not provided.

We identified that practices in mathematics education have supported the promotion of the SDGs of the 2030 Agenda, as the excerpts from the interviews explicitly referred to various goals, such as SDGs 1, 4, 11, 13, 14, and 15. The interviewees revealed ideas concerning public investments in research related to sustainability (Professor 3); work with financial and statistical literacy to promote economic and environmental sustainability (professors 8 and 9); the potential of global knowledge to be explored from mathematics for social sustainability (Professor 1); as well as disciplines and publications related to sustainability (professors 5 and 7).

In conclusion, the findings of this study have significant implications for the field of mathematics education, particularly in the context of integrating sustainability into educational practices. By highlighting the alignment between mathematics education and the sustainable development goals of the 2030 Agenda, this research underscores the potential of mathematics as a transformative tool for fostering sustainability literacy among students. The study demonstrates that mathematics educators can play a crucial role in bridging the gap between abstract mathematical concepts and real-world sustainability challenges. By incorporating themes such as financial and statistical literacy, educators can equip students with the critical thinking skills necessary to analyze and address complex issues like climate change, resource management, and social equity. Furthermore, the study advocates for a curriculum that not only emphasizes technical proficiency but also encourages students to apply mathematical reasoning in evaluating and solving sustainability-related problems. This approach not only enriches the educational experience but also prepares students to become informed and responsible global citizens. As such, the integration of sustainability into mathematics education is not merely an academic exercise but a vital component of nurturing a generation capable of contributing to a sustainable future.

Mathematics teacher practices to foster reasoning and communication through making connections

Judit Chico[1], Genaro de Gamboa[2], Edelmira Badillo[2] and Miguel Montes[3]

[1]University of Balearic Islands, Faculty of Mathematics and Computer Sciences, Balearic Islands, Spain; judit.chico@uib.cat

[2]University Autonomous of Barcelona, Spain

[3]University of Huelva, Spain

We present preliminary results from an exploratory study aimed at identifying aspects of teaching practice that are relevant to establishing intra-mathematical connections related to processes in the classroom. A content analysis of both small and large group discussions in the classroom was conducted, which revealed two types of connections associated with the processes of reasoning and proof, and one type associated with the process of communication. The analysis of these connections has allowed for the identification of two aspects of teaching practice that facilitate the establishment of connections: using students' contributions to focus the discussion on a specific aspect of a process and repeating the same connection related to a process across different sessions and in various social settings in the classroom.

Keywords: Mathematics connections, elementary education, mathematical processes, teacher practice.

Introduction

There is a consensus within the educational community regarding the importance of establishing mathematical connections in the classroom to foster a deep understanding of mathematical ideas, concepts, and procedures (De Gamboa et al., 2023; Rodríguez-Nieto et al., 2023). This consensus is reflected in the curricula of various countries, such as the United States (NCTM, 2000) and Spain (LOMLOE, 2020), which highlight the necessity for students to develop key competencies, such as making connections, to promote the view of mathematics as an integrated whole. While students may make connections spontaneously, it cannot be assumed that these connections will occur without some form of intervention from the teacher. In this regard, the teacher's role in establishing connections in the classroom is crucial, not only in the type of tasks they propose to their students but also in the management of mathematical activity and the teaching practices they employ (Mosvold, 2008). However, the lack of specific models for how to introduce and establish relevant mathematical connections in the classroom hinders teachers from incorporating connections into their regular practice (De Gamboa et al., 2023). In this study, we examine how the teacher promotes the establishment of connections in the classroom.

Specifically, we are interested in a type of connection identified in previous studies (De Gamboa et al., 2023): intra-mathematical connections related to processes such as reasoning and proof or communication. We focus on studying these connections for two main reasons. Firstly, it is well-known that developing mathematical processes in the classroom is crucial to move away from teaching practices focused on the acquisition of symbols and techniques, which doesn`t focus on the

strategic and effective use of mathematical content in various contexts. Secondly, there is a need for further research into the teacher's role in establishing connections that support the development of processes (Jakobsen et al., 2013; De Gamboa et al., 2023). Thus, the aim of this communication is to identify some characteristics of teaching practice to promote mathematical connections related to processes, through a case study in a primary school in Spain.

Theoretical framework

In the field of Mathematics Education, there is a growing interest in the conceptualisation of connections, which has led various researchers to characterise different types of connections that can be established in the classroom (e.g. Businskas, 2008; De Gamboa et al., 2023; Dolores-Flores & García-García, 2017; Eli et al., 2011; Rodríguez-Nieto et al., 2023). Broadly speaking, a primary distinction can be noted (De Gamboa et al., 2023) between extra-mathematical connections, which occur when mathematics is linked to a phenomenon external to mathematics (real-life connections as discussed by Mosvold, 2008), and intra-mathematical connections, which occur when two mathematical objects are connected (Font et al., 2013). Within this second category, two types of connections can be further identified: conceptual connections, which emphasise specific aspects of a mathematical concept, and connections related to processes, which are the focus of this study. The latter emphasise a process that can be applicable to various mathematical concepts, such as the communication of mathematical ideas or the validation of results (De Gamboa et al., 2023). We understand mathematical processes as process standards (NCTM, 2000), that is, ways of acquiring and using mathematical content, ideas, and procedures across diverse contexts. In connections related to processes, a mathematical concept is linked with a particular aspect of a process. For instance, in the communication process, one might emphasise the clear and comprehensible communication of ideas to others, the use of precise mathematical language, or the organisation and consolidation of mathematical knowledge through oral or written communication. In the reasoning and proof process, emphasis might be placed on making and validating conjectures, developing mathematical arguments, or using strategically different types of reasoning.

In a classroom context, such as the one analysed in this study, mathematical connections emerge as a result of the interaction between the teacher and the students. We understand both intra and extra-mathematical connections as networks of more fundamental connections that arise from the interactions occurring within the classroom (De Gamboa et al., 2023). These fundamental connections can link two representations (Businskas, 2008; De Gamboa et al., 2020; Dolores-Flores & García-García, 2017; Rodríguez-Nieto et al., 2023); common aspects of different concepts (De Gamboa et al., 2023; Eli et al., 2011); a concept with a procedure (Businskas, 2008; Dolores-Flores & García-García, 2017; Rodríguez-Nieto et al., 2023) or two procedures (De Gamboa et al., 2023); and two propositions (Businskas, 2008; De Gamboa et al., 2023; Rodríguez-Nieto et al., 2023). For example, in the context of a classroom discussion, a connexion related to the reasoning and proof process can emerge when the teacher and students propose related arguments, using a range of representations, procedures, or propositions. Each of these relationships that arise in such utterances constitutes a fundamental connection, and when understood collectively, they form the connection related to reasoning and proof.

Methods

This study is situated within a qualitative and interpretive paradigm with the aim of exploring, describing, and explaining (McMillan & Schumacher, 2005) how connections are established in the mathematics classroom. As part of a broader research project focused on studying mathematical connections in the classroom, we designed a sequence of five sessions for students in the final year of Primary Education (11–12 years old). The learning goal of the sequence is the modelling of the relationship between the circumference of a circle and its diameter. This was conducted in a classroom at a school in Catalonia (Spain) over a period of two weeks at the end of the 2023–2024 academic year. The tasks, developed in collaboration with the classroom teacher, provide potentially rich contexts for fostering various connections in the classroom, incorporating both real-world contexts and work with diverse semiotic representations. Students worked in small groups and were required to complete individually the dossier containing the tasks. The teacher regularly encouraged discussion in both small and large groups, without any specific guidance from the researchers regarding the establishment of connections in the classroom. In this communication, we focus on analysing the data from the first two sessions, in which students explored the relationship between the length of a circle and its diameter. In the first session, students experimented with labelling bottles using paper and scissors. In the second session, they used the dynamic geometry software GeoGebra. The following is the statement of the first task.

Task 1. Marina owns a company that specialises in labelling bottles. A mineral water company has requested a proposal for labelling bottles of a new water brand they plan to launch. Marina has been asked to present three label options for three cylindrical bottles of different sizes: one with a diameter of 10 cm, another with a diameter of 20 cm, and the third with a diameter of 30 cm. The labels must meet the following requirements: 1) Each label must have a height of 4 cm, and 2) The labels must be adhesive and wrap fully around the bottle without overlapping (i.e., no part of the label should stick on top of another part).

1. How can Marina determine the length of the labels if she only knows the diameters of the bottles? Fill the table with the diameter of each bottle and the length of the label.
2. How many times does the diameter of the bottle fit into the length of the label? You could explain this with a drawing.
3. How would you express the relationship between the diameter of the bottle and the length of the label?

Diameter of Bottle (cm)	Length of Label (cm)
10 cm	
20 cm	
30 cm	

Figure 1: First task of the didactical sequence

The classroom sessions were recorded following a non-participant observation approach (Cohen et al., 2007). A content analysis (Krippendorf, 2018) of the discussions in both small and large groups involving the teacher and students was conducted in two phases. The first phase involved identifying and classifying the connections (De Gamboa et al., 2023) established in the classroom interactions between the teacher and students. The basic units of analysis are episodes defined by the collection of utterances that form each connection. In the second phase of the analysis, we focused on examining episodes where intra-mathematical connections related to processes were identified. This analysis helps to identify key aspects of each process (such as proving, verifying, and communicating effectively) and to explore relevant aspects of teaching practice in the establishment of these connections. In both phases, validation through expert triangulation (Flick, 2007) was crucial to

ensure the meaningful interpretation of the data and to minimise interpretative biases. First the data is analysed individually by each author, then we compare the results, discuss the cases in disagreement and write the agreements reached in joint meetings.

Results

In the analysis of the first two sessions, we identified a total of 27 episodes where mathematical connections were established. Of these, 10 episodes involved connections related to the processes of reasoning and proof, and communication, linking a mathematical concept with a fundamental aspect of one of these processes. Specifically, for reasoning and proof, connections were associated with the justification of mathematical statements (3 episodes) and the verification of conjectures or results (3 episodes). For communication, we identified 4 episodes that emphasised the clear written communication of mathematical ideas to others. Below, we present three episodes from the first session that are representative of each type of process-related connection identified in the data analysis, as well as aspects of teaching practice that foster the establishment of these connections.

Justifications of mathematical statements

In these connections related to the process of reasoning and proof, the teacher emphasises the necessity of justifying mathematical statements. An illustrative example of this is provided by the following episode, which occurs when the groups begin working on the first task (Figure 1), empirically measuring the diameter and the length of the circumference of each bottle. The connection emerges when the teacher approaches a group of students who, during their exploration of prior ideas, had proposed that the length of the circumference is the diameter multiplied by Pi (π).

Student1:	So, what do we need to discover? The number Pi, why do we multiply?
Teacher:	What is the relationship between Pi and the diameter?
Student2:	I mean, Pi...
Student1:	But I have to multiply to find out.
Teacher:	Yes, but if you need to multiply, it means they are related, right? Pi and a diameter. So, what is the relationship? Why Pi and not some other number?
Student2:	To find out the number Pi, you have to multiply.
Student1:	But Pi is 3.14...
Teacher:	Right, but why do I multiply by 3.14 and not by 2.65 or the number e, for example? What is the relationship?
Student2:	Between the diameter and Pi.
Student1:	Why do you multiply by Pi? Summary?
Teacher:	I think multiplying means doing something a certain number of times, right? So why do I do the base of the bottle 3.14 etc. times? Why not do it two or four times? Am I making myself clear?
Student1:	Yes, yes, yes.
Teacher:	Where does this Pi come from? Why is Pi the number that I have to use as many times as the diameter? Yes?
Student1:	Because they felt like it.
Teacher:	Nooo, mathematicians never come up with things just because. There is always a reason and a rationale.

Although the students are already familiar with the formula, the aim of this task is to give sense to the modelling process based on experimental data. The aim is for the students to use empirical measurements of the diameter and circumference of the bottles to argue the origin of Pi. Throughout the episode, the teacher recurrently poses questions related to the task that clarify and specify the

task's requirement: to justify the formula they already know. The teacher reformulates or follows up the students' contributions, focusing the dialogue on the need to uncover the reasoning underlying the use of Pi as a proportional constant between the diameter and the circumference length. By the end of the episode, Student1 reveals a view of mathematics in which the formula is seen as an arbitrary result that does not require justification. The teacher uses this contribution to emphasise that mathematics is never arbitrary and that there is always reasoning behind general rules. This highlights how the teacher directs the dialogue towards mathematical justification, fostering the connection between Pi as a proportionality constant (the relationship between diameter and circumference, expressed as a formula) and the notion of justification/proof in mathematics. Establishing this connection can help students new to using formulas to understand that these formulas are derived from mathematical reasoning that they can comprehend and replicate, as well as to recognise proof as an essential aspect of mathematics. In the second session, two additional episodes of this type occur, where the teacher reformulates, follows up, or questions the conjectures or partial solutions provided by the students to direct the discussion towards the need to justify the mathematical statements.

Validating results

In these connections related to reasoning and proof, the teacher emphasises the need to explore different cases before establishing a conjecture about an observed pattern. The following episode occurs when the students are working in groups on solving the first task (Figure 1). The teacher had recorded empirical measurements of the length and diameter of various bottles in a two-column table on the board. The episode begins as the students are engaged in finding the relationship between the diameter and the length.

Student1:	Teacher, when you multiply the radius by the diameter, it gives you more or less… It's that here we've approximated…
Teacher:	The radius by?
Student1:	By the diameter. The diameter gives you the length, the perimeter.
Teacher:	The radius by the diameter?
Student1:	Yes.
Teacher:	So, here it would be…
Student1:	3.25 times 6.5. Well, it gave me 21.1250.
Teacher:	But with just one operation, can we say this is a rule? Or could it be a coincidence?
Student1:	Okay, but…
Teacher:	No, no, I'm just asking, simply asking.

In this episode, the teacher questions whether a property or general rule can be deduced from a single case when Student 1 proposes an incorrect property for finding the length of the label by multiplying the radius by the diameter. The teacher does not focus on the validity of the property itself but rather on the validity of the reasoning used to deduce it. The student's reasoning is based on a single particular case where the radius is relatively close to Pi, leading to a length result that is near certain approximations previously shared on the board for that case. Thus, the teacher reformulates and questions Student1's contributions to highlight the distinction between a particular result and an observed pattern (conjecture), emphasising the need to test more than one case (operation).

This episode demonstrates a connection between an incorrect relationship involving the radius, diameter, and length, and the notion of inductive reasoning for establishing conjectures. Establishing

this connection can help students understand that if a property holds in a finite number of cases, it cannot be assumed to hold universally. In other words, before establishing a conjecture or accepting the validity of a property, it is advisable to check various cases to see if the property holds. In the other two episodes of this type, the teacher again uses students' contributions to focus the discussion on the reasoning employed to validate a conjecture or general rule, reiterating the notion of inductive reasoning for formulating conjectures or verifying results.

Written communication of mathematical ideas

In these connections related to the process of communication, the teacher emphasises that written communication must be comprehensible to others. We present the first episode of this type of connection identified in the data. This episode occurs when the students are formalising in writing the relationship between the diameter and the length of the circumference after a class discussion aimed at deducing this relationship from the results of the diameter and length measurements of different bottles, which had been recorded in a table on the board.

Student3:	Should we ask this question about our bottle or the bottle of ten, twenty, and thirty?
Teacher:	Nooo… Based on what we know right now, right? Regarding the bottle and the discussion we've just had, we can answer.
Student4:	But are we making a bottle?
Teacher:	You can make it understandable. If a person uses the explanation here, they should be able to reproduce exactly what you're explaining. Okay?

In this episode, the teacher guides a small group on how to communicate mathematical ideas in writing. In the first intervention, the teacher clarifies that the written response must be based on the class discussion surrounding the results from experimenting with various bottles. In the second intervention, the teacher instructs that the explanation should be understandable to anyone, such that they could replicate the problem-solving strategy used. This approach connects a classroom activity where a pattern is observed, identifying Pi as a proportionality constant between length and diameter, with the process of communication. Later, while the students continue working in groups, the teacher reviews a student's response that relies solely on a drawing and tells them that "it lacks text," meaning written explanation. Addressing the entire class, the teacher states, "Think about this; that is, your explanation should enable someone who has not solved this problem with us to solve it. Right? They should be able to reach the same conclusion we have". This episode demonstrates how the teacher promotes the communication of mathematical ideas as a narrative construction that should enable an outsider to understand and reproduce the activity's content. Establishing this connection helps students consolidate their mathematical thinking through clear written communication that is understandable to others. Such interventions are repeated throughout the two sessions, addressing various aspects of the tasks and involving interactions with individual students, small groups, and the entire classroom.

Concluding discussion

The identified connections in the first phase of the study refine the definition of connections related with processes proposed by De Gamboa et al. (2023). While De Gamboa et al. (2023) defined these as connections between a concept and a process, our study has identified that such connections can also occur between an incorrect or incomplete procedure and a process. Additionally, this study

documents some intra-mathematical connections related to communication and reasoning and proof, contributing to the existing literature that predominantly focuses on extra-mathematical connections or intra-mathematical connections between concepts, procedures, or representations. Documenting these connections is important for understanding the role of connections in the development of processes in mathematics teaching and learning, and for promoting the development of rigorous and complex reasoning and communication from an early stage.

In the second phase of the study, we observed how the teacher encourages the establishment of connections by leveraging students' contributions to focus the conversation on specific aspects of a process. Throughout the two sessions, and in relation to different aspects of the task, the teacher repeatedly highlighted the same connections related to the written communication of mathematical ideas; the justification of the relationship between length and diameter; or the verification of results obtained experimentally (inductive reasoning). The combination of these two characteristics of teaching practice, both in small group and whole class interactions, appears to be crucial in establishing connections in the classroom. The use of student's contributions to trigger the repetitions of the same connections facilitates the institutionalisation of this mathematical knowledge within the classroom. Although these are preliminary results that may be reinforced with the analysis of the additional data of the three last sessions, this experience exemplifies the importance of classroom management and teaching practices enacted by the teacher.

It must be assumed that if primary students are to stablish connections, their teachers must be active agents not only in the selection of connection-rich tasks, but also in the classroom management of these tasks to promote the establishment of mathematical connections. Therefore, this line of research should result in the design of formative tasks for preservice prospective teachers to develop specific teaching practices that facilitate the identification and the establishment of mathematical connections.

While most research on mathematical connections in the classroom focuses on classifying types of connections, this exploratory study points to the importance of analysing teaching practices that facilitate the establishment of specific types of connections. In this sense, as a future line, we ask whether teaching practices that promote connections related to processes are similar to practices that promote other types of connections. Additionally, we wonder if the model of teaching that teacher hold has an impact on the promotion of connections, and if so, how are they related.

Identifying the needs of mathematics teachers during the implementation of new mathematics education goals

Ilze France[1], Ildze Cakane[1] and Astrida Cirulis[1,2]

[1]University of Latvia, Latvia; ilze.france@lu.lv

[2] Concordia University, USA

Latvia, like many countries, is implementing a new mathematics curriculum emphasizing understanding and problem-solving. The success of these changes relies heavily on teachers. This study aims to explore the opportunities for students to understand mathematics at different grade levels and the teaching profiles of Latvian mathematics teachers. This research, conducted in rural and urban schools, used an exploratory mixed-method design, observing and analysing 78 mathematics lessons from the year 2022 to 2024. The study found significant differences in teaching performance across various criteria. Better performance in clarity of content and lesson design was compared to student cognitive activation and metacognition. This highlighted the need for targeted professional development to address the specific needs of teachers to best meet new curriculum goals.

Keywords: Teaching performance, lesson observation, professional development, understanding.

Introduction

Every country defines mathematical competencies for its youth and structures its education system to achieve these goals. Historically, these competencies emphasized basic mathematics skills. However, the digital age and global challenges have redefined goals for mathematics teaching and mathematical competence. They now emphasize data literacy and critical thinking to navigate personal and societal issues in the 21st century (OECD, 2023). The authors' country, Latvia, like many others, is experiencing educational reforms and curriculum change. In any reform movement, teachers are key agents in the delivery of the new curriculum. Therefore, the potential success of the reform is heavily dependent on them (Shimizu & Vithal, 2023). In Latvia, starting in 2020, a new mathematics curriculum was introduced. It emphasizes conceptual understanding, seeing and formulating connections, problem-solving, and the use of multiple representations. This implies that teachers must have a deep understanding of the mathematics that they are teaching. They must also understand how students learn mathematics, including a keen awareness of the individual mathematical development of their own students, and be able to select strategies that will enhance learning (Van de Walle et al., 2010). Given the significant variation in teaching performance levels in Latvia, both between different schools and within the same school, there are concerns that for some teachers, acquiring and applying the necessary skills to implement the new competency-based approach may be challenging. Additionally, some teachers may find it difficult to change their beliefs and attitudes to effectively adopt this new approach. This concern was highlighted by a recent study on the support teachers need to provide a 21st-century education (UL ICEI, 2023). It is crucial to evaluate the current teaching performance of mathematics teachers and determine the next steps to enhance their practice. There is limited research in Latvia on the cognitive depth of students'

classroom experiences. Therefore, this study contributes to identifying the needs of teachers and the necessary support.

Theoretical framework

It is a cognitive process in which the transformation of ideas or concepts takes place. The newly learned is constructed based on what was previously learned, forming a connection and being included in the existing knowledge structure (Ausubel, 1968; Van de Walle et al., 2010). When constructing meaning, the transformation of the student's initial concepts takes place (Resnick, 1987). When students transform their initial ideas into scientific ones, the formation of misconceptions is also possible. Students must learn mathematics with understanding, building on prior knowledge and experiences, which can be enhanced through classroom discourse (Sawada et al., 2000). Meaning is formed by reasoning, not by mechanical memorization as reproduction. That is why learning tasks should be meaningful - to give the opportunity to construct meaning of what is to be learned (Möller, 2019). Deep learning requires an understanding of what has been learned and the ability to transfer what has been learned from one context to another, employing higher-order thinking skills (Biggs & Collis, 2014). Mathematical proficiency encompasses more than just procedural understanding. It integrates conceptual understanding, strategic competence, adaptive reasoning, and productive disposition. Despite this, many teachers still prioritize procedural fluency, focusing on memorizing number facts and mastering traditional algorithms (Mhuirí & Neary, 2024). Respecting teachers' existing knowledge while enhancing their capacity for new teaching methods and acknowledging their work are key principles in curriculum reform (Shimizu & Vithal, 2023). Research (Richland et al., 2012) indicates that teachers' knowledge and beliefs about mathematics, including the importance of connections of mathematical concepts and representations, significantly impact their teaching practices. Teaching practices can be measured using rubrics, both by the teachers themselves and by experts observing the lessons (Namsone et al., 2021). Understanding the diverse needs of teachers can enhance professional development (PD) activities and ensure maximum benefit for all participants (Stevens et al., 2013). Accordingly, two research questions were stated: 1) What opportunities do students have to make sense of mathematics at different grade levels? 2) What teaching profiles are characteristic of Latvian mathematics teachers regarding the opportunities for deep learning in their lessons?

Method

This research was carried out in rural and urban schools. The researchers collaborated with municipality and school leaders. To answer the research questions, an exploratory mixed-method research design and content analysis were chosen. School mathematics lessons were observed from the year 2022 to 2024. A total of 60 lessons in Grades 1 to 6 and 18 lessons in Grades 7 to 12 were observed and transcribed by experienced and specially trained experts. The experts analysed the transcriptions. The authors used a previously developed and validated instrument – the Framework of Teacher Performance Assessment to Support Teaching 21st Century Skills (Namsone et al., 2021). The selected instrument is a category-criteria framework, consisting of 17 criteria that conceptualize teacher classroom practices that support the acquisition of 21st-century skills in the authors' country's

educational context. The criteria are structured in 6 categories (i.e., student self-regulation, student cognitive activation) and three domains (planning, teaching, and classroom environment) derived from teachers' everyday practice. The authors selected 4 categories and 5 criteria that are highly relevant to teaching mathematics for understanding (Table 1).

Table 1: Categories and criteria that are highly relevant to understanding mathematics

Category	Criteria
Learning content representation (CR)	6.1. Clarity of learning content
Instruction (INSTR)	5.1. Lesson design, 5.2. Teaching technique.
Student cognitive activation (SCA)	2.1. Learning tasks for deep learning, 2.2. Discussions for deep understanding
Metacognitive strategies (MET)	1.2. Promotion of metacognitive strategies.

Teaching practice in each lesson was compared with the level descriptions of corresponding criteria for an example, see Table 2. The theoretical framework and descriptions of performance levels have been previously validated. The analysis was carried out by filling in a form in which the teacher's performance was evaluated in 5 levels (scale 0, 1, 2, 3 and 3+): not observed, beginner, developing, proficient and expert, where level 3 is the desired or expected good practice and level 2 is sufficient for achieving the necessary goals.

Table 2: Example of a Performance level description: 2.2. Discussions for deep understanding

Level	Description
2.2. Discussions for deep understanding: Variety of questions asked by the teacher; possibility for various answers. Time to think. Conversational, thought-provoking environment. Number of students who ask questions; types of questions asked. Clarity of discussion procedure; teaching students to ask and answer.	
0 (Not observed)	The teacher introduces information and explains concepts. If questions are asked, they are closed. Students mainly listen, observe, and take notes.
1 (Beginner)	The teacher's monologue dominates. However, some elements of discourse can be observed – the teacher asks questions but expects specific answers. Questions are only used for checking knowledge. If students fail to provide prompt expected answers, the teacher answers them. Students answer questions and/or ask very few questions.
2 (Developing)	Alongside explaining and asking questions, the teacher creates a situation where students have to pose questions about the content of the lesson. If needed, the teacher instructs students on how to form questions and how to engage in conversation. The teacher tries to provide enough time for students to think over their answers; however, the time is often insufficient. Students feel free to ask questions and engage in conversation.
3 (Proficient)	The teacher asks diverse questions, including those where there is no single right answer, and asks for students' reasoning. The teacher uses questioning and different student responses to extend the discourse either frontally or in groups (pairs). If needed, the teacher rephrases student questions. The teacher gives students enough time to think during the discussion. Students have a clear understanding of the procedure of classroom discourse – how to ask and how to answer. Students ask diverse questions.
3 + (Expert)	With appropriate questions, the teacher creates situations to engage students and deepen their thinking.

	Students ask diverse questions, initiate and lead discussions, and are active and fully engaged in thinking.

For the identification of different teaching profiles, the following schema (Figure 1) was used (UL ICEI, 2023). It is based on the prioritization of the categories corresponding to teaching for making sense of mathematics. The schema for identifying mathematics teaching profiles is tailored and includes the essential criteria necessary to evaluate the opportunities provided in lessons that develop an understanding of mathematics. There were 6 teaching profiles identified, where the 1st profile with a high level of performance, characterized as professional teaching etc. (Čakāne et al., 2024). The identified mathematics teachers' teaching profiles correspond to teacher profiles identified through TALIS teacher survey data analysis – clarity of instruction, classroom management, cognitive activation, control over planning and teaching (OECD, 2020; Özdemir et al., 2023; Jang et al., 2023).

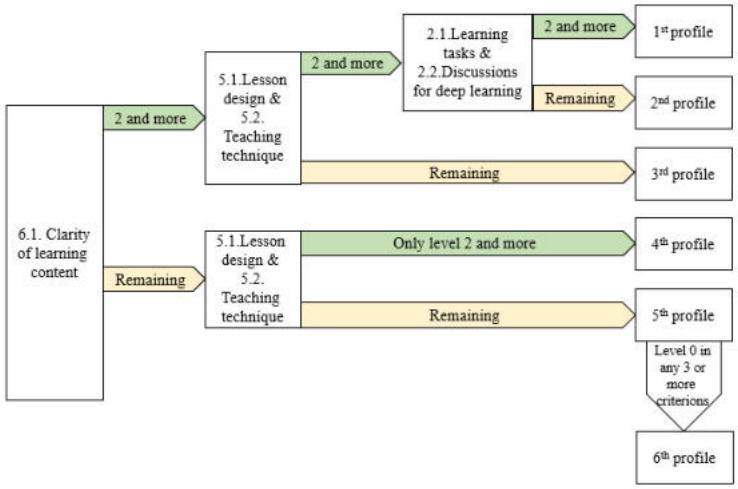

Figure 1: Schema for mathematics teachers teaching profile identification (using scale 0–3+)

Results

Results for Research Question 1

Table 3 shows the sample lessons' mean and median performance levels in the selected criteria, including data on teaching performance across five levels. It also indicates the minimal and the maximal observed performance distribution levels.

None of the teaching performances reached the desired competence level in all the selected criteria. Teaching mean performance levels in clarity of learning content, lesson design and teaching technique were overall better than in student cognitive activation and promotion of metacognition.

Analysis of the assessment of the six criteria shows significant differences in the opportunities provided to students between different grade levels. In 30% of Grade 1 to 6 and 73% of Grade 7 to 12 lessons, teachers selected appropriate learning content with appropriate representations, and efforts to develop conceptual development were evident (performance level 2 and above in criterion 6.1.). However, in 20% of Grade 1 to 6 and 6% of Grade 7 to 12 lessons, either the learning content was inappropriate or faulty and there were possibilities for students to form misconceptions. When

looking at the structure of the lessons – in 56% of Grade 1 to 6 and 78% of Grade 7 to 12 lessons, students' previous experiences were drawn upon to focus their attention, and tasks were consecutive

Table 3: Sample lessons in selected criteria characterizing teaching that promotes student conceptual understanding

Categories	CR		INSTR				SCA				MET	
Criteria/Results	6.1.		5.1		5.2.		2.1.		2.2.		1.2.	
Grade	1–6	7–12	1–6	7–12	1–6	7–12	1–6	7–12	1–6	7–12	1–6	7–12
Mean performance level	1,15	1,83	1,68	2,06	1,55	1,67	0,88	1,22	1,00	1,11	0,38	0,61
Median performance level	1	2	2	2	1	2	1	1	1	1	0	0,5
Performance level, 0,%	20	6	7	0	3	6	25	11	20	17	62	50
Performance level 1, %	49	22	36	22	48	39	61	56	59	61	34	39
Performance level 2, %	25	56	38	50	38	39	13	33	20	17	2	11
Performance level 3&3+, %	5	17	18	28	10	17	0	0	0	6	0	0

and necessary to reach the learning outcome (criterion 5.1.). In 86% of Grade 1 to 6 and 79% of Grade 7 to 12 lessons, most tasks required low-level thinking (performance level 0 and 1 in criterion 2.1.). In 79% of Grade 1 to 6 and 78% of Grade 7 to 12 lessons, the questions directed at students were mostly for checking their knowledge and not for seeing their reasoning and ideas (performance level 0 and 1 in criterion 2.2).

Results for Research Question 2

Following the previously shown schema (Figure 1), teaching was analysed, and profiling was conducted at six levels (Figure 2). Metacognition criterion (1.2.) was very low in both grade groups, it was used only as background information in the profiling of teachers.

The identified teaching profiles and median performance levels of each profile are presented in Figure 3. Highlighted are the criteria where differences between the two groups are observed.

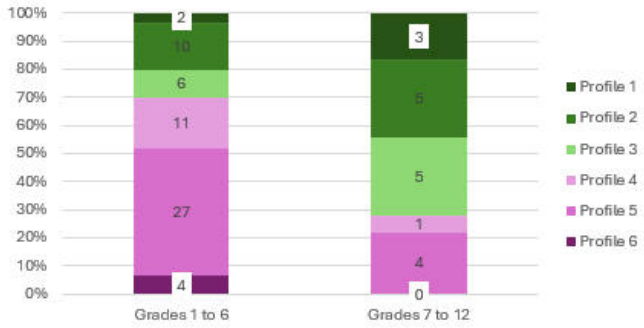

Figure 2: Teaching profile distribution

Grades 1 to 6

	6.1.	5.1.	5.2.	2.2.	2.1.	1.2.	N	%
Profile 1	2,5	3	2,5	2	2	0,5	2	3%
Profile 2	2	3	2	1	1	1	10	17%
Profile 3	2	2	1	1	1	1	6	10%
Profile 4	1	2	2	1	1	1	11	18%
Profile 5	1	1	1	1	1	0	27	45%
Profile 6	0	0,5	1	0,5	0	0	4	7%

Grades 7 to 12

Profile 5	1	1,5	1	1	0,5	0	4	22%
Profile 6	-	-	-	-	-	-	0	0%

Figure 3: Profile distribution and median performance level

Differences were observed between primary school teachers (Grades 1 to 6) and middle and high school teachers (Grades 7 to 12). More teaching corresponded to the 4th profile (the teacher's basic activities would be performed skilfully if the teaching content were delivered proficiently; opportunities for learning to reason are only present in isolated cases) of primary school teachers than that of middle and high school teachers. Significantly more primary school lessons corresponded to the 5th profile (teacher's basic activities are skilful only in certain elements) and 6th profile (inadequate teaching of the curriculum content, i.e., students are not provided with opportunities to learn successfully) which shows weak subject knowledge and classroom management skills. In Grades 7–12, more lessons fit the 3rd profile, which can be described as theoretical teaching of mathematics, compared to primary schools. The content is represented adequately, but teacher`s basic activities lack proficiency.

Discussion and conclusion

The results show that the teaching of mathematics in the observed lessons, in terms of promoting students' understanding, varies. The study reveals that while teachers demonstrate proficiency in certain areas such as clarity of learning content and lesson design, there is a need for improvement in promoting student cognitive activation and metacognition. The observed variations in teaching performance across different grade levels and the presence of inappropriate learning content in some lessons highlight the importance of targeted PD and continuous support for teachers. Such considerations are important when designing PD as teachers may have different needs based on specific characteristics (Stevens et al., 2013). This means that teachers require various methodological support. However, Darling-Hammond et al. (2017) admit that at the system level teacher PD is often determined without understanding what teachers need. The authors conclude that for each of the teaching profiles, there are different needs for PD. For example, teachers that fit the 1st profile (characterized by a high level of performance, students having the opportunity to learn to think during lessons, and the teacher's basic activities in the classroom are effective) can either improve their knowledge about deep thinking and corresponding tasks as well as their skills in leading classroom discussions and the art of asking questions for deep understanding or work on teaching and improving student metacognitive skills. The priorities for the 2nd profile (characterized by effectively performed basic teaching activities; however, only isolated situations are observed in lessons where students have the opportunity to learn to reason) should be aligned with the school's established goals. Yet, there is a clear necessity to enhance student cognitive engagement during

lessons. Teachers in the 3rd profile (characterised by skilfully delivered teaching content; however, the teacher's basic activities are not always implemented effectively, and opportunities for students to learn to think are observed only in isolated situations) are characterized by a skilled representative of theoretical and algorithmic mathematics teaching. They need to focus on lesson planning and instructional strategies to develop a coherent lesson structure that promotes cognitive challenges for students. For teachers in the 4th profile, it is essential to deepen their understanding of mathematics pedagogy and didactics, emphasizing the use of various representations and the transitions between them, as their foundational teaching skills are adequate. Teachers in the 5th profile, particularly novice teachers, require mentorship or other forms of individualized support. If a teacher's performance aligns with the 5th or 6th profile, it is crucial to address their motivation for teaching and to conduct further research to understand the prevalence of such practices in schools.

Schools or municipalities can use the profiling schema from this research as a self-assessment instrument to determine their professional development needs. To determine more precisely the necessary support for teachers, the next step in the research could be to explore their beliefs.

Teacher-student interaction in collaborative problem-solving: In-the-moment perspective on teacher noticing

Ellen Kristine Solbrekke Hansen[1] and Kristin Krogh Arnesen[2]

[1]NLA University College, Department of Teacher Education, Norway; ellenkristine.hansen@nla.no

[2]Norwegian University of Science and Technology (NTNU), Norway

Many teachers use students' thinking but often miss opportunities to advance groups of students mathematically. In this study we analyse a teacher's interaction with four seventh graders from a Norwegian classroom through a noticing perspective. We highlight the teachers' noticing actions while engaging with students' shared reasoning during solving a mathematical problem, the Coin Problem. Through a noticing lens on observational data, we found that the teacher appeared to aim for students to develop more generalized arguments. Although the teacher built on their ideas, the challenge was that students struggled to follow his line of reasoning. Thus, we examine how the arguments constructed during the teacher's interventions did—or did not—become part of the group's shared reasoning. The results provide insights into how a teacher use students' in-the-moment arguments, possible reasons behind the chosen approach, and its consequences.

Keywords: Teacher-student interactions, collaborative problem-solving, teacher noticing.

Introduction

Research has emphasised that students can better understand mathematical ideas through meaning-making and by constructing their own mathematical knowledge. Thus, teachers should organise for classroom activities which can elicit students' different ideas, for students to respond and build on each other's ideas. Therefore, mathematical reasoning and small-group work are highlighted in research as activities influencing students' construction of mathematical ideas (Maher et al., 2018). Collaborative problem-solving (CPS) combines mathematical reasoning and group work. Thus, it is a complex, yet important, interaction for teachers to facilitate. Howe et al. (2007) found that students' most productive collaboration occurred when a teacher offered little intervention. In those situations, students proposed and defended ideas, and produced their own solution methods. However, teachers who are prone to little intervention with students, often withdraw from intervening at all (Stein et al., 2008). Some teachers will avoid telling students what to do or honouring students' work and progress, due to lack of guidance on what they could do to encourage mathematical reasoning and thinking (Stein et al., 2008). Consequentially, teachers miss opportunities to move a class, or a group of students, or an individual student, forward mathematically.

In our study, teaching is connected to how students are afforded opportunities for developing convincing mathematical arguments (Jeannotte & Kieran, 2017) for solving a problem together. We do not see teaching as defined by a single method or a set of methods, but rather by the interaction between a teacher and students, connected to a mathematical content (Jacobs & Spangler, 2017). Thus, teaching mathematics is a relational practice consisting of a complex interplay of interactional components aimed at enhancing students' mathematical reasoning. In an interaction between a teacher and students collaborating on a mathematics problem, what captures a teacher's focus

depends on various factors, such as students' understanding, the dynamics of the group, or aspects with the problem. In this study, we utilize teacher noticing as a frame to gain insights on teaching practices connected to students' mathematical reasoning. We ask: How does a teacher interact with students' collaborative problem-solving process seen through a lens of teacher noticing?

Theoretical background

Teacher noticing is often viewed as "focusing attention on and making sense of what students say or do before actually responding to them" (Jacobs & Spangler, 2017, p. 771). Recent frameworks operationalizing teacher noticing illuminate two themes: 1) consideration of the contextual aspects related to noticing, and 2) attending to and interpreting students' mathematical thinking (Amador & Weston, 2024). These perspectives highlight the importance of how teachers actively observe and interpret key moments in classrooms. In this process, known as professional vision, it is crucial for teachers to develop a critical awareness of their surroundings, enabling them to recognize particular situations, evaluate them carefully, and respond with purpose. By focusing on these elements, research into teacher noticing not only contributes to a deeper understanding of classroom dynamics but also holds the potential to enhance teacher professional development.

To study teacher noticing three different approaches are often utilized (Sherin et al., 2011): 1) teachers describe teaching of others and express what they notice, 2) teachers reflect upon their own teaching where they think about the lesson, or view video from a lesson on which they comment, and 3) researchers make inferences about what a teacher notices from video of teachers' actions in their classrooms. We study teacher noticing through the last perspective: emphasizing what and how a teacher attends to students' mathematical reasoning during teacher-student interactions. One approach to framing a teacher noticing study is through the framework attending, interpreting, and shaping from van Es and Sherin (2021). We did not have access to the teacher's thoughts and reflections. Thus, when we consider attending, we are restricted to the events the teacher focused on or disregarded (i.e., what the teacher ignored or did not attend to) in conversations with students. Considering the aspect shaping, we make inferences about "the integrated relationship between the information teachers gather from their observation and sense-making of students' thinking and their plans to respond in the moment" (van Es & Sherin, 2021, p. 23). In shaping situations teachers have the opportunity to attend to details of students' reasoning, develop interpretations of their claims, mathematical anchoring and justifications, as well as support with relevant mathematical instructions. To study students' arguments in such situations, we identified arguments by using Toulmin's model of argument (Toulmin, 1958). This process included looking for *claims* in the discussions, and then of how these claims were justified—from which *data* they were built and how the inference from data to claim were supported by a *warrant* and sometimes additional *backing*. Some arguments can also include a rebuttal, which is a counterargument.

To investigate how a teacher engages with and shape students' shared arguments, we study another aspect of CPS: students' processes for how they maintain and build shared understanding, which was identified after the three processes suggested by Roschelle and Teasley (1995): building, monitoring, and repairing. There are three discursive actions needed to construct and maintain a joint problem space: *building* (introducing and accepting new elements of an argument), *monitoring* (repeating or

explaining shared elements, asking clarifying questions, or identifying disagreements), and *repairing* (negotiating and discarding elements). Thus, we focus on how a teacher engages with and shapes students' shared argument.

To further unpack the complexities of studying what teachers attend to in teacher-student interactions, we needed frames to support relations between noticing and mathematics. Stockero (2021) claims to provide such a mechanism through the "Coding Framework for Attributes of Noticing". This framework focuses on three attributes that were used to identify what prospective mathematics teachers attended to in their noticing of their own lesson: *agent, specificity of mathematics*, and *focus*. We have applied the structure of the framework but modified it for use to study a teacher in action, where we do not have access to the teacher's reflections. Table 1 provides an overview of the modified categories. The *agent* category was who or what as the object of the noticing. We narrowed this category to focus on who interacted: teacher-students or teacher-student. This distinction identifies whether a teacher mainly gives the whole group or an individual student the attention in the conversation. The second attribute is *specificity of mathematics*, which was whether and how the mathematics was discussed. Stockero (2021) used this attribute to identify mathematical ideas that were noticed. Adapted to our noticing lens, specificity of mathematics is how a teacher attends to students' arguments. The final category, *focus*, concerned what about the students that was attended to, including their mathematical thinking as well as affective issues or general understanding (Stockero, 2021). In our focus category, we consider what the teacher, through interaction with the students, is focusing the student/students towards. As in Stockero's categorization, potential foci include various aspects of the problem-solving process, as well as more general, pedagogical actions.

Table 1: Noticing attributes of teachers in the moment interaction

Agent	Specificity of mathematics	Focus
Who are interacting? • Teacher-student (individual) • Teacher-students (pair/groups)	How are the students' arguments attended to by the teacher?	What does the teacher focus the student/students towards?

Methods

The data for this paper was collected in a Norwegian seventh-grade classroom (students aged 12-13), during the third out of five lessons designed for a larger intervention study (Klock, 2024). The aim of the intervention study was to develop materials for teaching reasoning and proving in primary school. Thus, the lesson studied here included a task that focused on how to foster students' argumentation. The students worked in small groups as part of the design, but the intervention did not particularly consider students' collaboration. The teacher in the current data did not follow any instructions or support particularly directed towards teacher actions. However, all teachers in the intervention study participated in task design, and the researchers aimed towards creating a shared understanding between teachers and researchers of reasoning and proving, mainly based on Jeannotte and Kieran (2017). Neither of the authors of this paper participated in the intervention, but the second author closely followed the intervention as it took place.

In this study, we consider students' work on a task called the Coin Problem: "In the central bank, they are working on streamlining their money production (…) They are considering that it might be enough with 3-krone coins and 5-krone coins. What prices can be paid if only these two types of coins exist?" The task was designed so that the answer to the task (*all* prices can be paid) was not obvious to a seventh-grader, and thus held the potential to foster students' need of convincing each other of the truth of a mathematical statement. We use data from one group: Asja, Olivia, Andrea, and Lars (pseudonyms). This group was chosen because they were engaged in the problem-solving process, yet it seemed that the teacher's interactions with the group did not provide sufficient support to move the group forward. The group worked with the task for approximately 30 minutes, during which their teacher walked around the classroom, conferring with students both with and without request. The group's work was videotaped and sound recorded. Our analyses are based on transcripts of the recordings, students' written work, and videotaped material.

For the analysis, we began by decomposing the entire transcript into a series of episodes, each episode including an argument that was constructed. The arguments were identified using Toulmin's model of argument (Toulmin, 1958). Next, we used Rochelle and Teasley's (1995) model of collaborative problem solving on the parts of the transcript where the teacher was not present. Combining the two analyses, we could track which arguments seemed to be shared in the group (did other students than the one who introduced the argument accept it, ask questions about it, or repeat it?) or whether it seemed to be the argument of a subset (usually a single student) only. As a third step, we used our operationalisation of teacher noticing (Table 1) to analyse the teacher's interventions with the group.

Results

We present the problem-solving process as a chronological narrative. "Lines" refer to line numbers in the transcript, and excerpts are translated into English. We have collected the episodes where arguments are constructed into longer segments relative to the teacher's interactions. Episodes involving group interactions that occurred without the teacher's presence are presented to comprehensively observe how the teacher's actions influence the students' co-construction of arguments.

Before the first teacher interaction (lines 1–38)

The group agreed early on that the task was pointless, and during the first 20 lines, no mathematical argument was attempted. From line 21, they constructed their first argument, focusing on prices that are multiples of 5 which they claimed can be paid by using 5 kr coins. Lars, Olivia, and Asja all contributed to this discussion, with Lars being the main builder and Asja being the most negative due to the task's apparent absurdity.

The first teacher interaction (lines 39–81)

The teacher's initial question "How are you doing?" was met by exclamations of how "idiotic" the task was from Asja and Lars. The *agent* in the teacher's attention was the whole group when he tried to focus their discussion towards the mathematical content of the task: "Is it possible? The question is not about whether it is practical or not, but this is the task, is it possible. How can you show it?" (line 43). After some protests (from Asja) and non-justified claims (from Asja, Lars and Olivia) the

teacher picked up one of their claims: "No? Why not, then?" (line 50) and engaged in a turn-taking dialogue with Olivia (lines 51-62), where Olivia presented the following argument: "Because if you're going to buy a bag that costs 2 kr, and you only got a 3 left! [Teacher: yes] Then you can't exchange 3 and get 1, because then…(inaudible)." Here, Olivia used "have 3 kr" as data to claim that you cannot pay 2 kr, by the warrant that it is impossible to pay 3 and get 1 back. The teacher noticed the *specificity of mathematics* of Olivia's argument, and that the data was invalid. He explained: "(…) you can bring as much as you want. And the shop has as much [exchange money] that you want (…) Is it possible to buy a bag for 2 kr?" Then the teacher *focused* Olivia's attention to support her in building a new argument, with the corrected assumptions as data:

57	Olivia:	Yes …
58	Teacher:	How, then?
59	Olivia:	If you have a five.
60	Teacher:	Yes, what happens then?
61	Olivia:	You exchange it and get a three back.
62	Teacher:	Yes, that's the answer. So now you know that 2 is possible. Right?

However, in this interaction, the *agent* in the teacher's noticing was Olivia, not the whole group. This is evident because of the turn-taking conversation between the teacher and Olivia. Next, he turned to the whole group to ask whether they could pay 1 kr, to which they answered "yes" or "no" without justifications. In line 73, the teacher said: "You can manage it with two fives, and you're to buy something that costs 1 kr." Subsequently, Asja said "Yes!" and Olivia said "Oh yeees! It works because nine is in the three-times-table." Although Olivia's warrant required further explanation, the teacher immediately concluded that it was correct, and further prompted them to go on to check for prices 3, 4 and so on, thus *focusing* the students on a given strategy. Then he left the group.

Between first and second teacher interaction (lines 82–168)

The group was left to check for price 7, which they concluded worked without giving or trying to provide a warrant. Similarly, they simply claimed that 8, 9, and 10 worked. In this discussion, Olivia was the main builder, suggesting a strategy "Should we just continue going up?", whereas Lars and Asja contributed by monitoring. In line 97, Andrea made her first contribution in the problem-solving process, suggesting that 11 worked because "11 times 5 is 55". This was not a correct argument, but Lars immediately followed up: "11 works! With 33! (…) 11 times 3 is 33.". Until line 129, this incorrect argument dominated the group's discussion, with Lars, Andrea and Asja in monitoring roles. Olivia, however, was sceptic to the argument. She tried several times to explain the mistake, thus taking a repairing role: "If you're to buy something for 11, and you pay with 33. Then you'll get 22 back. How are you going to do that?" (line 114). In line 129, Olivia demonstrated that you could pay 11 by paying 4 fives, then get 3 threes back. There was no response to Olivia's suggestion, but the group seemed to accept that 11 was payable. They continued half-heartedly with 12, 13 (Asja: 5+5+3), 14 (Olivia: "we take it with 4 fives…"), and so on. They were unsure about 19, but they claimed that all numbers until 22 worked. Olivia went to get the teacher (she did not state why).

The second teacher interaction (lines 169–204)

Olivia and Asja explained to the teacher that they had checked for all numbers up to 22. Andrea asked whether they needed to write down all of them. The following turn-taking occurred:

176	Teacher:	No, you don't need that, but it could be alright to do it up to 10. For example. Right? What numerical system do we have? What's the name of the numerical system we've got? Ten?
177	Lars:	…times table!
178	Teacher:	Base ten…
179	Lars:	Base ten…
180	Teacher:	…numeral system, right? So, if it goes from 1 to 10?
181	Lars:	So, it goes to 40, 50, 60, 70, 80, 90.
182	Teacher:	Yes, then it goes for all numbers.
183	Lars:	And 1000, 2000, 3000 …
184	Olivia:	So, that means that, three and five, everything goes, it just takes time.

Here, the *agents* of the teacher's noticing were the whole group, because the teacher did not address the questions and hints to a specific student, he directed it to everyone. The teacher did not, however, probe further into the *specificity of mathematics* of students' claims. Moreover, the *focus* was to build an argument or common understanding that you can pay all prices with the three and five coins. The *argument* constructed was because you can pay all sums from 1 to 10 kr (data), you can pay all prices (claim), warranted by the fact that we use the base ten numeral system. The data in this argument were the conclusions from the students' work, which they informed the teacher of in lines 169–175. The claim, however, was given by the teacher, although Olivia and Lars seemed to repeat the claim. The warrant of this argument needed support by further backing, e.g., *all numbers can be written as a sum of tens and ones, so if we can pay all numbers up to 10, we can use this to pay any number*, which was neither given nor asked for by the teacher. Next, the teacher asked the students how to pay 1000 kr, again causing the students to react to the task's absurdity: "Who goes around with 200 fives?" (Andrea, line 198). Then, the teacher gave the group a sheet on which they should write their final argument, repeated that a good argument should include drawings and explanations, and left.

After the second teacher interaction (lines 205–250)

In the first discussion following the teacher's interaction, Asja asked why 1 worked, and Lars repeated that 3 and 4 worked. Olivia tried to explain her previous argument that 1 worked but was interrupted. In the end, Olivia dictated what to write on the sheet, after refusing to do the writing herself. On their finished sheet it was written: "One works because: If you pay with two tens [sic] you get back three threes. That is the same as nine. It works for one to ten which means it works until infinity". The mistake of two tens instead of two fives is due to Olivia, which Asja copied onto the sheet, although Lars tried to correct the mistake. They did not discuss the final claim of the argument at all.

Discussion

In a process of creating a teacher-student interaction, a teacher makes way for attending to and interpreting student thinking (van Es & Sherin, 2021). Thus, untangling aspects of the process may provide insights on relations between process (who were the agents, and collaborative processes for building arguments) and the outcome (attending to and interpreting students' arguments, and support for their collaborative interaction). From the first interaction, the teacher noticed that the group was not focused on the problem, and his actions were to help the group concentrate on the problem. Further, he noticed Olivia's incorrect argument, that you cannot pay a price of 2 kroner, and supported her in correcting her argument. He asked the whole group if 1 was possible, and then he encouraged them to go on and systematically check for other numbers. The teacher's in-the-moment response

(van Es & Sherin, 2021) concerned a noteworthy mathematical aspect to attend to, which the teacher attempted to use for shaping the group's further discussion. However, Olivia's exchange-argument was not taken into the group's shared reasoning.

The strategy of testing for all numbers was the main component of the group's shared understanding of the problem. Additionally, the group seemed to agree that multiples of 3 and 5 could be paid. These ideas were monitored by all group members during the problem-solving process. Thus, students attempted to build and maintain a shared understanding (Rochelle & Teasley, 1995), which is important during CPS. Moreover, three group members asserted that they could pay a kr because 3·a or 5·a are multiples of 3 and 5, respectively, an incorrect argument which was rebutted by Olivia and thus never became a part of the group's shared understanding. Similarly, Olivia's arguments using exchanges (for example for 1, 11, and 16) were not part of the group's shared understanding, because none of the other group members ever repeated or probed into them. In the second interaction, the teacher was informed about the group's progress. He noticed their results, but did not ask them to elaborate on their shared understanding for why all prices up to 22 could be paid. This time, the response to the specificity of mathematics (base ten) was directed to the whole group. The teacher probably attempted progress towards generalising their observations: all numbers can be written as a sum of tens and ones. However, the mathematical argument he attended to did not shape a shared understanding between the students and him. Previously, and in that moment, the group's shared understanding was the strategy of testing for all numbers, starting at 1, which we interpret made the teacher's suggestion seem too advanced or out of reach. Thus, the teacher's final argument for why all prices could be paid, using properties of the numerical system, never became part of the group's shared understanding. Concerning the focus-category (Stockero, 2021), the teacher could have focused the students' thinking towards one another, rather than towards his solution strategy.

While it might seem that one, several, or all students in a group have understood a concept or solution strategy or achieved a satisfactory outcome, we believe that this perception can lead teachers to feel content with the group's progression. However, after the final teacher-student interaction, the students did not discuss their concluding argument. Moreover, they were not given the opportunity to bring together their own ideas for solving the problem, let alone review and connect the teacher's generalized suggestions. We see this as a 'challenge of closure' of both problem-solving and making a final argument in teacher-student interactions. Thus, this study sheds light on the usefulness to view the relation of what a teacher and students do, through the lens of teacher noticing. Since a teacher's professional vision is to actively observe and interpret classroom situations (cf. Goodwin, 1994, referred to in Amador & Weston, 2024), this study emphasizes the importance of developing professional skills that identify how students interact (agents and agency alike), how mathematical ideas are presented by a group, and how to respond purposefully promoting a shared understanding in the group. Such effort puts students' thinking in focus of the classroom interactions (Jacobs & Spangler, 2017). It could present one solution strategy to deal with the challenge of intervening with students' CPS, or the lack of it (Howe et al., 2007; Stein et al., 2008) by recognizing who and how arguments are collaboratively built and maintained in a group. Our suggestion is "focusing attention on" who's the agents in the group, and "making sense of what students say or do" about the specifics

of mathematics—their arguments (claims, data, warrants, rebuttals)—"before actually responding to them" (Jacobs & Spangler, 2017, p. 771).

Practices in math discourses in inclusive primary school

Uta Häsel-Weide[1] and Marcus Nührenbörger[2]

[1]University of Paderborn, Institute of Mathematics, Germany; uta.haesel.weide@math.uni-paderborn.de

[2]University of Münster, Institute of Basic and Inclusive Mathematics Education, Germany

As a result of nationwide performance assessments, the promotion of basic skills in mathematics education is becoming increasingly important in the didactic debate in Germany. In order to make mathematics teaching a central place of support for all children, including those in difficulties in learning mathematics, it is necessary to design learning environments, that enhance the individual potential of each pupil. If mathematical learning is understood as a social-interactive process, the interaction between the teacher and the children is characterised by subject-specific and social practices that are established and shaped in the course of integrated support in the classroom. The focus of this article is on the reconstruction of these practices. They are analysed on the basis of videotaped classroom scenes, using interpretive classroom research, and critically reflected upon with regard to the possibilities and limitations of support.

Keywords: Inclusion, practices, discourse, participation, difference.

Introduction

Fostering basic skills in mathematics education is becoming increasingly important in the didactic debate in Germany as a result of nationwide performance assessments (Stanat et al., 2021). In this context, it is discussed how mathematics education can be organised in such a way that children with different abilities can learn together and receive the best support possible. Because of that, the question of how to organise inclusive teaching takes on a new relevance.

"Developing mathematical understanding requires that students have the opportunity to present problem solutions, make conjectures, talk about a variety of mathematical representation, explain their solution processes, prove why solutions work, and make explicit generalizations" (Frank et al., 2017, p. 230). Therefore, a learning environment must be offered that allows children with different competencies to improve themselves in collaboration with others, although, the practices in the classroom have to consider the opportunity for each child to engage in the ongoing discourse.

Our research therefore focuses on both areas. We develop learning environments for inclusive mathematics classrooms and investigate the interaction processes. In doing so, we ask for the mathematical practices that are established between teachers and students in inclusive situations where the teacher reflects on mathematical objects together with the inclusive learning group. Our contribution focuses on the social and content-related participation processes of learners who are in difficulties in mathematics learning.

Theoretical framework

According to the theoretical approaches of Steinbring (2005), mathematical learning is based on content-related social negotiation processes with focus on active explorations of mathematical

content and structures. The interactive negotiation of a common thematic meaning leads to the development of conceptual understanding at different individual levels. Accordingly, mathematical learning takes place through participation in collective mathematical constructions of meaning (Voigt, 1994). Learning mathematics in inclusive classes is always framed by the question of the extent to which the children, with their individual potential and approaches, have opportunities to participate socially and content relatedly in shared mathematics lessons with others.

In this sense, with view on the heterogeneity of an inclusive math class, there is a need for the design of learning materials for all children. A main goal of inclusive learning situations is "to involve all learners in quality learning experiences which empower them to become active participants in a more equitable system" (Scherer et al., 2016, p. 640). Häsel-Weide and Nührenbörger (2022) pointed out different guiding principles for the design of inclusive mathematics teaching. These design principles aim to "consider different potentials of the learners and to connect to them in a targeted way:

(1) accessibility to the common subject matter for all children,

(2) subject learning at different levels,

(3) active exploration of content connections and finally,

(4) initiation of common learning phases for all children with social negotiation processes of communicating, representing, and arguing" (Häsel-Weide & Nührenbörger, 2022, p. 4454).

From a praxeological point of view, mathematics education can be regarded as a social phenomenon and practices can be understood as a recurring pattern of how children and teachers act and speak across situations, through which the participants in the interaction take up and work on a specific teaching topic in relation to each other. Following Cobb and collages (2001, p. 121), "a practice is seen to be an emergent phenomenon rather than an already-established way of reasoning and communicating into which students are to be inducted".

In this sense, mathematical, subject-related practices are understood as ways of discursively dealing with subject-related questions that become established in classroom discourse, e.g. arguing mathematically or assigning subject-related meaning to signs and symbols (Cobb et al., 2001). Learning can be seen as increasingly competent participation in a practice (Lave & Wenger, 1991), and mathematical learning as a change in participation in subject-related practices (Heyd-Metzuyamin et al., 2019).

However, participation in subject-specific task-processing practices does not depend solely on the individual and their assets, but also on the way teaching discourse is understood as a discursive practice and its participatory possibilities. In the example of explaining, a distinction can be made between orchestrated explaining, in which several children explain knowledge under the guidance of the teacher, and solo explaining. The former is strongly guided by the teacher and follows a sequence described as initiation-response-evaluation (IRE), i.e. introduction by the teacher, response by the learners and subsequent evaluation by the teacher (Mehan, 1979; Voigt, 1994).

Design of the Study

In our project IGEL M (Inclusive practices in shared learning opportunities in mathematics) we develop existing learning environments further by conducting didactic teaching-learning experiments for inclusive learning settings and by analysing mathematical learning processes from a qualitative perspective (Häsel-Weide & Nührenbörger, 2022). We accompanied classes during their time in primary school and visited them 4–5 times each school year from 2018 to 2023. In cooperation between the teacher of the class and the authors of the paper we planned learning environments, selected material and developed further. Each subject was realised in two consecutive lessons. The lessons, carried out by the teacher, were video-graphed and used to a) answer the research questions as well as b) to reflect jointly the quality of the learning. The videos were qualitatively analysed by following an interactionist and epistemological perspective (Steinbring, 2005), focusing on mathematical, discursive and difference practices Our main question is: Which practices characterise the interaction between teachers and children with different assets? We distinguished between subject-related practices in discourse, discourse practices in mathematics and the relationship between.

The analyses follow five analytical steps: (1) Video scenes with episodes in which interpretive hypotheses can arise spontaneously according to the research question. (2) These are transcribed and (3) are paraphrased and interpreted in a turn-by-turn analysis by the participating researchers. (4) In discourse, a plausible typification of practices is elaborated by categorising patterns of interaction or activities. (5) The practices are compared with other analyses of other scenes and examined in a generalised way (Voigt, 1994).

Results

Result of the analyses are the reconstruction of content-related practices in discourse, discursive practices in the subject and practices of difference as well as their interwoven relationship (Häsel-Weide & Nührenbörger, 2022). In the following, they are characterised and illustrated by means of two contrasting examples. The examples are taken from a lesson in which the children were asked to find sequences of numbers that would lead to a target number (Figure 1, Steinbring, 2015).

Episode 1: Ilkay explains relations between numbers

When the teacher comes to Ilkay and Abdul, who are working together, she first asks how much the children have worked together on the task, emphasising that each child should be involved in the work process. She turns to Abdul and asks him, “Did you let Ilkay do something?” Abdul explains that they found the number sequences by sharing the sequences. Once the genesis of the number sequence is clarified in that way, the teacher asks the children to explain how they sorted the sequences (Figure 1). She poses the question directly to Ilkay, who explains:

1	Ilkay	Uh, this one here, calculating here, so here you always have one, two, three, four and so on
2	Teacher	Mmh.
3	Ilkay	And here we always count, wait (*4 sec. pause*).
4	Abdul	Ilkay, we always have this.
5	Ilkay	Here we always calculate minus one.
6	Teacher	Oh okay, right.

7	Ilkay	And here the middle number always remains the same.
8	Teacher	Aha.
9	Ilkay	And this, here.
10	Teacher	Mmh.
11	Ilkay	Here we always calculate plus one. And here, so these results are always.
12	Teacher	What was that again (*points at the target number of the first number sequence*)? How do you call that?
13	Ilkay	Forty-five.
14	Teacher	No, how do you call that this (*points at the target number of the first number sequence*)?
15	Abdul	(*points at the word "target number" on the worksheet*)
16	Ilkay	Ah, target number.
17	Teacher	Mmm.
18	Ilkay	That's always forty-five.
19	Teacher	That's amazing.

The discourse is one-sided between Ilkay and the teacher. The teacher gives Ilkay the space to demonstrate his technical knowledge and highlights his competences and positioned him as competent (Johnson et al., 2022), while Abdul can neither directly demonstrate his technical expertise nor receive recognition for his reticence. He takes part in the interaction when Ilkay shows difficulties and supports him by reminding him on of their procedure (turn 4) or pointing at the fitting word on the work sheet (turn 15). The teacher confirms the statements, and in some places a more precise explanation is requested. Overall, the teacher seems to be primarily concerned with gaining insight into Ilkay's findings. Ilkay's explanation focuses on the relationship between numbers in the same position. He describes for example, that in order to get to the number in the first position of the number sequence, you have to subtract 1. His description is correct, but remains mathematically superficial, describing the relationships between individual numbers without considering the opposing effects of the changes of the first and last number. The teacher strengthens the explaining practice with short confirmations and praises it at the end. Besides, she deepens his description by asking for the agreed terms (starting number, middle number, target number). To summarise, the impression arises that descriptive practice is established here with a focus on relationships between individual numbers using fixed terms.

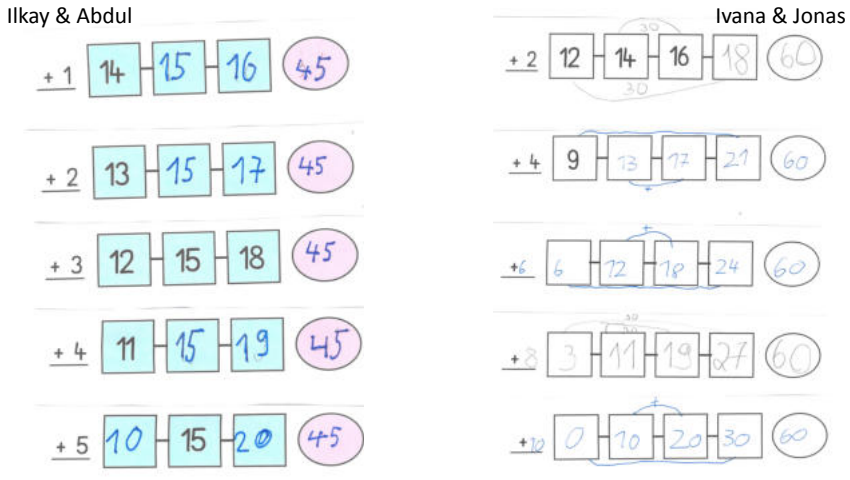

Figure 1: Sequences of numbers that are discussed in the episodes 1 and 2

Episode 2: Ivana and Jonas extend the border of natural number

The following episode is from the next day's lesson where the children are asked to find number sequences with an odd figure of numbers (Figure 1). Jonas and Ivana asked the teacher for help because they could not find more sequences:

1	Teacher	Mmm. Let's think about that, what is already given? What do you already know about this number sequence?
2	Jonas	Hmm, we know that this, uh, the result is always sixty (*points at the number sequences which are already filled in*).
3	Teacher	Why don't you fill that one in already? We're safe on that.
4	Ivana	(*writes 60 as the target, which adds plus 12*)
5	Teacher	Well done.
6	Jonas	And it has always been like this, here a plus, there a minus and always minus three here and plus three there.
7	Teacher	Mmh.
8	Ivana	And we did recognize something. We added this (*points at the number 18 of the first number sequence*) and this number *(points at the number 12*) and then it's thirty and if you add these (*points at the numbers 14 and 16*) then it's also thirty.

The episode shows that the children report their previous discoveries together, complementing each other without one child being addressed in particular. The order in which Jonas' mentions the changes between numbers (here a plus, there a minus) suggests that these findings were related. Ivana also describes relationships in a sequence, using concrete numbers that are general in nature. After the description of their discoveries, the teacher asks about the problem, without particularly much comment on the explanation. Jonas explains that they would then have to start the next sequence with the addition number 12 with a zero (Figure 1), because otherwise they would have to use a negative number and "That would not work". After the teacher brings this in question.

11	Teacher	Mmm. Why do you start from zero, when v you go down here (*points at the number sequence, which adds 12*)?
12	Jonas	Otherwise, you would need to start with a negative number and that wouldn't work.
13	Teacher	That wouldn't work? Why not? Where do you see that? Is it written anywhere, that you are not allowed to use negative numbers?
14	Jonas	(*shakes his head*)
15	Teacher	Which negative number would be fitting then?
16	Jonas	Minus three.
17	Teacher	Right, why don't you write that down?
18	Jonas	(*writes down -3 as starting number of the number sequence, which adds 12*)

After both children had been involved in the interaction on an equal footing at the beginning, an interaction develops here too, which primarily takes place between one child (Jonas) and the teacher. However, this seems to result from the course of interaction without Jonas being addressed exclusively. In turn 11, the teacher addresses both children. In terms of content, the argumentation makes it clear that the children have identified and used structures in the number sequences. After the formal border of the number set appears to have been fallen by the teacher's statement, they also have no difficulty finding the negative number. The discussion is not about the fact that or why there are numbers smaller than zero, but the socio-mathematical norm of working in the domain of natural numbers is overturned.

Comparing the two episodes

A comparison of the two scenes shows that the second scene is about extending the children's knowledge. The starting point of the interaction is a question from the children to the teacher, whereupon the teacher first obtains an overview of the content of the knowledge. The children practice an explanation that shows the understanding of relationships, supported by a corresponding presentation practice with arrows in the document. Erath (2017) describes this as an explanatory practice with which mathematical topics, representations or procedures are named, formulated, linked or even evaluated. This discussion, which is based on equal judgement, then leads to an extension of knowledge in a dialogue between the teacher and Jonas. In contrast, the interest in knowledge in the first scene is focused on the teacher, who wants to learn about a child's insights and addresses him accordingly. The findings that become visible in the argumentation practice are reinforced by demanding specialised terminology. Direct addressing allows children to show their competences, but at the same time it seems necessary to create space in the interaction to expand the insight. The interaction practices therefore appear to vary depending on the attributed capability of the children.

The content-related practices also differ, possibly depending on the competencies that the children show and the adaptive reaction of the teacher. However, there can also be a danger here if process-orientated practices are reinforced and no expansion is encouraged. It should be borne in mind that the selected scenes were small sections and that, of course, children with difficulties in particular can achieve very good individual performance in describing even the superficial level, which should then also be recognised.

Reconstructed practices in math discourse

Looking at the mathematical practices of explaining and representing more generally, the reconstructed practices can be located between two poles. Even, if the learning environments are following the idea of conceptual focus for all children, the reconstructed practices of explanation and representation do not necessarily reflect the understanding-orientated character. Instead, the interaction analyses show that the concrete discourse takes place between a rule-guiding and understanding-oriented character and also alternates between the two (Figure 2). In the learning support of a small group, i.e. in interactive situations between the teacher and some children, discourse practice support also moves between focusing on the child with difficulties in learning mathematics, who has been given the opportunity of professional and social participation in a special way at this moment, and opening up to the equal-based discursive participation of several children (Figure 2). This is also evident when the learning environment is designed for collaboration between children with different assets. This means that the teacher recognises and focuses on specific difficulties when supporting learning. A one-sided content and social support is established between one child and the teacher, while at the same time other children are not actively involved. If we look at the content of the discourse, we see patterns of interaction that are geared towards eliciting knowledge (Voigt, 1994), while discourses of extending and reflecting knowledge can be contrasted with this. These practices differ between different discourses in the same class and sometimes even change during the discourse.

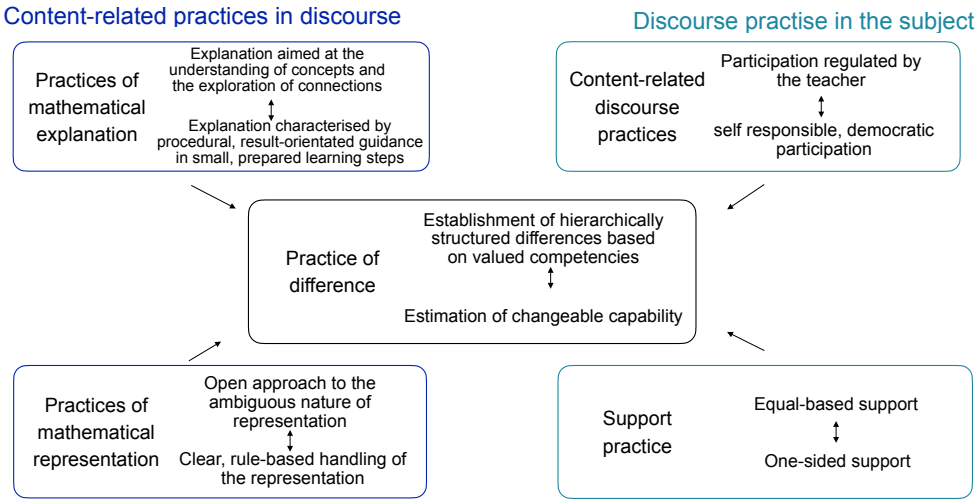

Figure 2: Practices in math discourse

Discussion and concluding remarks

The findings are not surprising in themselves, but reflect international findings on mathematics learning (Heyd-Metzuyamin et al., 2019; Moschovich, 2015). Of particular importance is the interplay between subject-specific and discursive practices, which in turn characterises differentiation practices.

In principle, it can be seen that the learning environment for exploring mathematical contexts offers the children a variety of approaches despite their different mathematical learning prerequisites and at the same time has the potential for interactive negotiation between the children. The children can communicate with each other and acquire knowledge collaboratively despite their different knowledge of the subject matter. This shows how individual math learning is woven into the practices. The practices of mathematical explanation and mathematical representation move in the field of tension between rather rule-guided and procedure-orientated interpretations of the content on the one hand and a rather open, ambiguous discourse about conceptual backgrounds and differences in interpretation on the other.

The mathematical practices establish themselves in connection with social practices of constructive support and discursive practices of negotiating knowledge (see Figure 2). The interplay of content and discursive practices creates differences that are revealed in the way in which participation in more rule-guided or understanding-orientated practices takes place and the extent to which this participation takes place as part of an equal discourse of all participants or as unilateral and initiated by the teacher and oriented towards a unilateral, dyadic discourse.

The Work of Listening to and Hearing Children's Mathematical Competence

Mark Hoover[1] and Deborah Loewenberg Ball[1]

[1]University of Michigan USA; dball@umich.edu

This paper focuses on the work of attending to children's mathematical productions. Young children speak in their own terms, use gestures and drawings and have their own developed ideas and ways of thinking. The predominant construction of mathematics as a domain of correctness and precision, with a particular conception of proof and proving, impedes the openness, attention, and curiosity required to hear children's ideas. This pattern is more pronounced for children of historically marginalized identities, who are regularly positioned through deficit lenses. Drawing on data from classroom discussions, this paper analyzes the demands of listening to and hearing the competence in children's mathematics. The analyses contribute to developing more dynamic theoretical models of mathematical knowledge for teaching (MKT) in intersection with deliberate practice to advance equity.

Keywords: Teaching, mathematical knowledge for teaching, student thinking.

Introduction

No aspect of the work of teaching is more fundamental than that of listening to students (Ball, 1997; Schultz, 2003). It is what makes teaching difficult, but also what makes it fascinating. Many learners, especially those of historically marginalized identities, experience mathematics classrooms as unwelcoming, where they do not feel seen or heard. One common pattern is for teachers to listen evaluatively for whether students "get it." Attending to what is wrong or lacking in children's thinking reinforces their identities as "struggling." The brilliance of their mathematical observations, methods, and solutions goes unseen and unheard (Leonard & Martin, 2013; Willis, 2020).

This paper argues that advancing children's mathematical flourishing depends fundamentally on hearing, valuing, and using their ideas. Based on analysis of data from videorecorded interactions during mathematics lessons, we describe and analyze the nature and demands of listening across differences in the work of teaching elementary mathematics. These analyses further contribute to advancing more dynamic theoretical models of mathematical knowledge for teaching (MKT), theorizing them as critically intertwined with deliberate practice to advance equity.

Theoretical framework

Listening to students with the aim of hearing their ideas and being able to see how they make sense is foundational to supporting their learning. This study of listening in teaching is shaped by three intersecting theoretical lenses.

First is positioning theory (Davies & Harré, 1990) which shows how the construction of self is shaped through discourses that form storylines about the nature of competence and who is seen as competent. These discourses exist at both the micro-interactional level of day-to-day relationships in classrooms and through systems, historical patterns, and dominant narratives that operate at the macro level. These levels are intertwined and together construct the environments in which children's identities

and competence evolve and, specifically, in which Black and Brown learners are regularly pushed away from mathematical identification and success. These patterns are of long standing, rooted in the history of worldwide scientific racism (Darby & Rury, 2018) together with a pervasive orientation to "error" in mathematics teaching. Teaching that seeks to break with deficit orientations that concentrate on students' "misconceptions" and shortcomings depends on close listening that assumes that children are making sense for good reasons.

The second frame that shapes this research is how mathematics functions as a racialized, classist, and gendered space that has not welcomed a broad range of thinkers to develop the knowledge of the field. Proof and proving, central to the epistemology of the domain, center particular ways of knowing and value them over others (Dahlgren, 2024; Ladson-Billings, 2000). These ways of knowing have been predominantly the property of Western, white, and male mathematicians; ethnomathematics, a central focus for many mathematics education scholars (Ascher, 2017; D'Ambrosio, 1999; Powell & Frankenstein, 1997; Rosa et al., 2016), is, however, still often perceived as "folk" or primitive (Hottinger, 2018). Teachers' narrow perception of mathematics and the narrow representation of mathematics narrowly in curriculum materials combine to portray the domain as one in which only some people belong, and in which only some ways of knowing are valued. This shapes the work of hearing the things students say, making it challenging to notice or appreciate ideas consonant with other systems of knowing. Listening depends on an openness about what mathematics is and what it means to know it, making it possible to hear unconventional ideas and nonstandard approaches to reasoning.

The third theoretical frame underlying this research is that of the theory of mathematical knowledge for teaching (MKT). Hearing students' ideas, valuing their thinking, and being able to identify the mathematical competence in their ideas and their ways of explaining and representing them is mathematically demanding work. It requires a special kind of mathematical understanding, different from the mathematical expertise of mathematicians (Ball, 2017; Ball et al., 2008). This kind of understanding entails a shift from one's own ideas and ways of reasoning to being able to take up others' perspectives — in this case, the perspectives of children. Believing in the brilliance of Black children (Leonard & Martin, 2013) and that equity matters are essential. This sort of real listening requires both a commitment to understanding students' strengths and flexible MKT (Ball et al., 2008; Hill et al., 2005). As we examine the work of listening, we seek to identify the mathematical knowing that arises in the course of teachers' efforts to hear.

Method

This research uses a qualitative case approach, situated in a mathematics program for young learners that our research group conducts every summer. This program is designed to foster the participating children's mathematical flourishing by engaging them in challenging mathematics problems, in working collectively to develop ideas, approaches, explanations, and language, and in exercising agency and competence in the work. This program is a central component of our research laboratory because it enables us to closely examine student thinking, the work of teaching, and the role and use of mathematical tasks. Further, it affords the opportunity to study how mathematical knowledge for teaching is fundamentally intertwined with attention to equity in instruction. The mathematical

content of the instruction in the program includes work on fractions as well as some complex and unfamiliar mathematics problems. Mathematical practices and techniques include explaining, representing, proving complex claims, presenting in public, and listening to others' mathematical ideas attentively, respectfully, and critically.

The specific class on which this paper is based involved 30 grade 5 learners: 21 African American, 5 Latine, and 4 White children. In the program, the children worked on mathematics for 2½ hours each day for five days each across two weeks.

In order to study what is involved in listening to students' mathematical thinking, we meticulously recorded every class in the summer mathematics program and all individual conversations, using high quality video and audio recording equipment and techniques. We created detailed transcripts of classroom discourse, and additionally we represented aspects of embodiment, including how teachers and students moved in the space and their facial expressions. We paid careful attention to students' and teachers' language and the interplay in their mutual construction of meaning (McMahon, 2022; Sfard, 2009). Students' writing and drawings, e.g., in their class notebooks and on end-of-class checks ('exit tickets'), comprised further sources of evidence about students' ideas. We examined teachers' conversations with students about their work, seeking to understand their sense-making of these representations as a different form of listening to students.

To analyze the data, we created transcripts as a secondary record of classroom discourse, but our primary approaches rely on direct viewing of the video recordings so that we did not reduce the records to listening only to language (Sfard, 2021). Our analyses involved two stages. First, we examined the classroom interactions and discourse and identified spaces in which teachers' efforts to hear were apparent. These spaces were of different temporal lengths: what unified them as units of analysis was that they contained evidence of teachers working to understand, interpret, and take up students' contributions. Signs we looked for include teachers' questions and reframing of questions, students' responses, teachers' revoicing of students' ideas, and teachers' responses to student contributions. We indexed these and conducted open coding for elements of teachers' listening to students. Following McMahon (2022), we look for instances of teachers and students working to "get on the same page" in terms of mutual understanding, as well as moments of "talking past one another." After indexing the interactions during the class lessons, we conducted four rounds of coding based on our theoretical frames: (1) the degree of familiarity or novelty in the children's mathematical claims, questions, and statements; (2) the attunement of teachers' questions to students' statements; (3) teachers' apparent uptake, interpretation, and understanding of these contributions; (4) patterns in teachers' listening to students of different identities.

Findings

Based on our analysis, we identified six aspects of the work of listening to students that make visible the challenges of this crucial aspect of the work of teaching. Each entailed specialized understanding and uses of mathematical knowledge "in flight." Listening required both close attention to the actual words, representations, gestures, and tone of children's utterances, but also fluent mathematical interpreting and responding. It was also striking how much tentative hypothesizing about children's

meanings was involved and how the interpreting and responding were crucial to the dynamic checking of those hypotheses. The six aspects were:

1) Attending to children's talk as an intertwining of embodied communication, representations, and words. We identified many instances of children pointing, gesturing, using diagrams, and words in combination to express a mathematical idea or solution. For example, in explaining how they determined the fraction of this diagram that was shaded, a student pointed at the figure and said, "I saw *this* was the whole and then I counted 1, 2, 3, 4 and I knew it was ⅛."

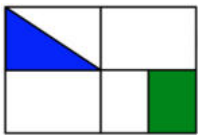

Figure 1: Fraction diagram for student discussion

The transcript of the student's words is incomplete as a representation of their statement. To fully hear what they are thinking requires watching where they point, seeing how they are counting 4, and what "this" refers to.

In another instance, a student showed a list they had written for equations for 10 and explained their strategy by indicating the list and saying, "I go up one and down one each time and that's how I know it is another one."

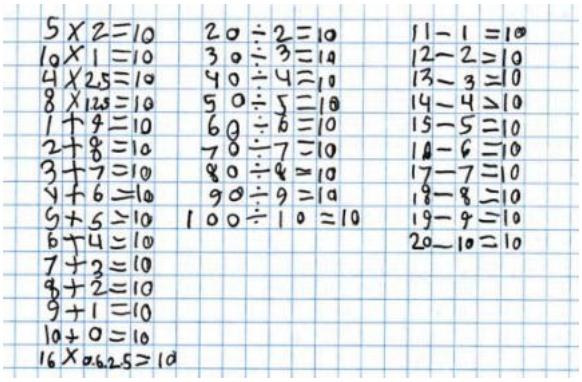

Figure 2: A student's list for equations for 10

We saw repeatedly that the work of listening required attending across more than words and interpreting the synchronized whole of children's "talk." The ubiquity of such "utterances" led us to avoid even enhanced transcripts for representing what students "said."

2) Suspending assumptions about children's use of language and probing for intentions and meanings. Children used language in ways that showed their sensible appropriation of words to describe something they are thinking, often using a term in a way that adults would not. Listening to students' ideas required a combination of mathematical knowing and an ability to hear and make sense of children's expressions and uses of language. This is a specialized kind of mathematical multilingualism necessary for teaching that includes the ways that young speakers use and invent language as they learn, combined with the differences in their out-of-school language contexts. We highlight here linguistic diversity related both to age and culture. One common example we saw

frequently in our data was children using the word "even" to refer to the idea of "equal" — e.g., when Chloe explains her classmate's reasoning for Figure 3, "Luis saw that the parts were not even so he made them even."

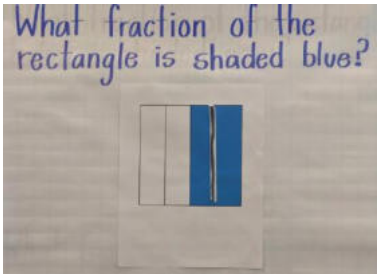

Figure 3: Fraction problem after Luis added a line to divide the single shaded blue rectangle in half

Children frequently used "boxes" for rectangles and said 0 was "not a number." In the course of explaining, they would use terms that made sense to them, and careful attention was needed for a teacher to hear their insight and not to immediately interpret them as wrong and interrupt their thinking. Using discretion to introduce a term is also part of this work, and we saw examples of refraining from pressing on language as well as using the opening to provide conventional language.

3) Thinking contextually and "historically" to construct possible hypotheses about how prior experiences with school mathematics might shape students' talk and thinking. As we coded the instances of teacher listening, there were examples of students saying things that reflected how they might have taken up an idea or an explanation in a previous grade in ways that distorted the math or reflected intermediate transition in their thinking. Examples included reading ½ as "one-twoth," a sensible generalization of the way other unit fractions are named, or saying that the 5 in 50 meant "fifty tens."

4) Posing questions that are understandable by students. We saw the regular need to probe or extend a student's idea, based on hearing and interpreting what they said. This complex work depended on, first, making sense of what the child said, and nimbly posing a question that opened an opportunity for the student to talk more, without leading or confusing their thinking. When Kassie, for example, argued that that "one and a half" of the rectangle was shaded, framing a question to follow up required quick thinking about what she was noticing:

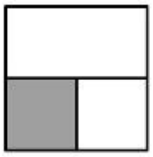

Figure 4: Fraction problem for Kassie's thinking

The work of following up a student's claim in ways that support their thinking was frequent and requires a quickness that is mathematically and pedagogically challenging.

(5) Managing the temptation to over-interpret out of a desire that students understand. Teaching is about helping students learn, and it is natural for teachers to hope that students

understand. The challenge we saw repeatedly was how to maintain both belief in a student's knowledge and simultaneously to be cautious and to probe so as not to assume common ground. One example was when a student, looking at the rectangle in Figure 4, said "I think it is NOT a fraction." This part of the work was, we identified, in tension with the second pattern above, suspending assumptions about students' use of language. "Not a fraction" might be a sensible way to make note of the fact that the parts are not equal. Or it could represent a conclusion that unless a figure is equally partitioned, it cannot be named with a fraction.

(6) Holding oneself accountable to students' talk and representations. Because students' expressions are often different in content, language, form, and even ideas, listening requires a conscious and deliberate effort to hear and make sense of what they are saying and showing. Further, it requires refraining from "taking over" students' utterances and restating them in accepted mathematical form and language. The tendency to revoice what students say often revealed a mis-hearing and an appropriation of their ideas to ones different from those they have expressed. In one example, a student named the number that the blue arrow is pointing to as "three fourths":

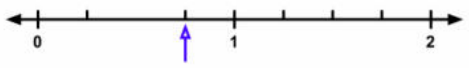

Figure 5: Blue-arrow fraction problem on a number line

Because this was the intended answer, an important next step in the work was to ask the student to explain their answer. Starting by pointing to the point labeled 0, the student counted, "One, two, three, four," pointing at each tick mark on the line. This explanation was a crucial contribution to the class's development of understanding about the number line because it surfaced the core idea that the interval from 0 to 1 constitutes the whole, and that one counts lengths, not tick marks. After the student explained their reasoning, it became the work for all the students to reach consensus about how to interpret this important mathematical object. If a teacher were to merely accept "three-fourths" without explanation, this mis-hearing would impede the mathematical work crucial to the content.

Although in this example, the student has an idea that might be seen as a misunderstanding, in fact it is part of the development of understanding of the number line that is crucial to emerge and be used in a class. When teachers do not recognize what students say, opportunities are lost. Many of our examples included cases where students had mathematically valid, if unexpected, ideas that, if unheard, would be missed opportunities to notice the competence of students' original mathematical thinking.

Discussion and implications

Across our analyses, three main themes stood out. One was the dynamic nature of using mathematical knowledge flexibly to hear students' language and other forms of expression. So much of the work of hearing students required listening "otherwise" (Lipari, 2009), stepping outside of one's own ways of thinking, yet depending on mathematical tools and sensibilities to make sense of others' meanings. Maintaining this duality in the effort to understand students' thinking was frequently evident and contributed to stretching the concept of MKT to be more about reasoning and using (Ball, 2017). A second theme was the importance of attending to racialized and gendered tropes about mathematical

competence and who is seen as competent. Actively working to disrupt patterns that value particular forms of talk and ways of presenting and expressing ideas was vital in listening to recognize their thinking and to hear their competence. The recurrence of this practice of hearing beyond normalized views of what counts as "knowing" and "understanding" required a broadening of conventional frames for competence. A third theme centered on language itself and reflected another crucial intersection of equity and mathematics. The learners in these data were linguistically diverse, including speakers of Black English and languages other than English. Further they spoke as children, not as adults. Our use of the term "multilingual" intentionally comprises the layering of child-language and ways of talking, as well as different linguistic identities and expression. We repeatedly documented the demands of listening multilingually tuned to mathematical ideas and reasoning.

These themes highlight the ways that listening mathematically comprises a combination of a special kind of ability to combine sensitivities to mathematical precision together with open attunement to young learners' own uses of language as they talk about mathematical ideas. It also entails a disposition to suspend the tendency to look for what is wrong, misunderstood, or incomplete that is often embedded in the very nature of mathematical analysis. Mathematical knowledge for teaching is fundamental to this work. Needed is a focus on supporting teachers to develop the fine-tuned capacity to listen mathematically. Important is to ensure opportunity to practice hearing, interpreting, probing, and responding to a variety of student talk and other forms of expression, beyond reading about students' conceptions or understanding. The dynamic nature of this work requires practice in real time with diverse students and varied contexts, and opportunities to identify threats to equity and practice with acting out commitments to listening "otherwise." Studies of ways to prepare and support teachers for this crucial work are an important next step to follow from this research.

Polya's method variant: Developing students' analytical thinking

Lavinia Lanting[1]

[1]University of Twente, Faculty of Electrical Engineering Mathematics and Computer Science, Enschede, the Netherlands; lavinia.lanting@gmail.com

In recent years, the level of basic mathematical skills as well as analytical thinking skills of secondary school students in the Netherlands has been on the decline, with consequences for the rest of these students' academic career. Polya's four step method for problem solving is a well-regarded and popular method throughout literature, which brings about the improvement of both students' attitudes towards mathematics and their (relational) understanding. In this paper a variation upon the method is proposed which aims to address the weaker aspects of Polya's method while enabling the students to develop their analytical thinking skills. In particular, the proposed method aims to promote the active use of mathematics as a language students can freely and easily express themselves in within the classroom so as to address the declining level of mastery within the subject mathematics.

Keywords: Polya's method, analytical thinking, systematic problem solving, mathematics teaching, reflection as a learning method.

Motivation

Thanks to the *Inspectie van het Onderwijs*, it has become clear over the last couple of years that the level for a number of basic (mathematical) skills of secondary school students in the Netherlands is too low. Especially critical reading, critical thinking and arithmetic, skills that play a role in almost every subject and that are important for developing analytical thinking skills of students, seem to remain very poorly developed. This often causes students to not understand what assignments require of them and to subsequently not be able to estimate or check the correctness of their own answers (Inspectie van het Onderwijs, 2022; Inspectie van het Onderwijs, 2023). The level of complexity and understanding that can be achieved for the subject of mathematics in particular suffers enormously from the low level of analytical thinking and reading comprehension (where, according to Prenger (2005), language knowledge and vocabulary also play an important role in the mathematical development of students). It is then becoming increasingly difficult to help students progress in their mathematical prowess: the students struggle with and remain stuck on the basics, leading them to learn in a purely instrumental way, using tricks and learning concepts by heart instead of really understanding the material and making it their own. This difficulty with basics results in repetition of what is supposed to be already acquired knowledge. This repetition then also becomes an increasingly significant part of the lesson, leaving little room for new topics, which must then be rushed through.

This decrease in mathematical knowledge is carried by the students throughout their entire academic career. In particular, in Inspectie van het Onderwijs (2022), it is reported that more and more secondary school students pass their final exams and proceed to tertiary education while the overall level of their analytical thinking and mathematical skills decreases. Students struggle then with the proposed mathematics courses in their further education, leading to high drop-out rates. In fact, correlation has been found to exist between the students' results in their final national high school exam, their GPA during their first year of university and their eventual graduation from a Bachelor

study programme (Hernandez-Martinez, 2016; Pinto & Koichu, 2023; Rach & Heinze, 2017; de Winter & Dodou, 2011). This knowledge gap between high school and university mathematics is a reoccurring issue which heavily impacts students and which is well documented across different countries and time periods (Higgins & Belward, 2009; Luk, 2005; Silius et al., 2011). The PISA 2022 study revealed for the EU in particular a trend in worsening educational performance and deeper inequality, with 30% of EU students not reaching a minimum proficiency level in mathematics (European Commission, Directorate-General for Education, Youth, Sport and Culture, 2024).

Students at the University of Twente have in past years had the opportunity to explore the advantages and disadvantages of Polya's four-step method for problem solving (Polya, 2004). Through this method, students were invited to complete assigned course work in a way that promotes understanding and mastering of the subject material. The method, with the addition of a reflection step (Mazur, 2016), was utilised by prof.dr. N.V. Litvak (Nelly) both at BSc (Bachelor of Science) and MSc (Master of Science) level for most of her courses (Litvak & Weedage, 2023). However, the introduction of the method brought about resistance from the students in spite of the clear benefits of utilising Polya's steps due to the amount of writing required, which the students were not used to.

The aim of this paper is to propose a problem solving method, inspired by Polya's method, to be introduced at the lower level of secondary school so as to provide students with a strong mathematical basis that they may trust upon throughout their academic career and to promote the development of analytical thinking from a young age. In particular, the proposed method is meant to bring forth the relational teaching and learning of mathematical topics and to bring about active discourse about mathematics through cooperation between students. Teaching within this method outlines the tasks of guiding the creation of an internal web through which students can place each new topic in relation to the ones already tackled, providing feedback as a form of personal development and assessment for the student, who may use this feedback to further grow and recognise both merits and demerits of their work and understanding, and promoting the cooperation among students. Teaching is here then understood as the fostering of the development of critical thinking among students and involves here also equipping the students with the understanding necessary to grade a fellow student and helping them develop mathematics as a (written) language students can clearly express themselves in.

In Heutinck (2022), a similar method to the one proposed in this work is introduced with the goal of replacing graded assessment with formative assessment that enables the development of relational understanding. The method proposed here has the final goal of being introduced as staple of the learning process within secondary school mathematics by which students regularly must use the method to complete exercises and develop a deeper understanding of the subject.

Theoretical framework

At the basis of this work sits the term **analytical thinking**, by which, based on the definition by Amer (2005), the ability is meant to be able to carry out the following thinking tasks upon a given problem:

- divide the given problem into main and sub-questions in order to be able to tackle the problem in a structured fashion;
- collect, organise and (possibly) visualise the data given in the problem;

- make connections between the given data of the problem;
- if possible, make connections between parts of the problem and own existing knowledge;
- make estimates for the answer required by the problem based on the given data;
- critically examine and analyse one's own process and the answer found so as to be able to indicate strengths, weaknesses and any present illogic;
- critically examine the process and the answer found by others so as to be able to indicate strengths, weaknesses and any present illogicality.

Someone portraying analytical thinking skills will, therefore, show interest in the workings behind processes and in the connections between subjects. This indicates that analytical thinking skills most likely develop in the presence of **relational understanding** (Skemp, 2006), understood as the ability:

- to understand how (mathematical) procedures, processes and rules work;
- to understand why certain methods may or may not work in certain situations;
- to understand why different areas of knowledge connect;
- to link new knowledge to existing knowledge.

Relational understanding is opposed to **instrumental understanding**, which can be understood as the application of rules without reason: while calculations can be performed, there is no understanding as to why the particular calculations should be carried out and why a certain method does or does not work. In particular, little to no connections are made between different pieces of knowledge, which makes memorisation rather difficult.

The idea of teaching analytical thinking skills to young students is not new. Morningside Academy, for example, has been implementing for years effective guidance in developing analytical thinking skills in the form of a variation on TAPS ('Think Aloud Paired Problem Solving') (Robbins, 2011), where students are taught to make use of 'private speech' (Berk, 1994) to guide themselves and classmates through new material and problems. Furthermore, analytical thinking is best developed through discussion and reasoning about the material, however, students hardly make use of such tools in the absence of the teacher (Murphy et al., 2014), meaning that thinking and sharing discoveries should be promoted in a different manner within the classroom.

The development of analytical thinking seems to be promoted by the use of modules regarding problem solving that includes the steps 'identify, define, explore, act, and look back' (Karenina et al., 2020), steps that are partially already present in Polya's method and which the method proposed in this paper aims to fully include. Additionally, previous research has shown the positive impact of Polya's method on students' attitude towards mathematics (Yapatang & Polyiem, 2022). In particular, Polya's method performs better than other educational methods (George & Enefu, 2019), is recommended as a classroom tool (Lee, 2017; Obiano & Parangat, 2023) and is even utilised as measure of mathematical thinking ability (Nurtamam & Jannah, 2024).

Proposed method

In Polya (2004), a method is described for solving problems systematically in four steps:

1. **Understanding the problem**: students are asked to read through the problem and to indicate in a clear manner what the question is asking of them and what (kind of) data is available to

them. Students are in this step then also invited to note down the interaction between the different pieces of data of the problem.

2. **Devising a plan**: requires students to use the data of the problem and known theory, situations and problems to come up with and write down a plan to be able to find a solution. The aim for students during this step should be to write down a sketch of the calculations needed to find the answer; it is not necessary to explain in extreme detail exactly what they are going to do. Students should in this step also write down any useful formulas as well as the theory and concepts that may be necessary for the assignment.
3. **Carrying out the plan**: students work out the problem based on their own drawn up plan.
4. **Looking back**: the purpose is for students to look back on the assignments so that they may learn from the process and better establish their knowledge. If the student has not found an answer, this step also serves as an opportunity to reflect on why their plan did not work and what the answer should have been.

While the method seems rather complete, it is the experience of the author and of many colleagues that step 2 very often poses a challenge to students and is experienced as unnecessarily difficult. Students, even university ones with much deeper knowledge of the mathematics necessary to complete the assignment, often get stuck at this step, causing them to either skip it or to abandon the assignment (Muniri & Choirudin, 2022). In addition, being able to reflect on one's own work is a skill that students learn best under the supervision of a teacher. Spending time within the classroom is a must to allow students to really develop this skill (Marzano & Miedema, 2018). For these reasons a new method is proposed.

The proposed method involves two separate stages: one outside of the classroom and one inside of it. During the outside stage, students are handed assignments to be solved by the time inside stage takes place. These assignments should be solved according to the following three steps:

1. **Preparation**: the students are asked to read through the assignment and to describe in own words what the goal of the task at hand is and what data is available to them. Students make in this step also an overview of the data and, if necessary, compile the data into a sketch to better describe the situation. In addition, students are here asked to indicate how they think the answer could be achieved. Some guiding questions may be provided to help the students along the way, such as: 'What pieces of information do you need to find the answer?'
2. **Calculations**: students are asked to follow up on step 1 by performing the calculations in an orderly manner. Students have to write out each calculation clearly by placing each new step on a new line and by indicating in a few words what they are doing.
3. **Explanation and Reflection**: students are asked to, by writing complete sentences, explain each step of their calculation. Guiding questions may again be provided to help students along the way such as: 'Why may you make this calculation' or 'Why did you take this step in your process and what did it help you achieve?'.
   If students are unable to reach a conclusion during this step, they are instead asked to explain what they were able to do and achieve (line by line) and to answer the following questions:
   - What have you achieved so far?
   - Where did you get stuck?

- Which pieces of information were you missing in order to continue?
- What did you expect the answer to be? Give an estimate and explain why you think this estimate could be correct.

By the beginning of the inside stage, students must have attempted to solve the given assignments and should bring their work to class to reflect upon their work and that of classmates.

During the inside stage, students are divided into groups and given time to discuss their solutions. This is a chance for students to actively talk about mathematics, their own process and to discover alternate routes that may lead to the same conclusion and learn the logic behind them. Additionally, students may in this step ask their peers about assignments they got stuck on and theory they did not understand. The teacher guides the discussion where needed and, by the end of the group discussion, solves the assignments on the board for all to see. Students must use this time to actively correct their own work and ask questions where necessary so that they may use what they learn for the final step: reflecting. At the end of the inside stage, students are handed a reflection sheet upon which they must indicate their understanding of the topics involved in the assignments (the list of topics is to be provided by the teacher), write down what type of mistakes they made and reflect on the qualities of their work. Students reflect here also on how to tackle the weaker parts of their knowledge.

Figure 1 visualises schematically the proposed method from beginning to end.

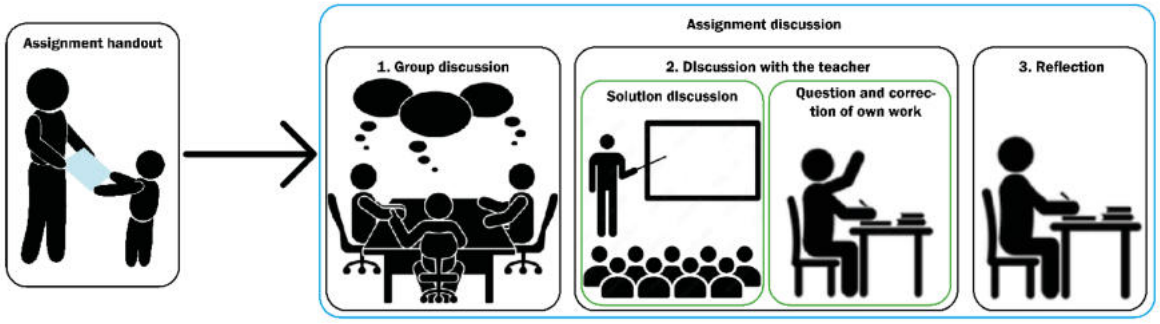

Figure 1: Schematic visualisation of the proposed method

Both stages should take place regularly, so as to invite students to often and consistently utilise mathematical terminology, logic and theory in the classroom. This way confidence in their mathematical skills may also be increased.

Compared to the standard Polya's method, the proposed approach has a number of theoretical advantages. The hurdle of having to set up a plan has been removed so that students may feel less discouraged to attempt the given assignment. Additionally, all the steps 'identify, define, explore, act, and look back' (Karenina et al., 2020) are properly addressed, with particular attention being given to the step 'look back', which now also lets students make use of 'private speech' (Berk, 1994) through having to explain their process in full sentences and through discussing their work with peers in a group discussion. Students are also given in this version of the method ample time and guidance within the classroom to learn how to discuss and reason about mathematics, effectively developing its use as a language with its own rules, demands and terminology, by which analytical thinking is then also better developed. The consistent use of the method throughout the students' secondary

school career may also prove to equip students with a valuable tool to tackle problems with: if a student feels stuck, they may refer back to the method, independent of the context.

Research and outlook

The proposed method was introduced within a K–8 class for a period of five weeks, during which students worked through one single chapter of their mathematics curriculum about Geometry. Three assignments were handed out to the students to work through according to the proposed method and, accordingly, three entire lesson hours were dedicated to the inside stage of the method. During the fifth week, the participating students had a test to conclude the chapter.

The implementation of this method during research was intensive, taking a lot of time out of the scheduled lesson time. This was due to the time constraints placed upon the research. A consistent implementation with few exercises per topic would benefit how time consuming the method can be.

Additionally, implementation in the class, due to the high amount of writing required by the method, was initially met with resistance. Preliminary results obtained in interviews with students reveal, however, that students later saw the benefits of the method and particularly appreciated being able to fall back on a clear plan whenever they would be stuck on an exercise.

Conclusion

The proposed method aims to be systematically introduced and applied within the subject of mathematics throughout secondary school (but may also be utilised within higher forms of education). The purpose is to use the method to help students develop strong analytical skills from a young age.

The proposed method improves upon aspects of Polya's method that, either according to literature or by own experience, may hinder the students' development of analytical skills and prevent, therefore, the development of mathematics as a language students may express themselves freely and easily in. Preliminary results already show a significant improvement in students' amount and quality of produced text in explanation to their steps when solving exercises.

The drawback to this implementation is the amount of classroom time required, which is a significant consideration when wanting to consistently utilise the method throughout secondary schools. For this reason, research on a greater scale and with greater consistency should be carried out as preliminary results do indicate that the method positively affects students: the produced text explaining students' steps in exercises increased both in quality and quantity. It would then also be of interest to compare the effects of the method across multiple countries, educational systems and schools.

How expert mathematics teachers play 'status games'

Nick McIvor, Jeremy Hodgen, Sai Loo and Rachel Marks

UCL Institute of Education, London WC1H 0AL, UK; nick.mcivor@ucl.ac.uk

This paper argues that the concept of 'status', as understood by practitioners of improvised theatre, can be usefully deployed to illuminate some of the ways in which expert teachers of mathematics interact with their pupils. It suggests that this idea from the theatre can be thought of as a simplification of 'positioning theory', as it has been discussed in mathematics education literature and that it may offer a practical approach for classroom practitioners who wish to implement certain potentially productive classroom practices. The final section re-examines a set of observation and interview data from an earlier study to exemplify what 'status games' look like in the classroom.

Keywords: Secondary school mathematics, improvisation, expert teaching, positioning theory, interactions.

Introduction

The concept of 'status' as a tool for actors was developed by Keith Johnstone (1933–2033) when he was working as a teacher at Royal Court Theatre in London in the early 1960s. Faced with a group of actors who appeared unable to create 'convincingly ordinary' conversations, he gave them the instruction, "try to get your status just a little above or below your partner's", and in so doing, invented his first 'status game'. He reported that "the actors seemed to know exactly what I meant and the work was transformed…scenes became 'authentic', and actors seemed marvellously observant" (Johnstone, 1981, p. 33). Johnstone viewed status primarily as a practical tool for performers but also understood that it could be used to interpret social interactions, and it is the second – interpretive – application which, I will argue, captures elements of positioning theory. No attempt will be made to suggest some kind of equivalence between the complex, multidimensional structure of positioning theory, and the the much simpler notion of status. What will be argued is that the original purpose of status – as a tool for performers – has the potential to help teachers enact practices which the more complex framework of positioning theory points to as potentially useful in the classroom.

Theoretical background

According to Johnstone "status is a confusing term unless it's understood as something one *does*" (1981, p. 36) and to illustrate the point, offers the vignette in Table 1. To fully understand the exchange, it is important to know that 'Duchess' is the highest possible rank in the British aristocracy.

Table 1: adapted from Johnstone (1981, p. 36)

SPEAKER	SPEECH	STATUS CODING
1 TRAMP	'Ere! Where are you going?	***Tramp lowers the status of the Duchess***
2 DUCHESS	I'm sorry, I didn't quite catch . . .	***Duchess raises the status of the Tramp***
3 TRAMP	Are you deaf as well as blind?	***Tramp lowers the status of the Duchess*** further

Line (1) from the Tramp lowers the relative status of the Duchess in two ways: the content of what he says positions her as the transgressor (presumably she has intruded on his space in some way), and with his aggressive tone he positions himself someone with the right to make demands of her, in this this case, the right to demanding an explanation. This single line draws attention to what Johnstone identifies as a feature of nearly all status moves, what he calls "the 'see-saw' principle: 'I go up and you go down'" (1981, p. 37). There are exceptions to this principle which Johnstone addresses, however, in this particular exchange, the reciprocal nature of these moves is strongly evident. The way in which I have described line (1) suggests that the Tramp's words are status-lowering for the Duchess, while the tone is status-raising for himself, but it would have been equally plausible to switch these justifications around; what would not have changed is the overall effect, which is the change in their relative status. In (2) the Duchess, perhaps surprisingly given her title, seems to accept this reduced status, accepting her given position as the transgressor, and raising the Tramp still higher (or lowering herself further?) with an apology. By the end of this line, the normal social hierarchy has been reversed, and, at least in the context this interaction, the Tramp now has a higher status than the Duchess. The Tramp now consolidates his position in (3), lowering the Duchess still further by adding the list of her failings and increasing the status gap between them. Although it sometimes difficult to identify whether the Tramp's status is rising, the Duchess's is falling, or both are happening at once, what is clear is the direction in which the see-saw is moving, and for this reason, Johnstone tends to talk of 'status transactions' (e.g. Johnstone, 1981, p. 27), in preference to individual status moves.

Johnstone says a good deal about the dramatic impact of status, and status changes, suggesting that very large status gaps – particularly when they reverse normal expectations as in the example offered above – are often associated with comedy. He goes on to make the less obvious claim that when actors learn to use "minimum status gaps" (1981, p. 70) this can lead to more 'authentic' performances (1981, p. 33), and it is this idea of the 'reducing the gap' in relative status proves to be significant in the teaching episode analysed later.

There are intriguing echoes of status in van Langenhove and Harré's (1999) account of 'positioning theory', for example, their claim that "fluid positionings, not fixed roles, are used by people to cope with the situation they usually find themselves in" (1999, p. 17) resonates with Johnstone's discussion of "the difference between the status you are and the status you play (Johnstone, 1981, p. 36). Positioning theory sets out to "understand the dynamics of social episodes" (van Langenhove and Harré, 1999, p. 6) aligning with Johnstone's secondary purpose for considering 'status transactions' but digging little deeper, important differences soon emerge. Lagenhove and Harré identify three salient features of these episodes on which they base their analysis: the first of these is described as 'the moral rights and obligations' of the participants, the second is their conversational history and the third is what they actually say during the episode. Johnstone, as a theatre practitioner, is concerned with what is happening in the moment and has no real concern in the second of these features, the 'history' of the participants only being of interest to the extent that it is made explicit in the drama of the scene being played. Additionally, Lagenhove and Harré describe their framework as "tri-polar", consisting of "positions, storylines and relatively determinate speech acts" (van Langenhove & Harré, 1999, p. 18) which can be thought of as vertices of a triangle. The speech acts

of each individual impact on the positions of all the participants in the scene, and also with the over-arching storyline which interact dynamically in a much more complex way than in Johnstone's see-saw with a protagonist at each end.

Applying these ideas to the exchange between the Duchess and the Tramp recorded above, we have an initial 'moral positioning' of the two central characters implied by their names, which are really markers of traditional social rank. The scene takes place in the UK, where tradition also assigns certain rights and obligations to these ranks – the Duchess is wealthy and has high social status, and can therefore assume a good deal authority in most social situations, in contrast, the Tramp is poor and his minimal social standing confers very few rights, and an obligation to 'know his place'. If these social positions play out in the standard way, we might expect one of the following 'storylines': the Duchess ignores him and continues on her way, or she takes pity on his unfortunate state and makes some charitable gesture towards him. What these two storylines have in common is that they are determined by the action of the Duchess, but the story that actually unfolds is very different from either of these: instead of being about a powerful individual demonstrating either generosity or hard-heartedness, it is one of the underdog standing up to the powerful. This story is initiated by the Tramp's first 'determinate speech act' (1), which asserts his moral right to pass judgement on the Duchess and demands an apology. Johnstone's narrow focus on the relative status of the participants offers no insight into the way the storyline has changed beyond the general observation that 'audiences enjoy a contrast between the status played and the social status' (Johnstone, 1981, p. 36). From an analytical viewpoint, this is a significant omission.

There are, however, significant overlaps between the analysis provided by the two frameworks. The Tramp's 'determinate speech act' (1), as previously stated, positions the Duchess as the transgressor and the Tramp as victim. According to Lagenhove and Harré's framework, this is a 'first order positioning' move, which assigns new – and perhaps unexpected – rights and obligations on both participants, a change which is also captured by the 'see-saw' metaphor dscussed earlier. The Duchess could potentially respond in 'second order positioning' move, reasserting her social superiority and wealth – in Johnstone's terms, a status-raising move – and challenging the positioning proposed by the Tramp, but in fact, her words in (2) reinforce the position she has been given, which was also captured by the earlier analysis. When we reach the Tramp's words in (3) he repositions her again as guilty of further trangressions – in Johnstone's terms, lowering her status further. It is therefore argued that Johnstone's one-dimensional notion of status, while ignoring major features of positioning theory, does, at least in this instance, capture one important aspect of the relative positioning of the participants.

I now turn from the rather unlikely scenario of aristocrats arguing with tramps, to the more familiar setting of the mathematics classroom.

Drageset and Ell's (2024) review of literature around talk moves and discourse patterns in the mathematics classroom is concerned with the issue of equitable access to mathematical ideas for all learners. Using the lens of positioning theory, they analysed 44 separate studies to identify patterns of interaction which "can help us think about the relationships among teachers, students, and mathematics and the implications of these for equity in mathematics learning" (Drageset & Ell, 2024,

p. 354). In line with the tri-polar framework described earlier, they summarise their findings by identifying 5 archetypal 'teacher positions' grouped within three 'transcendent storylines', associating each position with particular types of 'communication actions' (see Table 2).

Table 2: adapted from Drageset and Ell (2024, p. 359)

STORYLINE	TEACHER POSITION	COMMUNICATION ACTIONS
Teachers as providers of insight	A teacher who tells	Telling to initiate student work Telling how to do Telling about connections
	A teacher who supports	Reducing complexity Assessing Progressing student thinking
Teachers as facilitators of learning	A teacher who uses student ideas to create learning	Providing access and sharing Pointing out Reasoning with a student idea
	A teacher who orchestrates	Managing Developing ideas Focusing on peer thinking
Teachers as participants in learning	A teacher who participates	Collaborating Acting in role

In their description of the first of these storylines – teachers as providers of insight – the authors state that both of the accompanying teacher positions "are based on a teacher who claims power and consequently positions students as subordinate" (Drageset & Ell, 2024, p. 362). It would seem reasonable to interpret this using the language of Johnstone as 'the teacher claiming high status relative to the pupil'. There are, however, two different teacher positions that are aligned with this storyline which are described in quite different ways. 'A teacher who tells' expects the pupil(s) to either listen passively, or to ask for further clarification where necessary, but it does not allow for the possibility of the pupil to offering ideas of their own. In contrast, 'a teacher who supports', while still adopting a high status position, does allow limited space for the pupil to contribute, perhaps by sharing their work for the teacher to verify – or potentially challenge – its correctness. To seriously engage with a pupil's work positions them as at least potentially being the possessor of useful knowledge, so a teacher who does this can, in Johnstone's terms, be described as raising the status of the pupil involved. I therefore argue that 'a teacher who supports' is working with a narrower status gap between themselves and their pupils than one who merely tells.

The third position – a teacher who uses student ideas to create learning – "describes a position where the learning should start with the student's ideas" (Drageset & Ell, 2024, p. 365). A teacher who places pupil ideas at the heart of the classroom discourse is significantly raising the status of those learners. The teacher being described here is not simply acknowledging the value of pupil thinking but using it as "a springboard to develop thinking together" (Drageset & Ell, 2024, p. 366), which represents a much larger increase in the status of pupils than the one bestowed by the 'teacher who supports' and narrows that status gap between teacher and pupils still further. The fourth position of 'a teacher who orchestrates' continues this pattern – the gap between teacher and pupils has now

narrowed to the point where the teacher retains the right to manage the discussion, but all of the content is now provided by the learners – and the final position of 'a teacher who participates' describes a situation where the status gap has disappeared.

The teacher positions in column two can therefore be seen a hierarchy of 'status gaps' between teacher and students: it is largest on the top row, where the teacher is 'telling' and the students are listening passively, and smallest at the bottom where the teacher us collaborating with their students as equals. This narrowing of the status gap corresponds to increasing levels of student involvement, suggesting that a teacher who wishes to increase the involvement of their pupils in classroom discourse should consider ways of reducing that gap.

Next, I describe an episode in secondary school classroom which shows a teacher managing their status, and the status gap between themselves and their pupils, to conduct a productive discussion.

Data source

The interaction shown in Table 3 appears in McIvor et al. (2023) where it was used to illustrate a skilled mathematics teacher improvising in the classroom. The concept of 'improvisation' is peripheral to the discussion here, but it is helpful for the reader to understand that the dialogue recorded below was not part of the teacher's carefully planned exposition and emerged in response to many pupils revealing that they were unable to correctly draw a number line showing negative values. This had been addressed in detail in previous lessons, so the teacher had not prepared any material relevant to this content; everything she says and does in this episode is therefore 'improvised' in the everyday sense of 'made-up on the spot'. The mathematics teacher involved is a highly regarded practitioner teacher in her 12th year of professional practice. It was video recorded during a lesson with a group of 11–12-year-old learners which was the 5th in a sequence addressing the topic of directed numbers. The teacher was interviewed on the same day to discuss the decisions she made, and the videorecording used to remind her of key episodes. A full account of the data-collection procedure can be found in the original paper.

Analysis and discussion of a classroom interaction through the lens of status

Pupils had repeatedly failed to draw number lines which correctly showed the values -9 and -5 in relation to zero. The teacher collected three number lines drawn by different pupils on mini-whiteboards and the extract below describes the discussion of one (incorrect) representation.

Table 3: Number line discussion between teacher (T) and pupils (P1-P4) coded for status

	SPEECH/ACTIONS	STATUS TRANSACTION
1 T	What do we want to say about this, [Pupil 1 Name]? 	***Teacher claims high status*** by issuing a clear instruction ***Teacher raises the status of Pupil 1*** by addressing them by name and positioning them as the owner of valuable knowledge
2 P1	The 5 and the 9 should swap places because… because the number isn't… because it isn't…(*inaudible*)… like … on the positive side	***Pupil 1 raises their own status*** by providing an answer

3 T	(*Slowly, tentatively*) It doesn't go on the positive side… I think I know what you're trying to say to me. So, you're saying that the negative five and the negative nine should be the other way round.	***Teacher raises the status of Pupil 1*** further by reinterpreting their answer and designating it as correct
4 T	(*To class*) Why should they be the other way around? Think about the language that we're using with this.	***Teacher raises the status of all pupils*** by positioning them as knowledgeable
5 T	(T*o Pupil 2*) [Pupil 2 Name]?	***Teacher raises the status of Pupil 2*** by positioning them as knowledgeable
6 P2	Because negative nine isn't closer to zero than negative five	***Pupil 2 raises their own status*** by offering a correct, if convoluted answer
7 T	(*Slowly, unpicking what was said*) Yes, negative nine isn't closer to zero than…isn't closer to zero than negative five. Very nice.	***Teacher slightly raises the status of Pupil 2*** cautiously affirming their answer by repeating it
8 T	(*To class*) Anything… any other ways of phrasing that?	***Teacher raises the status of all pupils*** by positioning them as knowledgeable
9 T	(*Directly to Pupil 2*) That was really nice, actually.	***Teacher raises the status of pupil 2*** by repeating the earlier affirmation
10 T	(*To Pupil 3*) [Pupil 3 Name]?	***Teacher raises the status of pupil 3*** by positioning them as knowledgeable
11 P3	Negative nine is more negative than negative five.	***Pupil 3 raises their own status*** by offering a correct, clear answer
12 T	Okay, negative nine is more negative than negative five.	***Teacher raises the status of Pupil 3*** by affirming the answer immediately
13 T	So, they seem to be the other way round on our number line (*puts down board*)	***Teacher slightly raises her own status*** by starting to take control of narrative
14 P4	(*Eagerly holding up hand*)	***Pupil 4 tries to raise their own status*** by offering their own answer
15 T	(*To Pupil 4*) [Pupil 4 Name] what do you want to say?	***Teacher raises the status of Pupil 4*** positioning them as knowledgeable
16 P4	Negative 5 is closer to zero than negative nine	***Pupil 4 raises their own status*** by offering a correct, clear answer
17 T	Yeah, negative nine… negative five is closer to zero than negative nine.	***Teacher raises the status of Pupil 4*** by affirming their answer
18 T	So that's almost the same as what [Pupil Name 2] was saying.	***Teacher raises the status of Pupil 2*** by reaffirming their earlier answer
19 T	Okay, then… this one (*picks up next board*)	***Teacher raises her own status*** by taking charge of the agenda and moving on to the next example.

Having raised her status to bring the class together in (1), there are only two other occasions when the teacher raises herself. The first of these is in (13), when her statement "so they seem to be the other way round on our number line" combined with the act of placing the mini whiteboard back on the table suggest that she is taking control of the agenda (unsuccessfully, as it turns out), and the second in (18) when she decisively ends the current discussion and moves on to the next example. Nearly every other statement she makes can be seen as an attempt to raise the status of one or more pupils, with the effect of narrowing the gap between them and herself.

Her determination to achieve this status-raising objective is particularly evident when the responses from pupils are, from her point of view, 'sub-optimal' and the first example of this is (3), where the previous statement by a pupil has been so unclear that she is uncertain of whether or not it was correct. She resolves the confusion by creatively revoicing what the pupil has (perhaps) said, making a correct statement which she then ascribes to that pupil, raising their status in the process. A further example

of this is in (7) and (9) which record her developing a response to a technically correct, but hard-to-follow pupil explanation in (6). In (7) she first adopts the basic status-raising move of seriously engaging with what the pupil has said, in this case, by repeating some of the pupil's own words, then, having decided the pupil was correct, repeating it again and adding 'very nice.' After moving on to another pupil in (8), she seems to decide that her previous endorsement of Pupil 2's answer was insufficiently enthusiastic and returns to them in (9) to repeat the affirmation, raising their status once more, and further narrowing the status gap between herself and the pupil.

Perhaps the most surprising status-raising of a pupil is in (15) and (17). During the pre-lesson interview discussing what had been planned, this teacher had specifically referred to her desire to get the pupils to "use the language…[of]… becoming more positive, becoming more negative" so when she hears this language in (11) she has achieved her goal. This is reflected in the confident tone with she responds "okay" then repeats exactly what the pupil has said in (12). Since her first response to a pupil in (3) she has been working hard to minimise the status gap with pupils, or, in Drageset and Ell's terms, moving from 'reasoning with student ideas' in (3) to 'orchestrating' from (7) to (10). Having heard precisely the language she was hoping for in (11), she seems to have concluded that she can now move on to the next part of the lesson, and in (12) and (13) she starts to reassert her high status as 'a teacher who tells'. Unfortunately, Pupil 4 either fails to pick up on these signals, or simply ignores them, and makes a determined effort in (14) to be given space to contribute their own idea. The teacher's slightly offhand tone in (15) suggested that she had not intended to continue the dialogue, nevertheless she accepts the unsolicited offer and listens to what the pupil says in (16) before taking the opportunity raise their status in (16) and Pupil 2's status in (17). When asked in the post-lesson interview if she had kept the conversation going in order to hear as many different descriptions of the same error as possible, she replied:

> "Yes, but also giving them an appreciation of…like… all of their answers were right in in a different way, so it's like validating their explanations as well because they were correct in what they were saying."

Although she does not use the language of status herself, the teacher's desire to 'validate' what different pupils were saying suggests a commitment to recognising and publicly valuing pupil knowledge, and it therefore seems reasonable to describe her moves during this interaction as purposefully status-raising for pupils. The sequence from (15) to (18) also suggests that she is willing to prioritise raising the status of her pupils over 'getting on with the lesson'.

An important difference between Johnstone's example of the Duchess and the Tramp, and the classroom described above, is that in the latter case the 'see-saw principle' does not apply: when the teacher raises the status of her pupils by affirming their mathematical thinking, her own status does not fall. Johnstone acknowledges this possibility when he explains that "the exception… comes when you identify with the person being raised or lowered, when you sit on his end of the see-saw, so to speak" (Johnstone, 1981, p. 38). In the extract above, the teacher identifies with their pupils through an attitude of careful listening and the frequent use of 'we' and 'our', so they are able to raise the status of their pupils and narrow the status gap while maintaining overall authority in the room.

In contrast to the small number of occasions when the teacher raises her own status, the analysis above shows 12 separate instances of the teacher raising the status of learners. In terms of the language used in the title of this paper, the 'status game' being played by the teacher could be described as 'raise the status of pupils at every opportunity', and the consequence of applying this relatively simple rule was a near-constant narrowing of the status gap between teacher and pupils. It is interesting to recall Johnstone's observation that when he asked actors to minimise status gaps they 'authentic' and it may be that the most 'authentic' communication between pupils and teacher occur when such gaps are similarly minimised, or, in terms of positioning theory, when mathematics teachers 'aim for the bottom' of the list of teacher positions proposed by Drageset and Ell (2024). There is far too little evidence here to make any such claim, although the idea is an intriguing one.

Conclusion

I have argued that a mathematics teacher seeking to alter their position from one of "a teacher who tells" to one of "a teacher who uses student ideas" (Drageset & Ell, 2024, p. 359) could potentially make progress towards this goal by playing the Johnstone (1981) inspired game of 'minimise the status gap' between themselves and their pupils. I have further argued that this approach can be observed in the actions of at least some expert teachers of mathematics as they productively interact with their learners. In the final part of the discussion, I shared evidence that suggests some of these teachers justify those actions in in ways that resemble the ideas of Johnstone, although they may do so without using his language of status.

For teachers, there are two great advantages of status over positioning theory: first, it is simpler to understand, and second, status games, such as the one that was played by the teacher in the episode above, can be taught. The concept of status that has been outlined here was developed as a practical tool for performers to use in the rehearsal room and on stage, and over the last forty years, effective ways of training performers to manage their status have been devised and are used daily in acting classes around the world. If those approaches could be adapted to train mathematics teachers, it would offer the possibility of less experienced practitioners moving towards the kind of expert practice recorded above more quickly than if they were simply left to 'figure it out for themselves'.

Implementing the SIMPLE approach: A study on teacher fidelity and perceptions in Kosovo classrooms

Qëndresa Morina[1] and Naďa Vondrová[1]

[1]Charles University, Faculty of Education, Prague, Czech Republic; qendresamorina@outlook.com

This study explores the implementation of the SIMPLE approach, a constructivist-based intervention for enhancing word problem-solving skills through block models and metacognitive strategies in Kosovo's lower-secondary mathematics classrooms. Three teachers participated across three design-based research cycles, and data were collected via observations, interviews, and lesson recordings. Results show variation in fidelity, with one teacher closely aligning with the intervention, while others faced challenges adapting to pupil-centred teaching, block models and SIMPLE steps. Despite this, all teachers valued the approach for improving pupils' problem solving abilities, emphasising the need for thorough teacher training to support intervention success.

Keywords: Word problems, visual representation, block models, solving steps, teachers.

Introduction

Solving word problems (WPs) is a crucial skill that pupils need to develop, as it enables them, among other things, to apply mathematical concepts to real-life situations. However, solving WPs presents pupils with difficulties worldwide, including in Kosovo. Drawing on the literature on successful interventions focused on developing WP-solving skills, the first author developed a teaching intervention, the SIMPLE approach, aimed at lower-secondary pupils and embedded in socio-constructivism (Simon, 1995). Pupils are introduced to the block model method (Kho, 1987; Kaur, 2018) and to the model of solving steps fostering their metacognitive skills (Verschaffel et al., 2020).

The impact of the intervention on Kosovo pupils' WP-solving skills and the factors upon which reaching the desired goals depends are investigated within the first author's PhD thesis. This contribution focuses on only one factor: the teachers who implemented the proposed intervention in their lessons within the three design-based research cycles. We address the questions of how the teachers implemented the intervention after a short training, how they perceived the SIMPLE approach and its usefulness for their pupils' learning and how confident they were in applying it.

Theoretical background and literature

The rich literature focusing on the development of pupils' ability to solve WPs (Verschaffel et al., 2020) has informed the content of the proposed intervention in at least two ways. First, it focuses on visual representations, as a wealth of research shows promising results of using representations such as bar models in pupils' learning. Bar models visualise a situation model of the WP and mediate between verbal and symbolic representations (Kho, 1987; Kaur, 2018). Second, the intervention targets pupils' metacognitive skills, as awareness of one's cognitive processes when solving WPs improves achievement. We follow the work of others who developed scaffoldings for pupils to follow when solving WPs (e.g., CRIME [Careful reading; Recall possible strategies; Implement possible strategies; Monitor and Evaluation], Teong, 2003; SOLVE [Study the problem, Organise the facts, Line up a plan, Verify your plan with action and Evaluate your answer], Freeman-Green et al., 2015;

STAR [Search the problem; Translate the words into an equation in a picture form; Answer the problem; Review the solution], Özkubat et al., 2021]). None of the frameworks from the literature above includes an explicit step devoted to the visual component (bar model) and thus, they were modified and what I called the SIMPLE steps originated.

The intervention is embedded in the basic tenet of social constructivism (Simon, 1995), in which pupils are active participants in the learning process, and the teacher acts as a facilitator. It involves collaboration among pupils while solving WPs, as problem solving in groups is a rich learning experience and was found to support WP-solving skills (Ventistas et al., 2024). Nevertheless, much research shows that teachers find it often difficult to implement constructivist instruction. One of the reasons is that they do not accept that they are not the primary source of education, and often, the culture of the pupils in the classroom makes it difficult to comply with the constructivist philosophy (Windschitl, 2002). In this context, the concept of the didactic contract comes to the fore, an implicit agreement between teachers and pupils about their roles in learning (Brousseau, 1997). In a constructivist classroom, the contract involves pupil-centred learning, where pupils are encouraged to take responsibility for their learning and actively engage with the new material.

There is a difference between intervention-as-designed and intervention-as-implemented (Nelson et al., 2012). High fidelity is all the more difficult to achieve in teacher-led interventions, as they are the ones that deliver the intervention, and their understanding, commitment, and adaptability greatly influence its success. Thus, intervention studies involve the phase of teacher training. On the other hand, while strict adherence to the original design of an intervention is important, teachers often need to adapt to better meet their pupils' needs. These adaptations should not stray from the core components of the intervention to ensure that the intended outcomes are achieved (Carroll et al., 2007).

National context and research questions

The current Kosovo curriculum (MEST, 2016) aims to foster higher-order, critical and creative thinking, practical skills, and real-world competencies. It seeks to identify mathematics competencies that rely heavily on problem solving, focusing on contextual problems (WPs), and to improve the use of technological means, argumentation, reasoning, communication, and representation. However, lower-secondary mathematics textbooks in Kosovo provide little opportunity to support pupils in developing problem-solving strategies and higher-order thinking skills because most problems are routine and noncontextual (Berisha et al., 2013). The textbooks do not include visual representations for WPs, and teachers rarely, if at all, present visual representations when dealing with WPs in their lessons. Moreover, transmission whole-class work still prevails in mathematics lessons in Kosovo as teachers are only gradually adopting constructivist practices (Ismajli & Krasniqi, 2022). Thus, renegotiating the didactic contract from teacher-led to pupil-centred and involving group work are necessary prerequisites for implementing the intervention.

The study is guided by two research questions: RQ1. How did the teachers' implementations align with the three features of the SIMPLE approach? What were the causes of the misalignment? RQ2. How do teachers perceive the usefulness of the SIMPLE approach, and how confident are they in adopting it in WP teaching?

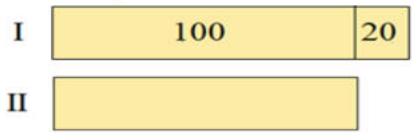
Methods

The current study is part of a design-based research project that aims to develop and refine a constructivist teaching approach for WPs, called the SIMPLE approach, in the context of Kosovo schools. The SIMPLE approach introduces pupils to the bar model method and metacognitive steps for solving WPs and is embedded in constructivism.

Overview of the SIMPLE approach

Bar model. The pupils receive two or three lessons in which types of bar models are introduced on examples, and WPs are solved with the help of bar models. Together, the pupils solve eight WPs, such as WP1_I, with the teacher's help or individually.

WP1_I. There were 120 visitors to Clara's art exhibit on the first day, which was 20 more than on the second day. How many visitors came to the exhibition on the two days?



$First\ day\ (D1) = 120$

$Second\ day\ (D2) = 120 - 20 = 100$

$Total = D1 + D2 = 120 + 100 = 220$

Figure 1: Bar model method for WP1_I

SIMPLE steps. In the following two lessons, the pupils are introduced to the SIMPLE steps: **S**tudy the problem, **I**nvolve the bar model method, **M**onitor the process, **P**repare/Present the solution, **L**ook over the solution again, and **E**valuate your answer (there is a similar acronym in Albanian). Pupils solve eight other WPs (such as WP2_I) explicitly targeting each step.

WP2_I: Of the 2,100 kilograms of potatoes in the warehouse, 942 kilograms were sold on the first day, whereas on the second day, 118 kilograms less than on the first day were sold. How many kilograms of potatoes are left in the warehouse?

Table 1: **Hypothetical solution**

S	*I have to find the kilograms of potatoes that are still unsold after two days. We know the number of those sold on the first day; we need to find for the second and then those left.*
I	*I draw blocks showing the kilogram of potatoes left on the first day. Then, another block is for those sold on the second day, and the third one belongs to those still unsold.* M	*Yes, I am on the right path since I know how much I must subtract to find the final answer.*
P	*Based on the blocks, we can do the calculations below:* $Day\ I = 2100 - 942 = 1158;\ \ Day\ II = 1158 - (942 - 118) = 158 - 824;\ \ Left = 334$
L	$334 + 824 + 942 = 2100$ / (*Left + Day I + Day II = Total*)
E	*The answer makes sense as we work backwards to arrive at the total kilograms of potatoes.*

Constructivist approach. Techniques promoting pupils' active involvement, problem solving, and reflection through group work and discussions with and among pupils are promoted.

Sample and data

Three lower secondary Grade 8 teachers implemented the intervention in three cycles of design-based research. They were willing to participate in the study, and their schedules enabled the first author to observe all the intervention lessons. The teachers were first instructed about the SIMPLE approach and provided with a detailed teacher guide. While a wealth of data has been gathered to evaluate all the research cycles, this study draws on the part of the data connected to teachers, namely, field notes made during the observations, audio recordings of lessons, teacher diaries, and semistructured interviews with teachers. The interviews and recordings were transcribed and analysed qualitatively.

First, in the transcribed recordings of lessons and the field notes, we identified episodes in which the teacher's implementation of the three features of the SIMPLE approach was visible. Second, these episodes were coded in terms of the alignment of the teacher's actions with the intended implementation. For example, whether the types of bar models were distinguished, how each of the SIMPLE steps was introduced, whether the teacher organised group work, how they managed discussions, and what support they provided to pupils. Third, the rest of the data were searched to triangulate information from the transcripts and the field notes and to find possible causes. For example, whether the teacher mentioned the coded episode in the diary or in the interview. Finally, all the data were revisited to find units where the teacher alluded to their perception of the SIMPLE approach and their confidence in its implementation.

Results

Alignment of the teachers' implementations with the SIMPLE approach as designed

Teacher 1: The first cycle was organised in School A in Gjilan and taught by a male teacher with 25 years of experience in teaching mathematics. He mentioned that WPs were part of his teaching and that he used them, especially with pupils participating in mathematics competitions. He claimed that he did not always use pupil-centred methods, as "pupils will misuse the situation and make unnecessary noise in the classroom". Before the intervention, the class covered the chapter on solving WPs via linear equations, and pupils were encouraged to solve WPs in such a way.

Next, we summarise how the teacher dealt with the three features of the SIMPLE approach.

The teacher solved WP1_I by drawing a bar model in front of the pupils. Then, he explained three types of bar models orally, e.g., by saying, "the part-whole type of bar model is when you connect two or more quantities to find the whole part". He mentioned a situation where "you have two books, and I have three more books, how many books in total are there?". No drawings accompanied the explanation. After that, he presented a WP similar to WP1_I for pupils to solve independently. The teacher drew the correct bar models for each WP solved during the lessons but never emphasised what type of bar model is associated with the particular WP and why. For example, for the problem "There are 550 books in total. On the first day, they sold 200 books, whereas on the second, they sold 50 more books. How many are left?" he drew a bar model for the total, then for the first day sold and for the second but did not refer to the types of bar models introduced earlier. The teacher introduced

the SIMPLE steps on the solution to WP2_I; he clearly distinguished each step and tried to make the pupils understand the importance of each one. Pupils worked mostly independently and could ask questions. However, we identified situations in which, after being asked if the solution was correct, the teacher said that the solution was not accurate, but he failed to associate it with the pupil's drawing and explained the mistake by pointing to the solution via an algebraic equation. Sometimes, the teacher felt unsure how to proceed with the lessons and asked the observer to help explain certain aspects of the SIMPLE approach to the pupils.

The data revealed several missed opportunities to initiate discussions and explore pupils' misunderstandings and ideas; for example, the teacher did not ask probing questions when pupils worked in pairs or discussed the homework solution and did not facilitate group work. During the interview, the teacher said, "They worked in pairs; if I had done group work, the class would have been messy."

Teacher 2: The second teacher was a woman from School B in the same city with 20 years of teaching experience. Based on our experience from the first cycle, more emphasis was placed on the aspects of the intervention in which Teacher 1 did not align with the teacher guide when instructing Teacher 2. Teacher 2 showed strong motivation and dedication in implementing the intervention to help pupils solve WPs. She agreed that the instructions provided in the guide fit with her teaching style and would not be challenging to implement.

The data showed that Teacher 2 adhered to the guide when introducing bar models and organising whole-class discussions in the classroom. She introduced the pupils to the SIMPLE steps one after the other by solving WP2_I on the blackboard and allowing them to practice it in other WPs. However, she focused on the step in which the bar model was to be made and did not give the same importance to all the SIMPLE steps as recommended by the teacher guide. Steps such as "evaluating your answer" or "monitoring the process" received much less attention. For example, for the "evaluate your answer" step, Teacher 2 said most of the time, "based on the result and the proof, the solution is correct" and told the pupils to write just "the solution is correct" or "the solution makes sense" without initiating a deeper discussion about evaluating the answer and monitoring the solving process. She probably did not ascribe much importance to these steps. She wrote in her diary: "…we do not need to ask pupils to write everything on paper if they are sure how to do it, to not take a lot of time while doing it". Second, as in the first cycle, the absence of group work was identified. In contrast to the guide, Teacher 2 allowed the pupils to choose whether they wanted to cooperate, and most pupils worked alone or with a friend sitting next to them.

Teacher 3: The third teacher was a female from School C with 12 years of experience teaching mathematics. Following the experience with Teacher 2, when Teacher 3 was instructed, all the steps in the SIMPLE steps were dealt with in-depth and group work was emphasised. The initial interview revealed that Teacher 3 tended to provide her pupils with an active learning environment in her lessons.

The data showed that Teacher 3 followed and implemented the teacher guide to a great extent. She adequately conveyed the lessons of the bar model method and the SIMPLE steps, organised group

work, and created a positive environment where pupils could raise questions and discuss solutions. The lack of time sometimes prevented Teacher 3 from providing feedback to all the groups.

The data confirmed that the constructivist underpinning of the intervention aligned with Teacher 3's usual style: "Implementing this approach was not hard, as I usually follow these rules in my teaching. I let pupils work together and do not interfere in their learning process, as sometimes they learn better from each other."

To summarise, the following differences between the intervention-as-implemented and the intervention-as-designed (Nelson et al., 2012) were identified:

- Introducing bar model types without visual illustrations (Teacher 1)
- Missing opportunities to initiate discussions and explore pupils' misunderstandings (Teacher 1)
- Failure to associate bar model types with the inner structure of the WP (Teacher 1)
- Failing to use visual representations to explain the solution; resorting to algebra (Teacher 1)
- Little group work (Teacher 1, Teacher 2)
- Failure to give adequate emphasis to all the SIMPLE steps (Teacher 2)

Teachers' perceptions of the SIMPLE approach

The teachers' perceptions of the new approach reflect the initial challenges and benefits observed in the classroom. Notably, during the interview, Teacher 1 stated that this approach, despite being challenging, was attractive and helpful for pupils. His diary entry indicates that, in his opinion, he and his pupils understood the SIMPLE approach well, but he feels that more time is needed for pupils to grasp it fully. Neither in the interview nor in the diary did Teacher 1 reflect on the situations in the lessons where he felt unsure of how to work with the new approach. He mainly appreciated that it was motivating for pupils and repeatedly expressed his intention to use it in the future.

Teacher 2 and Teacher 3 also benefited from the SIMPLE approach, in their opinion. For example, Teacher 2 said, "I liked it. After I did the intervention here, I also explained it to the 7th-grade class. We used it in some simple WPs, which helped them obtain a solution. […] I will continue to use it in mathematics classes."

For Teacher 3, it was easy to use the new method in the classroom: "No, it was not challenging at all. I think the block model made the new approach even easier to utilise, as it awakened curiosity and helped them [pupils] form the equation." She exhibited great faith in the new approach's potential to help pupils solve WPs and was enthusiastic about introducing it to pupils of other grades. For example, she brought three 9th-grade pupils about to participate in a mathematics competition to learn the SIMPLE approach, as she thought it would help them.

Discussion and Conclusion

This study investigated three teachers' practices while implementing the SIMPLE approach intervention. First, we focused on the fidelity of their implementation in terms of the content (introduction of bar models and SIMPLE steps) and pupil-centred teaching. For the former, the fidelity was high for Teacher 3, whereas Teacher 1 did not adequately present the types of bar models,

and Teacher 2 neglected some steps. While it was partially caused by the differences in the initial training of the teachers (each cycle informed the teacher's training in the next cycle), the teachers' teaching approach played an important role. Teacher 1's usual teaching style differed from that promoted by the SIMPLE approach, while it fit very well with Teacher 3 and partially with Teacher 2. The constructivist underpinning of the intervention went against Teacher 1's usual way of teaching. Teacher 2 did not initiate group work, and one can argue that group work is not an indispensable way of working within the intervention. Teacher 2 and Teacher 3 had to master only the bar model method and the SIMPLE steps, whereas Teacher 1 had to change his way of teaching substantially. The fact that we did not observe the teachers' regular teaching before the intervention and thus relied only on their descriptions is a limitation of our study.

Teacher 1's case revealed one of the most prominent challenges to implementation fidelity: the difficulty in adapting teachers' regular teaching to constructivist teaching (see also Windschitl, 2002). This is all the more important in Kosovo, as the transmission teaching method prevails.

The study's findings shed light on the importance of visual representation and metacognition in the solution of WPs, especially in the context where these factors are not usually used. Our data also highlight the necessity of thorough training before the intervention (Carroll et al., 2007). We underestimated Teacher 1's need to work deeper with the bar model method before presenting it to the pupils. Using visual representations for solving WPs is new for Kosovo mathematics lessons, as confirmed by the teachers involved in the intervention and the pupils we interviewed as part of the work on the PhD thesis. Thus, the length of the intervention should also be considered. While the first author's PhD thesis aims to evaluate a short-term intervention described in this contribution, the future use of the SIMPLE approach should be part of mathematics lessons in all grades.

Finally, regardless of the degree to which they adhered to active learning principles, all three teachers welcomed the new and could see benefits for pupils' ability to solve WPs. It remains to be seen how the intervention helped pupils solve WPs. It is performed within the first author's PhD thesis.

Explicating the work of monitoring students' mathematical thinking

Reidar Mosvold[1], Janne Fauskanger,[1] Raymond Bjuland[1] and Peter Liljedahl[2]

[1]University of Stavanger, Stavanger, Norway; reidar.mosvold@uis.no

[2]Simon Fraser University, Canada

Monitoring students' explorations is one of the practices of orchestrating mathematical discussions. Although studies have used different terms like observation, noticing, and listening and developed various frameworks, most studies have investigated empirically what teachers do, or the moves they use when monitoring students, and the focus is often on the mathematical ideas. This study takes a conceptual analytic approach to map out the terrain of what might be involved in the work of monitoring. We analyze an episode where a group of students explore a mathematical problem without any teacher interventions, and we identify plausible tasks of teaching that might be involved to map out the four domains of teaching that relate to mathematics, students, enactment, and issues.

Keywords: Work of teaching, domains of teaching, tasks of teaching, monitoring.

Introduction

In their paper on five practices for orchestrating productive mathematical discussions, Stein et al. (2008) present monitoring as a second practice of orchestrating discussions—following anticipation, which is carried out in the planning phase. Monitoring is thus the first practice of the interactive phase of teaching. Stein et al. describe this practice as monitoring the responses that students make when exploring tasks, and the practice of monitoring, when investigated in the research literature, thus tends to emphasize observations of students' mathematical contributions. Yet, anyone who has taught mathematics and observed students' explorations of tasks knows that the teaching practice of monitoring students involves much more than just attending to the mathematics that students put forth. It is a complex work that involves several challenges and decisions to be made. The present study aims at examining the practice of monitoring student responses when exploring a challenging task, to start mapping out the terrain of this slice of the complex work of teaching mathematics.

Theoretical background

Stein et al. (2008) state that the practice of monitoring student responses, "involves paying close attention to the mathematical thinking in which students engage as they work on a problem during the explore phase" (p. 326). Furthermore, they describe the goal of monitoring as identifying "the mathematical learning potential of particular strategies or representations used by the students" (p. 326). Although they are surely aware that teaching involves more than just attending to the mathematical contributions of the students, this is the aspect of the work of monitoring that Stein et al. (2008) highlight. In their effort to further investigate teachers' monitoring of students' groupwork, Ehrenfeld et al. (2020) emphasize monitoring of students' mathematical work, but they also discuss how monitoring involves attending to students' positioning and identity talk. Their framework of teacher moves includes how teachers approach the group (initiation), what they first say to the group (entry), what they attend to in their interactions with the group (focus), and the last thing they say

before leaving the group (exit). They also consider the patterns of participation in terms of whether the teacher interacts with the whole group or only parts of the group or individuals.

Sjöblom et al. (2023) apply Ehrenfeld et al.'s (2020) framework when they investigate the moves that some teachers made while noticing students' groupwork. In both studies, teachers' monitoring or noticing moves involved a lot of interactions with the students—including how teachers entered conversations with students, and how they used questions to initiate discussion or challenge students' mathematical thinking. Overall, Sjöblom et al. (2023) emphasize attending to the mathematical work of students, and this emphasis can also be found in other studies. For instance, Campbell and Yeo (2022) present a framework that emphasizes teachers' noticing of students' interactions around the mathematical content. They distinguish between the three elements of "attending to students' mathematical strategies, interpreting their understanding and deciding how to respond based on their understanding" (p. 492). In addition to these three aspects of noticing, their framework involves a mathematical dimension and a coordinated activity dimension. Jarry-Shore and Richardson (2024) study the role of teachers when noticing diverse kinds of struggle as students work on mathematical problems. They suggest that this aspect of teacher noticing involves attending to students' struggle, interpreting their struggle, and assessing whether students' struggle is productive or not. Whereas studies often refer to monitoring as teacher noticing, Hintz and Tyson (2015) unpack three types of teacher listening (evaluative, interpretive, and hermeneutic). Their focus is thus on what teachers attend to when engaging in various kinds of listening. Like in many other studies in this field, the examples Hintz and Tyson (2015) present and discuss in their paper almost exclusively focus on ways of attending (in terms of listening) to the mathematical content.

Where many study teaching in terms of what teachers do, or actions or moves that teachers make, our study takes a different approach. We follow Ball and Forzani (2009) who consider the work of teaching to be "the core tasks that teachers must execute to help pupils learn" (p. 497), and Hoover et al. (2014) who consider tasks of teaching to be decompositions of teaching into components that can be recognized by the professional community. Furthermore, Hoover et al. (2014) describe this decomposition as "identification of plausible conceptions of tasks of teaching around which professional consensus might be built" (p. 16). From this, we ask what constituent tasks of teaching that might plausibly be involved in the work of monitoring students' explorations, and what domains and sub-domains this slice of the work of teaching involves.

Methods

We explore data from the *Partners in Practice* project, an ongoing interdisciplinary professional development and research project. The project aims to establish a collaborative space for continuous development of teaching practice across subjects. Ten lower secondary mathematics teachers (teaching Grades 8–10) and three teacher educators were involved in the mathematics part of the project. In professional development sessions, the teachers solved mathematical problems and discussed a problem-solving approach to mathematics teaching. Teachers also tried out some of the ideas discussed in lessons with their own classes (students aged 13–16). We analyze data from one such lesson here, where a Grade 9 teacher tried out the "frame problem". The students were divided into groups of three, and each group got the problem on a sheet of paper (Figure 1).

We have an 8 × 8 region (light color), surrounded by a frame (dark color). The problem is to figure out a way to find the number of squares in the frame, without having to count them one by one. For each solution, try to create a mathematical expression that shows the number of squares in the frame. This figure has 10 squares along each side. What if there were 6, 40, 100, or *n* squares in the frame? Can you find a generic rule?

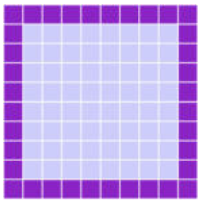

Figure 1: The "frame problem"

The teacher handed out the problem on paper and encouraged the students to find multiple solutions. We analyzed the discussion in a group of three students, as they began to share their ideas after having read the problem and considered it individually. The analysis followed four steps. First, we divided transcripts of the group discussion into units. A new unit was created whenever something new was going on in the conversation. These units were categorized by using the four teaching domains proposed in TWG19 (Mosvold et al., 2023). Second, inductive codes were developed to describe tasks of teaching that might be involved in each unit. In the third step, the tasks of teaching were sorted, and duplicates deleted. Lastly, tasks of teaching were grouped into the four domains, and sub-domains were identified inductively. Memos were written in all steps.

Unpacking domains of the work of monitoring

Below, we use the episode where a group of three girls (Anna, Berit, and Cecilie) explores the frame problem as a starting point for unpacking domains of the work of monitoring.

Mathematics

When students explore a mathematical problem, they are likely to suggest different solutions, strategies, or mathematical ideas, which teachers must attend to in their monitoring work. When analyzing this episode, we observe student contributions of various kinds—some contributions are expected, others are not; some contributions are mathematically correct, whereas others indicate misconceptions or are incomplete. The work of monitoring these diverse types of contributions might involve different tasks of teaching, which we will illustrate below.

There are several instances of strategies that teachers would likely have anticipated in the episode where the girls explore the frame problem. For instance, in the very beginning of the group conversation, Berit shares that she initially thought the problem was about finding the area of the inside square, but she has realized that is not the case. Next, she thinks, "what if it's 10, and it kind of becomes n, then it becomes like 10 minus, no n minus 2, times that again." When observing a student contribution like this, the teacher must attend to and interpret the student's thinking. For instance, Berit might be thinking about the enclosed region rather than the surrounding frame, or she might use the area of the whole and the inner area to find the number of squares in the frame, and this is something teachers might have anticipated. Cecilie then asks Berit to explain her thinking, and

Berit explains how she was initially thinking about the relationship between the outside frame and the side lengths of the inside square, saying "if there are 10 here, then there are 8 inside. If there are 6 here, then there are 4 inside." Cecilie agrees that there will always be two less on the inside, and Berit describes this as "n minus two times n minus two." For now, their mathematical ideas are incomplete, and their strategies do not yet help them solve the problem. After having agreed what the problem asks, Berit suggests that the frame consists of $10 + 9 + 9 + 8$ squares. This is a mathematically correct solution, and it is one that teachers would likely have expected. Berit adds that she initially "thought it was like ten times four, but it's not." This is also something teachers might have anticipated. Teachers who observe a group conversation like this must attend to the students' mathematical thinking. Monitoring also often involves interpreting students' thinking since the ideas and strategies that students propose are not always clear or explicitly formulated. During the monitoring phase, teachers must also consider if specific strategies are worth highlighting in a following strategy-sharing discussion or not.

Sometimes students produce unexpected mathematical ideas. After having spent some time pondering the pattern of $10 + 9 + 9 + 8$, realizing that the answer is 36 but not being convinced that this is a sufficient solution, Cecilie suddenly comes up with an idea. She remembers something they have learned in the previous semester about factorials, and she asks the others, "Didn't we learn something like that?" Not remembering what it is called, she tries to explain it in her own words: "The way it goes down, if you know what I mean. What is that sign called? So that it goes like this 10, 9, 8, 7, 6, 5, 4, 3..." Anna recalls that the sign is an exclamation mark, and the two of them spend some time discussing this idea. This is an idea that a teacher would not have expected to come up, and monitoring a discussion like this would both require attending to and interpreting the students' mathematical thinking. In addition, a situation like this would also require considering if this mathematical idea might be productive or not, and if it fits with the learning goal for the lesson. Anna then asks the others, "Is it possible to limit the exclamation mark?" This is an interesting mathematical idea, and it could have opened for exploring combinatorics and permutations. The contribution also involves a misunderstanding, as the students do not yet seem to recall that factorials involve multiplication rather than addition. Eventually, the students realize this and reject the idea, but this is an example of unexpected ideas that might be introduced when students explore problems, and that a teacher must attend to, interpret, and consider in terms of their mathematical potential.

Students

Monitoring students' explorations also involves becoming acquainted with the students as learners and people. We identify three sub-domains within this domain of work: attending to identity talk, talk that indicates uncertainty or doubt about own abilities, and several types of off-task behavior. We illustrate these sub-domains below and indicate tasks of teaching that might be entailed.

Students' explorations of mathematical problems often involve talk about how students view themselves. For instance, when Berit first starts sharing her initial idea about considering the area as $(n-2) \times (n-2)$, Anna comments, "I'm not a mathmagician, so I can't do this." A bit later she sighs, "I thought I was smart in math..." Some students might interpret their own struggling as an indication that they are not "smart." Such statements might develop into a more persistent identity

that might limit the student and her further progress, but it might also negatively influence the learning climate of the entire group. Teachers should therefore attend to this kind of identity talk in the mathematical discussions and consider approaching or even challenging them.

Sometimes students make comments or statements that indicate uncertainty or doubt about their own abilities. For instance, when the group is first stuck after realizing that the problem does not ask them to find the area of the interior square, Cecilie says: "Is it just us who are stupid, or is it like that... Or are we somehow supposed to know this?" A bit later in the conversation, she asks the others in her group: "Have other people figured out the answer?" There are several instances in the conversation where Cecilie makes comments like this, sometimes made with a chuckle, or in a low, whispering voice. Talk like this might indicate uncertainty or doubt about own abilities in mathematics, and this is something teachers should also attend to. Sometimes, it might be appropriate to engage the entire class in a conversation about uncertainty and doubt, highlighting that struggling and being stuck is common when approaching a mathematical problem, or when trying to solve a task that is unlike something they have worked on before.

Observing students' exploration of mathematical problems might also involve off-task behavior. For instance, after Berit has introduced her observation about the frame being $10 + 9 + 9 + 8$, Cecilie suddenly makes a comment about what day it is. Teachers must attend to off-task behavior in the work of monitoring, and they must consider if, when, and how to engage it. This leads to the next domain, as teachers' monitoring of this kind of behavior or talk might also involve considering what to do next, and how to organize and enact the interactions and discourse of teaching and learning.

Enactment

In the work of monitoring students' explorations, the domain of enactment is mostly about considering what to do and when. We identify five sub-domains of enactment.

The first sub-domain is to consider if, when and how to acknowledge students' contributions. Acknowledgment or praise can be given for several reasons, and teachers must consider this already as they monitor students' explorations. For instance, when Berit shares her first thoughts about the problem and how she initially believed that the problem asked about the interior square, a teacher might consider praising her for having the courage to share her misunderstanding and failed efforts. Also, when Cecilie follows up by asking Berit to explain how she has been thinking, the teacher might consider praising her for attending to another student's thinking, and for trying to understand it. Similarly, when Cecilie introduces the unexpected idea about factorials, or when Anna suggests "limiting" the exclamation mark, teachers might consider if these ideas should be acknowledged by presenting them to the entire class in a following strategy-sharing discussion.

Second, there are many instances where students make mathematical statements that are not immediately clear to a teacher, and the teacher might consider asking a clarifying question to elicit a student's thinking. For instance, when Cecilie suggests factorials, saying that "it goes like this 10, 9, 8, 7, 6, 5, 4, 3...", a teacher could consider asking where the student sees this sequence in the problem. When Anna and Cecilie start discussing the idea of factorials, Cecilie asks: "Is it possible to take *n* exclamation mark, and so on, since there is 8 in the middle, like that?" It is not immediately clear

what Cecilie is referring to by "8 in the middle" here. It could be the interior square, but a teacher might consider asking her to elaborate on this and explain how she thinks here.

A third sub-domain of enactment is to consider how long to let the students struggle and whether to interfere and help them along. Several instances in this group discussion indicate that the students are stuck or struggling. For instance, Berit's comment that her initial idea of $(n-2) \times (n-2)$ would not work because the frame is $10 + 9 + 9 + 8$ is followed by a long pause before Cecilie suddenly makes the comment about what day it is. This is an example of a situation where it might be tempting for a teacher to intervene, for instance by confirming that Berit's observation is correct, or by suggesting to explore if there are other ways of finding the number of squares in the frame.

Fourth, some instances would require teachers to attend to what students said and consider following up on this by engaging the group—or the entire class—in a conversation about meta-cognition or norms. For instance, when Cecilie asks if they are supposed to know this already, Anna comments that "it's a thinking task." This is something a teacher might consider noticing and coming back to in a discussion about what kind of task this is and strategies for approaching a task where there are no immediately available strategies. At another point, when the students are stuck, Berit goes back to reading the assignment aloud. This is another instance that a teacher could consider coming back to in a discussion about strategies for dealing with challenging tasks and emphasize that an initial part of the problem-solving sequence is to make sure you understand what the problem is.

A fifth sub-domain concerning enactment is to consider how to approach situations where students are dealing with uncertainty or doubt. For instance, when Cecilie and Anna engage in the idea of factorials, Cecilie reaches a point where she sighs, "I don't know, that's how it goes." There were many other instances in this conversation where students expressed doubt or uncertainty. In addition to considering such instances by attending to students' identity talk or consider making meta-comments about strategies for problem solving, teachers might consider letting the students stay in this state of uncertainty, or to encourage or nudge them to move forward.

Issues

As discussed by Hoover and Goffney (2019), students' explorations of mathematical problems might involve issues relating to race and gender, and situations where teachers must consider disruptive patterns of oppression. The situation analyzed in this paper is more limited in this sense, but we observe instances relating to two possible sub-domains here.

First, there are several instances where students make statements that might indicate potentially problematic social or cultural views about mathematics. For instance, Cecilie seems concerned that some of her ideas are not "math methods," which might indicate a view that mathematics is limited to application of approved methods or algorithms. Likewise, Cecilie's question about whether they are supposed to know this might indicate a social view of mathematics as a subject where you are only supposed to solve tasks that the teacher has already explained how to solve. Some of Anna's statements might also indicate social or cultural views about what it means to be "smart" in mathematics, and the teacher must consider if these are views that should be challenged somehow.

Second, there are instances where a student's behavior could be considered disruptive. For instance, when discussing the idea of factorials, Berit asks if factorials involve addition or multiplication, whereupon Anna says, "Oh yes," and she seems to realize that she has misunderstood this. After a pause, Cecilie starts laughing. When students start laughing in situations that involve failure or misunderstandings by other students, teachers should pay attention and consider if this is disruptive behavior that should be addressed or not. Since this situation involves three white Norwegian girls, other dynamics than race or gender might be at play. Still, these are considerations that teachers are faced with, already in the work of monitoring.

Concluding discussion

Monitoring students' exploration of mathematical problems is a challenging slice of the work of teaching. Some teachers seem to think that students' exploration or group work is time for the teacher to do something else, but there is important work involved in monitoring students' group discussions. Monitoring work is often invisible—the teacher might not say much or conduct any visible actions or moves—and our analysis indicates this. The potential tasks of teaching that might be entailed in monitoring typically contain verbs like *attending*, *interpreting,* or *considering*. These verbs, which correspond with the three categories of teacher noticing from Campbell and Yeo (2022), indicate that the work of teaching in this phase is mostly hidden, and it does not necessarily involve any verbal interaction or observable moves by the teacher. Whereas previous studies emphasize teachers' monitoring of students' mathematical explorations (e.g., Campbell & Yeo, 2022; Hintz & Tyson, 2015; Jarry-Shore & Richardson, 2024; Sjöblom et al., 2023), our study illustrates how the work of monitoring involves all four domains of teaching (cf. Mosvold et al., 2023). Like Ehrenfeld et al. (2020), we show how monitoring work also involves attending to students' identity talk, but we add the dimensions of considering further *enactment* and attending to broader social, cultural, and political *issues*. Our analysis highlights the complexity and involved nature of monitoring students' mathematical explorations.

Where other studies investigated monitoring by observing what teachers do, our study took a different approach. By considering a record of teaching—an episode where three Grade 9 students explore a mathematical problem—we have developed and tested ideas about possible tasks of teaching (cf. Hoover & Goffney, 2019). This follows Hoover et al. (2014), who highlight the idea of focusing on the tasks that teachers must deal with in their work—rather than what they do—and to develop plausible candidate descriptions of such tasks for further deliberation in the professional community. We acknowledge that our study is limited by the records we have analyzed. For instance, our data has limited potential to highlight issues of race and gender that might be involved, and we acknowledge that teacher monitoring can vary with different problems or tasks. Still, we suggest that our explication illustrates some important qualities as well as challenges that this work might entail, and we believe that our unpacking of this work might be useful for further studies of the work of monitoring students' mathematical thinking, and for mathematics teacher education. Our study also illustrates how the four proposed domains of teaching (cf. Mosvold et al., 2023) can be a useful analytic framework.

Tensions in teachers' attempts to balance mathematical challenge with students' diverse learning needs

Samaher Nama[1], Despina Potari[1], Giorgos Psycharis[1] and Chrissavgi Triantafillou[1]

[1]National and Kapodistrian University of Athens, Faculty of Mathematics Education, Greece; samaher.yassin@gmail.com

We study how a group of six mathematics teachers in Greece balance mathematical challenge with students' diverse needs, focusing on the tensions they experienced and how they handled them during reflective discussions in a video club setting. Using an analytical model (the Teaching Triad) we characterize the teachers' tensions into three interrelated domains of teaching. Our findings reveal four categories of teachers' tensions: pedagogical, curricular/institutional, cultural/social, and epistemological. A range of actions that teachers propose or enact to handle these tensions were identified, such as fostering exploratory discussions, providing guidance through enabling and extending prompts, creating a safe and supportive environment, and encouraging small group work.

Keywords: Mathematical challenge, differentiation, teachers' tensions.

Introduction

A range of studies have highlighted the importance of engaging students in cognitively challenging work to enhance their mathematical learning and reasoning (Tomlinson, 2014). Compelling global evidence suggests that opportunities for differentiation play a crucial role in supporting mathematical learning for all students. This process involves aligning learning targets, tasks, activities, resources, and support with the unique needs, preferences, learning styles, and paces of individual learners (Tomlinson, 2014). Therefore, teachers must be supported in effectively differentiating their teaching practices within heterogeneous classrooms (Pozas et al., 2020). Research shows that mathematics teachers often encounter tensions when planning and enacting instruction (e.g., Stouraitis et al., 2017). The tensions teachers experience when balancing mathematical challenge with students' diverse needs remain underexplored in research (Potari et al., 2023). There are some studies that address teachers' perceptions of their students' mathematical abilities and the way teachers can engage them in high demanding tasks (e.g., Horn, 2007; Jackson et al., 2017). However, few studies (e.g. Vasilopoulou and Triantafillou, 2023) focus on the tensions teachers experience while they attempt to balance mathematically challenging teaching with all students' diverse needs. This study aims to contribute to this area by examining these tensions and how teachers manage them so as to achieve this balance. Our data source is reflective discussions in a video club setting (project EDUCATE, https://websites.ucy.ac.cy/educate/en/). The research questions are:

1. What tensions do teachers face while attempting to balance mathematical challenge with students' diverse needs in whole-class settings?
2. How do teachers handle the tensions they encounter?

Theoretical background

A number of studies have identified teaching strategies for balancing challenge with students' diverse needs such as: using tasks with a low entry point to allow all students to find a solution, while also

providing opportunities for advanced students to extend their thinking; using enabling or extending prompts based on students' performance; highlighting, synthesizing, and extending of important mathematical ideas while interacting with students; utilizing a variety of resources; and creating an inclusive and mathematically challenging learning environment (Charalambous et al., 2023; Psycharis et al., 2019; Sullivan et al,. 2016). These strategies can be seen as possible ways by which teachers attempts to manage the tensions involved in balancing mathematical challenge with students' diverse needs.

The Teaching Triad (TT) has been used as a research tool to study mathematics teaching and the balance between mathematical challenge with students' needs (Potari & Jaworski, 2002). The TT characterizes mathematics teaching through three domains: *Management of Learning (ML)* (the creation of the classroom learning environment)*, Sensitivity to Students (SS)* (awareness of students' emotional, cognitive, and social needs) *and Mathematical Challenge (MC*) (presenting challenges to promote mathematical thinking, and engaging students in meaningful activities). Research indicates that harmony between MC and SS indicates an effective learning environment. The TT has been extended to provide interpretations of the interactions between its three elements in the context of the activity of teaching considering the tensions that the teacher faces (Potari et al., 2023). This study uses the TT in its current development to study the activity of six teachers who attempt to balance mathematical challenge with students' diverse needs in the micro level of the classroom in relation to the tensions they experience and their handling at both the micro and macro levels of the teachers' activity.

Mathematics teachers often encounter tensions in their professional lives, particularly in planning and enacting teaching. These tensions can include pedagogical conflicts that arise during teaching-learning processes (Stouraitis et al., 2017) or conflicts related to teachers' expectations and perspectives on professional development (Yamagata-Lynch & Haudenschild, 2009). Herbst and Chazan (2012) provide a characterization of tensions through the construct of professional obligations. These include: (1) *Interpersonal tensions,* related to classroom interaction; (2) *Disciplinary tensions* related to the mathematical knowledge taught; (3) *Institutional tensions,* involving external obligations such as department policies; and (4) *Individual tensions,* stemming from teacher's attempts to consider and respect each student's unique physical and psychological traits. Horn's (2007) study illustrates how teachers often perceive a disconnect between their students' abilities (e.g., "fast kids," "slow kids," "lazy kids") and the rigorous curriculum they are expected to engage with. This perception often leads to tensions as teachers strive to balance the demands of high curriculum standards with the diverse learning needs of their students. From a similar perspective, Jackson et al. (2017) used the diagnostic and prognostic framework to analyze how teachers explain the sources of students' difficulties in mathematics (diagnostic framing) and how they describe their responses or solutions to these difficulties (prognostic framing). The study shows that many teachers do not view all students as capable of engaging in rigorous mathematical activity, often attributing difficulties to inherent student traits or external factors. This deficit-oriented perspective can further exacerbate the tensions teachers experience as they attempt to implement ambitious reforms while addressing the diverse needs of their students. The latter two studies implicitly address teachers' tensions, as their main focus is on teachers' views on students' capabilities. Only a limited number

of studies have specifically focused on teachers' tensions related to mathematically challenging teaching and students' diverse needs. For example, Vasilopoulou and Triantafillou (2023) explored teachers' tensions as they tried to create inclusive mathematics settings for both competent students and those who struggle with mathematics. They found that these tensions are related to selecting tasks that are both inclusive and challenging, teachers' personal perceptions of students' mathematical abilities, and institutional rules imposed by the educational system (e.g., limited teaching time). Our study contributes further to this direction by exploring teachers' tensions related to balancing mathematical challenge with students' diverse needs in teaching and learning as evidenced in teachers' reflective discussions in a video club setting.

Research context and participants

EDUCATE is a European professional development program with four partner countries (Cyprus, Greece, Ireland, and Portugal) addressing issues of cognitive activation and differentiation and supporting teachers in engaging all their students in challenging tasks. In this paper, we use data collected in Greece involving two teacher educators (TE1 and TE2), and six practicing secondary school mathematics teachers: T1 (Aleka), T2 (Aris), T3 (Apollon), T4 (Eli), T5 (Grigoris), T6 (Penelope) (all pseudonyms). The teachers were all degree qualified (e.g., master's degree, participation in several PD programs) with an average of 15 years of teaching experience.

The data collected comprised eight videotaped meetings. In this paper, we analyze and report results from two of these meetings. Meeting 2 focused on mathematical challenge and meeting 3 focused on differentiation. During these meetings, each teacher presented video clips that they selected from their own classrooms, highlighting what they considered significant in relation to the focus of the PD program. Participants then watched and discussed these clips through the lenses of mathematical challenge and differentiation. The data analysis aimed to explore the teachers' tensions related to balancing mathematical challenge with students' diverse needs in teaching and learning, as well as the potential or actions taken to handle these tensions. The discussion around each video clip that the teachers presented during each meeting was treated as a unit of analysis.

The analysis was conducted in three phases: **Phase 1:** We identified episodes within each unit that indicated teachers' tensions related to balancing mathematical challenge with students' diverse needs as well as potential or actual actions taken to handle these tensions. **Phase 2:** We coded the teachers' tensions identified in Phase 1 within each episode. Adopting grounded theory techniques and using the TT, we categorized these tensions into its three interrelated domains of teaching (ML, SS, MC). The tensions were interpreted in terms of the classroom interactions (micro level), and in the broader contexts (e.g., curricular, social) outside the classroom (macro level). **Phase 3:** We focused on identifying and analyzing the potential or actual actions aimed at handling these tensions. Actions discussed could be mentioned by the teachers themselves or their peers during the meetings. Grounded analysis was combined with theoretical ideas for balancing mathematical challenge with students' diverse needs. Below, we provide a brief example of the analysis:

Phase 1 involved identifying an illustrative episode (3rd meeting) demonstrating the tensions involved in balancing mathematical challenge with students' diverse needs as well as potential or actions taken to handle these tensions.

Penelope: I chose to design a lesson with an attempt to integrate some elements of differentiation. My aim initially was to use the basic tool concerning the property of the median of a triangle that divides it into two new ones with the same area … I struggled a lot to find a way to integrate differentiation. By inserting different exercises? How could I link differentiation to the management of the exercises in class? … I asked myself: What am I teaching? Areas. …So, I formulated the problem to have elements recognizable by students – plots of land, a square, etc.

Phase 2 involved two steps. **Step 1:** Coding the tension. Penelope's tension, as evident in the described episode, revolves around the challenge of balancing lesson planning and engaging all students with mathematical challenge. This tension arises from the need to effectively plan a lesson that caters to students with varying cognitive levels. We coded it as pedagogical tension related to lesson planning and student engagement. **Step 2:** Link to the TT: we categorized these tensions into three interrelated domains of the TT. Penelope's tension as evident in the episode revolves around the challenge of balancing lesson planning (ML) and engaging all students with mathematical challenge (MC). This tension arises from the aim to plan a lesson that caters to all students' varying needs (SS).

Phase 3 involved identifying and analyzing the potential or actual actions aimed at handling these tensions. To address this tension, Penelope decided to *introduce the mathematical concept within a real-world context*. By presenting data related to plots of land with geometric shapes she aimed to make the task more accessible to students.

Results

We first present the teachers' tensions. Next, we provide the teachers' actual or potential actions for handling them.

Teachers' tensions related to balancing mathematics challenge with students' diverse needs

Our analysis reveals four main categories of tensions (see Table 1): Pedagogical tensions; Curricular and institutional tensions; Cultural and social tensions; and Epistemological tensions.

Table 1: Teachers' tensions related to balancing mathematics challenge with students' diverse needs.

Tensions	Description	Example	Short analysis of the example
Pedagogical: Lesson planning/ enactment and Potential/actual student engagement	This tension arises when teachers attempt to balance the structured objectives of their lesson plans with the dynamic and unpredictable nature of student engagement during the lesson.	"I chose to design a lesson with an attempt to integrate some elements of differentiation. My aim initially was to use the property of the median of a triangle that divides it into two new ones with the same area … I struggled a lot to find a way to integrate differentiation…" [Penelope]	Penelope's tension revolves around balancing lesson planning (ML) and engaging all students with mathematical challenge (MC). The tension arises from catering to students with varying cognitive levels (SS).

Curricular and institutional: Curriculum and institutional demands and ML	This tension lies between balancing curriculum and institutional demands (i.e., mathematics inherent in the task, depth of content knowledge, program schedule, tools and resources) and ML (i.e., task planning, teaching strategies)	"I gave the students a task requiring them to find the sum and product of the roots of given equations, understand the concept of equivalent equations, and apply Vieta's formulas in various exercises... The equation had a negative discriminant... I struggled to discuss and explain it fully to students… due to limited time … The curriculum didn't cover this concept in-depth." [Grigoris]	Grigoris' tension arises from addressing advanced mathematical concepts that are not part of the curriculum. The limited time available to explain these concepts further compounded the issue, impacting his teaching (ML).
Cultural and social: Existing and new norms of classroom communication and potential/actual students' engagement	This tension arises when teachers struggle to create new norms of classroom communication facilitating mathematical challenge for all students.	"In the past, students' standing at the blackboard was a common classroom practice, ... However, as this tradition has declined, even capable students resist such activities… A student recently expressed reluctance to solve a problem on the board due to a lack of experience. How much should we push students out of their comfort zones..." [Aris]	Aris' tension arises from promoting new classroom norms (ML) and engaging students in challenging tasks (MC), while being sensitive to their emotional well-being and prior experiences (SS).
Cultural and social: Students' cultural background and potential/actual students' engagement	This tension arises when teachers struggle to balance students' diverse cultural backgrounds with fostering their engagement in mathematically challenging activity.	"I have a lot of foreigners… they have many problems … they struggle with the language… and in general I have children who are studying for half an hour at home [limited]… I also have a child in this class who is with Asperger syndrome… The challenge in this lesson is the way students developed an understanding of the triangular inequity with the use of sticks... " [Aleka]	Aleka's tension lies between planning lessons (ML) and fostering student engagement (MC) when dealing with diverse cultural and learning backgrounds (SS).

Epistemological : Nature of mathematical challenge	This tension arises from differing perspectives among teachers regarding the nature of the mathematical challenge.	"I would give them only the first task (asked students to find the Sum *S* and the product *P* of the roots of several equations) and somehow let's also put a parameter like gamma... then ask them to make a guess about the sum and the product …but in this case I could do only the first task… "[Grigoris]…"I wouldn't even ask them to find the roots… as initial questions we can find if the roots have the same or different signs without solving them... which is very challenging as an introductory task." [Apollon]	From Grigoris' point of view doing many exercises with demanding calculations is one way that students engage with mathematical challenge. For Apollon, students engage with mathematical challenge through inquiry and not through procedural tasks.

Teaching actions for handling the tensions

Our analysis reveals a multiplicity of actual/suggested actions aimed at handling the tensions aroused. These include: Making useful modification(s) to tasks so that students can productively address the task; Providing guidance (enabling and extending prompts); Utilizing manipulatives as a strategy for learning; Encouraging small group work; Encouraging different solution strategies; Introducing the mathematical concept with Real-World context; Fostering exploratory and conceptual discussion; Creating a safe and supportive environment; Using a smaller number of inquiry tasks rather than a set of exercises of different levels of difficulty. These strategies are essential for fostering an environment in which all students can engage meaningfully with challenging mathematical content. **To address curricular and institutional tensions**, fostering exploratory and conceptual discussions was the most frequently employed strategy. **In managing cultural and social tensions**, providing guidance through enabling and extending prompts, creating a safe and supportive environment, and encouraging small group work were highlighted. For instance, Aleka (see Aleka's tension in Table 1) used manipulatives, such as sticks, to enable further students' involvement while facilitating paired activities, addressing tensions arising from students' diverse cultural backgrounds and needs. For **pedagogical tensions,** a comprehensive range of strategies was suggested, including defining the lesson's theme and objectives and introducing mathematical concepts within real-world contexts. For example, Penelope (see Penelope's tension in Table 1) strategically focused on introducing mathematical concepts within real-world contexts, such as plots of land with geometric shapes, to enhance students' accessibility and engagement. **For epistemological tensions**, using a smaller number of inquiry tasks rather than a set of exercises with varied difficulty was suggested. For example, TE1 advised Grigoris (see Grigoris's tension in Table 1) that fewer, well-designed inquiry tasks are more effective for student learning than multiple procedural exercises.

Discussion and conclusion

This study contributes to the growing body of research on mathematics teachers' tensions. Previous studies have focused on tensions in teaching activities, such as pedagogical, curricular, and epistemological tensions (e.g., Horn, 2007; Potari et al., 2023). Our findings extend these studies by

employing the TT framework to explore the tensions teachers face when attempting to balance mathematical challenge with students' diverse needs at the micro level of the classroom in relation to the tensions they experience and their handling at both the micro and macro levels of the teachers' activity. In line with previous studies, this study identifies four key categories of tensions: pedagogical, curricular/institutional, cultural/social, and epistemological. Several aspects of the EDUCATE project allowed these tensions to be expressed. The discussions that took place during the meetings among teachers as they analyzed video clips from their own classrooms—viewed through the lenses of mathematical challenge and differentiation—emerged as a significant factor in alleviating these tensions. This collaborative approach aligns with existing research that highlights the benefits of mathematics teachers sharing and critiquing their experiences as part of professional development in video-club settings (van Es, 2012). Another aspect relates to the classroom environment and the students' diverse backgrounds and needs. Aleka's experiences with students from diverse cultural backgrounds underscored the cultural and social tensions inherent in her teaching practice. Her action of using manipulatives to simplify mathematical concepts exemplifies a culturally responsive teaching approach, which is supported by research emphasizing the importance of inclusivity in education (Tomlinson, 2014). In the case of Grigoris, curricular and institutional tensions arose from the constraints of the mathematics curriculum and the limited instructional time available. His actions to address complex mathematical concepts within the confines of the curriculum highlight the broader institutional pressures. This finding resonates with research that emphasizes the impact of external factors, including curriculum demands and institutional policies, on teachers' instructional decisions (Herbst & Chazan, 2012). While prior research has identified strategies for promoting differentiation and balancing mathematical challenge with students' diverse needs, such as using enabling and extending prompts (e.g., Charalambous et al., 2023; Sullivan et al., 2016), this study extends those findings. It highlights several strategies teachers employ to manage their tensions both at the micro level of classroom interactions and the macro level of their broader teaching activities. Overall, the teachers' actions to handle their tensions align with the aforementioned research that prompt teachers to balance mathematical challenge with students' diverse needs, such as using enabling and extending prompts (Charalambous et al., 2023). Further analysis of our data will also help us to identify emerging patterns of relationships between the tensions and the actions. The interplay of pedagogical, curricular, cultural, and epistemological tensions reveals the multifaceted nature of teaching mathematics in diverse classrooms. These insights underscore the necessity for ongoing professional development and support for teachers, enabling them to build an inclusive learning environment meeting all students' needs.

This study aims to determine which problems and in what sequence prospective elementary teachers select for a problem-posing task to handle them in classrooms, as well as the factors that mobilize their selection. We presented eight problems to 40 participants, developed according to various criteria for a problem-posing situation. They were asked to select four of these problems and explain their reasons for their selections. The findings provide data on the participants' problem selections. Furthermore, we identified seven factors that influenced their reasons for problem selection, two of which—focusing on mathematical content and varying the complexity—were more emphasized.

Keywords: Problem posing, problem selection, prospective elementary teachers.

Introduction

The primary source of problems brought into the classroom is often textbooks or teachers; however, students themselves can also serve as sources of problems (Kilpatrick, 1987). This aspect implies the incorporation of two critical skills in the classroom: having students generate problems and/or reformulate existing ones (Silver, 1994), which, more broadly, pertains to problem posing. The endeavor to integrate problem posing into mathematics classrooms is valuable because it fosters students to become independent learners and encourages them to take greater responsibility on their learning processes (English, 1997).

The idea that students' own problems can serve as the starting point for instruction (NCTM, 2000) highlights the critical role of teachers in problem posing. For example, recent instructional frameworks on problem posing recommend selecting some of the problems generated by students and addressing them in classrooms from various perspectives (e.g., Cai, 2022). It would neither be feasible nor logical to discuss all the problems generated by students in classrooms. Consequently, teachers must select the problems they intend to address from among the student responses, determine the order in which to present them to optimize learning, and establish the criteria for analyzing these problems. Furthermore, learning through problem posing takes place while students pose problems or discuss some of these problems within the classroom (Zhang & Cai, 2021). Therefore, teachers' decisions for selecting and sequencing problems will influence the opportunities provided to students through problem posing. That is to say, the steps of selection and sequencing are critical not only for the integration of problem solving into mathematics instruction (Smith & Stein, 2011) but also for the effective integration of problem posing (Cai, 2022).

The present study aims to explore which problems, and in what sequence, prospective elementary teachers (PTs) select for a problem-posing task to be addressed in classrooms, along with the factors that mobilize their selections. The literature on problem posing emphasizes the need for more research on how teachers integrate problem posing into mathematics classrooms to more effectively. This study can contribute to deepening our understanding of the opportunities PTs intend to provide students in the context of problem posing, by focusing on the selection and sequencing of problems, which are critical aspects of their instruction. Furthermore, illustrating a critical aspect of PTs' instructional practices related to the problem posing can provide a valuable foundation for developing their knowledge and practice regarding the integration of problem posing into mathematics classrooms. Thus, this study holds the potential to contribute to both following perspectives outlined in the research trends on problem-posing studies focused on teachers: the teacher as manager of the dynamics of problem posing and the potential of problem posing for teacher education (Montes et al., 2024).

Theoretical Background

Theoretical frameworks have been developed regarding how problem posing can be integrated into classrooms. Cai (2022) proposed a task-based instructional model in which the teacher presents the problem-posing situation and prompt, the students pose problems, and (students and) teachers handle posed problems in the classroom. He proposed instructional practices for the final step of the model, which include analyze, select, sequence, and solve. In the analyze practice, the teacher examines the problems generated by the students from various perspectives, such as whether they are mathematically correct or not. In the select practice, the teacher decides which problems will be handled in the classroom. The teacher can make decisions based on criteria such as learning objectives and the difficulty level of the problems. Afterward, the teacher determines the sequence in which the selected problems will be handled, and the problems are solved in the order established through collaboration with the students.

A limited number of studies on problem posing, due to their classroom-based reports, offer some insights into teachers' pedagogical intentions regarding the selection and sequencing of problems. Zhang and Cai (2021) found that teachers tended to disregard problems that were irrelevant to the instructional objectives of the lesson, while considering the difficulty level for those that were relevant. Furthermore, teachers provided quick guidance to students during class discussions for easy problems; however, they either assigned more challenging problems as homework or indicated that these would be solved in the next lesson. Teachers showed a tendency to engage in discussions of moderately challenging problems. In a study investigating how problem posing is addressed in an elementary school classroom (first grade, 6- and 7-year-old students), Possamai and Allevato (2024) reported that the teacher encouraged students to share the problems they had created by reading them aloud to their peers in class. However, their findings revealed an absence of reflections on the structure of the problems and a lack of exploration of possible solutions. Montes et al. (2024) found that pre-service teachers' problem modification intentions were focused on deepening understanding of the mathematical content, varying the level of complexity, improving comprehension of the problem statement, and assessing understanding. Considering these findings within the context of our study, it suggests that the choices made by PTs may be influenced by factors such as the complexity

of the problems, the mathematical concepts and relationships they involve, and their effectiveness in evaluating student understanding.

Although the studies summarized above provide some insights regarding problem selection, they do not offer information on certain aspects, such as how in-service and pre-service teachers respond to mathematically incorrect student problems. From a behaviorist perspective, errors are considered detrimental, as they have the potential to reinforce incorrect responses (Santagata, 2005). Conversely, within the constructivist approach, they are regarded as an integral component of mathematics classrooms. As highlighted in Principles and Standards for School Mathematics document (NCTM, 2000), "mistakes are not viewed as dead ends but rather as potential avenues for learning" (p. 144). This study can also provide insights into how PTs address mathematically incorrect problems or those with insufficient data through their teaching practices related to problem posing.

Methods

Participants and the task

The study involved 40 PTs who were in their third year of an elementary school teacher training program at a state university in Türkiye. PTs must successfully complete a four-year teacher training program in order to be certified as elementary school teachers (teaching students aged 6 to 10 in grades one through four). The PTs were given one month to complete the assignment (Figure 1), and data collection occurred during the period in which the participants were enrolled in the Mathematics Teaching-II course.

We utilized the road-trip situation in the problem-posing task because it has been featured in numerous studies (e.g., Silver & Cai, 1996). The selection of the eight problems in the data collection tool was guided by the sample problems from the literature: (i) problems that were answered by doing operations with the existing data (P1, P3, and P4), (ii) problems whose answer was readily available in the existing data (P2), (iii) problems that were mathematically incorrect (P5), (iv) problems that were created by adding new conditions to the existing data (P6 and P7), and (v) problems that had insufficient data (P8). In this study, the data from the first two questions of the data collection tool were utilized to address the research questions (see Figure 1).

Data analysis

The frequency distribution of the types of problems selected, based on the order of responses, has been provided to illustrate the PTs' problem choices. Qualitative content analysis was used to determine which factors the PTs mobilized in their problem selections (Mayring, 2014). Two coders, who are also the authors of this study, identified a total of 24 codes for the reasons behind problem selection. Some of these codes were observed quite rarely in the sample, and in this context, codes that appeared in only one participant's problem were eliminated (e.g., assessing student mathematical knowledge, supporting classroom communication, and highlighting expectations from the problem). The final 21 codes are therefore listed in the findings section under seven categories.

Problem posing task: Mehmet, Ali, and Hasan drove their car back home after their vacation. Hasan drove 120 kilometers more than Ali did during the trip. Ali drove twice the distance that Mehmet drove. In this trip, Mehmet drove 80 km.

Dear students, based on this situation, create a problem for your classmates.

A teacher presents this task to one of 4th-grade mathematics classes and gives students 10 minutes to individually pose a problem based on the given situation. After that, the teacher aims to select and discuss some of the students' problems in the classroom. Below, you are presented with 8 problems of the students in this fictional lesson.

P1: How many km did Hasan drive?

P2: How many kilometers more did Hasan drive than Ali?

P3: How many kilometers did the three of them drive together?

P4: How many more kilometers did Hasan drive than Mehmet?

P5: How much longer is the total distance driven by Mehmet and Ali than the total distance driven by Hasan?

P6: If they refuel the car every 150 km during the trip, how many times do they need to refuel it in total?

P7: If the car consumes 2 TL of fuel per km during the trip, how much fuel do they spend in total?

P8: When they went on vacation together, Hasan drove 160 kilometers more than Ali did. Accordingly, how many kilometers did Hasan drive on the way to and from the vacation?

Accordingly, please answer the following questions:

1. If you were the teacher and wanted to choose four of the problems listed above to address in the classroom, which ones would you choose? Why?
2. In what order would you consider examining these problems during the lesson? Why?
3. Write a scenario for the teaching you plan to carry out, taking into account the problems you chosen and their order.
4. Explain the situations you focused on, considered important, or paid attention to while designing your scenario.

Figure 1: Data collection tool

Findings

Findings on the distribution of problems according to response order

In their first choices, PTs selected one of the options P1, P2, or P3 (as illustrated in Figure 2). The key characteristic of these problems is their focus on understanding the variables and their relationships in the situation. In this context, participants prioritized problems that would enable students to analyse the mathematical content within the problem-posing situation. Among these, P1 was the most frequently chosen. Participants highlighted several reasons for starting with such problems, including its potential to help students understand the mathematical relationships involved, contribute to solving subsequent problems, and be relatively easy for the initial attempt. For example, PT5 explained her selection as follows:

> [Referring to P1] The question clearly states how many kilometers only Mehmet drives. I adopt the working backwards strategy and try to find out how many kilometers Hasan, P1's answer, drives. In fact, while trying to find out how many kilometers Hasan drives, I have to find out how many kilometers Ali drives, so that I actually find out how many kilometers the people mentioned in the problem drive. By finding the unknown points in the problem, it will be easier for us to answer the questions that will come in the following stages.

For the second choice, participants' selections demonstrated a wider distribution, with a notable preference for problem types P3 and P4 among the six problem types. These problems are consistent with P1, which was predominantly chosen for the first choice, as solving P1 facilitates the solutions of these subsequent problems. Similar to their second choices, PTs' selections for their third and fourth problems were distributed across a broad spectrum (as shown in Figure 2). In these choices, P6 and P7 were particularly prominent. The primary characteristic of these two problems is their potential to expand mathematical understanding by introducing new data into the existing problem-posing situation.

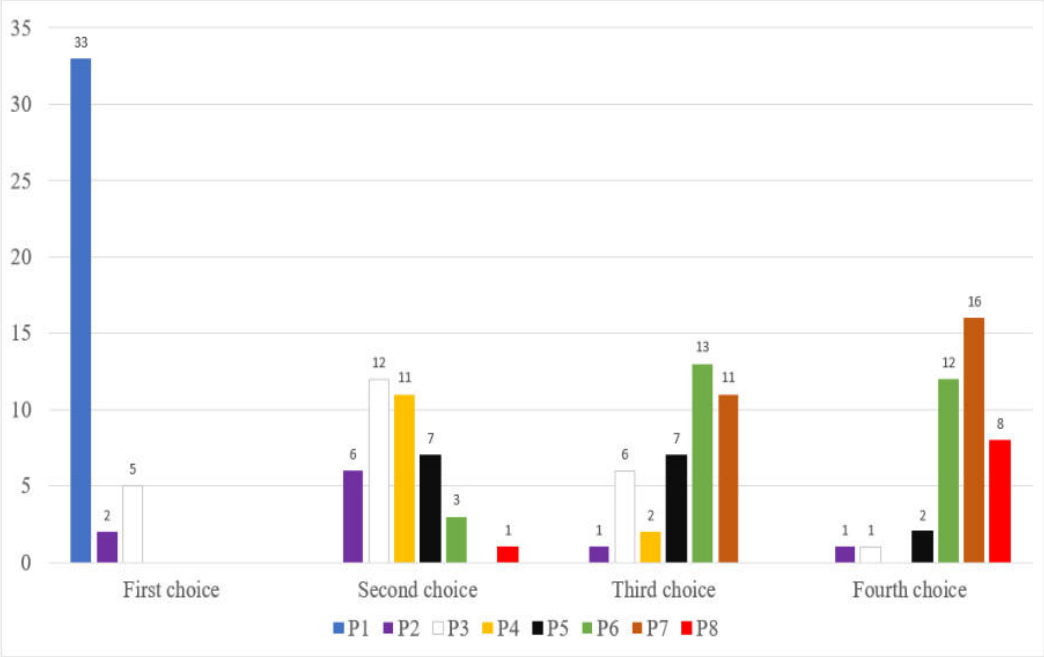

Figure 2: Distribution of problems based on response order

Given that PTs often highlighted the complexity of the problems as a rationale for their choices, they tended to introduce such problems in the third or fourth order in the classroom. PT36's explanation includes the following:

> I would choose R1, R3, R7 and R6, (respectively). The reason for my selection was to act according to the principle of simple to complex. At the beginning, I chose problems that were easy to understand and solve, and as I progressed, I wanted the problems to become more complex and difficult.

Another notable finding of the study is the low preference for analysing P5 and P8 in the classroom, with P5 being mathematically incorrect and P8 containing missing data. When all problems are grouped, P1-P4 and P6-P7 exhibit similar characteristics and were predominant across the sample. On the other hand, P5 appeared in two-fifths of the sample, while P8 was present in just over one-fifth. These results suggest that participants did not show a strong tendency to explore incorrect or incomplete problems within the learning environment. Additionally, when comparing the two types

of problems, incorrect problems were preferred over incomplete ones. Participants who selected the P5 and P8 for classroom discussion sought to illustrate to students both the error in the problem and that not every problem has a solution.

Moreover, some PTs failed to recognize the errors or missing data in the problems and instead justified their choices by emphasizing the skills required to solve the problem. For example, PT2's explanation includes the following:

> I would choose problem 5 as the third problem because I think that they will be able to solve this problem easily with the information in the second problem. Additionally, comparing among drivers will improve their comparison skills and addition-subtraction activities through this problem. That is; Mehmet = 80 km. Ali = 160 km. Hasan = 280 km. Mehmet + Hasan = 80 km +160 km = 240 km. 280 km-240 km = 40 km

According to another finding of the study, answer of the P2 is situated within the current problem-posing situation. Only one-fourth of the sample selected this problem for classroom discussion. Among them, only PT10 explicitly stated that she selected this problem to discuss the expectations from students in a problem-posing situation. A part of PT10's explanations are as follows:

> I would choose the problem "P2: How many kilometers more did Hasan drive than Ali?" Because the answer is given in the problem, I can show the students that this problem does not constitute a problem.

Distribution of reasons for PTs' problem choices

The reasons for problem choices were classified into seven categories: (i) focusing on mathematical content, (ii) considering reading comprehension skills, (iii) supporting association and representation skills, (iv) varying complexity, (v) motivation, (vi) supporting problem-solving skills, and (vii) considering instructional flow.

Within the first category, participants offered justifications related to enhancing students' arithmetic skills, supporting and reinforcing mathematical understanding, and focusing on identifying and addressing errors in problems. Five codes were identified within this category, appearing a total of 66 times across the sample. In the second category, a single code was identified. Two participants noted that the selected problem could allow for a focus on students' reading comprehension skills. An excerpt from PT1's explanation is as follows:

> P2: The reason I chose this problem is to measure students' reading comprehension skills. The answer to the problem is clearly stated in the story. It does not require additional operation. This provides convenience for students and increases their attention.

Under the third category, two codes were identified and appeared eight times in total. PTs noted that the problems they selected were relevant to daily life and that some problems allowed for the use of visual models as justifications for their selections. In the fourth category, varying complexity, six codes were identified and appeared 45 times in total. Participants provided explanations regarding the difficulty level of the problems, citing reasons for their selections such as increasing the complexity of problems in sequence, adding new data to make problems more challenging, ease of

solving, and complexity based on the types of arithmetic operations involved. In the fifth category, motivation, a single code was identified and appeared nine times in total. Participants emphasized that adjusting the difficulty level of problems according to the students' capabilities would enhance their interest in problem solving. PT25, who provided explanations related to both varying complexity and motivation, shared the following:

> The solution order would be 1, 2, 6 and 7 because I think it will be more understandable for students in terms of evaluating the problems in a sequence from easy to difficult and from simple to complex. I also think that solving easy problems first will be motivating for the students before moving on to other problems. When they cannot solve the first problem, they will have a negative attitude towards other problems.

In the sixth category, supporting problem-solving skills, three codes were identified and appeared 10 times in total. Participants indicated that the selected problems encourage the use of problem-solving strategies and help students understand that not every problem can be solved with the available data. Finally, under the category of considering the instructional flow, three codes were identified and appeared 34 times in total. Participants emphasized that certain problems act as prerequisites for others, and some problems assist in solving subsequent ones (Please refer to PT5's explanations in the first section of the findings).

Conclusions

In this study, the PTs tended to select problems with low mathematical complexity for the initial problems. In their subsequent problems, they attempted to make the problems more complex. Zhang and Cai (2021) found that teachers tend to assign problems they consider mathematically complex as homework, while they engage in classroom discussions on problems they perceive as moderately difficult level. Furthermore, our study suggests that PTs also consider incorporating complex problems into classrooms, yet the prevailing tendency is to address these in subsequent problems rather than in the initial ones. Moreover, the PTs did not frequently select problems with insufficient data, mathematical errors, or answers that were readily available in the data set, despite experimental studies showing that these problems are commonly seen in students' responses (e.g., Kar et al., 2024; Silver & Cai, 1996). Due to lack of knowledge on how to handle student problems— particularly those presented in textual form that do not involve any mathematical demands—teachers commonly limit their interaction by asking students to simply read their problems aloud (e.g., Possamai & Allevato, 2024). Our research highlights another aspect of classroom discourse that PTs neglect, namely, engagement with incorrect mathematical problems. When the instructional stance of the PTs is evaluated from behaviorist and constructivist perspectives (Santagata, 2005), they align more with the former in addressing errors, showing limitations in perceiving errors as "potential avenues for learning" (NCTM, 2000, p. 144).

The PTs provided multiple reasons for selecting problems and highlighted several reasons together for the selection of a single problem, indicating that they consider multiple variables when making decisions about problem selection. The problems were chosen primarily based on their mathematical content and complexity, as was to be expected. However, aspects such as developing a problem-solving culture, utilizing problems to assess students' knowledge, and affective factors had less of an

impact on the PTs' selection of problems. Our results highlight the strengths and weaknesses of PTs' preferences regarding the selection and sequencing when implementing problem-posing task in the classroom. Therefore, we believe our study could be helpful in the endeavour to enhance teachers' proficiency in integrating problem-posing into mathematics classrooms in various ways.

Mathematics teacher practice in inquiry-based lessons: A case study in a Japanese upper secondary school

Toshihiko Ogawa[1] and Takeshi Miyakawa[2]

[1]Waseda University, Graduate School of Education, Japan; toshi.k2@fuji.waseda.jp

[2]Waseda University, Faculty of Education and Integrated Arts and Sciences, Japan

The purpose of this paper is to advance the understanding of mathematics teacher practice characteristics in inquiry-based lessons. From the perspective of the anthropological theory of the didactic, we investigate the practices of mathematics teachers in the process of preparing lessons at a Japanese upper secondary school. Specifically, by regarding these practices as 'teacher inquiry' and analysing them with the notion of praxeology, we identify the types of tasks they were working on during their meetings and the concerns they encountered. As a result, we found that the following two types of teachers' practices are dominant in our case, which are not often carried out in the preparation of ordinary mathematics lessons: exploring teaching contents from multiple perspectives and designing teachers' supporting questions for students to promote their own inquiry.

Keywords: Mathematics teacher practice, Inquiry-based learning, Secondary schools, Anthropological theory of the didactic.

Introduction

Inquiry-Based Learning (IBL) has drawn considerable attention in international mathematics education research over the last two decades (Artigue & Blomhøj, 2013). IBL is a learning form modelled on researchers' works, in which students address questions as inquirers, using various resources (e.g., books, internet, PC) and support (e.g., teachers, colleagues) at their disposal. This learning form differs from ordinary mathematics lessons in that the mathematical knowledge to be learned is predetermined, and the available tools and support are limited.

Focusing on *teaching*, teacher practice in IBL lessons should also have characteristics that differ from those of ordinary lessons (Dorier & Maass, 2020). The teachers' roles in IBL lessons are not to explain mathematical concepts, provide problems, evaluate students' answers, and so forth. Therefore, IBL lessons require teachers to possess knowledge and skills specific to such forms. It is expected, for example, that teachers will have some experience with mathematical inquiry by themselves (Artigue & Blomhøj, 2013; Chevallard & Strømskag, 2022) and some skills to facilitate students' inquiries.

Given the above background, we are interested in the mathematics teacher expertise required to conduct such IBL lessons. In this study, as a preliminary phase, we focus on mathematics teacher practice *involved in* IBL lessons and aim to advance the understanding of its characteristics. In this paper, *teaching* is considered not only the teacher practice within the classroom but also outside it. Specifically, we investigate a specific case of a Japanese upper secondary school mathematics teacher who was engaged in the design and implementation of IBL lessons through one year, with the support of a researcher. By employing analytical tools developed within the *anthropological theory of the didactic* (ATD), we analysed the meetings for IBL lessons to shed light on the teachers' work and identified the characteristics of teachers' practices in this context.

Theoretical perspectives

This study adopts two conceptual tools developed within the ATD to investigate teachers' practices related to IBL lessons.

The first tool is *teacher inquiry*, which allows us to investigate teachers' practices in terms of the inquiry (Trouche et al., 2019; Miyakawa, 2022). In ATD, inquiry is an important object of study, and its process and structure are formulated as the notion of *Study and Research Paths* (SRP) (Chevallard, 2019). SRP is a series of inquiry activities that develop in a learning environment with all available resources (called *media* in ATD). The inquiry usually begins with a lively generative initial question (Q_0), new questions are derived progressively by pursuing Q_0, and it is further deepened by addressing these questions. This process is characterised as the *dialectic of questions and answers* and is a fundamental concept in SRP (in particular, questions). In fact, the design of an ordinary mathematics lesson begins with the initial question 'How to teach a particular mathematical content?', referring to all available resources such as textbooks and teaching resources and learning any necessary content for teaching as needed, and the final answer '$A^{\heartsuit}$: A design of the process of one lesson' is obtained. This process can be seen as SRP. Using this tool, the dynamic process of teachers' work can be described in terms of the questions and answers they handle during meetings.

The second tool is the notion of *praxeology*. In ATD, any human activity and knowledge can be modelled using praxeology (Chevallard, 2019). Praxeology comprises a *praxis* block that describes activities and a *logos* block that provides a theoretical background. The praxis block is described by *a type of tasks T*, which refers to the family of tasks or problems, and *a technique* τ, which refers to the method of solving the task. The logos block is described by *a technology* θ, which generates, justifies, and explains the technique, and *a theory* Θ, which does the same to the technology. Using this concept, a student's mathematical activity and a teacher's practice *inside* the classroom can be modelled respectively by a *mathematical praxeology* (MP) and a *didactic praxeology* (DP), and a teacher's practice *outside* the classroom by a *paradidactic praxeology* (Miyakawa, 2022). For example, the situation of solving a linear equation in middle school, like $2x + 3 = x - 5$, can be described as a MP, where T is to solve a given linear equation, τ is moving terms, θ is a property of the equation or an image of balance, and Θ is the theory of linear equation in middle school mathematics. We specifically use paradidactic praxeology to analyse teachers' practices in the preparation and reflection of IBL lessons.

Methods

In this study, the IBL lessons were conducted in a new subject called *Period for Inquiry-Based Cross-Disciplinary Study* at a Japanese public upper secondary school. This subject aims to nurture students' competence to conduct cross-disciplinary inquiry based on their knowledge of ordinary subjects. As part of a research project exploring the potential of mathematical inquiry within this subject based on SRP, a sequence of lessons was implemented for one year, consisting of 53 fifty-minute lessons. These lessons were collaboratively designed by a teacher (called Mr T) and a researcher (first author; called Supporter), both of which participated in this research project. Twenty-two Grade 12 students attended this class and were divided into seven groups of two to four students. Each group selected a

different theme: three were purely mathematical, and four were related to the application of mathematics. Mr T mainly led the lessons, while Supporter primarily observed them.

Meetings for the IBL lessons were organised for Mr T and Supporter before and after each lesson, which lasted from 15 min to 1 hour, totalling over 100 times. Mr T was a high school mathematics teacher with 10 years of teaching experience but less experience of teaching IBL lessons. Supporter was a PhD student who had some knowledge of didactic theory, such as ATD and SRP. The discussions during these meetings primarily focused on the design of slides for the next lesson and the reflection on each group's inquiry after the lesson. The discussions also progressed with reference to the students' activities, worksheets, and other materials used in the lessons.

In the analysis, we first created a *Q-A timeline* for each meeting (See Figure 1). In this study, the meetings were regarded as part of *teacher inquiry* (SRP), and we identified the questions and answers addressed by Mr T and Supporter in a chronological order. The initial question for pre-lesson meetings was 'How will the next lesson be?' while for post-lesson meetings, it was 'How was today's lesson?'. The discussions during the meetings were chronologically divided into stages according to the main questions. The activities in the meetings can be modelled using the concept of paradidactic praxeology. In this context, the main types of tasks were classified into four categories: *Exploration of MP*, *Evaluation/Selection of MP*, *Exploration of DP*, and *Evaluation/Selection of DP*. In other words, the main activity in the meetings can be seen as *investigating* MPs and DPs that will occur (or had already occurred) in the lessons. The answers at each stage were therefore identified and classified according to these four categories of the types of tasks in paradidactic praxeology.

After creating the Q-A timelines, we investigated the *concerns* encountered by Mr T and Supporter. We hypothesised that these concerns reveal mathematics teachers' practices that are both critical and unique to IBL lessons. Specifically, by focusing on the specific moments at which the concerns arose, we investigated what questions they raised and how they solved them.

Results

In this section, we outline the students' inquiries and provide the main questions that arose in the meetings, followed by an analysis of the post-lesson meeting in which some concerns were discussed.

Students' inquiries

In the first semester (20 lessons), students determined the inquiry themes in the first eight lessons and then started their inquiry in the remaining 12 lessons. In the second semester (23 lessons), students progressed with their inquiry and had opportunities to report their findings at the mid-term presentation as well as at the poster presentation organised at the later part. At the end of this semester, students began to work on their final reports and continued to work in the third semester (5 lessons).

In the second half of the first semester, the lessons comprised two phases: inquiry toward the mid-term in-class presentation (five lessons) and inquiry with teacher individual supervision (seven lessons). In the first phase, the inquiry was conducted over four lessons, including time for deciding on the themes, and each group gave an oral presentation in the final fifth lesson. In the second phase, each group had the opportunity to discuss the progress of their inquiry with Mr T during the lesson.

Main questions in the meetings (in the second half of the first semester)

Twenty-four meetings were conducted for 12 lessons in the second half of the first semester. The main questions addressed differed according to the pre- or post-lesson meetings. In the former, the questions repeatedly raised were as follows:

Q: How do we organise the students' activities in the lesson? (Exploration of DP)

Q: How do we support students to encourage them to advance their inquiries? (Exploration of DP)

These questions were related to *Exploration of DP*, in which the teacher's techniques and classroom interventions were investigated. Some activities were required as part of the school policy to be included: conducting the mid-term presentation (progress report) and the final presentation, and writing the final reports. The content and organisation of the lessons, excluding these activities, were left to the teacher's discretion.

Specifically, in the pre-lesson meetings held for the fourth and fifth lessons during the presentation phase, they worked on the question 'Q: How do we organise the session of the students' presentations?' In other pre-lesson meetings, the question 'Q: How do we organise the teacher supervision?' was also raised. In addition, in the pre-lesson meeting held for the last lesson during the supervision phase, as the summer break came after this phase, the question 'Q: How do we organise the inquiry during the summer break?' was discussed, and they decided to assign two tasks: summarising the results in the first semester and working on the questions provided by the teacher.

In contrast, the questions that were repeatedly raised in the post-lesson meetings were as follows:

Q: What are the possible directions for each group's inquiry? (Exploration of MP)

Q: What support should the teacher provide to promote these possibilities? (Exploration of DP)

Q: Was the teacher's support appropriate to promote their inquiry? (Evaluation/Selection of DP)

In the post-lesson meetings, after debriefing each group's activity and the teacher's support in the lesson, they often discussed the possible directions of each group's inquiry and the teacher's questions to promote these possibilities. Because each group worked on a different theme, much time was devoted to considering the teacher's support that would be more appropriate for each group's inquiry. The details of the specific discussion are described in the next section.

They also evaluated whether teacher support and lesson organisations were appropriate for advancing student inquiry. For example, during the presentation phase, in the post-lesson meeting after the presentation, they discussed the question 'Q: Is it necessary to set up a presentation session in every phase to provide comments?'. They found that the session was not effective because Mr T could not ask enough questions and provide suggestions to each group. As a result, they decided to implement teacher supervision in the next phase. In the post-lesson meeting during the supervision phase, in contrast, another question 'Q: Could we support other groups during the supervision of specific groups?' was addressed. They concluded that supporting only specific groups was not effective and decided that the first half of each lesson was used for the individual supervision (two groups per lesson), while the second half was that Mr T circulated in the classroom and provided occasional support to other groups. In this way, they improved their support and lesson organisations accordingly.

Post-lesson meeting of the fourth lesson in the presentation phase

Let us analyse the meeting discussion more precisely. A post-lesson meeting was held after the fourth lesson in the presentation phase. In the next fifth lesson, each group was expected to give a 5-min oral presentation on the progress of their inquiry. Up to the fourth lesson, for example, Group A had been working on the first question 'Q_0: How to calculate 20 decimal places of π by paper and pencil?' and tried to carry out an approximate calculation of π using the Ramanujan formula.

This post-lesson meeting was divided into 11 stages according to the main questions raised during the meeting (see Figure 1).

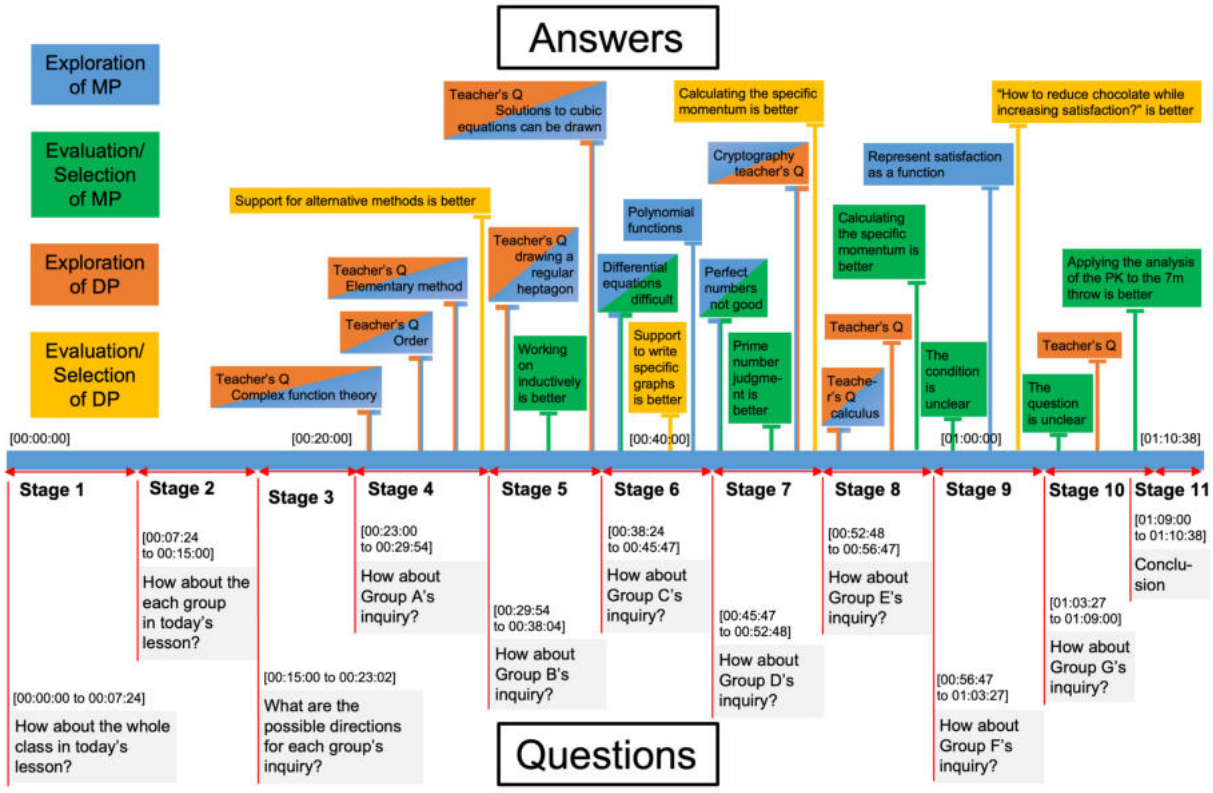

Figure 1: Q-A timeline for the post-lesson meeting of the fourth lesson in the presentation phase

In this meeting, Mr T and Supporter mainly discussed the students' work up to that point and directions for future inquiry after the presentation. In Stage 1 and 2, Mr T reported his overall remarks on the entire lesson and the progress of each group's inquiry. We did not provide any answers on the timeline because these were not directly related to the four categories.

In Stage 3, they discussed the comments/questions to ask each group in the next presentation. In this stage, Mr T expressed concerns about anticipating the possible directions of students' inquiry in response to the main question 'Q: What are the possible directions for each group's inquiry?' Supporter responded to this question by suggesting some ideas. In Stage 4, there was a seven-minute discussion about Group A's inquiry (calculation of π), they proceeded the following dialogue:

Supporter: When Group A addresses the question 'Why is the coefficient so strange?', the inquiry could go into university or graduate school mathematics content.
Mr T: Hmmm...
Supporter: Yes, well, it can go into an area related to complex function theory.
…
Supporter: One possibility would be to address the question of 'how quickly does it converge?' by working on the method that Group A is currently employing. Well, the inquiry will be about how it converges as n increases, and the order of magnitude involved in the question of "how do you judge how quickly it converges?" Well, I think that working on the question like this in the future would be one possibility.
…
Supporter: From a historical perspective, if Group A addresses the question 'How did people in the past, such as those who did Wasan (Japanese traditional mathematics), calculate?', we can expect that Group A will be able to find more, well, elementary methods.
Mr T: Ah.
Supporter: For example, methods of approximate calculation using 355/113.

They discussed three possible directions for future inquiry in Group A: complex function theory (the background theory of Ramanujan formula), order (speed) of convergence, and elementary calculation methods (e.g., a method of Japanese traditional mathematics, Wasan). While thinking about these possibilities, they also discussed the questions that Mr T could provide to Group A to promote in these directions (in Figure 1, these answers were represented as 'teacher's Q'). In this situation, different categories of answers are considered almost simultaneously, two of which are written as one answer on the Q-A timeline (in Stage 4, the answer of Exploration of MP occurs after Exploration of DP). At the end of Stage 4, they concluded their discussion on Group A with the following dialogue:

Supporter: From a historical perspective, there have been many investigations into how to improve the accuracy of approximations of π, so I think the method investigated by Group A is probably the best modern method to have a quick convergence.
Mr T: I think so too.
Supporter: However, there are various problems with this method, such as the difficulty of the calculations, so it might be good to support other methods and compare them with the current method.

Finally, they chose to direct Group A to the calculation of π using elementary methods because the Ramanujan formula was too difficult for them. This is related to the type of tasks in the Evaluation/Selection of DP. Similar discussions to those in Stage 4 were also held with the other groups from Stages 5 to 10. One may say that Mr T's main concern in this meeting was the possible directions for further inquiry, and much time was devoted to discussing them (two-thirds of the total).

Discussion and conclusion

In this section, we focus on two main concerns identified in the analysis of the post-lesson meeting: *possible directions for inquiry* and *supporting questions*.

As observed in the previous analysis, one of the main concerns in the meeting was to explore the mathematical content related to students' inquiry to identify directions for further developing those inquiry. In IBL or SRP, particularly in the inquiry subject implemented in Japan, the mathematical content or knowledge to be taught is *not predetermined*, unlike ordinary mathematics lessons. Students are therefore exposed to various topics as they progress through their inquiry. In such

circumstances, it is understandable that Mr T and Supporter were constantly investigating possible directions to provide students with appropriate support. In addition, it is noticeable that for ordinary mathematics lessons, teachers are also required to explore the mathematical knowledge before teaching (often called *kyozaikenkyu* in Japan), but this knowledge is predetermined in the curriculum, and teachers are familiar with it. These teachers' practices differ from those of IBL lessons. Therefore, *Exploring MP from multiple perspectives* should be one of the characteristics of teacher practice involved in IBL lessons. Furthermore, teachers may encounter unknown knowledge in such lessons (e.g., neither Mr T nor Supporter knew well Ramanujan formula). An inquirer's attitude is to behave as if knowledge is still to be discovered and conquered. In this case, this attitude, *procognitive attitude* (Chevallard, 2015), is critical in the design and reflection of IBL lessons.

Another important concern in the meetings was the design of supporting questions. This concern is closely related to the didactic gestures required for the lessons and their preparation. The teacher's role in IBL lessons is not to validate or summarise students' answers but to support students' inquiry so that they can deepen their own topics. One important type of tasks in DP is to provide *lively* and *generative* questions that students may be interested in and generate new questions to advance the inquiry, particularly when the inquiry is stagnating. As mentioned earlier, in SRP, questions play a critical role as a lever for advancing inquiry. In IBL lessons, teachers are therefore required to provide appropriate questions according to the progress of students' inquiry. Similarly, in ordinary mathematics lessons, teachers often provide students with questions, but these questions are supposed to be answered in a short time. The nature of such questions is, in fact, different from that of IBL lessons, and the same applies to their preparation work. Therefore, *designing supporting questions* should be one of the characteristics of teacher practice involved in IBL lessons.

However, these concerns arise because of the distinct nature of inquiry activities expected in the classroom, which markedly differ from ordinary mathematics lessons. As noted by Artigue & Blomhøj (2013), a critical aspect of mathematics teacher expertise in IBL is the first-hand experience of inquiry. In fact, when supervising PhD students (this is also an inquiry-based instruction), experienced researchers and university scholars do not necessarily explore questions and prepare supporting questions beforehand. Therefore, it is still questionable to what extent the characteristics of teachers' practices identified in this paper are general or whether they can be found under specific conditions. Furthermore, the roles of 'Supporter' in this case are not clear. Future research is required to analyse the nature of researchers' interventions in relation to mathematics teacher collaboration.

What do teachers notice when reflecting on vignettes of discussion-leading practices? A topic-specific case study

Monika Post[1] and Dilan Şahin-Gür[1]

[1]TU Dortmund University, Germany; monika.post@math.tu-dortmund.de

Discussion-leading practices are a central part of teachers' expertise and are substantially influenced by what teachers notice in the complexity of classroom discussions. With engaging teachers in reflecting on crucial content-specific aspects of classroom discussions, we aim to enhance their noticing and deepen their awareness. This paper presents a case study investigating what teachers notice when reflecting on a classroom discussion during a professional development course. The results indicate that teachers vary in the extent to which they reflect on content-specific aspects, such as concept element or representations.

Keywords: discussion-leading practices, *noticing*, *professional development* (*PD*).

Theoretical background

Design research agenda of decomposing discussion leading practices and teacher noticing

Mathematical learning opportunities can be created, for example, by well-designed tasks, however their effectiveness largely depends on teacher's enactment. Research thus concentrates on investigating and decomposing teaching practices (da Ponte & Chapman, 2006), particularly discussion-leading practices (Jacobs & Empson, 2016). Teaching practices constitute a central component of teachers' expertise (Prediger, 2019), enabling them to handle the "complex situational demands of subject-matter teaching" (p. 370). Qualitative decompositions of teaching practices, such as discussion-leading practices focusing on dealing with multiple representations (Post & Prediger, 2024), reveal variation in teachers' actions. These differences seem to be influenced by teachers' noticing, their ability to perceive, interpret, and respond to classroom events: For example, joint discussion of video clips from lessons of other participating teachers supports teachers' "ability to notice and utilize student thinking for instructional decisions" (Wallin & Amador, 2019 p. 515).

Research on teacher noticing emphasizes the importance of awareness and sensitization to specific aspects of teaching practices (Mason, 2011; Weyers et al., 2024). Sherin et al. (2011) describe noticing as a complex process "through which teachers manage the 'blooming, buzzing confusion of sensory data' with which they are faced" (p. 5). This process involves filters of perception and consists of two key components: "attending to particular events in an instructional setting" and "making sense of events in an instructional setting" (ibid., p. 5). For the second process of making sense, Sherin et al. (2011) highlight the relevance of categories: interpreting means "relating observed events to abstract categories and characterizing what they see in terms of familiar instructional episodes" (ibid., p. 5).

Many studies investigate the sub-processes of teacher noticing, such as how teachers perceive student thinking or classroom events, interpret them, decide how to respond, and subseqeuntly enact in classroom (Weyers et al., 2024). Rosaen et al. (2008) use the concept of noticing to investigate for three pre-service teachers how using videos can support pre-service teachers in reflecting on their

practice. Reflections based on video analysis compared to reflection based on memories support teachers to reflect more specifically and with a stronger focus on instruction and the students rather than on classroom management alone. Detailed analyses of the reflections showed that the pre-service teachers, for example, examined the impact of specific prompts in the conversation or the development of learners' thinking while analyzing their own classroom videos. The authors suggest that video analysis might support teachers in leading discussions, a possibility that requires further investigation. However, as van Es and Sherin (2002) emphasize, it is crucial to learn to focus on the relevant aspects while noticing.

This case study is part of a larger study that aims at investigating how teachers can be made more aware of discussion-leading practices for dealing with multiple representations for the case of conditional probabilities, and how they can be supported in establishing these practices. Previous studies have identified constituent elements of those practices using a topic-specific approach (Post & Prediger, 2024). This study aims to expand the research field by examining which aspects teachers actually notice when reflecting on their teaching practices.

Topic-specific approach for conceptualizing discussion-leading practices

Following Prediger et al. (2022), we conceptualize discussion-leading practices "as the teachers' steering trajectories on a content-specific navigation space" (p. 7). This includes in particular that the representations referred to and the relevant aspects of the content in view are key to capture the discussion leading practices (Post & Prediger, 2024). For instance, for the content of "interpreting statements on conditional probability", the part-whole relationship is a key conceptual element of probability statements: Analyses of learning processes and analyses of discussion-leading practices of different teachers (Post & Prediger, 2024) show that explicitly addressing the part-whole relationship, rather than focusing only the part and the whole separately, seem crucial for fostering a deeper understanding of conditional probabilities. Connecting representations consciously also plays a crucial role in promoting conceptual understanding. Understanding a complex statement such as "The probability that a buyer doesn't buy a bag on the condition that he doesn't buy a shirt", requires grasping this part-of-part structure: "All buyers who don't buy a bag and a shirt out of all buyers who don't buy a shirt."

Teachers' discussion-leading practices vary significantly in how explicitly they address the part-whole relationship and guide the discussion towards connecting the elements across different representations in the discussion (Post & Prediger, 2024). While some teachers focus on explicating the part-whole relationship in plenary discussions (*conceptual focus*), others limit their attention to the part and the whole separately or emphasize procedural steps for determining the correct probability (*procedural focus*). This study adopts the conceptual framwork of discussion-leading practices to analyze the aspects teachers address when reflecting on their practices. Particularly, the focus lies on whether teachers refer to *key concept elements, representations* and *connections for the topic in view*.

Research question

The primary goal of this study is to investigate what teachers notice when reflecting on discussion-leading practices, particulary in PD courses. We therefore ask: *Which aspects do teachers focus on*

when reflecting on vignettes of discussion-leading practices and their own practices? To what extent do teachers address the aspects of content-related discussion-leading practices?

Methods

This study is part of the larger professional development (PD) research project QuaMath (Prediger & Selter, 2024) in PD design research methodology (Cobb et al., 2017) and is applied, among others, on PD courses focusing on conceptually focused mathematics teaching.

In this paper, we examine teachers' noticing during a vignette-based activity conducted within a three-hour, synchronous online PD program. In this focused PD session centered on language-responsive teaching of conditional probability 26 German middle and high school mathematics in-service teachers participated. They had varying years of teaching experience and already some previous experience to the topic of language-responsive teaching. Before the activity, participants unpacked the mathematical topic of conditional probability into key concept elements and language demands. They also discussed the utility of a visual model and examined typical student misconceptions, laying the groundwork for deeper reflection during the vignette discussions.

The investigation specifically examined teachers' noticing during the vignette-based activity, informed by prior research on teacher noticing, which emphasizes the importance of identifying curcial aspects of teaching practices (Mason, 2011; van Es & Sherin, 2002).

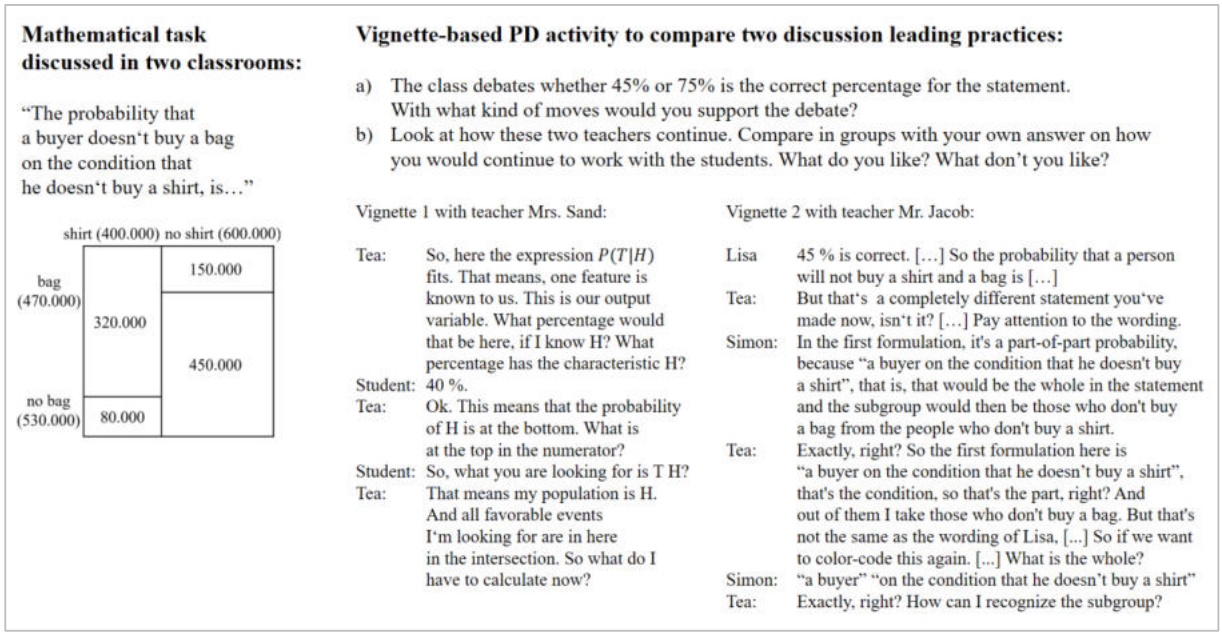

Figure 1: Vignette-based PD activity comparing the discussion-leading practices of two teachers

In part a) of the PD activity in Figure 1, participating teachers were asked to consider how they would continue working with students by documenting their own strategies (teaching moves). Part b) presented two short vignettes illustrating other teachers' discussion-leading practices. These vignettes were stylized for clarity from real transcripts of authentic discussion processes (Post & Prediger, 2024). The first vignette features Teacher Mrs. Sand, focusing on the procedure for determining the correct probability for a slightly different statement than in Figure 1. She examines the numerator

(the part), the denominator (the whole), and how to position both in the given formula. The second vignette, featuring Teacher Mr. Jacob, directs students' attention to the part-whole relationship and the connections between the given statements using meaning-related language to articulate this relationship.

The data corpus for this paper consists of two short transcripts from small group work in breakout rooms where participating teachers (Anna & Markus and Tobias, Melanie & Saskia) analyzed and compared the vignettes at the end of a three-hour PD session. The small group work was video-recorded and partly transcribed. The qualitative analysis of teachers' noticing used a deductive coding procedure. Main codes emerged based on whom the participants focused on in their observations: comments referring to *student* learning processes, *teachers' practices* in the vignettes or participants' *own practice*. To address the research question, we examined the topics participants addressed in relation to their practice: *cross-content moderation* or *content-related instructional actions* with a procedural or conceptual focus (operationalized by focusing on either the procedure for determining the correct probability or on explicating the part-whole relationship). Further, we analyzed in detail what aspects participants noticed about the content of teachers' or their own actions: addressed *concept-specific elements* (part-whole relationship, part, whole, ratio), *representations* (e.g., visual model, symbolic representation, given statement) and *connections* between concept elements and representations.

Empirical insights

The case of Anna and Markus

Anna and Markus begin their reflection by analyzing Mrs. Sand's teaching situation (as depicted in the first vignette in Figure 1):

7	Markus:	Here the teacher immediately specifies what is required […]?
[…]		
10	Anna:	[…] So Mrs. Sand would not have helped me as a student.
11	Markus:	Nope. Yes, especially if I specify it and then just show it like this. And what do you have to insert now? Well, […] that is far too tighly controlled.
[…]		
20	Anna:	So at the bottom she catches herself a bit, right? My basic population is H. […] So probably she shows that in the field. And the favorable ones are in there, in the part.
21	Markus:	Yes, but of course it's so very predetermined#
22	Anna:	#Yes, yes. Exactly.
23	Markus:	[…] that does not eliminate the misconception. […]

Focus of observations: In their reflection, Anna and Markus mainly focus on describing Mrs. Sand's actions. In Turn 23, they briefly address the students by considering that Mrs. Sand's approach may be inadequate for dealing with misconceptions. Overall, their observations center on evaluating here Mrs. Sand's teaching practices.

Aspects addressed: Markus observes that Mrs. Sand provides the formula und focuses on identifying the correct values (Turn 11). In Turn 20, however, Anna highlights the conclusion of the teaching situation, where Mrs. Sand addresses the whole and the part before asking the students to calculate. Anna supplements this by adding the term "part" and assuming that the teacher points to the

corresponding areas in the visual model. Anna and Markus mainly comment on content-related instructional actions, noticing Mrs. Sand's procedural focus. In Turn 11, Markus critiques the level of student involvement as "far too tightly controlled", reflecting on a moderation aspect closely linked to Mrs. Sand's instructional approach. Their reflections implicitly reveal that Mrs. Sand primarily addresses the part, the whole and the formula for determining the correct fraction. Anna appears to view the separate focus in the part and the whole positively, especially when combined with visually locating both values.

The group then focuses on the students briefly (for 3,5 minutes) before moving to the second vignette:

74/ 76	Anna:	I always find that so difficult, because in that situation I would have said: You somehow still do not agree. One says 45 percent, the others believe in 75 percent. Who can convince me of either of these solutions with the help of this area model? Explain to me again#
77	Markus:	#Yes, yes.
78	Anna:	How to find the numbers using this square. That you can tell me that again, I mean, that is the point of the thing, otherwise I would not need it.
79	Markus:	Yes, I would also pass the ball back again. And, above all, perhaps focus on the wording again. And the question is, is it part of the part or part of the whole? And to aim a little bit at which, how can I recognize that in this task?
80	Anna:	#Yes, yes.

Focus of observation: After analyzing the first vignette (Turn 7–28), the group shifts its attention to the students (Turn 29–69) and finally to their own teaching practices (Turn 74–80).

Aspects addressed: Anna proposes an alternative moderation strategy, suggesting that students should explain their reasoning again by using the visual model and contrasting their statements (Turn 74, 76). Markus builds on this idea, advocating for students to explain how the part-whole structure can be identified in the statement (Turn 79) and linking this to the visual model (Turn 81). By explicitly addressing the part-whole relationship as a key concept element and connecting it to the given statement and the visual model, Markus focuses on content-related actions with a strong conceptual focus/emphasis. In comparison, Anna primarily emphasizes moderating the discussion and engaging students, rather than focusing on content-specific elements/content-related actions. While she mentions the importance of linking representations, she does not explicitly address specific concept elements. Nevertheless, her approach encourages students to provide explanations, which could facilitate connections between representations and promote reflection on the underlying structure (Turns 74–78). Neither Anna nor Markus acknowledge that Mr. Jacob already addresses the part-whole relationship in the vignette.

The case of Tobias, Melanie and Saskia

This small group begins by reflecting on the teaching strategies (teaching moves) formulated by Tobias in the first part of the task. They then proceed to analyze the given classroom situations.

68	Melanie:	And Mrs. Sand is very much#
69	Saskia:	# in the formal language.
70	Melanie:	Yes, exactly. In procedures already # somehow, right?
71	Saskia:	# Yes. And Mr. Jacob starts with […] the ideas of percentages.
72	Melanie:	Do you know, what I have just noticed? Mr. Jacob needs a lot more text.
73	Tobias:	Yes.

74	Melanie:	So, and, um, well, I find this formulaic language very highbrow. […] But for students, it can be quite far away, depending on how long and how well they've been dealing with the topic. But Mr. Jacob takes a very long time to explain it. And I know that the longer I talk, the less they can take in.
[…]		
77	Saskia:	However, he basically remains in the image that the students themselves are currently thinking.
[…]		
80	Tobias:	[…] As I said, very fast with the formulas and perhaps over- so it can also be very good that this overwhelms one or the other, that you now immediately go into the fraction and immediately into procedures. Completely away from the picture.
81	Melanie:	Mhm.
82	Tobias:	But then immediately switches to, yes, formulaic language. I can also see that this could be difficult... Yes.

Focus of observations: In Turns 68–82, the participants' comments focus on the teaching practices depicted in the vignettes, with Melanie, Tobias and Saskia comparing Mrs. Sand and Mr. Jacob.

Aspects addressed: While comparing the two teachers, the participants highlight the content-related actions of both (Turns 68–71, 77–82). They note that Mrs. Sand primarily addresses procedures, while Mr. Jacob prioritizes ideas and student thinking. The group implicitly recognizes that Mrs. Sand focuses on the formula as a concept element. Tobias critiques the rapid transition to the formula and comments to the use of representations. However, the participants do not explicitly reflect on additional concept elements. Melanie shifts the discussion to cross-content moderation, focusing on the length of the vignettes.

The discussion continues:

83	Saskia:	The problem is, if the student is not clear about what is meant by this buyer on the condition that#
84	Tobias:	#Yes.
85	Saskia:	That is core of the conversation with Mr. Jacob. And if that's the crux of the matter, that they don't understand that, it doesn't help that he mentions it so often […]
86	Tobias:	Mhm.
87	Saskia:	That could be critical, that he stays in this picture, that there is no further change […]
[…]		
90	Tobias:	I mean, Jacob already justifies it a bit based on Lisa's statement.
91	Saskia:	Mhm.
92	Tobias:	No? That you confuse combined and conditional probability. That is what Lisa is doing here. […] omits the fact that we are only looking at people who do not buy a shirt […]
[…]		
94	Tobias:	[…] But I think it is nice that Lisa does not talk at all afterwards, only the other students. […]
[…]		
100	Tobias:	You might have to make sure that the conversation goes more in Lisa's direction and that you consider her misconception and take her with you again.

Focus of observation: In Turns 83–100, the group continues reflecting on the teachers' practices, with a brief focus on student processes in Turn 83, where Saskia identifies a central obstacle for students.

Aspects addressed: In the first part of the discussion (Turn 83–92), the comments primarily address Mr. Jacob's content-related actions. Saskia assesses Mr. Jacob's discussion-leading practices as insufficient, asserting that he merely repeats his own statements. Tobias provides a more refined view, noting that Mr. Jacob justifies his statements by reflecting Lisa's response and clarifies confusing formulations (Turn 90–92). By reflecting Mr. Jacob's teaching situation, the group observes that he focuses on explaining and comparing the statements. But they suggest that a more explicit explanation for comparing both formulations and a connection to representations could improve the teaching approach (Turn 81, 87). Despite these reflections, Tobias, Melanie and Saskia do not address specific concept elements or propose alternative approaches to consider concept elements. In Turns 94–100, the discussion shifts to moderation strategies, focusing on student involvement but neglecting content-related aspects.

Discussion and outlook

The participants' reflections primarily focused on the actions of the teachers in the vignettes, with occasional references to student learning processes. Notably, only Anna and Markus extended their reflections to include an analysis of their own teaching practices. Both groups identified the procedural focus in Mrs. Sand's teaching. However, Tobias, Melanie, and Saskia provided additional observations on the use of representations, discussing potential modifications to enhance instructional effectiveness. Their reflections on content-specific aspects, such as concept elements or connections between representations, were relatively superficial and often overshadowed by a focus on cross-content moderation. In contrast, Anna and Markus demonstrated a stronger focus on content-specific aspects, particularly the key concept elements of the part-whole relationship (Post & Prediger, 2024). Markus, in particular, highlighted the importance of connecting representations to conceptual structures, implicitly contrasting this approach with Mrs. Sand's procedural focus. This deeper engagement underpins the potential of structured reflection activities to enhance teachers' content-related noticing, a key factor in promoting conceptual understanding among students.

The analysis reveals that the extent to which participants notice and reflect on content-related aspects significantly affects the quality of their reflections, underscoring the importance of noticing critical elements like conceptual connections and representations (Mason, 2011; van Es & Sherin, 2002). Despite the study's small scope and specific focus, the findings align with research highlighting the role of content-related noticing in fostering conceptual understanding and effective teaching practices (Prediger et al., 2022). Building on these insights, future professional development programs should prioritize strategies that support teachers in deepening their noticing of content-related aspects, such as a focus on the meaning-related structure of the mathematical concept that is addressed in various representations. Structured video analysis and guided reflection, as suggested by Rosaen et al. (2008), could further enhance teachers' abilities to identify and address critical elements of their practices, ultimately improving student outcomes.

Acknowledgment

The study is part of the QuaMath PD research program, funded by the Standing Conference of State Educational Departments. We thank project leader and our mentor, Susanne Prediger, for her guidance and resources, as well as our colleague Volker Eisen for his cooperation in this PD project.

Interactions between talk moves and other teaching moves in classroom discussions in ambitious mathematics teaching

Kjersti Wæge[1] and Reidar Mosvold[1,2]

[1]Norwegian University of Science and Technology, Norwegian Center for Mathematics Education, Trondheim, Norway; kjersti.wage@ntnu.no

[2]University of Stavanger, Norway

This study explores the relationship between talk moves and the categories of teaching moves of exploring, encouraging and connecting to formal notation. Data from nine classroom co-enactment sessions in a professional development program aiming to support Norwegian teachers in learning ambitious mathematics teaching were analysed. We present a case from one of the co-enactments to unpack the moves that the teachers used and the interaction between them. The findings reveal that the teacher used different categories of teaching moves simultaneously and in interaction. The teaching moves of exploring and connecting to formal notation were made in ongoing interaction between talk moves, student talk and representing students' strategies. The findings also show how talk moves can be used within different categories of teaching moves.

Keywords: Teaching moves, talk moves, professional development, ambitious mathematics teaching.

Introduction

Leading discussions is often considered a core or high-leverage practice (e.g., Ball & Forzani, 2009; Jacobs & Spangler, 2017), and researchers have identified different groups of moves that teachers can make to stimulate discussion. "Teaching moves" – a common umbrella term to describe what teachers do – can be defined on different levels, and with different goals (Jacobs & Spangler, 2017), and the connections between frameworks of such moves can be unclear. In ambitious mathematics teaching, for instance, researchers have identified sets of talk moves (e.g., Chapin et al. 2009; Kazemi & Hintz, 2014), which are specific moves, often defined on an utterance level (Michaels & O'Connor, 2015). In another framework, Jacobs and Empson (2016) specified four high-level categories of moves that teachers can make when interacting with students to support their development of mathematical thinking: 1) *ensuring* that students make sense of the problem, 2) *exploring* details of students' thinking, 3) *encouraging* students to consider other strategies, and 4) *connecting* students' thinking with other representations. Jacobs and Spangler (2017) suggest that future research on leading classroom discussions should aim at developing and adapting new instruments, while building on the strength of existing instruments. As a contribution to such efforts, the present study aims at exploring how the teaching moves identified by Jacobs and Empson (2016) might interact with talk moves, as identified by Chapin et al. (2009). We explore this by analysing data from the Mastering Ambitious Mathematics teaching (MAM) project.

Theory

Talk moves have been proposed as a foundation for facilitating equitable and productive mathematical discussions (Kazemi & Hintz, 2014; Murata et al., 2017). Chapin et al. (2009) identified five talk moves that promote student thinking and participation: revoicing, repeating, reasoning,

adding on, and wait time. Kazemi and Hintz (2014) added two more talk moves: turn and talk and revise thinking. Using talk moves productively in response to students' ideas and building on the diversity of students' thinking to guide their attention towards key mathematical ideas is challenging (Michaels & O'Conner, 2015). Murata et al. (2017) show how variations in use of talk moves might create different environments for students' learning and development of strategies. They suggest that "for talk moves to be used productively in mathematics classrooms teachers need to effectively break down, represent, and discuss student strategies at an appropriate grain size while connecting with other strategies" (p. 312). In our study, we explore how talk moves are used in interaction with the more high-level categories of teaching moved identified by Jacobs and Empson (2016).

Jacobs and Empson (2016) present four major categories of teaching moves that promote student thinking. The first category involves ensuring that the students understand the problem, and this move is often used during the launching phase of a problem or early in the interaction with students. The second category involves exploring details of the students' strategies, and highlights four subcategories: posing general starter questions to initiate whole class discussions or conversations with students; pressing the students for an explanation of specific parts of their problem-solving processes by asking situation-specific questions to elicit the details of students' thinking and thus make their explanations richer; linking the students' representations and the story context; and expanding the students' understanding. The third major category is about encouraging the students to consider other strategies and thus providing opportunities to compare different strategies and ways of reasoning. The fourth category emphasizes the importance of connecting students' thinking to symbolic notations and involves representing students' ideas in writing and making connections between their talk and representations (Jacobs & Empson, 2016). Ambitious mathematics teaching highlights students' emerging ideas and their mathematical sensemaking. Core principles include positioning students as sensemakers, providing equitable access to learning for all students, orienting students to each other's thinking, and seeing teaching as both intellectual work and a craft (e.g., Kazemi, 2017; Lampert et al., 2013). Being responsive to students' thinking and using their ideas in relation to mathematical goals is a complex and challenging part of ambitious mathematics teaching (Richards & Robertson, 2015). We explore how the teacher might use talk moves in interaction with different categories of teaching moves to facilitate equitable and productive discussions in mathematics, and we focus on the categories of exploring, encouraging and connecting (Jacobs & Empson, 2016), which are central to this work.

Methods

We analyse data from a group of seven Norwegian elementary teachers, who participated in the MAM project, where they collaboratively engaged in cycles of enactment and investigation to learn ambitious mathematics teaching (Wæge & Fauskanger, 2021). The cycles included six phases: 1) preparation; 2) collective analysis; 3) co-planning; 4) rehearsals; 5) classroom co-enactment where one teacher teaches an instructional activity with a group of students while the other teachers observe; and 6) collective analysis (Wæge & Fauskanger, 2021). We analysed data from the classroom co-enactment phase, to explore the moves they used when leading discussions.

We used *Sportscode* video-analysis software for analysis, and this allowed us to code the video data directly instead of analysing transcripts. Data consist of video recordings from nine four-hour sessions, all of which include the six phases described above. In our coding, we identified segments of data that were distinguished by "conceptual breaks" (Jacobs & Empson, 2016). An example of such a conceptual break is when the teacher switch from launching the problem to posing a question to explore students' thinking. This would constitute a conceptual break between two of the main categories in our codes. The size of the segments varied.

In our coding of the interactions that followed the launching of the problem, we used the following categories and codes from Jacobs and Empson's (2016) framework:

- Exploring details of students' thinking
    - Starter questions
    - Pressing for explanation
    - Linking students' representations
    - Expanding students' understanding
- Encouraging students to consider different strategies
    - Sharing other strategies
    - Making connections between other strategies
- Connecting strategies to formal notation
    - Representing students' strategies

To explore whether and how these teaching moves might interact with talk moves, we added talk moves as codes in each of the main categories of teacher moves.

Findings

In what follows, we report on a close analysis of the teaching moves from one of the co-enactments with students to exemplify our analysis process and to present a case that unpacks the teaching moves and illustrates the interaction between talk moves and different categories of teaching moves. The episodes are from an enactment of a *quick image*. The learning goal for students was to learn about the distributive property of multiplication ($a \times (b + c) = a \times b + a \times c$). The teacher, Anna, showed the students a quick image for a few seconds and then asked the students how many dots they saw (see Figure 2). The first episodes starts when Anna asks the students to share their thinking. Figure 1 shows the different teaching moves that Anna used in this episode. We see that Anna starts with *exploring* the students' strategies and *connecting* their strategies to formal notation. She then *encourages* the students to share other strategies, and this is followed by an *exploration* of several different strategies. Below, we analyse in more detail how the teacher engaged these different categories of teaching moves.

In the beginning of this episode, Anna is exploring details of students' thinking and we notice that there is an interaction between the teacher's use of *talk moves*, *representing* student ideas on the board, and *student talk*. We join the enactment as Anna asks the students a starter question about the number of dots (line 1), which is followed by *wait time* in which the teacher gives the students time to think before sharing their own ideas (line 2). One of the students, Lisa, then *shares her thinking*

(line 4). Anna then begins to draw on the quick image on the board, pausing to check with Lisa about the accuracy of the drawing. She is using the talk move of *revoicing* to make sure that she and the students in the class understand Lisa's ideas: "So, you were thinking, first you saw that it was five and that it was four? And when you got to see the picture for the second time, you saw that there were three fives and three fours?", whilst simultaneously *representing* the strategy on the board (line 5) (see Figure 1).

	Time	Student talk	Exploring	Connecting to formal notation	Encouraging
1	00.57–01.06		Starter question

Figure 1: Teacher's use of teaching moves when sharing strategies

After representing Lisa's strategy on the quick image, Anna asks the students to generate a numerical expression to connect with Lisa's informal strategy and thus make connections between multiple representations (line 6). She gives the students a few seconds to think (*wait time*) (line 7), before she asks them if anyone will share their thinking (line 8). This is followed by another *wait time* (line 9).

One of the students, Martin, *shares his thinking* (line 11), suggesting they can represent it as four times three and five times three. After having discussed with her colleagues what she might do, Anna *represents* what the student said on the board: $(5 \times 3) + (4 \times 3)$ (line 12). She then uses the talk move of *reasoning* to ask the students whether this number sentence represents Lisa's strategy: "Is this (the numerical expression) the same as Lisa said?" (lines 13). One of students responds by saying "No, because you forgot the parentheses" (line 15). Anna agrees, and then she repeats the question (line 16). Another student responds by saying "yes" (line 18). Anna follows up his response by using the talk move of *revoicing*: So, you think it is the same? (line 19).

After *exploring* Lisa's strategy, Anna is *encouraging* the students to share other strategies: "Did anyone think differently?" (line 20). She then *explores* the details of the other strategies (see Figure 1), and similarly to the exploration of the first strategy, we notice that there is an interaction between *talk moves*, *student talk*, and *representing* students' thinking on the board.

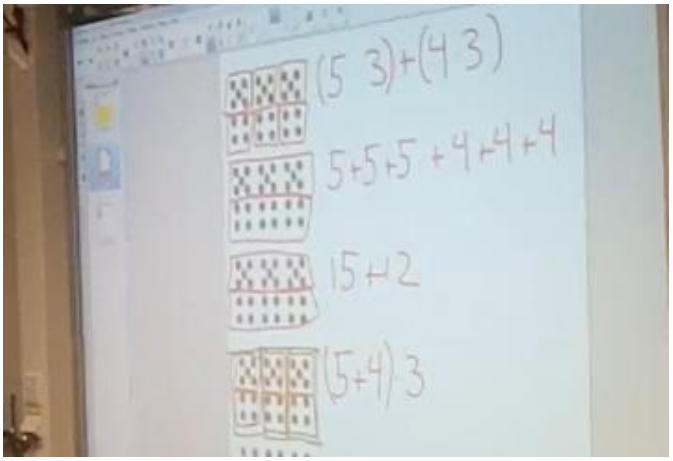

Figure 2: Student strategies for finding the number of dots

During this exploration, one of the students, Peter, presents a strategy that Anna and the other teachers had anticipated and wanted to highlight. He says that he added the five and the four, which equals nine, and then he multiplied nine by three (see Figure 2).

Later in the lesson, when the students had shared different strategies for finding the number of dots, Anna wanted the students to compare and make connections between two of the strategies: the one at the top, $(5 \times 3) + (4 \times 3)$, and the one at the bottom of the board, $(5 + 4) \times 3$ (see Figure 2).

The second episode starts when Anna asks the students if there is any connection between these two strategies. Figure 3 shows the different teaching moves that Anna used in this episode. We see that Anna *encourages* the students to make connections between strategies. She then *explores* the students' thinking about connections, before she *encourages* them to find more connections. Below, we analyse in detail how the teacher engaged these teaching moves.

In the beginning of this episode, Anna is *encouraging* the students to compare and make connections between the two strategies $(5 \times 3) + (4 \times 3)$ and $(5 + 4) \times 3$ and we notice that the teacher uses *talk moves* to give the students room to think and discuss possible connections. For instance, Anna starts with *asking about connections*: "Is there any connections between them (two strategies)?" (line 64). She then uses the talk move of *wait time* (line 65) before she asks them to *turn and talk* with their neighbour (line 65). Students then pair up and take turns explaining their thinking to a partner while the teacher (and observers) is listening and observing.

After the students have discussed their ideas with each other, Anne starts to *explore* their thinking, and we notice that there is an interaction between the teacher's use of *talk moves*, *student talk*, and the teacher *pressing* for explanations or justifications. Anna asks the students a *starter question*: "Is there anyone that would like to share what you talked about?" (line 67). Two of the students, Maria and Eli, *share their ideas*, explaining that the numbers are the same in the two numerical expressions,

but that there are two threes in the top one, while there are only one three in the lower one (line 69). Anna then *presses* the students to explain why (line 71) and gives them a few seconds to think (*wait time*) (line 71). The same two students, Maria and Eli, *follow up* her question by saying that on the top one there is five times three and four times three, and on the bottom one there is five plus four times three (line 73). Anna continues to *press* for more explanations and asks the students to discuss why we get the same answer for both strategies (line 74) and she then uses the talk move of *turn and talk* (line 75). One of the students, Tom, *gives an explanation* that is similar to what Anna and Eli said, emphasizing that the four and the five are added together in the one at the bottom (line 77). Anna summarises what the students have said (line 78). She then *encourages* them to find other connections: Do you see other connections?" (line 79) and uses the talk move of *wait time* (line 80).

	Time	Student talk	Exploring	Connecting to formal notation	Encouraging
64	10.05–10.35				Make connections

Figure 3: Teacher's use of teaching moves when connecting strategies

However, after having conferred with her colleagues, Anna goes back to Tom's explanation and asks the students if they can *repeat* what Tom said (line 81). One of the students, Heidi, then try to repeat what Tom said in her own words (line 83), and Anna uses the talk move of *revoicing* to make sure that she and the students understand his explanation (line 84).

Concluding discussion

From our analyses, we make two observations about categories of teacher moves and use of talk moves. First, we observe that there tends to be interactions between different categories of teaching moves. Although identifying individual teaching moves can be useful for research and education of teachers (Jacobs & Empson, 2016; Jacobs & Spangler, 2017), our analyses illustrate how teaching moves are not made in isolation but are used in ongoing strings of interaction. This corresponds with

how Cohen et al. (2003) describe teaching as interactions between teacher and students around some content. Although the discussion in the first example primarily aimed at exploring students' thinking, we saw how the teaching moves of exploring and connecting to formal notation were made in ongoing interactions between the teacher's use of talk moves, student talk, and representing students' strategies on the board. For instance, we saw how the teacher responded to the students' contributions by using the talk move of revoicing, in which she repeated what the student said and asked the student to verify if her revoicing was correct whilst simultaneously representing the strategy on the board. She stopped frequently to confirm with the students that she was representing their thinking accurately. Thus, the teacher used the two categories of teaching moves – exploring students' thinking and connecting it to formal notation – simultaneously and in interaction. We saw how the teacher never left the students as she revoiced and represented their ideas and asked them questions that allowed them to elaborate on their own strategies. With this approach, ownership of ideas remained with the students. This corresponds with how Murata et al. (2017) describe the dialogue as bouncing between the teacher and the students throughout the explanations, where the teacher breaks down and represents students' strategies at appropriate grain size. The second example, which was a sequence where the teacher aimed at encouraging students to make connections, illustrates the interaction between the teacher's use of talk moves, student talk, and the teacher pressing for explanations or justifications to highlight key mathematical ideas. We saw, for instance, how the teacher asked students to turn and talk after having pressed them to provide an explanation of a specific connection. Thus, she gave students space to explain and discuss their thinking.

Second, our analyses illustrate how talk moves can be used in different categories of teaching moves. For instance, the first episode illustrates how the teacher used the talk move of wait time when exploring the details of students' thinking. After having posed starter questions to invite students to share their thinking, she used the talk move of wait time to give students space to think and make sense of the questions. In the second episode we also observe how the teacher used specific talk moves within the category of encouraging students to compare and make connections between strategies. For instance, after the teacher posed a question about connections between specific strategies, she used wait time followed by turn and talk. Thus, she provided the students with space to make sense of it and to explain their thinking. By giving students time and space to engage with each other's ideas, she provided them with opportunities to connect their emergent ideas with learning goals and key mathematical ideas (Murata et al., 2017). We agree with Jacobs and Spangler (2017) that the promise of teaching moves hinges on their enactment, the learning goal, and the context in which they are enacted, and our analyses illustrate how the use of specific talk moves to enact the more overarching categories of teaching moves also depends on the context and the learning goal.

This study is limited by the scope of the episodes analysed. Yet, our study provides an existence proof that teaching moves are carried out in ongoing interactions, and that talk moves can be used to enact different categories of teaching moves – depending on the learning goal and the instructional context. Further research should be made to explore if there are other patterns of interactions among overarching and specific teaching moves, and if similar patterns can be found also in the move of ensuring that students make sense of the problem.

Learning support practices in the fostering of basic arithmetic skills

Inga Neufeld[1] and Uta Häsel-Weide[1]

[1]University of Paderborn, Faculty of Computer Science, Electrical Engineering and Mathematics, Paderborn, Germany; inga.wienhues@math.upb.de

According to sociocultural theories, teaching consists of a collection of practices in which the participants interact and mathematical learning takes place. But which learning support practices do prospective teachers use when fostering children in difficulties in basic arithmetic skills? In this paper, the reconstruction of self-reported practices of learning support is presented as an example and preliminary results are discussed. The case selected as an example shows rather unproductive learning support by the prospective teacher with potential for further development into productive learning support. Further analyses of the underlying action-guiding beliefs are required.

Keywords: Teaching practices, prospective teachers, learning support, basic arithmetic skills.

Introduction

Central aim of German mathematics lessons at primary level (first to fourth grade) is to develop an understanding of basic mathematical concepts. The basic mathematical skills of understanding numbers, place value and operations are critical obstacles in the mathematical learning process. For example, the basic arithmetic skill "number sense" includes the idea of numbers as relations (Tubach & Nührenbörger, 2016). When learning these central concepts, particular difficulties can arise. Therefore, the children need targeted fostering and teachers who can organize this in a beneficial way. Crucial to fostering learners' skills is the professionalisation of teachers in demanding situations they must deal with (Prediger, 2019). Since both the disposition and the actions of the teachers are decisive (Clarke & Hollingsworth, 2002), a descriptive analysis of the practices and underlying beliefs could provide more insight into where there is a need for professionalisation and where the training of teachers can be targeted. This paper focuses on the teacher practices.

Key tasks for teachers are diagnosing the competencies and difficulties that arise as well as providing targeted teaching and fostering. In addition to selecting and adapting tasks, this also includes assisting the learner's learning process while working on the tasks and reflecting on and evaluating the learning process and the suitability of the activities (Prediger & Buró, 2021). We define the interaction that takes place in the assistance of the learning process while working on the tasks as learning support (Foster et al., 2023).

Theoretical Framework

Teachers realise teaching in so-called teaching practices, which we understand in the sense of Prediger (2019, p. 370) "as the recurrent patterns of teachers' utterances and actions." According to sociocultural theories, practices already exist in advance, but the individuum shapes its implementation of the practice (Cobb et al., 2001). People who learn practices, i.e. who are new to the community of participants in the practice, in turn influence the practice through their identity, which is why the practice continues to develop over time (Lave & Wenger, 1991). Hence, prospective teachers, as learners of teaching practices, should further develop and elaborate the learned teaching

practices and contribute their own way (Heyd-Metzuyamin et al., 2019). Teaching practices of learning support are among the key teaching practices, that need to be learned (Prediger & Buró, 2021). To foster students in their professionalisation process in the best way, it is necessary to first identify the productive practices of learning support.

To identify which learning support practices are productive, teaching practices and teacher actions are reconstructed in various studies and examined in terms of their impact on learners' performance and understanding (Prediger, 2019). Effective teaching practices of learning support are those that foster learners in controlling their own thinking process and gaining an awareness of their own activities (Cusi & Malara, 2013). These include practices that focus more on the meta-cognitive dimension rather than solely on the subject matter (Cusi & Malara, 2013). This is in line with the considerations of Foster et al. (2023), who divide professional learning support actions into those content-specific teacher actions that initiate high learning potential, such as stimulating reflection, providing further impulses or emphasizing central elements of understanding, and other content-specific teacher actions that are considered to be of lower quality in fostering the learning process, such as small-step guidance and an evaluation of the work status. Teachers are more likely to use practices and actions that are considered to be unproductive than productive ones (Foster et al., 2023).

This raises the question, of how teaching practices can be established that encourage active-discovery learning and further thinking and therefore are productive to prepare for the discovery of richer mathematical experiences in the classroom (Heyd-Metzuyanim et al., 2019). In their considerations on *situated learning*, Lave & Wenger (1991) conceptualise learning as increasingly competent participation in a practice. Heyd-Metzuyanim et al. (2019) transfer these considerations to teaching practices and describe the process of participation in teaching as initially imitative, rigid and process-orientated to explorative, flexible and goal-orientated. The change is supported by a bilinear approach: on the one hand through trying out a practice and reflecting on different learning outcomes, and on the other hand through the further development of one's own disposition (Clarke and Hollingsworth, 2002). To enable the teaching practices to be trialled, vignettes and complexity-reduced settings such as in teaching-learning labs are often used in teacher training in Germany (Fraefel, 2022). Reducing complexity here means simplifying the practical situation in comparison to later use at school, e.g. by teaching smaller groups or in a team. Regarding the learning of productive teaching practices, the focus is on the prospective teachers' learning to distinguish between practices with high and low potential, to try them out in practice and to reflect on their use in a theory-led way (Fraefel, 2022). One key point here is that the change of practices is slow and fragile and the prospective teachers first need to 'believe' and 'understand' how and why to teach in a certain way, before they can actually do it' (Heyd-Metzuyanim et al., 2019, p. 287).

While practices for supporting and fostering in inclusive teaching are already being researched at teacher level (i.e. Prediger & Buró, 2021), little is known about the practices of prospective teachers in fostering children in difficulties in basic arithmetic skills. Some studies use vignettes (i.e. Ulusoy, 2020) and therefore focus primarily on individual, hypothetical actions of the students. The suggestions for action made by the prospective teachers in Ulusoy's (2020) study aimed to improve the quality of the questions asked and the representations used by the teachers in the video vignettes, to use the learners' mistakes as a learning opportunity and to use correct technical language. However,

a good half of the prospective teachers did not formulate any suggestions for action for the first vignette, which assumes that formulating suggestions for action is very challenging for the prospective teachers (Ulusoy, 2020). In the few studies exploring prospective teachers learning support practices in real-life contexts, it was shown that prospective teachers established practices in which they gave learners time to think, considered and addressed learners' ideas, and followed up on learners' thinking (Santagata & Yeh, 2014; Sun & van Es, 2015). However, the correct answers and procedures of the learners were the primary focus of the prospective teachers (Sun & van Es, 2015).

There is a need for deeper insights into which practices prospective teachers use in situations in which they actually have to act ad-hoc and which disposition lies underneath. In this paper, we therefore focus on the following sub question of the project: Which practices of learning support of prospective teachers can be reconstructed in self-reports on fostering children in difficulties in basic arithmetic skills? We chose to focus on self-reported practices rather than the actual discursive practices during the fostering sessions, because they provide more insight into the underlying beliefs, which is a further central research interest of the larger study.

Methods

Sampling. The target group are prospective teachers studying to become teachers of special needs education in their second or third year of the bachelor program. They attended a seminar in which they fostered children in difficulties in basic arithmetic competencies as a team of two over the course of a semester. The aim is to develop productive practices in diagnosis and fostering. In line with the intended triad in teaching-learning labs, the planning, implementation and reflection of the fostering sessions, the individual fostering program is linked to the attendance of an accompanying seminar. There the prospective teachers deal with basic theories, plan and reflect their lessons and reflect video graphed situations of the fostering lesson jointly in a theory-based manner. In the summer semesters of 2022 and 2023, 24 prospective teachers attended the seminar and worked in twelve pairs, each fostering one child in difficulties in mathematics.

Data gathering. Two interviews were conducted to ascertain the practices of learning support from the prospective teachers' perspective as well as a possible development. The twelve pairs of prospective teachers were interviewed together after the second or third fostering sessions and after the seventh or eighth of nine fostering sessions (period of April to June) using self-developed semi-standardised interview guidelines. At the beginning, both prospective teachers were each asked to select a situation from the corresponding fostering session that they considered to be particularly decisive in the child's learning process so that individual actions and utterances can be reported as specifically as possible. To reveal how the actions and utterances emerged, the situations were focused on one after the other in the main phases of the interview with regard to the choice of situation, the child, their own actions and utterances and a reflection in accordance with the facets of professional teacher noticing. This resulted in a total of 24 interviews with 46 situations selected by the prospective teachers. The main phases of the interviews were transcribed in full.

Data analysis. To reconstruct the reported practices, a qualitative approach is required, which is why a structuring and summarizing procedure based on the qualitative content analysis was chosen. Because we conceptualise teacher practices of learning support by decomposing the practices into the

actions and utterances teachers use in relation to the actions and utterances of the children and the didactic subject matter, a category system of teachers' actions and utterances was created based on existing lists (Cusi & Malara, 2013; Foster et al., 2023), in the course of deductive-inductive category formation. The category system is shown in the analysis overview (Table 1). The data analysis was carried out in three steps:

- Step 1: In the main phase of an interview in the selected situation of a prospective teacher, the reported teacher actions and utterances were reconstructed in meaning sections and coded according to the categories. For the reported teacher actions and utterances that could not be assigned to a deductive category, an inductive category was developed. The categories *praise*, *restrain*, *linguistic role model* and *organisation* are developed inductively.
- Step 2: The assigned codes are displayed in the analysis overview according to the meaning sections, in which the turn section of the interview is noted
- Step 3: A comparative analysis of the analysis overviews was used to form types that represent the reported teaching practices

In this paper, we present an example of an analysis in the sense of the first step, which leads to the presentation of the analysis overview (Step 2, Table 1). The exemplary case is then assigned to a previously identified type (Step 3). All presented parts of transcripts were translated from German.

Case: Guided processing with minimal activation

In the following, the analysis of the main phase of the second interview with the prospective teachers Britta and Jessica, who do the fostering program with Jana (age 8), is presented using Britta's selected situation as an example.

The situation chosen by Britta arose in a mathematical game situation in which Britta and Jana were playing the game “Who has more?” (Tubach & Nührenbörger, 2016). The aim of the game is to find the difference between two numbers. To do this, both players roll the dice and place the corresponding number of dots in a vertical field (see Figure 1 using the example of 5 and 6 as the numbers rolled). The difference between the numbers is determined. The person with more tokens can keep the difference in tokens as points. The first person to have ten points is the winner. The prospective teachers extended the rules of the game so that the numbers are written down symbolically and the qualitative comparison is fixed with a larger/smaller/equal sign (see Figure 1).

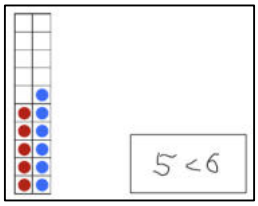

Figure 1: Reconstructed table setting in the situation reported by Britta

When asked to describe the situation in more detail and explain what Jana did, Britta reports:

21 Britta: So we played several rounds in a row. And um in some cases it worked out that way, then she rolled the dice, put her points there, then I rolled the dice, put my points there (.) then we put the note in front of her, where she then

always wrote it down directly. And then in one situation she also said, (..) oh I can't remember what exactly she rolled. But for example (*laughing*) I think there were five or six or so. Five is smaller than Six. And then she went straight for the one and (…) distributed one point

Britta reported that she *simulates the learning partner* by taking over the role of the opponent in the game. Parallel, she describes that she placed the piece of paper in front of Jana and thus implied the order in which Jana should complete the task. Through this *small-step guidance*, she provides Jana with a processing strategy.

The teacher's action of *small-step guidance* can be reconstructed in various actions reported by Britta. When asked what Britta herself did in the fostering session, she answers:

45 Britta: If she (.) didn't say directly on her own initiative, um, what she had written down, so (..) the number is smaller than the other or the number is larger than the other, then I said again yes, um, and what did you write down now?

For Britta, it seems crucial that Jana completes the task in full, which for her seems to include verbalising her own results or intermediate results. With her question, she explicitly asks Jana to verbalise the (interim) result. This focus on verbalisation is also evident in the following statement:

51 Britta: I then asked in any case, what is more now. Um, so yes, especially with questions, I somehow tried to get her to act and talk a bit.

It seems that Jana is not working on the task on her own initiative, but Britta encourages her to act and speak by asking questions. She reports that she asked the question "What is more now?" and in doing so once again provides a *small-step guidance* for the next processing step: After the two quantities have been displayed in the token field, Jana should first determine the qualitative difference. A third teacher action reported by Britta is shown in the following transcript excerpt:

63 Interviewer: How did you react to her actions and statements?
64 Britta: Mmm (*thinking*) um (..) yes, I would say that it was so reinforcing, because what she said was mostly right (*laughing*).
65 Interviewer: Mhm (*neutral*).
66 Britta: Um and then, yes, great, that's right, exactly, and then (.) we can carry on and yes, so I would say more in an appreciative and encouraging way, that you show her, yes what you're doing is exactly right and it can definitely go on like this.

Britta therefore reports that she *praised* Jana for correct interim results. This seems to be predominantly positive in the chosen situation, as Jana usually acts correctly. The following transcript excerpt shows what happens when Jana makes a mistake:

67 Interviewer: To what extent have her actions and utterances influenced your actions and utterances?
68 Britta: Mmm (*thinking*) (*pause of 7 sec.*) Um I don't think it was that strong in that situation, because she (.) mainly said the things that we would have expected, I would say. Um (…) except at the beginning when she said um, that if you have two and four and then four is the difference.
69 Interviewer: Mhm (*neutral*).
70 Britta: Um and that I then asked again in more detail and then, look again, where exactly do we have that it would be the same. Or how much would we have to take away so that it would be the same or something like that. Um in that situation it did influence the fact that we went into it more. But apart from that, she said a lot of things as we would have expected.

Jana determines the difference incorrectly. It can be interpreted from Britta's report that she seems to give Jana a *small-step guidance* to the correct result in two ways. (1) By first finding out to what point the quantities are equal and then determining by how much the quantities are different ("where exactly do we have that it would be equal"). (2) By taking away so much of the larger quantity until both quantities are equal and the quantity taken away makes up the difference ("how much would we have to take away to make it equal").

A deviation from the otherwise small-step approach becomes clear towards the end of the main phase:

89 Britta: Yes, sometimes um we also asked um, for example, um she rolled a five or something and then I asked which number would I have to meet to aim lower than yours, and she was able to tell us beforehand.

With Britta's reported question "Which number would I have to meet to aim lower than yours?", she gives a *further impulse* encouraging Jana to consider which numbers that can be met are smaller than her own. In this way, she encourages Jana to mentally determine the qualitative difference.

Britta's reported actions and utterances can be summarised as follows in the analysis overview:

Table 1: Analysis overview of teacher actions by Britta

Content-related with high learning potential							Other content-related learning support				Other
Further impulse	Emphasising central elements of understanding	Modelling	Stimulating reflection/ Evaluating of	Restrain	Linguistic role model	Simulating the learning partner	Evaluation work status	Small-step guidance	Errors or alternatives unused	Praise	Organisation
						T21		T21			
								T31			
								T45			
								T51			
										T66	
								T70			
T89											

The practice reported by Britta, is primarily located in the area of other content-related learning support. The accomplishment of the task through small-step guidance is supplemented with content-related teacher actions with high learning potential, such as in this case the simulation of the learning partner and the further impulse. Overall, the picture that emerges is of reported teacher actions that can be characterised as practice of guided processing with minimal activity. In terms of the didactic subject of quantity comparison in the game situation described, the teaching practice shows that a comparison of quantities is carried out by asking questions about the same quantity and checking the

symbolically noted numbers. This means that the comparison of quantities is first broken down into small steps and then initiated on a hypothetical level with stimulating questions.

Discussion and conclusion

The reported practice highlighted in the case study fits in with the previous findings on the learning support of prospective teachers, that the practices focus primarily on the procedure and correct response of learners (Sun & van Es, 2015). It seems as if the correct processing of the task is ensured at the beginning in a small-step procedure and therefore located primarily in the other, content-based learning support (Foster et al., 2023). This indicates that the focus is more on the correct result and procedure than on the child's understanding process. But building on this, the development of a conceptual understanding is stimulated by further impulses. It remains to be seen, whether these practices can be reconstructed in the learning support of other basic arithmetical skills.

The case analysis presented here originates from the initial development of the analysis method, so the preliminary results must be viewed with caution. So far, it has been shown that the analysis method can be used to reconstruct the prospective teacher's practice content based and to map well how the practice can be located in its productivity. The results presented here must be sharpened by further comparative analyses with behavioural patterns (presented in the analysis overviews) of other prospective teachers and placed in a larger context. However, the present study has the potential to deepen the insights into the practices of prospective teachers' learning support through the research in a real context and the data basis of the interviews and thus contributes new insights. Perspectively, it will become clear which other reported learning support practices of prospective teachers can be reconstructed. The results can provide a basis for evaluating and further developing the professionalisation of teaching practices of learning support. The first findings emphasise the need of opportunities for (prospective) teachers to test and reflect on their practices and to develop their teaching practices further.

One limitation of the study is certainly that it analyses reported practices that do not necessarily correspond to actual practices (Mullens & Gayler, 1999). Nevertheless, the self-reports provide insights into the action-guiding beliefs of the reporting persons, which is a central further interest of the research project.

A Preservice Mathematics Teacher's Reflection on In-The-Moment Noticing of Students' Mathematical Thinking

Ayten Öykü Yaşar[1], Mine Işıksal Bostan[2] and Erdinç Çakıroğlu[3]

[1]Nevsehir Haci Bektas Veli University, Faculty of Education, Türkiye; oykuyasar@nevsehir.edu.tr

[2] Middle East Technical University, Faculty of Education, Türkiye

[3] TED University, Faculty of Education, Türkiye

This study aims to investigate a preservice mathematics teacher's reflection on her in-the-moment noticing of students' mathematical thinking after her one-to-one teaching experience with a 7th-grade student based on pattern generalization activities. Following her pedagogical practice, the preservice teacher reflected on her in-the-moment noticing of students' mathematical thinking through a reflection paper and an interview. The analysis was based on her reflections. The preservice teacher attends to student thinking, such as student understanding, connections, and characteristics, as well as teacher action of disregarding some student understanding. Even though she provided some explanations for what she noticed, mostly her explanations were not well-grounded. She identified how she responded to student thinking by offering examples and materials, and asking questions. Moreover, the preservice teacher provided possible pedagogical decisions for future lessons.

Keywords: In-the-moment, teacher noticing, preservice teacher, student thinking, video case.

Introduction

In the literature, there is no consensus on the definition of teacher noticing; however, research studies regarding teacher noticing are united under the importance of noticing by stating that "noticing matters" (Schoenfeld, 2011, p. 223). Teacher noticing is considered an active perception process in which teachers intentionally choose the things that attract their attention (Erickson, 2011; Mason, 2011; Sherin & Star, 2011). As teacher noticing is considered as creating responsive interactions with students, responding to student thinking is not the end but creating other instances to attend and interpret (Jacobs et al., 2011; van Es & Sherin, 2021). Preservice teachers have challenges with attending, interpreting, and reflecting on students' thinking, and these skills are considered learnable and would be conveyed through teacher education programs (Jacobs et al., 2010; Sherin & van Es, 2005). Franke et al. (2001) stated that development in teachers' noticing skills through professional development programs would be sustained. In other words, preservice teachers would pursue their skills in future teaching careers. For developing teacher noticing, videos are commonly used tools since videos would provide "… access to teachers' in-the-moment noticing than has been available before" (Sherin et al., 2011b, p. 80). Teachers would identify missed opportunities or disregarded student thinking based on their in-the-moment responses. Since classrooms are a "blooming and buzzing" (Sherin et al., 2011a, p. 5) environment, preservice teachers struggle to identify and focus on student thinking in the classroom setting. One-to-one teaching was chosen to direct the preservice teacher's attention to student thinking and respond to students' thinking without concerning classroom management issues, thereby devoting her attention to various students' thinking that occurred simultaneously.

Pattern generalization is selected as context for preservice teacher's teaching practice since algebraic thinking and pattern generalization are recognized as key to mathematics (Kieran, 2022). Pattern generalization involves identifying and extending patterns and using different thinking strategies and mathematical language. Students have difficulties with pattern generalization, and teachers struggle to identify these difficulties (Girit, 2016). This study aimed to examine a preservice mathematics teacher's reflection on her in-the-moment noticing of student's mathematical thinking based on the one-to-one teaching regarding the pattern generalization concept since it provides a context for preservice teachers to notice various students' strategies, thinking, and difficulties.

In the literature, the study of Çatman-Aksoy and Işıksal Bostan (2023) focuses on the attention and interpretation of an in-service teacher in the context of geometry; however, this study extends it by including preservice teacher's responding skills and making student's algebraic thinking central focus of the study in terms of preservice teacher's noticing skills. Preservice teachers' challenges with noticing students' thinking are articulated in the literature, and this study would help to picture what the preservice teacher learned from her practice, which she would translate into the classroom in her future career.

Based on the purpose of this study, research questions are as follows: What aspects of student thinking did the preservice mathematics teacher attend to when she interacted with a 7th-grade student? How did she interpret what she attended to in the student's thinking in her reflection? How did she respond during her instruction? What kind of pedagogical decisions did she offer for future lessons?

Theoretical Framework

The commonly cited and used frameworks that rely on teacher noticing are the learning-to-notice student mathematical thinking framework by van Es and Sherin (2011) and the professional noticing of children's mathematical thinking framework by Jacobs et al. (2010). This research study focuses on how a preservice teacher responds to student thinking in addition to attending to and interpreting student thinking. Therefore, professional noticing of children's mathematical thinking framework is chosen since it addresses three connected skills: "(1) attending to children's strategies, (2) interpreting children's understandings, and (3) deciding how to respond based on children's understandings" (Jacobs et al., 2010, pp. 172–173). Furthermore, the analytic framework of Taylan (2017) and some categories from the study by Çatman-Aksoy and Işıksal Bostan (2023) are utilized, focusing on attention and interpretation skills, as they provide insight into the aspects of student thinking that the preservice teacher attended to and interpreted.

Methods

This research study requires an in-depth analysis of a preservice mathematics teacher's in-the-moment noticing of student's mathematical thinking; therefore, the case study method was adopted within qualitative research methodology (Yin, 2014). Concerning the framework of Jacobs et al. (2010), the unit of analysis is the preservice mathematics teacher's expressions regarding what she attends to, interprets, and how she responds to students' thinking.

Participants

This study's participants comprised one volunteer from the first author's PhD dissertation study. Mason (2011) articulated the awakening and developing of inner witness through intentional reflection as a purpose of noticing. Therefore, the participant's willingness to join this study and openness to develop her noticing skills and explain herself made her a participant in investigating the change in her inner witness towards student thinking in-depth. She was a senior undergraduate student in a mathematics teaching program at one of the state universities, and her sole experience with students through registration to practice teaching courses. Before participating in the study, she was informed about the research study and consented to join the study.

Data collection and analysis

The data collection of this part of the study was composed of the written and oral reflection of video recording of the preservice teacher's one-to-one application of the lesson plan with 7th-grade student. She participated in the larger study, which aimed to develop teacher's noticing of student thinking study, which covers five weeks of video case analysis sessions. She created a lesson plan and implemented it for one 7th-grade student in a public middle school in Türkiye. Her lesson plan was based on finding the general rule and the desired term of pattern generalizations. In the main activity, she used an ethnomathematical knitting model by stating a grandmother wants to knit a vest with a flower pattern for her granddaughter. The student drew the first few steps of the pattern and made a table to find the general rule of the pattern. The student was able to find a general rule but had difficulty naming variable and using different notations to represent the same variable. The main pattern generalization activity and the student's solution regarding this activity are demonstrated in Figure 1.

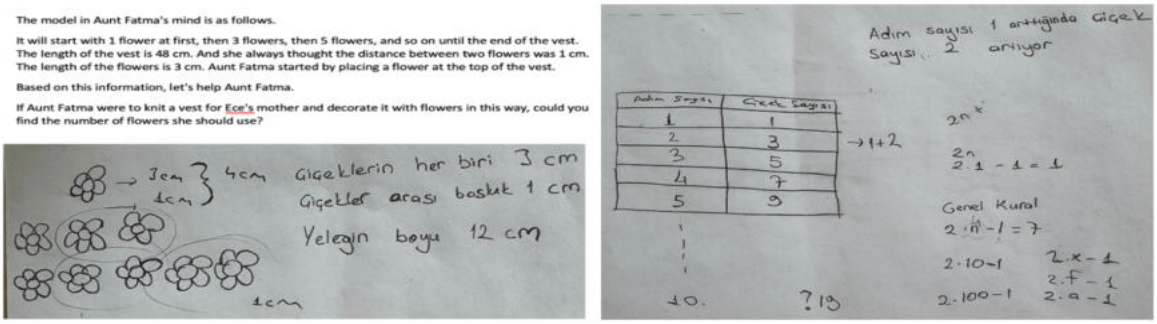

Figure 1: Pattern generalization activity example from the lesson plan and student's solution

The lesson was recorded by a camera facing the student and preservice teacher. The preservice teacher watched this video recording and wrote a reflection based on what she noticed, how she interpreted and reflected on student thinking in the moment, and what she would do if she had another chance to teach this lesson. She also reflected on these points in an interview conducted by the first author. The written reflection and the verbatim transcript of the interview with the preservice teacher compose the data of this study. The data was analyzed with MAXQDA (VERBI Software, 2024) based on Jacobs et al.'s framework (2010). For the attention component of the framework, student understanding, difficulty, characteristics, and connections occurred in the study, which is compatible

with the analytic framework of Taylan (2017). For the interpretation component, making connections between student and other students' thinking and teaching goals occurred in the data set, and these categories were adopted from Taylan (2017). For this component, making claims about student thinking without giving evidence is adopted from Çatman-Aksoy and Işıksal Bostan (2023). The explanation for these categories is provided in the table in the relevant section. Apart from these, the categories that emerged during the data analysis are provided in tables in the findings section.

Findings

Preservice Mathematics Teacher's Attention to Student Thinking

The preservice teacher pays attention primarily to student thinking. She noticed, both during her teaching and reflecting on her teaching, that the student had a conceptual understanding of the variable and that the variable referred to the number of steps in the task. During teaching and in her reflection, the preservice teacher noticed that the student was able to use step number and replace it as a variable, but the student was having difficulty using variable notation and finding the value asked for in the question when an inverse functional relationship was given. The preservice teacher also noticed that the student related the number of steps with the number of flowers by making mathematical connections to find the general rule of the pattern. Furthermore, she had difficulty understanding how to rename a variable. As in her explanation, the student was aware of the variable concept but was unable to call it a variable.

Another feature that the preservice teacher was able to notice is student characteristics. She stated in the interview that she noticed student's prejudice against mathematics. As a teacher action, she articulated that even though the student said she did not know how to name a variable, she was not able to attend to this student's understanding in-the-moment. The instances about student characteristics and teacher actions were only identified in her reflection after watching the video recording of her teaching. The examples of preservice teacher's attendance to student thinking, characteristics, and teacher action are provided in Table 1 with direct quotations from the interview and reflection paper.

Table 1: The instances that preservice mathematics teacher's attention to student thinking

Categories		Instances
Student Thinking	Student understanding (Taylan, 2017)	She said that n is the number of steps, and it is something that is constantly changing. She also knew that we should write that number instead of n, according to the number of steps asked. In other words, she is aware that it is a variable.
	Student connections (Taylan, 2017)	The student preferred to express the rule of the pattern by establishing a relationship between the number of steps and the number of flowers. This situation gave us the idea that the student understood the concept well.
	Student difficulty (Taylan, 2017)	I noticed that students can easily see and understand similar ideas, and after solving similar questions, they think a lot about when asked questions, which establishes an inverse relationship. For example, when finding the number of

		flowers in Step 7, the student could establish a relationship without much difficulty, but she thought more when there were seven flowers.
	Student lack of conceptual knowledge	I asked what n was, and she said the number of steps. I asked if the number of steps is fixed. She said no. It changes constantly; it becomes 1, 2, 3, 5, but she did not say the special name for it. She said there was none. I noticed this while watching the video.
Student Characteristics	Student characteristics (Taylan, 2017)	Generally speaking, the student was good. She was a bit prejudiced at first. She had a prejudice against herself; in other words, a prejudice against mathematics.
Teacher Action	Disregarding student thinking in-the-moment	That variable… when I asked what we call it, would we say something special, she said no directly, actually in there, I said that we call it variable. I didn't ask while teaching, but if it were right now, I would say, okay, this is something that changes; for example, this n is constantly changing.

Preservice Mathematics Teacher's Interpretation of Student Thinking

When the preservice teacher was asked to explain student thinking, she mainly did not explain or interpret student thinking without providing evidence. Even though she offered some explanations for what she noticed, mostly her explanations were not well-rounded based on the reasons behind her assumptions. She made some comments about relating the student she taught to the other students in the video club sessions that she attended and general comments about these students. In one instance, she stated how her expectations related to connecting ratio and pattern generalization were met by the student since the student was able to make mathematical connections between them. These instances are exemplified in Table 2 in the light of the preservice teacher's reflection on her teaching and student thinking.

Table 2: The instances that preservice mathematics teacher's interpretation of student thinking

Categories	Instances
Making claims about student thinking without giving evidence (Çatman-Aksoy & Işıksal Bostan, 2023) *The preservice teacher attends to student thinking but does not provide evidence*	When I asked the question in the problem situation, the student found the general rule by associating the steps and the number of flowers. In this case, I realized that the student had the right idea about how to find the general rule.
Use of evidence in making claims about student thinking (Taylan, 2017) *The preservice teacher interprets student thinking by providing evidence of a specific incident*	When we ask for the number of steps, she can find the number of flowers, but for example, when we ask which step has so many flowers, she thinks a little bit about it. In this sense, you had asked why this is the case, but it is actually a little more difficult to think in reverse. It is a little more challenging to establish a relationship.

Making connections between student thinking and other students' thinking from video case analysis sessions *The preservice teacher makes a connection between students' thinking*	I noticed that students can easily understand similar ideas after solving similar questions; they tend to think more about questions involving establishing an inverse relationship. For example, when finding the number of flowers in Step 7, she could establish a relationship without difficulty, but she thought a little when there were seven flowers.
Making connections between student thinking and teaching goals (Taylan, 2017) *The preservice teacher makes a connection between student's thinking and her teaching goals*	I wanted the student to move from ratio to pattern. The student was able to establish this relationship quickly. And we actually made a mathematical connection. The student realized that mathematics is not just a science consisting of formulas and rules, but that subjects can actually be related to each other by making connections.

Preservice Mathematics Teacher's Response to Student Thinking

During her teaching practice, the preservice teacher responded to student thinking by questioning, providing various examples, giving materials that would be used to facilitate student understanding, and providing multiple representations regarding pattern generalization. She acted towards any possible misconception about representing variables with different labels. She reflected on these instances in her reflection, as provided in Table 3. Furthermore, apart from how she responded to the student's thinking during her teaching, the preservice teacher provided possible pedagogical decisions that she would make for future lessons in her reflection on teaching. The examples of the actions she offered during the interview and in her reflection paper are provided in Table 3.

Table 3: The instances that preservice mathematics teacher's how to respond to student thinking

Categories	Instances
Questioning	The student knows that n is something that changes, but when I ask her if it has a special name, she says it doesn't. I would ask the student what name you would give to something that changes, since the concepts of variable and constant are essential.
Providing different examples	In the case of thinking in reverse, I would give different examples for this situation.
Providing materials to facilitate student discovery	I realized she had difficulty establishing an inverse relationship when I asked her which step is where we have 7 flowers. We developed our thoughts by thinking about this with the help of materials.
Using different representations	I first established a relationship between the amount of money accumulated without thinking about that 50. We had 50 liras at the beginning, didn't we? I added 50, 50+3, 50+6, 50+9. Then, together, we tried to find the rule for 3, 6, and 9 increases. I expressed it with a table so that she would see it better at the table, and she found that 3, 6, 9.
Taking actions towards preventing possible student misconceptions	For example, there is a variable, something that changes. She wrote 2n by herself, and we created a table. Then I stated that it could be 2x; it could be 2f, which is the first letter of my name, and 2a is the first letter of your name. It could be 2a-1 so that she would not think it is only expressed with that n, so that she would not have such a misconception.

Discussion

This research study examines a preservice mathematics teacher's in-the-moment noticing of students' mathematical thinking based on her reflection on students' mathematical thinking according to the video of her one-to-one teaching. She reflected on her teaching by identifying and interpreting student understanding and the difficulties students had during her teaching. Examining her teaching video provides a chance to consider the student's thinking that she missed in the moment of her teaching, as van Es and Sherin (2021) suggest the importance of things that teachers missed. In her reflection, she commented on student's difficulty that she missed in the moment. She informed her practice by recommending alternative decisions she would have made and recommended some pedagogical moves that she would take in future lessons toward developing her student thinking. While reflecting on her teaching, she had a chance to compare her student with other students she encountered during video case analysis in the dissertation study of the first author she attended. This would allow her to create a general picture of students' thinking and notice the different perspectives or incidents she would encounter while teaching. Even though the preservice teacher made interpretations of student's thinking, in most cases, she did not provide well-rounded evidence regarding her interpretations. Since the preservice teacher in this study had only one chance for one-to-one teaching, increasing preservice teachers' teaching practice would have allowed them to develop their noticing skills further and provide evidence for their interpretations by encountering various students' thinking. As Jacobs and colleagues (2010) stated noticing is a learnable skill in which the preservice teacher, as in this case, interpreted the things she noticed in the moment or the things she noticed while watching the video recording of her practice. Preservice teachers would learn about various students' thinking and how to notice it through armchair reflection (Erickson, 2011, p. 24). That would lead to development in their noticing abilities, which would translate into classroom teaching in their future career as this context provides an opportunity to practice their skills. As Sherin and van Es (2005) suggested, videos would contribute to noticing student thinking missed in the moment of teaching and develop preservice teachers' noticing skills.

The implementation of a new curriculum in Greece: The case of learning and teaching statistics

Georgia Athanasiou[1], Konstantinos Stouraitis[1] and Despina Potari[1]

[1]National and Kapodistrian University of Athens, Department of Mathematics, Athens, Greece; athanasioug@math.uoa.gr

Keywords: Implementation, curriculum resources, statistics.

The study aims to investigate the way mathematics teachers enact a new curriculum in Greek schools. Trying to comply with current international perspectives about teaching and learning, the new curriculum dedicates a significant part to statistics, in contrast to the previous one. We focus on the relationships between influential factors, innovation enactment, and outcomes for the teachers. Our research question is: how the innovation enactment and the outcomes relate with teachers' understandings of the a) epistemological characteristics of statistics learning and b) ways to promote this learning, as both are underlined in the new curriculum? The influential factors can be traced in the tensions that the teachers experience. The importance of this study is highlighted by a gap in implementation research focusing on statistics.

Theoretical Framework

Teachers can use multiple material, cultural, and human resources in their design work. Among them, curriculum resources appear to have an important role in introducing reforms. The process of implementing a new curriculum has been the focus of researchers for the last decades. Koichu et al. (2021) addressed the relationship between implementation and resource by considering "implementation as a change-oriented process of endorsing an action plan based on a relatively well-defined resource (such as a research finding, a digital tool, a curriculum, a textbook, or an institutional policy)". In this paper our motivation lies mainly on one out of the five dimensions that Century and Cassata (2016) consider important to study implementation: we try to understand relationships between influential factors, innovation enactment, and outcomes. We also adopt the perspective of the "adaptation model" of implementation that emphasises the process of implementation and the conditions and contexts that affect it (Century & Cassata, 2016).

Today, one of the most crucial qualifications that a student should obtain while studying on secondary education is data literacy, which will lead to the ability to gasp how our data-driven world operates. Garfield and Chance (2000) stressed the basic elements of statistical thinking such as understanding the purpose, logic and process of statistical investigations and developing the mental skills to recognize, pose and answer questions that arise from the data. The new curriculum adopts those perspectives. All of the above create an unprecedented scene for secondary educators, requiring their preparation and familiarity in order to implement it effectively.

Methods

Our research is a case study of a group of teachers who worked together for a semester to design and enact lessons in their classrooms based on the new curriculum. In this paper we study a piloting process of six upper secondary mathematics teachers working in experimental/model schools. In this

project the group's discussions were focused on the teaching of statistics. The new curriculum shifts from a computational and procedural approach to a more creative, interpretational, inquiry based and problem-solving style. Data was gathered by recording four of the group's meetings held on approximately a monthly basis. We analysed their meetings using the Grounded Theory Method. Based on our data, we identified three main dimensions that emerged from the teachers' sayings and those led to the core of each episode's analysis. Those dimensions are about: i) epistemological and content specific issues, ii) teaching and learning issues and iii) emerging tensions during the process of implementation of the new curriculum.

Results and discussion

In the teachers' discussions we see epistemological issues emerging about teaching and learning statistics. Specifically, teachers are trying to make a decision about designing tasks that focus on a) computational procedures and b) interpretational statistical reasoning. Teacher 1 (1st meeting) proposes splitting the task into two parts so that in the first level students be introduced to statistics' basic calculations and then interpret the statistical concept involved. Teacher 2 (2nd meeting) proposes that teaching a statistics concept should firstly be introduced without focusing on a certain context and then be applied in a realistic context to produce interpretations. An effort to overcome the tension between the computational and interpretational dichotomy is being made by providing the needed formulas to the students to ease the computational procedures and focus on statistical conclusions. Furthermore, in meetings 3 and 4, while reflecting on their actions in class, teachers recognised that realistic context and statistical interpretations raised students' interest. This recognition highlights the teachers' struggling to coordinate the epistemological assumptions of the new curriculum with established perspectives and teaching approaches on statistics. Those epistemological issues appear as tensions. The factors involved are in the one hand, the new curriculum materials that provoke teachers to innovate and adapt their teaching into a new reality and in the other, their established perspectives and teaching approaches. These tensions are intertwined with institutional restrictions based on students' interests and time pressure.

In the implementation process of a new curriculum those epistemological issues concerning statistics need further study. This study will support our understandings of teaching and learning statistics and reinforce the implementation of the new curriculum.

Support shifts in how teachers view their students' capabilities when co-teachers develop ambitious instructional practice

Anna Bengtsson

Linnaeus University, Department of Mathematics, Sweden anna.bengtsson@lnu.se

Keywords: Co-teaching, ambitious instructional practice, ambitious teaching, coherent system, systematic literature review.

Introduction

Informed by decades of research, policy reforms and professional development programs aimed at raising educational standards have had only limited impact on teachers' instructional practice and student achievement. These results, from Sweden and many other countries, raise questions about critical features and coherence in teacher professional development programs. Also, the call for ambitious instructional practice in mathematics classrooms has intensified (Lindvall et al., 2022).

Ambitious instructional practice fosters problem-solving and reasoning skills and enhances a deeper understanding of mathematical concepts and procedural fluency. However, such ambitious goals are difficult to achieve without the critical features of teachers' knowledge and beliefs. A structure for teachers' learning and development toward these goals is also key to impacting teachers' instructional practice. Further, instructional materials, student assessments, and additional support for struggling students must also be coherent and align with the goals of ambitious instructional practice to impact student achievement (Cobb & Jackson, 2021).

Co-teaching has been recognized in response to classroom diversity and to address diverse student needs in inclusive educational settings, particularly in mathematics. It involves two or more educators working collaboratively in the same classroom and can manifest in different forms. Co-teachers may share the responsibility for planning, instructing, and assessing students, or one teacher may lead the instruction while the other is providing individual support to students as needed. Co-teaching can contribute to social and didactical inclusion and addresses all students' mathematical learning if it is flexibly organized (Gardesten, 2023).

Peer-reviewed academic articles examining co-teaching in Swedish mathematics classrooms are few to be found, however, several national reports describe successful implementation of co-teaching in Swedish schools. For example, findings indicate that co-teaching improves student outcomes and strengthens teachers' learning.

A hypothesis is that co-teaching, as an already implemented approach in many Swedish schools, may support coherent critical features to impact teachers' instructional practice and student achievement aligning with the call for ambitious instructional practice. This poster aims to present the results of a systematic literature review addressing the question *How may co-teaching support ambitious instructional practice?*

Method

The systematic literature review examined the relationship between co-teaching and ambitious instructional practice, providing a foundation for a forthcoming educational design research study.

The review followed the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines to ensure a transparent and replicable process. The search was conducted in ERIC, Web of Science, and Teacher Reference Center focusing on peer-reviewed academic articles. Keywords were organized into three main blocks: "ambitious instructional practice", "co-teaching" and "mathematics". The search identified 15 articles that addressed the research question and were included in the review.

While analyzing the articles, a deductive approach was applied; hence, themes were specified in advance. The themes were conceptualized as coherent critical features to support ambitious instructional practice. Ambitious goals, teachers' knowledge and beliefs, quality instructional materials, additional support for students in need, and structured professional development for teachers must all work in harmony in a coherent system (Cobb & Jackson, 2021).

Results and discussion

The results will be more detailed and presented in the poster. Still, the hypothesis is somewhat confirmed: Co-teaching may support coherent critical features to impact teachers' instructional practice and student achievement aligning with the call for ambitious instructional practice. Co-teaching has been shown to improve teachers' instructional practice by combining different competencies in the classroom, which can help students at various levels achieve better outcomes. Proactive support for struggling students is often established in cases where the educational teacher and the special education teacher share the responsibility for planning, instructing, and assessing students. This contrasts with situations where the special educator takes the role of the second teacher only providing individual support to students as needed. The most important finding concerns the critical features of teachers' beliefs and ambitious goals. Co-teaching may support ambitious instructional practice as it includes teachers' learning and supports shifts in how teachers view their students' capabilities. Crucially, the belief that all students are capable and can succeed in mathematics must be shared by teachers (Cobb & Jackson, 2021).

Teaching mathematically gifted students in secondary schools: A systematic literature review

Peter Kaiser[1] and Moritz Zehnder[2]

[1]Karlsruhe Institute of Technology, Germany; peter.kaiser2@kit.edu

[2]University of Bayreuth, Germany

Keywords: Mathematically gifted, gifted education, learning environment, secondary schools.

School performance studies such as PISA show that the proportion of pupils with very good mathematical skills has decreased significantly in Germany over the last 10 years (Reinhold et al., 2019). This may be related to inadequate or inappropriate support for mathematically gifted pupils. While there are many suggestions for mathematical support programs in the literature, often based on practical experience, the empirical evidence regarding relevant design features of support programs still seems to be limited (Leikin, 2021), especially at secondary level.

Theoretical background

We understand *mathematical giftedness* as the individual potential to develop mathematical abilities (Ulm & Zehnder, 2020). Learning processes, which are often designed by teachers, are central to the realization of this potential in students. To this end, teachers design *learning environments* and define tasks, content or methods for the teaching and learning process (Ulm & Zehnder, 2020). Prediger et al. (2022) identify five principles for high-quality mathematics teaching (conceptual focus, cognitive demand, student focus and adaptivity, longitudinal coherence, and enhanced communication) that can be used to design learning environments. However, it is unclear to what extent they can be transferred to gifted education or, for example, have different relevance for it.

Research questions

In this study we would like to address the following questions: (1) What empirical evidence is already available on the design of teaching and learning processes for mathematically gifted students in secondary schools? (2) To what extent do these design features correspond to the five principles according to Prediger et al. (2022)?

Methods

The basis for answering the research questions is a systematic literature review (Newman & Gough, 2020). In a first step, a search for relevant articles, book contributions and monographs is carried out in four databases (ERIC, Fachportal Pädagogik, Scopus and Web of Science). The search terms include MATH*, GIFT*, PROMIS*, TEACH* and EDUCAT*. Subsequently, the titles and afterwards the abstracts as well as research questions and methods are screened, and inappropriate hits are sorted out using previously formulated exclusion criteria (e.g. “No reference to mathematical giftedness”). The remaining sources are read in full and appropriate hits are finally selected using inclusion criteria. Finally, suitable coding of the resulting sources, for example with regard to the investigated feature of a learning environment, allows the two research questions to be answered (see Figure 1 for an outline of the process of the systematic literature review).

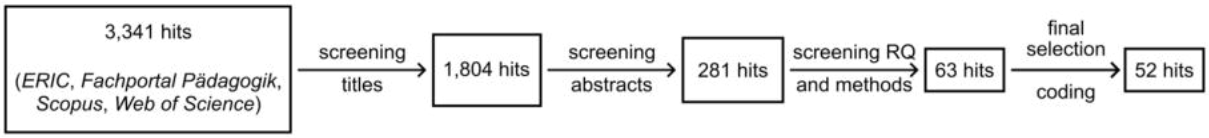

Figure 1: Process of the systematic literature review

Results

The previously described procedure of successive exclusion made it possible to reduce the 3,341 hits obtained in the first step to 52 sources, which were read in full and coded after the final selection, focusing on the characteristics of the design of promotional activities for the mathematically gifted (see Figure 1). The current review provides three key preliminary findings. (1) There is a large number of programs to support mathematically gifted students. These are often offered by schools or universities and have a variety of formats, such as summer camps or math clubs. In most cases, these are enrichment programs that take place alongside regular math lessons. (2) While there are many recommendations for promotion based on practical experience, i.e. anecdotal evidence, the small number of remaining hits shows that only few studies address specific features that should be considered when designing learning environments for mathematically gifted students. The majority of the reported features focus on partners in the learning process (e.g., the competences of the teacher or other students) and the mathematical tasks used. (3) Although the five principles by Prediger et al. (2022) are not explicitly mentioned, all but longitudinal coherence can be identified in the results. Their weighting and any necessary extension of the principles still need to be discussed.

Help-seeking interactions in primary school mathematics classrooms

Emine Shaka[1], Natalie Fischer[1] and Elisabeth Rathgeb-Schnierer[1]

[1]University of Kassel, Germany; shaka@uni-kassel.de

Keywords: Subject-specific support, help-seeking, student-teacher interaction, primary school.

Introduction

One integral part of teaching consists in supporting students in their learning processes. Especially the art of supporting effectively constitutes a significant issue which concerns every teacher (Lozano Botellero et al., 2023). As Pianta (2016) states, the interaction between student and teacher entails a particular purpose or learning objective that preferably enhances the learner's performance.

In general, support situations can be initiated in different ways. When a student requests support, for example, by asking the teacher a question, this behaviour is referred to as *help-seeking* (e. g. Nelson-Le Gall, 1981; Newman, 2000). Being able to perceive one's own need for help is considered to be an important self-regulatory skill (Newman, 2000) since it represents a strategic move to keep the learning process going (Nelson-Le Gall, 1981). In order to potentially receive support which is adaptive to these needs, it is also necessary for the help-seeker to convey the difficulty accurately enough (Newman, 2000). However, a broader understanding of the help-seeking interaction can be obtained if not only the learner but also the teacher is taken into account (Davison et al., 2023). In these student-teacher interactions, the type of support teachers respond with is commonly distinguished into three separate domains (Lozano Botellero et al., 2023). The Teaching through Interactions (TTI) framework, for instance, includes the emotional, organisational as well as instructional domains and classifies the latter into general and content-specific instructional supports (Hamre et al., 2013). Even though research on support situations in secondary education exists, it mainly reports on general instructional support, whereas the focus on a specific subject is scarce (Lozano Botellero et al., 2023). Similar to secondary school, the small amount of investigations on teacher support in primary school does not include content-specific instructional support.

Methods

In an effort to gain more insights into the way teachers respond to content-related need for help, this study focuses on student-teacher interactions in which support is provided. Fyfe and Brown (2020) draw upon psychological as well as educational research stating that a learner's outcome on learning tasks is linked to, inter alia, teacher guidance. As the support of learners constitutes a typical classroom situation, it can be derived that teacher support pertains to teaching processes. Accordingly, teaching unfolds when interaction evolves. These perspectives are consistent with the posit of the TTI framework stating that "much of the effect of teachers . . . on student learning is located in the interactions that take place between teachers and students" (Hamre et al., 2013, p. 479).

Since help-seeking has usually been investigated to a lesser extent within the classroom (Davison et al., 2023), findings on support situations which are initiated by students who solicit help will be displayed on the poster. More precisely, it will be focused on the support teachers give students who demand content-related help while working on their tasks in a lesson. For this purpose, several

videotaped mathematics lessons in primary school, which are provided by the DFG Graduate School INTERFACH, will be analysed. The teachers who participated in this video study were supposed to conduct a lesson in which the students explored and worked with a generally well-known arithmetic problem format in Germany called *Zahlenmauer* (number wall). Considering that, a coding system was designed which comprises five primary domains of support, namely the content-related, strategic, organisational, affective and unspecific domains. Adjusted to working with Zahlenmauern, the content-related domain is further divided into various subject-specific categories. Based on the content-related request for help, the teacher's help-giving responses will be examined and presented. Up to now, it appears to be that teacher support mostly aligns with the learner's issue regarding the addressed domain. While these support situations usually start with providing broader hints, they conclude in more narrow indications. Only sometimes the teacher tends to change the subject-specific category so that previous steps of the task are revised or deeper processes are promoted.

TWG 20: Mathematics Teacher Knowledge, Beliefs and Identity

Introduction to TWG20: Teachers' Knowledge, Beliefs and Identity

Miguel Montes[1], Veronika Hubenaková[2], Federica Ferretti[3], Thorsten Scheiner[4,5], Felix Woltron[5]

[1]University of Huelva, Spain, Miguel.montes@ddcc.uhu.es

[2]University of Pavol Jozef Šafárik, Slovakia

[4]Free University of Berlin, Germany

[5]Australian Catholic University, Australia

[6]University of Viena, Austria

This paper presents an overview of Theme Working Group 20 (TWG20) at the 14th Congress of the European Society for Research in Mathematics Education (CERME 14), with contributions and emerging themes from discussions on teachers' knowledge, beliefs, and identity. TWG20 featured 25 contributions from researchers across 15 countries and five continents. The overview reveals six cross-cutting themes that emerged from group discussions: the dual role of tasks in research and education, contextual considerations in teacher education, the centrality of mathematics in teacher education research, inclusion and special needs, theoretical framework diversity, and ethical considerations in research. This reflection aims to inform future research directions and enhance understanding of the complex interplay between teachers' knowledge, beliefs, and professional identity in mathematics education.

Keywords: Teacher knowledge, Teacher beliefs, Teacher identity, Teacher education, Mathematics Education

Overview of TWG20 in CERME 14

TWG20 at CERME 14 featured 25 contributions, including four poster presentations. Consistent with previous CERME conferences, the group demonstrated remarkable diversity, encompassing participants from 15 countries across five continents. This diversity provided an exceptional foundation for scientific exchange concerning mathematics teachers' knowledge, beliefs, and identity, whilst facilitating critical reflection on how sociocultural factors permeate research in these domains.

The group maintained a balanced composition between newcomers to CERME and experienced researchers, with approximately two-thirds being new to TWG20. Early career researchers represented about one-third of participants, contributing fresh perspectives to established research traditions within the group.

The working group used a structured approach across six thematic sessions. The opening session introduced TWG20's research heritage and outlined the conference structure. Each subsequent session was designed around transversal themes that served as focal points for reflection:

Session 1: Diverse theoretical perspectives in teacher education research

Session 2: Teachers' self-perception and professional identity

Session 3: Professional knowledge and its connections to broader educational concerns

Session 4: Methodological diversity, from intervention studies to large-scale research

Session 5: Problem-solving and problem-posing in teacher education

Session 6: Classroom inclusivity and formative task development

The closing session facilitated discussion of transversal themes identified by the TWG20 leadership team. Each session followed a consistent format: five-minute presentations followed by 30–40 minutes of small-group discussions, concluding with whole-group synthesis to share insights across subgroups.

Research on Knowledge, Beliefs and Identity in TWG20

This section characterises the research presented at CERME 14 concerning the three themes of the working group (knowledge, beliefs, identity). Each subsection examines the distinctive features of papers addressing the corresponding theme.

Mathematics Teachers' Knowledge

The nature and development of mathematics teachers' knowledge emerged as a recurring conference theme, with particular attention to how such knowledge is conceptualised, enacted, and supported in teacher education and professional learning. Rather than treating teacher knowledge as static or merely cognitive, discussions foregrounded its situated and dynamic character, arising from the interplay between disciplinary understanding, pedagogical reasoning, and specific teaching contexts.

Research on pre-service teachers (PSTs) revealed a significant disconnection between mathematical understanding and effective instructional application. Whilst PSTs often demonstrate confidence in their reasoning, they frequently encounter difficulties when adapting their knowledge to specific teaching situations. This suggests that apparent knowledge deficits more accurately represent a lack of access to knowledge-in-action, shaped by cognitive framing, varied pedagogical perspectives, and unexamined assumptions.

Consequently, teacher knowledge must be understood as inseparable from the capacity for reflection, critical distance from one's thinking, and engagement with multiple perspectives. This multifaceted understanding challenges traditional conceptualisations of teacher expertise.

Discussions drew upon established frameworks such as Mathematical Quality of Instruction (**Hill et al., 2008**) and Mathematics Teacher's Specialised Knowledge (Carrillo-Yañez et al., 2018). Whilst these frameworks aim to render teacher knowledge observable and comparable, participants noted inherent challenges in codifying teaching expertise—particularly that of experienced practitioners whose practices are guided by tacit understanding. The question of how to make implicit expertise visible and support its appropriation by novice teachers emerged as a critical concern.

Cultural and institutional factors were recognised as central to shaping both the nature of teacher knowledge and how it is valued and fostered. Comparisons between the Japanese model—characterised by practice-oriented approaches involving textbook writing and collaborative lesson

study—and Western contexts with more theory-driven orientations opened debates about the advantages and limitations of both perspectives.

Rather than positioning these approaches in opposition, discussions highlighted that cultural transposition should not be viewed as comparative exercise, but rather as an opportunity for critical reflection on one's educational system and thinking beyond conventional boundaries.

Ultimately, discussions invited a fundamental rethinking of what it means to 'know mathematics for teaching'. Teacher knowledge emerged not merely as content knowledge or pedagogical content knowledge, but as a complex, context-sensitive, and fundamentally human dimension of professional practice—one deeply entangled with motivation, beliefs, and identity. Recognising and supporting this complexity in both teacher education and professional development remains a central challenge for TWG20.

Mathematics Teachers' Beliefs

Consistent with previous CERME conferences, many TWG20 contributions focused on beliefs, typically examined in conjunction with knowledge and identity. Across various studies, researchers demonstrated shared interest in investigating how (prospective) teachers' beliefs influence their mathematics education practices, particularly in inclusive contexts.

A notable methodological similarity emerged in the widespread use of Likert-scale questionnaires for data collection, offering structured approaches to capturing teachers' beliefs across different contexts. Despite these methodological consistencies, studies demonstrated considerable diversity in focus and scope.

Research ranged from investigations of teachers' beliefs about assessment and standardised testing to content-specific areas such as word problem teaching or facilitating secondary-to-tertiary mathematics transitions. Some studies primarily mapped existing belief landscapes, providing comprehensive overviews of how educators conceptualise their roles and responsibilities. Others sought to broaden prospective teachers' beliefs through targeted interventions and professional development initiatives.

Studies revealed interesting divergences in theoretical frameworks and definitions. Whilst some research drew upon established definitions such as Philipp's (2007) interpretation of beliefs and frameworks like Ajzen's Theory of Planned Behaviour (1991), others did not explicitly adopt particular frameworks. This reflects ongoing field discussions about the need for shared definitions in beliefs research.

Future research considerations include questions of transferring findings into teacher education and practice, as well as ensuring clear participant identification. Given international teacher shortages, various countries have adopted different strategies: some education systems allow prospective teachers to begin teaching during training, whilst others offer alternative certification programmes for career changers. When evaluating teachers' beliefs, it is essential to consider that teachers may possess vastly different teaching experiences.

Collectively, TWG20 studies reinforce the understanding that teachers' beliefs constitute multifaceted, context-dependent constructs central to fostering rich and inclusive mathematical learning experiences. The observed divergences in research focus, conceptual frameworks, and cultural dimensions highlight the necessity for ongoing scientific dialogue and theoretical refinement.

Mathematics Teachers' Identity

Research on teacher identity revealed challenges similar to those in beliefs research. In some contexts, individuals enrolled in teacher education programmes discover during their studies that they do not wish to pursue teaching careers. These individuals are essentially students of teacher education rather than future teachers, raising the relevant question: *To what extent can we meaningfully speak of teacher identity in such cases?*

Conceptualising mathematics teachers' identity meaningfully remains complex. Whilst TWG20 expects papers to address mathematics teachers specifically—with findings not easily generalisable to other subject teachers—no robust theoretical framework deals explicitly with mathematics teacher identity. Consequently, authors often rely on general conceptualisations such as Sfard and Prusak's (2005) framework or avoid the term identity altogether, opting for constructs like self-perception that may not clearly align with identity as a construct.

This naturally raises questions about boundaries between beliefs, identity, and subjective theories. Whilst these constructs are not neatly separated in individuals' minds, research perspectives require careful attention to specific concepts being studied and consideration of how investigating particular constructs contributes to improving mathematics teaching and teacher development.

Papers in TWG20—consistent with previous years—seem to perpetuate the 'super-teacher' metaphor. These studies assess teachers' knowledge and beliefs, often implicitly conveying that teachers are failing if unable to respond correctly to researcher-selected tasks. Given that many researchers operate in dual roles as both researchers and educators, this perspective carries particular significance. Research should not foster impressions amongst students that they can become good teachers only upon possessing relevant knowledge and supportive beliefs.

Cross-cutting Issues

During TWG20, various cross-cutting themes emerged in discussions. Some have been recurrent in recent years, whilst others stem from more recent interests. We present six transversal axes of reflection, each with distinct nature and scope.

Tasks in Teacher Education Research

Most TWG20 contributions utilised tasks for teacher education in some capacity. Task usage represents a recurrent feature in teacher education research, typically serving dual roles as learning assignments and research instruments. However, despite this duality, research presentations commonly lack detailed explanations regarding design and development decisions.

This raises critical questions about how the dual nature of tasks—as both learning tools and research objects—is being articulated. Do tasks originate as learning tools subsequently used for research, or

vice versa? The former case raises methodological rigour concerns: to what extent can learning tools, used without explicit research adaptation, serve as adequate data collection instruments?

The term 'task' encompasses wide varieties of teacher assignments, yet more in-depth exploration of task nature seems necessary. This includes examining relationships to teachers' future classroom practice and intended task purposes. Such research would prove valuable both for structuring research processes in task-based teacher education and for organising teacher education according to expected professional activities.

Contextual Considerations

Context has been an implicit yet consistently highlighted element in recent TWG20 meetings. When using 'teacher education', we tend to assume speakers and listeners refer to the same concept—but this is not necessarily the case. 'Teacher education' carries multiple connotations heavily dependent on context.

Connotations are often shaped by national teacher education systems. Depending on country and targeted educational level, teacher education may be organised by discipline or follow generalist models where teachers train across subjects. Each context features distinctive structural characteristics, including those dedicated to mathematics content, mathematics education, or in-school training, as well as specific school-based training foci.

Implicit or explicit norms—frequently unwritten—govern educator profiles responsible for delivering different professional development types, significantly impacting teacher education. Mathematical-cultural aspects require consideration in certain studies. This ultimately can even affect the very nature of mathematical content. For example, two division algorithms are traditionally used in Europe—the French method and the Anglo-American long division method—while the partial quotients method has recently gained traction in some countries. Research that addresses this topic without specifying the algorithm in use can create communication barriers, particularly for researchers unfamiliar with the specific traditions or norms followed in different European contexts.

Increasing recognition exists for providing thorough descriptions of relevant contextual factors in each study to foster more effective and meaningful knowledge exchanges. Characterisations of context and its impact on mathematics teaching and teacher education (e.g., Brodie, 2025) can helpfully frame necessary reflections on this issue.

Mathematics in Mathematics Teacher Education Research

Recent TWG20 meetings have seen strengthening discussions regarding mathematics' role in presented research. Mathematics **education research** focused on teacher education gains meaning—in contrast to general education research—through specific connections to mathematics. This is often evident in teacher knowledge studies drawing upon precedents emphasising (pedagogical) content knowledge as distinguishing elements (e.g., Shulman, 1986; Ball et al., 2008; Carrillo et al., 2018).

However, when addressing teachers' beliefs or professional identity, the subject discipline's role in mathematics education research appears increasingly relegated to secondary positions in various studies. Among different ways mathematics can be approached in mathematics education

(Thanheiser, 2023), increasing numbers of studies treat it as contextual element, aiming to respond to primarily pedagogical issues equally applicable to any discipline.

This situation raises identity questions for mathematics education research, particularly teacher-focused research, regarding specialisation focus adopted in scholarly work. We believe it essential that, as a research field, we ask ourselves with each study: *Why is this mathematics education research? What mathematics is present in my research, and why is it relevant?*

Inclusion and Special Needs

During this TWG20, several researchers demonstrated evident interest in studies addressing situations involving particular sensitivity towards specific student populations, favouring their attention and classroom inclusion. This research often polarises around spectrum ends: students with learning difficulties and gifted students—those with cognitively-based special needs.

Group discussions highlighted the necessity of addressing inclusion from dual perspectives. First, preparing teachers for inclusive teaching practices responding not only to students with cognitive special needs but also those facing social exclusion or living in non-normative sociocultural contexts. Second, addressing inclusion within teacher education itself by reflecting on inclusion notions regarding prospective teachers' backgrounds and how mathematics teacher education can support future teachers from groups with various needs—cognitive, social, or otherwise.

Theoretical Frameworks: Evolution and Integration

TWG 20 has undergone significant evolution regarding theoretical framework usage. From CERME 9—where many studies aimed to underscore chosen frameworks' potential for educational research—to recent conferences where diverse constructs serve as means for studying different teaching aspects, there has been both focus shifts and framework employment manner changes.

Two theoretical models have become recurrent in recent TWG20 years, both centred on teacher knowledge: the MKT model (Ball et al., 2008) and the MTSK model (Carrillo et al., 2018). Whilst these models remained present in the most recent conference, wide varieties of theoretical constructs were represented in submitted works (including Anthropological Theory of the Didactic, TPACK, various belief frameworks, among others). This diversity enriches the group, fostering perspective exchanges.

We have observed developments toward networking between existing frameworks, aiming to complement their use in analysing diverse situations—from those specific to studied mathematical concepts to those allowing connections between constructs such as beliefs and knowledge, exemplified in Krišáková and Hubeňáková's (in this volume) work. Future conference contributions to TWG20 could consider adopting such theoretical articulation as foundations for understanding mathematics teachers' knowledge, beliefs, and professional identity in more complex and integrated ways.

Ethical Considerations in Mathematics Teacher Education Research

Ethics in mathematics teacher education typically does not receive direct attention. We may assume research is conducted ethically because we follow personal principles and values and established field

customs that presumably conform to ethical research standards. However, reflection on less evident aspects is necessary. These aspects are linked to a common circumstance: the often dual role we play as both teacher educators and researchers. This duality often involves us in research while simultaneously being involved in designing professional learning, yet there is insufficient reflection on our role within such research, how we might bias collected data, or how research process dynamics may limit teacher education effectiveness for given groups of prospective teachers.

This issue becomes particularly relevant when using methodological approaches involving control groups and intervention groups receiving different professional development—potentially denying control groups access to learning enhancements for research purposes. Another reflection point concerns informed consent related to the teacher educator-researcher duality. As educators of (prospective) teachers, hierarchical relationships exist with (prospective) teachers who may perceive educators' wishes to involve them in research activities as directives from authority figures. It is important to question whether informed consent is truly free or whether existing power dynamics exert implicit pressure on (prospective) teachers as potential research participants.

Finally, though sometimes related to educator-researcher duality, there is the issue of adopting deficit-based perspectives (Adiredja & Louie, 2020) in research. Studies focusing on shortcomings often overlook fundamental learning process characteristics and professional development importance, specifically building upon what learners already know and can do. Beyond this, deficit discourses imply researcher moral superiority (and their personal and sociocultural stances) toward studied future teachers, contrasting with needs to conduct research with them in support of their development.

Conducting research ethically involves commitment to treating teachers participating in our research as equals in the broadest sense of equality.

Conclusion

TWG20 at CERME 14 provided a rich forum for examining current research in mathematics teachers' knowledge, beliefs, and identity. The diversity of participants and contributions highlighted both the vitality of the field and the challenges that remain. The six cross-cutting themes identified through group discussions—tasks, context, mathematics centrality, inclusion, theoretical frameworks, and ethics—provide a roadmap for future research directions.

As the field continues to evolve, researchers need to remain attentive to the complex interplay between these themes and issues while maintaining focus on improving mathematics teaching and teacher development. The international and multicultural nature of TWG20 serves as a reminder that solutions must be culturally sensitive and contextually appropriate while advancing our collective understanding of mathematics teacher education.

The reflections presented here result from rich discussions among all TWG20 participants, whose contributions made this synthesis possible. Their diverse perspectives and collaborative spirit exemplify the best of international research cooperation in mathematics teacher education.

Beliefs of elementary school teachers regarding the inclusion of special education students in mathematics lessons

Bital Amir and Esther S. Levenson

Tel-Aviv University, Israel; bitalam@gmail.com

Considering that mathematics teachers' beliefs play a critical role in their practice, this study examines how professional development (PD) can impact elementary school mathematics teachers' beliefs regarding the inclusion of Special Educational Needs or Disabilities (SEND) students in mainstream classes. A mixed-methods approach was used in the study, combining questionnaires, reflections, and discussion. Involved were 34 teachers who participated in a 10-session PD program focused on teaching multiplication and division in inclusive classrooms. Findings indicated that the most notable positive change in teachers' beliefs was related to social integration, while obstacles appeared to outweigh their commitment to academic integration.

Keywords: Special educational needs, inclusive education, beliefs, professional development.

Introduction

Students with special education needs (e.g., learning disabilities) are prone to experience failure in mathematics, a field which requires generalization and abstract thinking, along with procedural competency (Geary, 2004). These students are characterized by having difficulties in cognitive skills such as working memory and automation of quick tasks (Willburger et al., 2008). Due to the increasing implementation of new laws that strive to integrate and include SEND students in mainstream classrooms (Blass, 2022), researchers have begun to study issues related integration and inclusion of Special Educational Needs or Disabilities (SEND) students in mathematics lessons (Lambert & Tan, 2019; Lindenskov & Lindhardt, 2020). The current study focuses on elementary school teachers' beliefs regarding the inclusion of SEND students in mainstream mathematics classes.

Background

Teachers' pedagogical knowledge and beliefs can impact the success of integration and inclusion (Brownell et al., 2010; Beswick, 2008; De Boer et al.,2011). Philipp (2007) defined beliefs as lenses that affect a person's views on some aspect of the world or as tendencies to act. Unlike knowledge, beliefs can be held at different levels. Beliefs are more cognitive than feelings and attitudes. Philipp (2007) emphasized that researchers, teacher educators, and professional developers are usually not only interested in measuring teachers' beliefs but also in changing them. Because teachers' beliefs influence their practice, having teachers reflect on their teaching can be a significant factor in supporting positive beliefs and practices. For example, Furinghetti & Morselli (2011) found that high school teachers' beliefs significantly influenced their approach to teaching mathematical proofs, affecting how they present and prioritize different aspects of proofs in the classroom. They emphasized the importance of raising teachers' awareness of their own beliefs and incorporating this understanding into professional development (PD) to enhance teaching practices.

Beswick (2008) determined that teachers develop professionally following professional learning experiences. Examining the beliefs of 22 mathematics teachers, she found that the teachers held

different beliefs regarding teaching mathematics to underachieving students compared to other students. The teachers believed that conceptual teaching was not suitable for underachieving students and that those students needed more basic mathematical skills to survive as well as some technical assistance in providing the correct answer. As a results, the curricula for underachieving students were narrower and less enriching and challenging compared to those for the mainstream students. However, after PD, there was encouraging evidence that teachers' beliefs regarding mathematics, mathematics teaching, and underachieving students could change. The teachers testified that they were motivated to improving their students' learning and were willing to change the teaching and learning processes in their classrooms.

Jordan and McGhie-Richmond (2010) found a connection between how teachers interact with their students and their beliefs regarding the abilities of integrated special education needs (SEND) students in their classes, as well as their role in fostering learning. About 25% of the teachers viewed disability as a fixed, internal condition that cannot be changed, blaming the student or their family for learning difficulties and spending less time with students with disabilities. In contrast, around 20% of the teachers saw disability as influenced by social and educational factors, taking greater responsibility for creating learning opportunities and investing more time in supporting students. This study incorporated PD through observations and interventions designed to enhance inclusive practices. It showed that teaching practices changed mostly among teachers who perceived disability as being shaped by social and educational influences.

In both studies presented, a PD program was conducted regarding teachers' beliefs about teaching students with difficulties. However, Jordan & McGhie-Richmond's (2010) research did not focus on mathematics, and Beswick's (2008) research focused on underachieving students, not those students characterized by special needs. Additionally, Beswick (2008) studied teachers with varying levels of seniority teaching mathematics in different settings, from kindergarten to high school. In a related article, Yada and colleagues (2022) noted that despite training and experience, changes in teachers' beliefs and attitudes towards inclusion, do not always occur.

The purpose of the current study is to examine the beliefs of elementary school teachers regarding the inclusion of SEND students in mathematics lessons before and after PD. The PD focused on the topic of multiplication and division in inclusive classes, operations relevant to students from second grade forward. Our research questions are: (1) What are the beliefs of mathematics teachers regarding the inclusion of SEND students in their classrooms, before and after PD? (2) What were the reasons that led some teachers to change their beliefs while others did not?

Methods

The research involved 34 elementary school mathematics teachers, with professional training in mathematics pedagogy and at least three years of experience teaching in inclusive classes. They were recruited through a city-wide registration system for teacher PD and had chosen to participate in this specific PD program entitled, "Inclusion and Integration of SEND Students in Multiplication and Division Lessons in Mainstream Classes."

The PD took place using the Zoom platform, and consisted of 10 sessions, each lasting three hours. The program content consisted of three parts: pedagogical content knowledge for teaching

multiplication and division, understanding the characteristics of SEND students, and implementing teaching practices suited for differentiated classrooms. During the PD, teachers worked in school teams to create teaching iterations for inclusion and integration in their mathematics classes. Additionally, the teachers experimented with various teaching practices and discussed their effectiveness. All sessions were videotaped and reviewed after each session to adjust the following sessions as various issues arose.

This research was conducted in accordance with the ethical guidelines as outlined by the Chief Scientist of the Ministry of Education and the Internal Review Board of the university. All participants signed an informed consent to participate in the study.

When researching beliefs to better understand beliefs, it is important to use different tools; quantitative tools provide a general picture, and qualitative tools provide depth about the beliefs. Thus, we used both quantitative questionnaires and observations as research tools. The beliefs questionnaire, given out during the first and last session of the PD, was based on Barnett's (2015) research. It included four statements (see Table 1) regarding teachers' beliefs about SEND students included in mathematics classes with a 1-9 Likert scale. Two mathematics researchers and two special education teachers validated the questionnaire.

All sessions of the PD program were videorecorded. During the second-to-last session, the teacher-educator asked participants the following two questions: “Do you feel you can successfully integrate SEND students in mathematics lessons? Who within your school community can facilitate the achievement of this objective?” These questions served as a catalyst for a vibrant discussion.

During the last session, participants reflected about teaching SEND students in mathematics lessons and were asked to comment in writing on the following two questions: (1) After the training, you were asked to try different assignments that integrate SEND students into mathematics classes. What insights have you gained about student characteristics from these experiences? Please provide details. (2) We spent five months together. During this period, have you noticed any changes in your teaching practices concerning the students in the integrated class or in general?

Qualitative analysis was carried out with the aim of understanding why some teachers changed their beliefs, while others did not. Towards this end, nine teachers were identified (see Table 2) for in-depth analysis.

Findings

Regarding the beliefs questionnaire, Cronbach's alphas showed high reliability for the four items, both before (0.824) and after (0.892) the PD program. Prior to the program, teachers were ambivalent regarding the inclusion of SEND students in mathematics classes (M=5.34, SD=1.71) and after the program there was a slight leaning towards being more positive (M=5.97, SD=1.75). The difference in their beliefs was nearly significant (t (33) =-1.960, p=0.058).

Taking a closer look, Table 1 shows results for individual items. The third statement (B3) showed the greatest increase and was the only item with a significant difference. In other words, after the program, teachers believed that SEND students integrated in mainstream classes would succeed better in society compared to SEND students studying in separate special education classes. However, when

it came to learning mathematics (items B1, B2, and B4), a change in beliefs was not found. We would like to note that teachers strongly believed in providing SEND students the opportunity to learn mathematics in mainstream classes.

Table 1: Changes in Individual Items from the Questionnaires Mean pre compared to Mean post

Statements	pre	post	t	df	p
B1. SEND students should be given the opportunity to study math with mainstream education students.	6.73	7.02	-0.635	33	0.530
B2. SEND students learn math best in mainstream classrooms that integrate them.	4.73	5.29	-1.569	33	0.126
B3. SEND students learning mathematics in mainstream classes have a greater chance of societal success than those learning in special education classes.	4.82	6.17	-3.206	33	0.003
B4. SEND students learning mathematics in mainstream classes have a better chance of success in mathematics than those learning in special education classes.	5.08	5.41	-0.787	33	0.437

Based on the questionnaires, we classified the teachers into nine categories according to their beliefs before and after the program (see Table 2). Teachers whose average response was less than 4.5 were classified as having a negative belief towards integration and inclusion. Those with an average response greater than 5.5 were classified as having a positive belief. Teachers with an average response between 4.5 and 5.5 (inclusive) were classified as neutral in their beliefs towards integration. The numbers in Table 2 indicate the number of participants classified in each category, and the letters represent specific teachers within those categories discussed further below.

Table 2: Frequencies of changes in teachers' beliefs

Post / Pre	Negative	Neutral	Positive
Negative	4 (RO)	2 (D)	4 (O)
Neutral	1 (M)	2 (L)	6 (RI)
Positive	- (A*)	2 (T)	13 (V)

According to the frequencies in Table 2, more than one-third of the participants (13) held positive beliefs about integration in the pre-program questionnaire and maintained those positive beliefs afterward. Furthermore, more than one-third of the participants (12) underwent a change in their beliefs about integration: 2 shifted from negative to neutral, 6 shifted from neutral to positive, and 4 moved from negative to positive beliefs. The specific teachers denoted by letters in Table 2 were

selected for further analysis based on their active participation and expression during the discussion in the second-to-last session and/or their reflective writing in the final session, expressing their reasons for being positive, neutral, or negative about integrating SEND students into mainstream classes. According to the results of the questionnaire, there were no teachers who were initially positive and then later became negative. Yet, we placed Participant A in Table 2 as going from positive to negative with an asterisk, because although her beliefs were positive in both the Pre and Post questionnaires, during the discussion (see below), she expressed opposition to academic inclusion, while supporting inclusion mainly from a social perspective.

To understand these results in more depth, and why little change seemed to occur, we analyzed the discussion which took place during the second-to-last session, and the teachers' reflections written during the last session.

From the questionnaire (item B3), we already noted that teachers believed inclusion could have social benefits for SEND students. This was expressed clearly during the discussion:

V: Our question as a society is not whether we are raising children who all have maximal proficiency in mathematics, but whether we ultimately want to accustom my children and yours that there are children with special needs in our society...

M: I think this conversation is sliding into two areas...there's a difference between seeing them as part of society, which is a very beautiful and correct thing to raise children and know to accept those who are different and know he's there, there is no debate among educators... But the second thing, the learning of mathematics and knowing from here how we deal with the situation? How can we advance them?...

RO: ... I understand that socially it's important, but if I want to advance them optimally, they need their small group.

During the meeting, challenges related to integration and inclusion were raised, along with discussions on how to address them. Below is an excerpt from that discussion:

T: In my class, it really depends on the child… The children I manage to advance are the ones where I can create cooperation with the parents. At school, it's mainly the principal who helps and supports when there are difficulties…

RO: I think there's no definitive answer; there are many factors... Everything we've learned and talked about requires resources from the teacher. If the teacher has other students she needs to help, it ultimately takes the time of the attention needed by the SEND students. In the end, there's one teacher who has to plan the 45 minutes optimally... We need to make a program that requires a budget and advances the children in a small group, and then integrate them into the class. This will advance them and create less frustration.

A*: I agree with RO. In my class, there are 12 integrated children... there's no way I can reach everyone, and there's no way I can advance with the material.

In the above exchange, we observe that the participants discussed the academic difficulties of integrating SEND students into mainstream classes. Some participants expressed frustration with these difficulties, and it was evident that these challenges hinder them from changing their beliefs about integration and inclusion. For example, T highlighted the academic challenges of integration and noted that a main factor is the cooperation of the students' parents. This participant showed a change from a positive to a neutral stance after the PD. Conversely, A* expressed great frustration and asserts later on that the education system failed by allowing parents the option to choose whether to integrate SEND students into mainstream classes. This is why we considered A* to be negative,

despite a positive trend shown in the pre and post-questionnaires. It may also be that A* is ambivalent. The conversation then turns to what can be done to cope with challenges.

RI: I don't quite agree... There are students whose difficulty is attention, and that's something we as teachers … can neutralize. And there are students whose difficulty is, for example, a girl in my class with dyscalculia, and it's true it's very difficult to integrate her into the mainstream class. However, I can integrate her into a group with children who will be good for her and help her...

A*: The children in my class are integrated into classwork and play, but I claim, on a general level, that the education system has failed in the last ten years when it gave parents the decision to integrate into a mainstream class...

RI: But that's the situation in the classes now; we can't change the education system. The question is what we can do within the existing framework.

V: It's really difficult and challenging, but it depends on the perspective we take. For a moment, if I put the teachers aside and look at the personal aspect, there's no doubt that integration is right for those children and for us as a society... I agree that it's difficult for teachers, and I also agree that the system doesn't give us enough tools; there isn't enough preparation, there isn't enough support... It's really necessary to train for it; it needs to be part of the training in colleges, and it's still not there.

RO: If my goal is for them to learn math and I want them to achieve in math, then I need to provide them with all the help they're supposed to get. Therefore, having them in my class means that they don't get all the help... because I don't have the ability.

Above, Participants suggest ways to address academic difficulties. For instance, participant RI, who shows a change from neutral to positive, mitigates challenges for students with attention disorders and dyscalculia through differentiated work groups tailored to each student. In contrast, RO, who remains negative, argues that the issue as systemic, he suggests advancing the students academically in a separate classroom and integrating them into the mainstream class during different lessons to promote social integration without hindering the teacher and the rest of the class.

Reflective writings from the final session provided additional insights and strategies for integrating and including SEND students. O, who shifted from a negative to a positive stance, wrote about the importance of individualized approaches to help each child succeed and especially stressed listening to the students:

> It is necessary to examine in each class for each child individually what is the optimal way to bring them to success... Following the PD, I learned to listen, examine processes, try to diversify, engage more, as well as deeply evaluate what can help and what does not.

M, who moved from neutral to negative, discussed the need to adjust the teaching pace and increase repetitive practice:

> I felt that I automatically had to lower my teaching pace, even my speaking pace, so as not to miss someone who can understand like everyone else, but at a slower pace... In addition, I felt there was a need for more practice exercises...

D, who transitioned from a negative to a neutral stance, emphasized the importance of paying more attention to students with special needs and finding appropriate learning methods for them:

> The training helped me to notice more and pay attention to the special needs students. Because I addressed them in various activities that were submission assignments, and I worked with them one on one... that there is a possibility to help them learn by seeking ways that suit them.

A recurring theme in the reflective writings was the acknowledgment of challenges alongside the variety of teaching methods introduced during the PD, enabling some teachers to overcome those challenges and move towards being more positive about inclusion.

Discussion and conclusions

Our first research question was: What are the beliefs of mathematics teachers regarding the inclusion of SEND students in their classrooms, before and after PD? The answer to this question is not clear cut and findings of this study highlight the complexities surrounding mathematics teachers' beliefs about the inclusion of SEND students in mainstream classrooms. Quantitative data revealed no statistically significant change in overall beliefs following the PD program, with teachers remaining ambivalent or only slightly more positive. The most substantial shift occurred regarding the societal benefits of inclusion, as reflected in a significant change in responses to Item B3. However, teachers' beliefs about the academic efficacy of inclusion remained unchanged, indicating persistent skepticism. These findings are consistent with Yada et al. (2022) and Bosse et al. (2016), who emphasize that teachers' beliefs about integration are relatively stable and resistant to short-term interventions. Qualitative analysis further underscored teachers' willingness to support social integration and equal opportunities for SEND students, even as they voiced concerns about the effectiveness of inclusion for academic progress.

In answer to the second research question, what were the reasons that led some teachers to change their beliefs while others did not, we first reflect on the PD program. A significant portion of time during the program was spent on enhancing teachers' knowledge for teaching multiplication and division, rather than expanding their understanding of what SEND students can achieve. This focus may have limited the program's overall impact on shifting beliefs. As Lambert and Tan (2019) suggest, emphasizing what SEND students can accomplish when provided the right opportunities, rather than focusing on their limitations, could have a more profound effect on teachers' attitudes. Teachers who reported positive shifts valued practical differentiation strategies introduced during the PD, but systemic obstacles like inadequate support and high academic standards continued to hinder change. Teachers who did not experience a belief shift often cited the challenge of meeting diverse student needs within a conventional classroom setting.

Future research could examine whether teachers' beliefs about the inclusion of SEND students differ across various mathematical topics, such as geometry, beyond the current focus on multiplication and division. It would also be valuable to explore whether the mode of professional development, online versus face-to-face, impacts program effectiveness and shapes teachers' beliefs about inclusive education. Although PD programs can lead to positive changes, fostering meaningful beliefs about academic inclusion may require more sustained interventions. Future initiatives could include initial teacher interviews to better tailor the program and emphasize the potential of SEND students. Additionally, ongoing qualitative research is essential to deepen the understanding of teachers' perspectives and develop PD programs that prepare teachers for diverse classrooms.

How teacher education program experiences affect pre-service mathematics teachers' designated teacher identities?

Okan Arslan

Burdur Mehmet Akif Ersoy University, Türkiye; oarslan@mehmetakif.edu.tr

This study aims to explore the impact of experiences in a teacher education program on the designated teacher identities of pre-service mathematics teachers upon the completion of their final year. Participants were asked to share the three most influential experiences during the program that shaped their understanding of the teacher identity they aimed to develop or avoid. Analysis of the narratives written by the pre-service teachers revealed that 40.4% of the narratives (69) were related to developing didactical expertise, 35.7% (61) to pedagogical expertise, 20.5% (35) to self-referential characteristics (attributes not directly related to mathematics teaching), and 3.5% (6) to subject matter expertise. The narratives indicated that pre-service teachers' designated identities were primarily influenced by the behaviours and teaching methods of their instructors or the teachers they observed during their practicum.

Keywords: Designated identity, pre-service teachers, narrative, teacher education program.

Introduction

The process of teacher identity development often begins with observing teachers during the pre-service teachers' own years as students (Flores & Day, 2006). This development continues within teacher education programs through both cognitive and affective growth related to mathematics teaching (Van Zoest & Bohl, 2005). Studies focusing on the identity development process in teacher education programs are crucial for determining the extent to which these programs support the development of teacher identities aligned with national educational policies (Beauchamp & Thomas, 2009). Such studies are particularly significant when there is a discrepancy between pre-service teachers' prior educational experiences and those encountered in teacher education programs. In the context of this study, pre-service teachers primarily come from teacher-centered educational backgrounds but are expected to experience mathematics education in a more learner-centered manner through their program experiences. Therefore, this study focuses on the mathematics teacher identities that pre-service teachers aim to develop upon completing their teacher education program.

Theoretical background and related literature

Sfard and Prusak (2005) theorized identity from a narrative perspective and defined it as "collections of stories about persons or, more specifically, as those narratives about individuals that are reifying, endorsable, and significant" (p. 16). They conceptualized identity as two-dimensional, comprising actual identity, which consists of "narratives about the actual state of affairs," and designated identity, which consists of "narratives presenting a state of affairs that is expected to be the case, if not now then in the future" (Sfard & Prusak, 2005, p. 18). They described learning as the process of closing the gap between these two types of identity. Designated identities are crucial in guiding individuals' behaviours and determining the direction of learning (Sfard & Prusak, 2005).

The role of individuals' experiences in their social communities is significant in developing this type of identity. Previous studies have shown that individuals' designated identities are shaped by the expectations of their society and families (e.g., Lutovac & Kaasila, 2014; Sfard & Prusak, 2005) or by the expectations of their working communities (e.g., Haggarty & Postlethwaite, 2012). Consequently, the effect of pre-service teachers' experiences in teacher education programs on the development of their designated teacher identities becomes crucial. However, few studies specifically focus on designated mathematics teacher identity (Arslan & Haser, 2024). Strong designated identities are difficult to change (Sfard & Prusak, 2005) and can be decisive in pre-service teachers' careers, especially when aligned with educational policies, as they shape the effort teachers invest in achieving their goals (e.g., Arslan et al., 2022).

Research purpose

The purpose of this study is to investigate how the designated identities of pre-service mathematics teachers are shaped by their experiences upon completing four years in their teacher education program. In line with this purpose, the following research question is addressed: How do teacher education program experiences affect pre-service mathematics teachers' designated teacher identities?

Methods

Participants and context

The participants of this study were fourth-year pre-service mathematics teachers enrolled at a public university in Türkiye. The teacher education program spans four years, aiming to qualify them to teach mathematics in middle schools (grades 5-8). In the first year of the program, the curriculum is primarily focused on educational sciences, general culture, and pure mathematics courses. From the second year through to the end of the fourth year, pre-service teachers take various courses on mathematics teaching methods. These courses primarily focus on learner-centered approaches and activity-based learning in alignment with the national mathematics education policy. Pre-service teachers have their only teaching practicum experience in the final year, spending one full day (six hours) per week in schools each semester. While most of their time is dedicated to observation, they are responsible for teaching at least two lessons per semester.

Data collection and analysis

The data for this study were collected during the final week of the fourth year in the teacher education program. All 57 pre-service teachers in the program voluntarily participated in the study. The pre-service teachers were asked a single open-ended question: "Considering all your experiences in the teacher education program, what are the three experiences that have most influenced your desire to become or avoid becoming a certain type of teacher?" The pre-service teachers did not provide their names or any identifying information in their responses to this question. Therefore, it is assumed that they shared their honest views in their narratives.

The analysis of the data was conducted in two stages. In the first stage, it was examined whether the pre-service teacher's statement could be considered as reflecting their designated identity. In this regard, it was checked whether the designated identity statements (such as can, cannot, want, should,

have to, and must) as defined by Sfard and Prusak (2005), were present in the narratives. It was determined that there was a total of 171 narratives satisfying Sfard and Prusak's (2005) criteria for designated identity statements. In the second stage, it was identified which domain of teacher identity was present in these designated identity narratives. An analytical framework developed by Beijaard et al. (2000) and refined by Löfström et al. (2011) was used for this stage (see Table 1). Each designated identity narrative was coded for the domain it pertained to and the reasons influencing this effect. While this analytical framework may appear familiar due to the researcher's prior studies (e.g., Arslan, 2023; Arslan & Haser, 2024), the methodological limitation of the analysis being conducted by a single researcher should be acknowledged.

Table 1: Teacher identity domains used in data analysis

Domain	Description (focusing on…)	Example of designated identity narrative
Subject Matter Expertise (SME)	Teacher's knowledge of content	A teacher cannot have a limited knowledge of the content that they teach.
Didactical Expertise (DE)	Teacher's teaching methods specifically to support students' learning	I want to support my students' meaningful learning in mathematics by using appropriate methods.
Pedagogical Expertise (PE)	Teacher's relationship with students and role in their development as human being	I want to be a role model for my students through my behaviour.
Self-Referential (SR)	Teacher's characteristics and features that are not directly related to teaching (such as being smart, patient, amusing)	A teacher should be funny so that students are not afraid of them.

Findings

The analysis revealed that pre-service teachers' designated identities were affected by their teacher education program experiences mostly in didactical and pedagogical expertise domains. Narratives in these two domains comprised 76 percent (130 narratives out of total 171) of all narratives (see Figure 1).

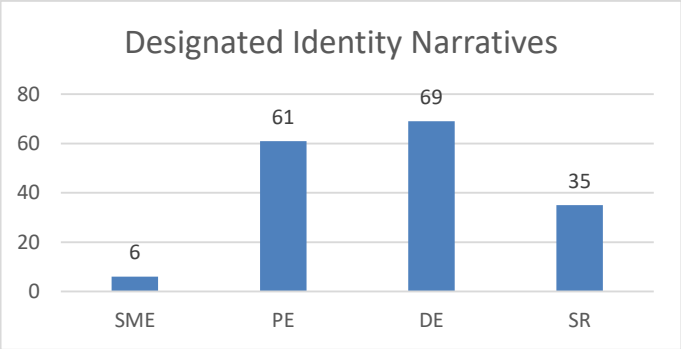

Figure 1: Analysis results of designated identity narratives

For the remaining narratives, self-referential characteristics were the most common category, while only a few narratives addressed the impact of the teacher education program on subject matter expertise. The details of the analysis for each category are provided below.

Didactical Expertise Narratives

Didactical expertise was the most frequently mentioned category, appearing in 69 of the pre-service teachers' designated identity narratives (40.4 percent). Pre-service teachers frequently referred to their experiences in the teacher education program that led them to adopt learner-centered mathematics teaching practices in their designated identities. These experiences were sometimes related to specific instances in which they participated in learner-centered activities and, at other times, to their general experiences throughout courses designed to introduce learner-centered methodologies to pre-service mathematics teachers.

> As a mathematics teacher, I want to teach in a way that allows students to learn by doing. In one of our courses, we went to a village school to do an activity with the students. I designed an educational game to teach the properties of geometrical shapes. Observing how much the students enjoyed and learned from the activity was amazing. It was the best day of my university life.

> I don't want to just lecture; I want to conduct activities that make the content meaningful for students. I had teachers, like [names], who showed me how a mathematical topic can be taught using different methods. They broadened my perspective on teaching with various activities and materials. They will always be my role models.

On the other hand, some pre-service teachers shared their negative experiences in courses where the instructor used teacher-centered methods, limiting active student participation. These pre-service teachers emphasized that they do not want to adopt this approach when they begin teaching.

> I don't want to teach by simply lecturing from the board. In one of our second-year courses, [course name], our teacher would just open the presentation on the board and read from it. This method did not help me learn anything. Without active participation, it is difficult to stay focused on the lesson. I never want to be that kind of teacher.

A significant portion of the experiences in this category pertained to the teaching practicum. Pre-service teachers highlighted positive outcomes from their observations and practical applications of learner-centered methods in mathematics. Conversely, they also described negative experiences associated with teacher-centered approaches.

> During my practicum, I observed two different teachers. The teacher I observed in the first semester constantly engaged students with activities and used various materials to make concepts concrete. However, the teacher in the second semester would just open the topic on the smart board and solve problems from there. The students in the first semester were much more engaged and learned better. That's the kind of teacher I want to be.

Pedagogical Expertise Narratives

In 61 narratives (35.7 percent), pre-service teachers discussed their experiences in the teacher education program that shaped their identities in terms of developing pedagogical expertise. They highlighted both positive and negative memories with their instructors and emphasized the importance of teachers developing close relationships with their students, which they aspire to achieve.

> As a mathematics teacher, I want to be someone whom my students feel comfortable with, can share their concerns with, and see as a friend. When I first came to university, I had a prejudice that instructors would be strict and that communication with them would be difficult. However, my own instructors were not like that; they treated me like a friend, which made me admire them. [...] During a period when my motivation was low, one of them called me to their office, discussed the reasons with me, and tried to help. The way my instructors, whom I nervously knocked on their doors, treated me like this was very valuable to me.

Similar to the narratives of didactical expertise, practicum experiences significantly influenced their designated identities in terms of their intentions regarding their relationships with future students. Based on their observations of student-teacher relationships during their practicum, they expressed their goal to develop close relationships with students throughout their teaching careers.

> I aspire to be a teacher who maintains strong, close relationships with students. This desire stems from my observations during practicum, where I had the opportunity to observe two different types of teachers. One teacher only communicated with students on an academic level. The other teacher, however, shared aspects of daily life, students' lives, and their own life outside of class. I never saw students eagerly anticipating the first teacher's classes, but they would be happy when the second teacher's class was about to start. I want my students to smile when coming to my class.

Self-Referential Narratives

Pre-service teachers focused on the self-referential characteristics that a teacher should have in 35 narratives (20.5 percent). These characteristics can be summarized as follows: being respectful towards the profession and students, having high motivation to teach, being fair, honest, energetic, clearly communicating expectations with students, and being open to professional development. Among these characteristics, the notion that a teacher should be fair emerged most prominently. This idea was influenced by various experiences within the teacher education program where teacher candidates perceived themselves as not being treated fairly. Based on these experiences, there was an emphasis on their desire not to become teachers who treat their students unfairly.

> I will be teaching at middle school level, and I believe fairness is crucial for this level. I want to treat my students fairly and equally. [...] One of my instructors at university [name], had favourite students. They received more attention and communication. It felt like the class was conducted primarily with those 3-5 students.

> I aspire to be a fair teacher who treats all my students equally. I have seen some instructors not act this way, which negatively affected me and decreased my interest in those classes. Therefore, I will never treat one student differently from others.

Another common self-referential characteristic was the aspiration to be a teacher eager for professional development to enhance student learning. This seemed to be influenced by their observations of some practicum teachers. Pre-service teachers positioned themselves differently from those teachers who did not demonstrate a commitment to ongoing professional development.

> I want to be a teacher who continually develops, especially in terms of educational technologies. My practicum teacher was not like this. When I used technology in my own lessons, it captured

the students' attention, and they were very engaged. Therefore, I believe a teacher should be open to self-development.

Subject Matter Expertise Narratives

Developing subject matter expertise was mentioned only six times (3.5 percent) in pre-service teachers' designated identity narratives. In these narratives, some pre-service teachers referred to the subject matter knowledge of their instructors from the teacher education program.

> I want to be very proficient in my content area. I can give two examples of such teachers at the university. When I was in their [names] classes, I could easily recognize that they truly knew what they were teaching. That made me admire them. A teacher should have a thorough understanding of the content they teach.

Some other pre-service teachers referred to their practicum teachers, both positively and negatively, regarding their subject matter expertise. Being able to answer all the questions from students was perceived as an indicator of subject matter expertise by these pre-service teachers. They believed that this capability influenced classroom management, based on their practicum observations.

> I want to be very knowledgeable in mathematics and be able to solve any kind of questions coming from students. [...] Our practicum teacher [name] was that kind of teacher. I observed that when you have such knowledge, students show respect to you and your lesson as well.

> I want to know every aspect of the mathematical content that I will teach and respond to any related questions that students ask. [...] S/he [Name] could not answer some questions coming from successful students. When you cannot answer the questions from students, they do not respect you. This negatively affected classroom management as well. Therefore, I want to be very proficient in mathematics.

Discussion

This study examined how pre-service mathematics teachers' designated teacher identities, the identities they aspire to develop or avoid, are influenced upon completing their teacher education programs. The findings of this study corroborate earlier research by demonstrating that developing didactical expertise is a primary component of pre-service mathematics teachers' designated identities (see Arslan & Haser, 2024). This result is anticipated, given that the teacher education program comprises numerous courses focused on learner-centered methods aimed at fostering students' meaningful learning in mathematics. Many pre-service teachers underscored their experiences within the program, expressing their aspiration to adopt these learner-centered approaches in their teaching. However, a notable number of narratives also highlighted the prevalence of traditional, teacher-centered methods observed among university instructors and practicum teachers. The pre-service teachers indicated their intention to avoid such approaches. Considering the objective of cultivating mathematics teacher identities aligned with learner-centered practices, the existence of conflicting teaching models within the program raises concerns about its structure and coherence.

It has been observed that the development of pedagogical expertise holds significant importance in the designated identity narratives of pre-service teachers. This focus may be influenced by their view that middle school years are crucial for students' behavioural development (Kasten et al., 2014). Additionally, the teacher employment policy suggests that their initial teaching assignments will probably be in schools with socio-economically disadvantaged student populations. This leads them to believe that these students will have a greater need for teachers who can build strong connections with them (Arslan & Haser, 2024). Some of the experiences that triggered this desire were related to their own positive or negative experiences with university instructors, where they positioned themselves as students, while others were based on their observations during their practicum in schools. Considering that establishing close relationships with students is an essential part of teacher identity development (Van Putten et al., 2014), these findings can be seen as desirable outcomes.

Emphasis on aspiring to be a fair teacher in narratives concerning self-referential characteristics has been notable. Particularly, these aspirations often stem from negative experiences in certain courses within the teacher education program, which may be viewed unfavourably. To prevent such situations in teacher education programs, pre-service teachers should be encouraged to freely express their experiences through anonymous narratives from the outset of their teacher education program, and necessary measures should be implemented. Otherwise, the feeling of being treated unfairly could potentially hinder their development of teacher identities throughout the program.

For effective mathematics teaching, it is evident that a deep understanding of mathematics is necessary. However, interestingly, only a few narratives were focused on developing subject matter expertise. This situation may stem from participants' perceptions that they already possess a profound knowledge of mathematics suitable for teaching at the middle school level. Nevertheless, some narratives indicated that pre-service teachers interpreted subject matter expertise not as understanding mathematics deeply and meaningfully, and establishing relationships between concepts, but rather as providing quick and accurate answers to students' questions. Therefore, future research could delve deeper into understanding what developing subject matter expertise means from the perspective of pre-service teachers.

Across all domains, narratives highlighted the significant impact of pre-service teachers' practicum experiences on their designated identities, reinforcing studies that emphasize the crucial role of practicum teachers in identity development (e.g., Arslan, 2023). Future research could further explore how both actual and designated identities evolve during the practicum, offering a broader perspective on teacher identity development. Furthermore, examining how actual and designated identities develop in practicum contexts where pre-service teachers have more opportunities for practice than those in this study could provide valuable insights into teacher identity development.

In summary, this study aimed to contribute to the literature by examining the impact of teacher education programs on the development of pre-service mathematics teachers' designated teacher identities. The analysis of pre-service teachers' retrospective experiences revealed that the dimensions of didactical and pedagogical expertise were most significantly influenced in their designated teacher identities. Future research could investigate the longitudinal development of pre-

service mathematics teachers' designated identities throughout their teacher education programs to gain deeper insights and inform necessary adjustments in these programs.

Teacher knowledge and the incorporation of inclusivity in a primary level generalisation problem

Ángeles Chico[1], Elisabetta Robotti[2], Nuria Climent[1], and Inmaculada Gómez-Hurtado[1]

[1]University of Huelva, Faculty of Education, Spain; angeles.chico@ddi.uhu.es,

[2]University of Genova, Dipartimento di Matematica, Genova, Italy

This case study analyses the carrying out of a primary level generalisation problem with a neurodiverse class of seven students (aged 9 to 12), one with Autism spectrum disorder, in a rural school. The lesson was videorecorded and subjected to a content analysis of the knowledge deployed. The results demonstrated that the teacher's specialised and pedagogical content knowledge were interconnected with the three inclusivity principles of the Universal Design for Learning framework. More specifically, we identified knowledge descriptors specifying teaching strategies for generalisation problems which were found to be closely related to inclusive practices for promoting comprehension, with one such connection especially strong.

Keywords: ASD, problem-solving, generalisation, inclusion, teachers' knowledge.

Introduction

This presentation draws on a doctoral thesis (Chico, 2024) which researches educational practices within the domain of problem-solving to support students with Autism spectrum disorder (ASD). In 2022, a problem-solving workshop for students with ASD was inaugurated, using teaching resources developed by TEACCH (Treatment and Education of Autistic and related Communication Handicapped Children). With the aim of translating the research results into classroom practice, we observed a series of problem-solving sessions in which primary teachers implemented problems from the workshop. This study focuses on one of these sessions, involving a generalisation problem. It analyses the specialised knowledge and principles of inclusivity demonstrated by the teacher, which we believe can contribute to an inclusive approach to mathematics teaching in teacher education.

Theoretical framework

We consider generalization as the process by which regularity is perceived over a series of instances, and hence involves establishing relationships between variables (Blanton, 2008). Primary school students use different registers to discover and express regularities (Blanton, 2008; Pinto & Cañadas, 2021), deploying different forms of thinking, from recursive to functional (Stephens et al., 2017). Students with ASD bring neurodiversity to the typical classroom, and their particular characteristics should be taken into account. Reviews of research into mathematics and ASD underline the important role of resources and structured teaching (Gevarter et al., 2016). Root et al. (2018) illustrate the benefits of concrete representations such as visual organizers in problem solving. Such proposals recognise the reliance on visual skills associated with ASD, as well as the difficulties related to executive functioning (organization, prediction and self-regulation), text comprehension and global processing (Root et al., 2018), which are key in problems involving generalisation.

Teacher education needs to equip prospective teachers with the tools to meet their responsibility to teach all their students across the spectrum of neurodiversity (Lambert, 2018), which means covering

not only knowledge of mathematical content and pedagogy, but also knowledge of inclusive practices and methodology. This study analyses the classroom practice of a teacher working with a neurodivergent pupil in order to identify his knowledge and the implications for inclusive teaching.

The Mathematics Teachers' Specialised Knowledge (MTSK) model (Carrillo et al., 2019) is used for analysing the teacher's knowledge. Problem solving, such as used in the lesson under analysis, mobilises mathematical knowledge (MK) of topics (KoT), connections between topics (KSM) and mathematical practices (KPM). At the same time, it involves the deployment of pedagogical content knowledge, which encompasses knowledge of teaching mathematics (KMT), the characteristics of learning (KFLM) and notions of learning standards (KMLS) (see Figure 1). For example, solving a problem involving generalisation might activate knowledge about different registers of representation (KoT), the sequencing of topics (KMLS), the value of examples in looking for regularities (KMT) and the use of heuristics as a tool for solving problems (KPM), among other aspects.

Domains	Subdomains	Categories	Subcategories
Mathematical knowledge	KoT	Phenomenology and applications

Figure 1: MTSK domains, subdomains and categories (Escudero-Ávila, 2023)

At the same time, we draw on the principles of Universal Design for Learning (UDL) (CAST, 2018) in order to capture inclusive teaching. UDL is a framework of teaching practices which aim to optimise teaching and learning for all people (Meyer et al., 2014). It offers a range of suggestions for presenting information, motivating learners, and helping them to process and express their learning (across the three core principles of engagement, representation, and action and expression, Figure 2). TEACCH methodology (Schopler et al., 2013) is fully consistent with these principles.

UDL has been linked to Mathematics education (Lambert, 2018; Root et al., 2020), whereas this study emphasises the specialised knowledge and inclusive actions teachers require to foster inclusive mathematics in the classroom. The aims of the study were to: 1) identify possible connections between elements of specialised knowledge and the principles of UDL in a teacher's management of a generalisation problem solving task; and 2) obtain descriptors of enacted knowledge underpinning an inclusive approach to a problem-solving task involving generalisation.

Figure 2: Graphic organizer summarising the UDL principles, guidelines and checklist (CAST, 2018)

Methodology

The study took an exploratory-descriptive design, in which a novice teacher in a rural school, Andrea (pseudonym), was observed giving a lesson based on a generalisation problem. The class consisted of seven primary students (aged 9-12), among whom was included a pupil with ASD.

The lesson was thriven on the 'Archaeologist problem' (Figure 3), which involved generalising from two variables, the height of the steps and the number of boxes required, which were related according to the function f(x)=(x(x+1))/2. Some TEACCH resources (Figure 4) were provided as structured and visual support, considering ASD features (Root et al., 2018). Both the problem and resources had been tested previously in a workshop with students with ASD (aged 11-12) (Chico et al., 2023).

An archaeologist wants to clean the museum's dinosaur models. She doesn't have a ladder, but she has found a pile of boxes, all the same size, which she can stack to reach the dinosaurs. Each box is 1 metre high, and she can stack them as in the picture. How many boxes does she need to reach the height of the Velociraptor (2m), the Stegosaurus(4m), the Gigantoraptor (8m), and the T-Rex (10m)?

Figure 3: The Archaeologist Problem

Figure 4: TEACCH material: Eva foam pieces, organiser and Velcro stair pictograms

In the week leading up to the lesson, the researchers gave Andrea a teaching guide which included: (a) a brief description of the key characteristics of ASD pupils; (b) a list of the advantages and limitations of the TEACCH material provided; (c) guidelines for managing the task, including organising the students, using the resources, and the overall aims of the problem; (d) examples of the strategies employed by the pupils with ASD to tackle the task during the previous workshop. The task, with a flexible, open format, allowed Andrea for decision making and reflection on the students' understanding and needs (Coles & Brown, 2013), so as to relate the content on generalisation with didactic strategies. Therefore, teacher's knowledge and skills might emerge.

The lesson was video recorded and transcribed. This was then subjected to a content analysis (Krippendorff, 2018), paying special attention to the specialised knowledge mobilised by the teacher (according to the categories of Figure 1), and evidence of inclusivity (following Figure 2). This process involved identifying units of information (strings of text sharing semantic content) which provided evidence of the two focal points. This analysis was carried out separately by the first two named authors, who then met to agree on a single version, which was then scrutinised by the third author – experienced in applying MTSK – and the fourth – a specialist in ASD – before a consensus

was reached on the definitive analysis. With respect to the use of the MTSK model, when an element of knowledge pertaining to a particular category was identified, the researchers generated an appropriate descriptor to capture it (examples of these descriptors can be found in the results section).

Once all the units of information had been analysed, we quantified the co-occurrence of instances of specialised knowledge and inclusive practice. This was done by quantifying all units tagged by both frameworks. Hence, by way of example, if a given unit of information was tagged by two descriptors (say knowledge on *Examples for conjecture* and *Counterexamples*) pertaining to a category within the MTSK framework (say, KPM *demonstration*), each occurrence of an item from the UDL guidelines linked to that unit was counted twice — once for each descriptor: two connections between the MTSK category and the UDL checklist would be counted. All such connections were registered in an Excel file and then fed into the open source Sankeymatic programme to produce a Sankey flowchart (Figure 5), representing the co-occurrence and emergent relationships of MTSK and UDL.

Results and discussion

In line with the aims of this study, we will first consider the connections between the teacher's specialised knowledge and instances of the principles of inclusivity (Figure 5).

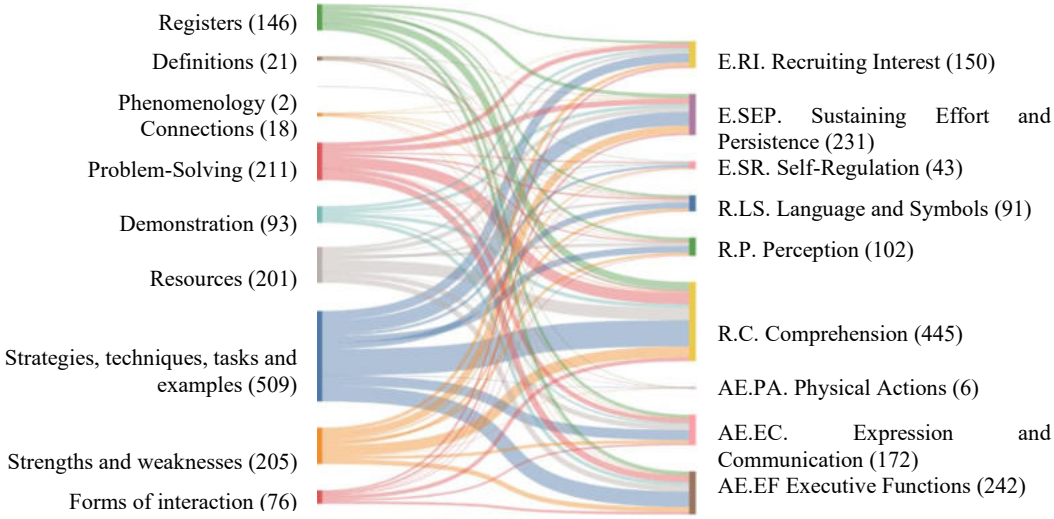

Figure 5: Flow diagram showing MTSK-UDL co-occurrence in Andrea's lesson

As shown in the flowchart, connections are established between categories within all the MTSK subdomains and the 9 UDL guidelines and checkpoints. In terms of the total number of connections in each case, the most frequently occurring categories in MTSK are *Strategies, techniques, tasks and examples*, followed by *Problem-solving strategies*, *Teaching resources*, and *Strengths and weaknesses in learning mathematics*. With respect to inclusive practice, the results indicate that C*omprehension* is the most frequent element within the UDL framework, followed by *Executive functions* and *Sustaining effort and persistence*. The strongest connection is that between Andrea's knowledge of *Strategies, techniques, tasks, and examples* (KMT) and the guideline *Comprehension* (UDL principle of *Representation*). The category *Strategies, techniques, tasks, and examples* also has strong connections with the guidelines concerned with *Executive functions* and *Expression and communication* (principle of *Action and Expression* within the UDL), and those concerning

Sustaining effort and persistence and *Recruiting interest* (within the UDL principle of *Engagement*). In like fashion, Andrea's knowledge of *Teaching resources* (again KMT) and the *Practice of problem solving* (KPM) show a significant connection with the UDL guidelines for *Comprehension*.

In order to consider the results regarding the second aim of this study, a more detailed analysis of the connections between the KMT categories and the UDL guidelines is offered below. The strongest interconnection between Andrea's specialised knowledge and his inclusive practices occurs between descriptors pertaining to *Strategies, techniques, tasks, and examples* (KMT) and the guideline *Comprehension* (UDL principle of *Representation*), the full range of which are shown in Table 1.

Hence, in the brief excerpt below (U170), for example, we can see Andrea's knowledge put into effect by suggesting that students work with smaller more manageable examples, a strategy aimed at encouraging them to formulate and/or check conjectures about the generalisation required for solving the problem. This strategy explores patterns, guides information processing and supports generalisation (R.C.2, R.C.3 and R.C.4, respectively) corresponding to *Comprehension* guidelines:

> Andrea: In the one with three, OK, the area of the square is three by three, only it's not a complete square. Three are missing. That actually matches the height you have searched for. So now I say: Let's see if there's a connection. (U170)

Immediately prior to this extract, Raúl had conjectured that the key to calculating the number of blocks required to reach four high was to consider the blocks as forming part of complete square. Andrea suggested that he consider a set of steps 3 blocks in height so as to put his conjecture to the test. In other words, Andrea suggested working with an example that was smaller but consecutive, enabling him to visualise a complementary set of steps. This strategy can be characterised by two other descriptors corresponding to the MTSK category *Strategies, techniques, tasks and examples*: first, focussing on contiguous terms to encourage the search for regularities; and second, using "complementary steps" to visualise the problem. These strategies support the pupil in his search for patterns and key aspects (R.C.2), help him to calibrate the mental model he needs to process the information (R.C.3) and so maximise generalisation from the results of the example (R.C.4).

A little later in the lesson, Andrea returns to Raúl's conjectures and paraphrases how he had realised that the pattern to calculate the total number of boxes required to construct the steps was not half the square of the corresponding height (U296):

> Andrea: [Indicating the drawing on the board] You realised that working out half of the area (8) doesn't give us the part that's not there. He said that the area of this square which is four by four, has an area of 16. 16! So he said that 16 into two, gives eight. Eight here and eight here [indicating the drawing on the board]. And then he said: No, there aren't eight here, because here there are 1, 2, 3, 4, 5 and 6. (U296)

This extract illustrates Andrea's knowledge of the strategy of paraphrasing in order to draw the class' attention to a pupil's solution and go over its details, and likewise his awareness of the capacity of visual representations to help pupils perceive the pattern when she returns to the complementary steps drawn on the board. In terms of the UDL guidelines, the strategies involve the guidelines *highlight critical features* (R.C.2) and *guide information processing and visualization* (R.C.3).

Andrea is aware that the pictorial register alone is unlikely to be enough for them to discover the pattern, and so recommends the students incorporate the numerical register after they have constructed their set of steps using EVA foam pieces. In this excerpt, Andrea aims to guide the pupils'

processing of the information, and to maximise their generalisations by measuring and annotating the figures they have put together:

> Andrea: OK, look, now I recommend that those who have made their figure, don't take the figure off your desk, and with a pencil, you can start writing here, on your desk, in pencil, either at the top or at the bottom, the number of metres it goes up to. (U100)

Finally, it is interesting to note that Andrea's understanding of the need to attempt non-contiguous terms in the sequence in order to encourage the students to go from recursive strategies to functional ones, is also interconnected with the final three checkpoints in the *Comprehension* guideline:

> Andrea: And if I put that here for you, OK? Alright, Antonio, are you seeing how it progresses? This one is two metres high and is made of three boxes. How many boxes do you need to make one 28 metres high? So, have a think about that. (U215)

Table 1: Descriptors of knowledge of Strategies, techniques, tasks, and examples (KMT) with connections to the UDL checklist of guidelines for Comprehension (principle of Representation)

Knowledge DESCRIPTOR	Checklist in the guidelines for Comprehension			
	RC.1: Activate or supply background knowledge	RC.2: Highlight patterns, critical features, big ideas, and relationships	RC.3: Guide information processing and visualization	RC.4: Maximize transfer and generalization
Importance of the understanding stage		x		
More manageable example to encourage establishing or checking of conjectures		x	x	x
Importance of the variable "complementary steps" to perceive regularity	x	x	x	x
Importance of the variable "boxes for adding" to perceive regularity		x	x	
Capacity of graphical representation to aid pattern perception	x	x	x	x
Need to incorporate numerical register to the pictorial so as to perceive pattern	x	x	x	x
Focus on contiguous terms to encourage search for regularity	x	x	x	x
Focus on contiguous terms to encourage recursive strategies to make generalisations		x	x	
Focus on non-contiguous terms to encourage functional strategies to make generalisations		x	x	x
Paraphrasing as a strategy for drawing group's attention to individual's solution	x	x	x	x
Paraphrasing as a strategy for reviewing a conjecture			x	x

Conclusion

This study of a teacher's lesson on a generalisation problem identified interconnections between their specialised knowledge and aspects of their inclusive approach. The first finding to underline is the large number of co-occurrences between instances of specialised knowledge and inclusion. The most frequently occurring strand of inclusive practices is that of *Representation*, and in particular the pertaining to the *Comprehension* guidelines, namely *Highlighting patterns, critical features, big ideas and relationships* (R.C.2), and *Guiding information processing and visualization* R.C.3).

Andrea's inclusive practices are particularly founded on Pedagogical content knowledge– something to be expected in a neurodiverse primary school lesson– through the categories *Teaching resources* and *Strategies, techniques, tasks and examples* (KMT), and *Strengths and weaknesses* (KFLM). Also, indications of knowledge about generalisation and patterns, mathematical demonstrations, and heuristics for problem solving are evidenced: *Registers of representation* and *Definitions* (KoT), *Problem solving* (KPM). Evidence of specialised knowledge on problem-solving, such as heuristic approaches and solving phases, align with expressions of pedagogical knowledge (Carrillo et al., 2019), concretely, through the numerous, diverse descriptors of *Strategies, techniques, tasks and example.* Previous research into pre-service teachers' specialised knowledge in a generalisation task (Pinto et al., 2023) and the archaeologist's problem (Chico et al., 2023), revealed higher levels of expected and mobilised knowledge in mathematics teaching (KMT) and learning features (KFLM).

This paper has specified how the connections were established by identifying descriptors within the category of *Strategies, techniques, tasks and examples* which corresponded to *Comprehension*, evidencing a link between specialized knowledge (MTSK) and inclusive actions (UDL). Indeed, the analysis has been developed regarding the whole Andrea's session, not only those interventions with the ASD student. Hence, inclusive mathematics teaching is naturally embedded within classroom practices, rather than supplementary measures for students with special needs. Considering the need for approaching inclusion in the ordinary classroom (Root et al., 2020), these findings might contribute to support the advancement of more inclusive teacher education in mathematics. Future research will explore concrete teacher actions permeated by MTSK and UDL perspectives.

Pre-service teachers' professional development and mathematics large-scale assessment

Maria Chiara Cibien

University of Ferrara; mariachiara.cibien@unife.it

This research aims at investigating the knowledge and beliefs of a sample of Italian secondary school mathematics pre-service teachers (PSTs) regarding the INVALSI national large-scale tests. The units of analysis are the PSTs' answers to an online questionnaire, in which some items taken from the past INVALSI national tests are proposed and discussed individually by the participants, and the collected data are framed with the Mathematics Teacher Specialised Knowledge (MTSK) model (Carrillo-Yañez et al., 2018). The main purpose of the research is to identify the educational needs of the study sample, to then use them as a starting point for the construction of a model for teachers' professional development based on an innovative bottom-up approach. Results show evidence of beliefs and many different aspects of PSTs' knowledge, categorised in the Pedagogical Content Knowledge (PCK) domain of the MTSK model.

Keywords: Pre-service teacher education, Large-Scale Assessment (LSA), MTSK model.

Rationale

A new field of research has been emerging in recent years, aimed at investigating how to integrate results, methods, theoretical frameworks and findings from Large-Scale Assessment (LSA) into the actions of teachers, teacher educators and researchers, both in the school and classroom context and in the broader one of educational institutions (De Lange, 2007; Meinck et al., 2017). My research belongs to this framework and fits within the strand of research linking LSA with teacher professional development (Campbell & Levin, 2009, Ferretti & Santi, 2023). Several studies in this area have been carried out from macro-phenomena that emerged at the Italian national level about INVALSI LSA (Ferretti et al., 2022); starting from what is already known, the focus of my research is to investigate Italian pre-service teachers' (PSTs) knowledge and beliefs regarding national LSA to identify their educational needs, inspired by studies already conducted in teacher education contexts (Montes et al., 2019), with a view to contributing to the development of a new model of teacher education. My study is, indeed, part of a larger project, the Italian National Research Project "*Mathematics standardized assessment as a tool for teachers' professional development*", which involves several researchers from different Italian Universities and whose aim is to create a model for teachers' professional development, consisting of theoretical and operational tools, starting from the results collected from the Italian national assessment tests INVALSI. The INVALSI tests are administered nationally by the National Institute for the Evaluation of the Education and Training System; the administration involves students at all school levels (primary school grades 2 and 5, low secondary school grade 8, and high secondary school grades 10 and 13). The framework within which they are developed is consistent with the Italian Ministerial Curricular Guidelines and with the main results of research in mathematics education. All the information and data collected from the INVALSI tests are disseminated and made public on a regular basis and each school receives its own data processed and compared with different benchmarks. Having such information available, it is possible to use the data

provided by INVALSI as interpretative tools for some aspects of the mathematics teaching-learning processes specific to the Italian context, also and above all with a view to teacher professional development. In contrast to the traditional (top-down) impact of LSA, the innovative idea of the project in which my research is framed is to provide these instruments for a bottom-up approach, in which the results are used directly by pre- and in-service teachers, also with a view to integrate data from LSA with a formative perspective.

Thus, the research question this study aims to address is: *What are the knowledge and beliefs of pre-service Italian mathematics teachers regarding the national INVALSI standardized assessment tests?*

Theoretical framework

The main purpose of the Italian National Research Project to which my study belongs is creating a model for the teachers' professional development, inspiring the one outlined in Ferretti et al. (2020). The model aims to enhance specialized knowledge for teaching mathematics. To ensure an informed and conscious construction of the model and to meet the real training needs, a questionnaire was created. The design of the questionnaire and the analysis of the data are framed within the Mathematics Teacher Specialized Knowledge (MTSK) model (Carrillo-Yañez et al., 2018). In the MTSK model, mathematics teacher's knowledge consists of the two domains of Mathematical Knowledge (MK) and Pedagogical Content Knowledge (PCK), and the two areas are interrelated by the teachers' beliefs, both about mathematics and its teaching-learning processes. The main aim of the research phase addressed in this paper is investigating the knowledge and beliefs of Italian teachers regarding the mathematics teaching and learning process, rather than focusing strictly on the mathematical knowledge, so the data analyzed in this study are mainly framed within the subdomains of PCK. They are: *Knowledge of Mathematics Teaching - KMT* (concerning theoretical knowledge of mathematics teaching, i.e. strategies, resources, teaching theories, etc.); *Knowledge of Features of Learning Mathematics - KFLM* (knowing, in general, how students interact with mathematics while also considering affective aspects); *Knowledge of Mathematics Learning Standards - KMLS* (knowledge of the national indications for curricula, for any school grade).

Methods

The research tool used in the first phase of the study is a pilot questionnaire, declined into different versions containing similar questions but formulated according to the group of participants involved (pre- and in-service teachers) and the school level in which they are teaching/will be teaching (focusing on grade 5, 8 and 10). It contains questions on several INVALSI mathematics items, taken from the GESTINV database (www.gestinv.it) and chosen because they are indicative of national educational macro-phenomena, namely items where the percentage of correct answers is very low and the distractor choices can be framed within well-known constructs in mathematics education. There are also questions that can be defined as "transversal", aimed specifically at investigating the participants' perceived purpose and usefulness with respect to INVALSI tests and the impact of these tests on their teaching practice (or future teaching practice). The questionnaire was administered online by using a Google Form: in this way, it was possible to reach a larger and more varied sample of pre- and in-service teachers; regarding the PSTs, this was also important because it allowed us to reach participants from different universities, that were not influenced by the same mathematics

didactics courses attended. Moreover, the choice of this tool was also useful in the data analysis phase; in fact, in addition to the open questions, participants were also asked several closed-ended questions on a Likert scale: using the form, it is possible to have an immediate analysis of the participants' response rates.

Table 1 is an example of a part of the questionnaire for secondary school PSTs, whose responses will be discussed in the following sections.

Table 1: Question posed to PSTs and related to the item 15 of the 2011 INVALSI test, grade 10, proposed in the questionnaire

Consider the following INVALSI item proposed to the secondary classes of the Secondary School. **D15. Dividere un numero per 0,2 è lo stesso che moltiplicarlo per** ☐ A. $\frac{1}{5}$ ☐ B. $\frac{1}{2}$ ☐ C. 2 ☐ D. 5 Translation (by the author): "*Dividing a number by 0.2 is the same as multiplying it by…*"
1. In your opinion, what does this item predominantly evaluate?
2. The correct option is option D. What do you think has been the most popular wrong option nationwide? Why?
3. On a scale of 1 to 4, how consistent do you think the item is with the National Curricular Guidelines for High Schools and the Guidelines for Technical and Professional Institutes? (1 = not at all, 4 = completely)
4. Imagine you are teaching in a grade 10 class. On a scale of 1 to 10, how difficult do you think this item is for students? (1 = very easy, 10 = very difficult)
5. Imagine you are teaching in a grade 10 class. On a scale of 1 to 4, how influential do you think the wording of this item is in determining the difficulty of the item for students? Motivate your answer. (1 = not at all, 4 = completely)
6. Imagine you are teaching in a grade 10 class. On a scale of 1 to 4, how appropriate do you think the item is for assessing student learning? (1 = not at all, 4 = completely)

7. Would you use this item in the classroom? If yes, why and how? If not, why?

INVALSI item 15 was chosen because close to the Italian school curriculum: as stated in the National Guidelines, among the specific learning objectives, it is mentioned that "The student will develop their skills in calculation [...] with rational numbers both in fraction form and in decimal representation" (MIUR, 2010). Hence, the theoretical knowledge required for the correct resolution of this item involves knowledge of the concept of rational numbers and the required competence is about grasping and managing the various semiotic representation of rational numbers (Duval, 2006). In addition, it is a closed-answer item and, thanks to the GESTINV database, national percentages are available and these show that the item represents a macro phenomenon at national level (as described in the previous paragraph). The percentage of correct answers is very low (only 24.4% of students choose the correct option D) and the most chosen distractor is option A, with 46.1%, followed by option B with 20.2%. It can be interpreted that the students who answered A only focused on the numerical part of the problem and thus thought they only had to carry a treatment (in the sense of Duval) between the decimal representation of the number and its representation as a fraction of integers, without considering the operation verbally requested in the assignment. Those who have chosen option B also acted in the same way, but they also made a mistake in treatment.

Questions asked to PSTs allow us to collect information about the PCK sub-domains of MTSK model. Question 1 is aimed at revealing PSTs' cognition about the mathematical knowledge and competence that a student must have acquired to answer the item correctly; thus, highlighting if and what aspects of the KMT emerge from the sample. The purpose of question 2, on the other hand, is to explore which, if any, didactic constructs are used to interpret possible mistakes made by students and, in this case, we are within the KMT subdomain. Question 3 investigates another subdomain of PCK, i.e. KMLS; PSTs are asked whether the item is consistent with the National Guidelines or not, so we want to find out if they are informed about the national curricula. Questions 4 and 5 are still intended to bring out different aspects of KFLM; in particular, by asking for reasons about the choice of the score given on the Likert scale in question 5, it is also highlighted any beliefs of the PSTs concerning the students' learning processes. The last two questions are aimed at investigating what other aspects of the KMLS arise and, at the same time, what are the PSTs' beliefs about assessment and about their possible future teaching practices.

The teachers' answers were analysed differently depending on the type of request. Regarding the data collected from the open-ended questions, such as question 1, the units of analysis were divided into categories, to distinguish the different argument given by the PSTs to justify their answers. This approach allowed for an investigation of the aspects that actually emerged in relation to the considered knowledge domain. On the other hand, in the case of closed-ended questions with a Likert scale, such as question 3, the percentages collected and processed directly from the Forms platform were examined to deduce information regarding the knowledge domain of reference.

A total of 20 PSTs (all students enrolled in the master's degree program in Mathematics) completed the questionnaire for high secondary school and their answers are analysed in the next section.

Data collection and analysis

The answers to question 1 can be grouped into different categories depending on students' mathematical competences and knowledge PSTs consider necessary to be able to solve the problem. Most of the participants state that several skills (e.g. being able to carry out the treatment between the decimal and fractional representation of the number) and several knowledge (e.g. being able to carry out operations with rational numbers, with particular reference to division) are required. A few claim that the question mainly assesses only the ability to perform operations with rational numbers, while others identify the criticality only in the management of representations. Responses of this type can reveal an awareness of the theory of semiotic representation registers (Duval, 2006), even though no participant explicitly mentions it in their answers. In addition, consciousness of the intuitive "partitive division" model, which leads students to think that the quotient must be smaller than the dividend (Fischbein et al., 1985), emerges in several answers. An example is the following extract from a PST: "This item aims to make the student realize that a quotient is not necessarily less than the dividend, as one is used to with, for example, divisions between natural numbers." Even in these cases, however, there is no explicit reference to the didactic construct. It can be therefore identified in this data, as assumed a priori, some elements that can be framed into the KMT sub-domain of PCK. It comprehends knowledge (both personal and institutional) specific to the process of teaching mathematics, which stems primarily from research in mathematics education; these include aforementioned constructs implicitly highlighted in the PSTs' answers.

Regarding question 2, it is immediately noticeable that the majority of respondents (70%) state that the most chosen wrong answer among students is exactly the one chosen by the national sample (option A, selected by 46.1% of the students). The reasons given are various, but the main ones can be categorized into (in brackets, the number of PSTs who gave that motivation):

- Inattentive reading/distraction mistakes (2)
- Problems with the wording of the text: the treatment takes place between the two representations, but the operation is not completed because the words related to the division and multiplication operations are written in letters, while the students "give priority" only to the part of request where the numerical data appears (3)
- Misconception linked to the multiplication that increases (2)
- Difficulties in performing the operation correctly (6)

It is observed that, although most of the answers refer to mistakes strictly related to the procedure, other factors are linked to students' erroneous conceptions and/or the wording of the text. In the first case, we can frame those responses as evidence of the KMT subdomain within the MTSK model, because (as in the case of the previous question) the PSTs do not explicitly mention the mathematics teaching theories they are referring to, but they still show that they are aware of criticalities expressed by them (for instance, when they talk about "misconceptions", in the sense of Fischbein). On the other hand, assertions regarding the "problematic" formulation of the text can be framed within the KFLM subdomain. This type of knowledge, indeed, includes the ability to recognize which features of a specific content may be advantageous or disadvantageous to learning. From the PSTs', it emerges that the item's formulation is perceived as unfavourable for students' understanding of the task. There

is also a small percentage of PSTs (15%) who claims that the most chosen distractor is B, since when computing between decimal and fraction there is confusion between the numerical parts of the two representations (2 is present in both "0.2" and "1/2"). These responses can also be classified as KFLM due to the fact that they also refer explicitly to where students have difficulties and how they might act to solve the item, considering the possible obstacles.

Almost all the PSTs (95%) consider the item consistent with the National Curricular Guidelines for High Schools and the Guidelines for Technical and Professional Institutes; 25% of these consider themselves "in agreement" and 70% "very in agreement". This is evidence of a highly developed knowledge within the KMLS domain, which includes knowledge of what students should be able to know and do upon reaching a specific grade level, in accordance with the curriculum established in the given context. In our case, the PSTs show to know what the learning goals of grade 10 are.

Furthermore, the item is generally perceived as difficult for students: that 70% of PSTs choose 6 or more on the Likert scale. Additionally, 65% of them answer question 5 saying that the item's wording may have had a significant effect on its difficulty. The main reason given is that the words "dividing" and "multiplying" express two opposite concepts but are present in the same prompt, thus confusing the students. Compared to what was previously analyzed in the responses to question 2, this finding seems inconsistent. In fact, initially, few PSTs considered the wording of the text as a possible cause of mistake (only 3 among those who identified the most chosen distractor at the national level, and none of the others). After reflecting on question 5, however, the percentage of participants who contemplate it as a factor of difficulty, and consequently the likelihood of making mistakes, rose significantly. These responses can also be framed within the KFLM subdomain, as the PSTs demonstrated an awareness of how students might approach an item based on its phrasing, and how this factor could influence their learning process.

In addition, 80% of PSTs consider the item suitable for evaluating students' learning; this is probably because, being considered very consistent with the indications given at national level for school curricula, it can be considered a useful tool for confirming or not the achievement of the learning purposes foreseen by them. There is hence a sort of belief in the PSTs, which can be expressed as: "if a mathematical question/problem is consistent with national curricula then it can be useful in terms of assessment, regardless of its intrinsic characteristics" (which, in this case, are considered problematic for students by PSTs themselves, as seen in the previous answers). In agreement with this last observation, almost the same 80% says that they would use that item in the classroom: of those who would not use it, 3 out of 4 are those who did not consider it suitable for assessment, and therefore remain consistent with their idea. The main reasons listed for using the item in class are (in brackets, the number of PSTs who gave that motivation):

- overcoming possible misconceptions (3)
- identifying and correcting any lack and/or consolidating previous knowledge (5)
- reflecting on the reasoning needed for the solution (4)
- mastering the management of a number's representations (2).

Most PSTs would let students work individually on the item and then engage them in a collective discussion; alternatively, it would be used to design laboratory activities and/or group work. Others

would also set up an individual class activity on it and/or with the use of technology. Those who claim that they would not use the item during their future teaching practices, on the other hand, express as their main motivation its formulation, which makes it confusing for the students, and unsuitable for evaluating their learning processes. For example, a PST stated: "*I don't like to formulate questions that have tricky discursive texts, like double negations or things like that. That is, if I want to test whether they can translate a fraction into decimal, I ask only that; if instead I want to test if they can invert a fraction, I give them a numerically formulated text*.". Since the respondents to our questionnaire are PSTs who have mostly never had any class experience, their answer to these last questions about classroom practices can be categorised as beliefs they have on them.

Discussion and conclusion

The INVALSI tests can be a key tool for investigating the knowledge and beliefs of mathematics teachers: having the data from the national sample available, it is possible to use them to induce pre- and in-service teachers to think about some crucial aspects related to LSA resources. This is what was done in this research, in which findings suggest that a large part of the knowledge that emerged can be framed in the three subdomains of the PCK described by Carillo-Yanez et al. (2018), as hypothesized during the design phase of the questionnaire. At the same time, several beliefs about students' behaviour during the performance of mathematical tasks (e.g. inattention) and good teaching practices that a teacher should adopt during assessment (e.g. being as explicit as possible about the proposed requests) also arise.

In these terms, it is possible to identify if and what strengths and weaknesses stand out from the PSTs' answers, which can then be used as a starting point for the implementation of the teacher training programme addressed by the Italian National Research Project. For example, from the analysis conducted, it can be observed how important the wording of a mathematical question is considered (implicitly or not) for its correct understanding and performance by the students. Initially, few PSTs identified this as the main cause of students' mistakes, but when their attention was directed to the explicit question 5, the percentage of them claiming that the wording is deliberately misleading and/or can create confusion increased significantly. This must be considered during the design of the training model, in the sense that it would be appropriate to carry out activities aimed at enhancing this awareness, so that it develops as an established future teaching practice of mathematics teachers.

In future studies the intention is also to make a comparison between the responses of PSTs and in-service teachers to the same questionnaire. The aim is to analyse any similarities and/or differences: firstly, to see if and how the classroom experience can influence the development of the different knowledge areas of the MTSK model and, secondly, to identify further educational needs to be met by the teacher professional development model.

Prospective mathematics teachers' specialised knowledge in response to a task on the density property of rational numbers

Rosa Delgado-Rebolledo[1] and Diana Zakaryan[2]

[1]Universidad de Valparaíso, Instituto de Matemáticas, Valparaíso, Chile; rosa.delgado@uv.cl

[2]Pontificia Universidad Católica de Valparaíso, Chile

This empirical study examines the knowledge demonstrated by two prospective mathematics teachers in their responses to a task focused on the density property of rational numbers within the real number system. The data are analysed using the Mathematics Teachers' Specialized Knowledge model. The findings reveal key aspects of the teachers' knowledge including their understanding of the density property, their teaching strategies for conveying this concept, and their insights into students' common understandings and misconceptions regarding this property. Furthermore, while not originally anticipated in the task design, the study identified other categories of knowledge. These include the expected level of conceptual development related to density, students' difficulties in grasping this property, and teaching theories. In conclusion, the potential of the task to enhance the knowledge of prospective mathematics teachers in relation to the property of density is highlighted.

Keywords: Specialised knowledge, Prospective mathematics teachers, Real numbers, Density property.

Introduction

Tasks for mathematics teacher training are currently of great interest to the research community due to the important role that they play in the development of knowledge and skills of prospective mathematics teachers. In this sense, according to Ribeiro et al. (2021), task for mathematics teacher training should address the development of specific knowledge required by prospective mathematics teachers. According to the author these tasks could be formulated based on dimensions or models of teacher knowledge. Among the different conceptualizations of teacher knowledge that are intrinsically connected to teaching and learning mathematics, in this work we used the Mathematics Teacher's Specialised Knowledge model (MTSK, Carrillo et al., 2018).

The design of tasks for teacher training based on the MTSK model represents a recently emerging area of research. Climent (2023) provides a comprehensive overview of studies in this field, outlining the characteristics of tasks specifically crafted to support mathematics teacher training. The tasks are organized into three primary groups. The first group encourages prospective teachers to engage in reflective practice by examining classroom scenarios, instructional interactions, or student responses to mathematical tasks. This reflective process is intended to foster prospective teachers deeper understanding of student thinking. The second group of tasks focuses on analysing various facets of teaching practice, including teacher-student interactions, classroom management, and the role of educational resources in teaching. These tasks aim to help prospective teachers to identify essential elements of practice, with an emphasis on offering alternative approaches to teaching. The final group utilizes video excerpts from mathematics classes to facilitate reflection among prospective mathematics teachers. By observing real-life teaching situations, prospective teachers are encouraged

to understand the complexity of classroom situations. In all cases, the MTSK framework provides the basis for both the design and implementation of these tasks.

Additionally, tasks for teacher training based on the MTSK model have primarily been developed within the context of primary education. Thus, further research is needed to investigate the application of MTSK-based tasks in the training of secondary mathematics teachers (Climent, 2023). In response to this gap, the present work proposes a teacher training task designed specifically for secondary education, focusing on the density property of rational numbers.

The density property of rational numbers in the real numbers (henceforth, density property) asserts that given two real numbers, a and b, with $a < b$, there exists a rational number q such that $a < q < b$. The density property implies that the successor of a rational number cannot be determined, distinguishing rational numbers from natural and integers numbers. Vamvakoussi et al. (2011) present several studies in which students of various ages mistakenly assert that there is a finite number of numbers between two rational numbers or incorrectly identify the successor of a specific rational number. Consequently, students' difficulties with the density property stem from their tendency to over-apply the discreteness of natural numbers to rational numbers (McMullen & Van Hoof, 2020). Similar difficulties are reported in the study by Merenluoto and Lehtinen (2004) regarding the understanding of the density property among mathematics teachers. Furthermore, the concept of infinity associated with the density property is introduced (albeit informally) in secondary school teaching: rational numbers are infinite because it is always possible to find another rational number between any two rational numbers (Montoro et al., 2016). However, the idea of an infinity of numbers between two values is counterintuitive and poses difficulties for students and mathematics teachers, as it requires an understanding of actual infinity, a notion that is cognitively and epistemologically complex.

In view of the difficulties that students and mathematics teachers face in grasping the density property, the present study aims to answer the following question: What specialised knowledge do prospective mathematics teachers demonstrate when engaging with a task focused on the density property of rational numbers?

The Mathematics Teachers' Specialised Knowledge

The MTSK model is proposed as a useful tool for understanding the knowledge that mathematics teachers possess or mobilize in their professional activity (Climent & Montes, 2022). The model is structured into two domains of knowledge, each one with its respective subdomains and categories. Additionally, the model describes a domain of teacher beliefs about mathematics, its teaching, and learning. In this work, we will focus on the domains of knowledge according to the descriptions provided by Carrillo et al. (2018) and Climent and Montes (2022).

Mathematical Knowledge (MK) characterizes teachers' knowledge of mathematical content, the structural nature of mathematics based on the idea of connections and the syntactic nature of mathematics. Knowledge of procedures, definitions, properties and their foundations, registers of representation, and phenomenology and applications of mathematical content, are grouped under Knowledge of Topics (KoT). Knowledge about connections between a topic and other mathematical

contents that could be based on increased complexity, based on simplification and transversal or auxiliary connections is included in the Knowledge of the Structure of Mathematics (KSM). The knowledge related to the construction, validation, and communication of mathematical knowledge is named Knowledge of the Practice of Mathematics (KPM) which includes knowledge of practices such as proving, defining, problem-solving, and understanding the role of mathematical language. Teachers' knowledge of the density property, which belongs to the KoT subdomain, is an example of MK.

Pedagogical Content Knowledge (PCK) is described by three sub-domains that characterise what the teacher knows about teaching and learning directly related to mathematics. Knowledge of mathematics teaching (KMT) encompasses three categories of knowledge: Theories of mathematics teaching includes both formal theories established in the research literature and personal theories derived from teaching experience; teaching resources includes both physical and digital resources used in the teaching process; strategies, techniques, tasks and examples includes a range of approaches to delivering mathematical content. The sub-domain Knowledge of Features of Learning Mathematics (KFLM) includes teachers' knowledge of formal and personal theories of mathematical learning; strengths and weaknesses that students exhibit in learning mathematics; understanding of the emotional aspects involved in learning mathematics; and knowledge of the ways in which students interact with mathematical content, recognising the typical and unconventional strategies that students develop in response to specific mathematical concepts, and the language that students use to articulate these concepts. The subdomain Knowledge of Mathematics Learning Standards (KMLS) includes knowledge of how to arrange topics within a course in relation to preceding or subsequent courses (sequencing of topics), knowledge of the mathematical content expected to be acquired within a course or educational level (expected learning outcomes), and knowledge of the depth at which mathematical content should be covered in a particular course or educational level (expected levels of conceptual or procedural development). Teachers' knowledge of students' difficulties in transforming finite decimals into fractions, which belongs to the KFLM subdomain, is an example of PCK.

Method

The data for this study were gathered from a written task proposed in a third-year course within a secondary mathematics teachers' training program at a university in Chile. During the first two years of the program, prospective teachers undergo mathematical coursework covering topics such as Calculus, Real Analysis, Algebra, and Geometry. Subsequently, in the third year, the curriculum focuses on teaching practices and didactics of mathematics encompassing the teaching and learning of numerical systems, functions, and geometry. The task was implemented at the end of one of the didactic courses with a total of 36 prospective teachers (henceforth PTs) as participants.

In this task, which is to be completed individually in written form, a real classroom situation taken from Zakaryan and Ribeiro (2016) is considered. The scenario presented in the written task depicts a mathematics teacher engaging with their eighth-grade students (aged 13-14). Upon posing the question, "Why is the set of rational numbers said to be dense?" most students responded that it is so

because it contains infinite numbers. Given the above situation, the PTs were asked: (1) interpreting the students' response and (2) providing an explanation they would give to correct this response.

In the context of the classroom, the teacher is referring to the density property in terms of the possibility of finding a rational number between any two of them and the impossibility of finding the successor of a rational number. Also, considering the analysis of teacher knowledge in this classroom situation developed by Zakaryan and Ribeiro (2016; 2019), it is expected that PTs provide answers to interpret students' response by referring to misconceptions that students might have about the density property (KFLM, *strengths' and weaknesses in learning mathematics*), students' understanding of density and infinity and the words that students use to talk about infinity (KFLM, *ways in which pupils interact with mathematical content*). For the explanation to correct students' response, it is expected that PTs refer to definitions and properties of the different numerical sets (N, Z and Q) (KoT, *definitions, properties and foundations*), expose counterexamples of infinite sets that are not dense in the real numbers (KPM, *proving practice*) and to propose examples or strategies for teaching the density property (KMT, *strategies and examples*). Additionally, other knowledge in both MK and PCK that could emerge in PTs' responses.

This work forms part of a broader research project that conducts an in-depth examination of the MTSK and the practices demonstrated by a group of PTs. These teachers were selected based on two criteria: the comprehensiveness of their responses and the explanatory power they displayed. Given the limited space and the objective of this work, we will focus on analyzing the responses provided by two of these participants, hereafter referred to as PT1 and PT4.

Results

When addressing to interpret the students' response, PT1 points out the following:

> PT1: The teacher indicates that the rational numbers are said to be "dense" this last word can be interpreted by the students as something quite large, therefore, they assure that this is because the rational numbers are infinite. Additionally, in eighth grade, students can recognize that the natural numbers are found, followed by the integers (composed of the natural numbers and negative numbers), later the rational numbers are found, where the natural numbers, integers, and fractions and decimals are located. Given the above, the students can affirm that the rational numbers correspond to a set that includes the largest number of numbers.

In this intervention, PT1 elucidates that the term "dense" is often interpreted by students as "quite large", yet it is also frequently associated with the concept of infinity. This results in students developing a relationship between density and infinity. This understanding of how students perceive the concept of density illustrates PT1's knowledge of *ways in which students interact with mathematical content* (KFLM). Additionally, PT1 refers to possible students' ideas of that rational numbers as "the largest number of numbers" reflects their tendency to focus on a limited range of numbers based on their existing knowledge. This expected understanding of numerical sets from eighth-grade students is based on PT1 awareness of the way in that rational numbers are introduce in secondary instruction. In other words, knowledge of what students should have learned in previous courses about numerical systems and to what extent, according to the national curriculum. PT1's knowledge of the *expected level of conceptual development* (KMLS) is identified.

Subsequently, to provide an explanation to correct the students' response, PT1 mentions the following:

> PT1: It is important to clarify to the students that the numbers that they know are infinite regardless of the numerical set in which they work. So, I would give the following devolution: Can you tell me about the last number in the set of natural numbers? Then, I would work with the students to build a scheme about the contention of numerical sets. Subsequently, I would ask the following question: Is there another number other than the rational ones? The idea is to find numbers like π or Euler's number, later I would highlight that there are also real numbers which contains the other numerical sets already mentioned.

In the above excerpt, we observe that PT1 presents a question that she identifies as a "devolution", a notion that is part of the Theory of Didactical Situations. PT1 mentions having studied this theory and the notion of devolution in one of their didactic training courses. In this sense, PT1 demonstrates her knowledge of this *formal teaching theory* (KMT). Additionally, PT1 mentions using a scheme to illustrate the concept of the density to students. In this sense, she demonstrates her knowledge of a *teaching strategy* (KMT) of density property.

In the case of PT4, when addressing to interpret the students' response, he states the following:

> PT4: Students should have related the word dense to quantities or cardinals. Then, when they hear that rational numbers are a dense set, they understand it to mean that rational numbers have many numbers or that it is a "large set" because it is infinite.

In the above intervention, PT4 suggests that students understand the word infinite as a quantity, synonymous with many and large. This insight into how students interpret the concept of density demonstrates PT4's knowledge of the *ways in which students interact with mathematical content* (KFLM). Continuing with his response to the task, PT4 refers to the explanations he would give to the students as follows:

> PT4: First, I would make them note that the set of rational numbers is not the only infinite set. The natural numbers, the integers, the irrational numbers are also infinite, and that is not why they are said to be dense in the reals. Then I would talk to them from a more historical-epistemological point of view about the fact that there are infinities that are greater than others and that, although it is difficult to understand, there was a mathematician named Cantor who proved this and that this is the reason why rational numbers are called dense in the reals.

According to the above, PT4 presents the naturals, integers and irrationals as infinite sets. He points out that being infinite does not imply being dense in the real numbers (KPM, *counterexamples*). However, he includes the irrational numbers in his statement without considering that these numbers do in fact fulfil the property. PT4 also recognizes the existence of distinct types of infinity and references proofs associated with the infinities of specific sets (KoT, *properties*). Following this idea, the PT4 refers to the process in which the infinity was constructed as mathematical object referring to the historical-epistemological point of view. The above, is a way to comprehend *students' difficulties* (KFLM) to understanding infinity based on the inherent complexity of the concept.

Discussion

When the two PTs interpret the response given by eighth-grade students to their teacher, knowledge of how students understand the property of density (KFLM) is demonstrated, as was expected in the

designing task. In this response, they coincide in mention students' interpretation of infinity as a quantity or very large number, which is acknowledged as one of the misconceptions students often have about infinity (Medina-Ibarra et al., 2019). In relation to the explanation provided by PTs to address the students' answers, the categories of knowledge about definitions (KoT), counterexamples (KPM) and teaching strategies (KMT) that were anticipated in the context of the designed task were identified.

PT1 demonstrates categories of knowledge was not part of the expectation of knowledge in the development of the task. For instance, the presence of KMLS underscores that learning standards, particularly the national curriculum, is considered as an organizing element of the teaching-learning process. In this context, it is important to note that while density may not be explicitly outlined in the Chilean curriculum as a property to be taught in eighth grade, it is implicitly present in the textbook tasks related to the representation of rational numbers on the number line. It is also noteworthy that PT1 refers to Theory of Didactical Situations (Brousseau, 2002) to address a classroom situation. This exposes a transition from theoretical comprehension to potential practical application. In this vein, PT1 serves as an example of the usefulness of didactic theories in teacher training, facilitating both reflective analysis and action within classroom contexts.

Additionally, PT1 elucidates a potential interpretation of students' comprehension of the infinite cardinality of rational numbers in relation to quantity and the inclusion of other numbers, which is consistent with the teaching strategy of employing a number-contention scheme to illustrate density. The ideas put forth by PT1 align with the usual conceptualisation of real numbers that is typically encountered in secondary education. This conceptualisation introduces the notion of real numbers as a means of encompassing numbers that extend beyond the set of rational numbers (Bergé, 2008). Nevertheless, we question whether this approach is appropriate for illustrating the density property and whether it is sufficient for students to recognise that density is not solely dependent on the infinity of sets.

On the other hand, PT4 demonstrated knowledge of students' difficulties despite this aspect of knowledge not being among the anticipated responses for the second question of the task. In this sense, he offers a potential explanation for the students' difficulties (KFLM) considering their understanding of infinity and associated theorems (KoT). The above relationship may be identified as an inter-domain relationship, as described by Delgado-Rebolledo and Zakaryan (2022). This type of relationship provides an illustration of the integrated character of MTSK (Carrillo et al., 2018) whereby teachers' knowledge is not comprised of isolated items.

Conclusions

The task presented in this work addresses teachers' knowledge of the density property, a property that poses difficulties in both teacher training and mathematics instruction. Crafted from a real-life classroom scenario, the task allows PTs to reflect on a context that closely resembles the challenges and experiences that they are likely to face in their professional teaching careers. This helps them to develop knowledge and teaching strategies that are directly applicable to real-world classroom settings. In this sense, we consider the importance of the design and implementation of training tasks aimed at helping PTs develop their knowledge and skills.

Developed with reference to the research of Zakaryan and Ribeiro (2016; 2019), this task serves as an example of how research findings can be effectively incorporated into teacher training. However, we consider that in future implementations of the task, it could be expanded to address other important aspects of density, such as the idea of infinity within the density property and the utilization of the number line and schemes to represent rational numbers. Also, additional questions could be added to the task to explore the knowledge of connections between the density property and the infinity with other mathematical concepts. This would provide a more comprehensive understanding of how prospective teachers approach these concepts.

On the other hand, the task served a dual purpose: it allowed PT to mobilize their MTSK from a teacher training perspective, while also provide an opportunity for inquiry on it from a research perspective. This aligns with the aim of other studies, as the work of Ribeiro et al. (2021). By combining both perspectives, we emphasize that when PTs respond to the task, they not only demonstrating the expected knowledge outlined in the task design but also demonstrate knowledge from other subdomains of their MTSK. The emergence of these different categories of knowledge in PTs responses highlights potential of the task in fostering the development of the MTSK of PTs.

Following the above, MTSK-based tasks would facilitate learning, promote critical thinking, and enhance PTs' ability to apply their specialized knowledge in real-world classroom scenarios. Other research has shown as through the performance of tasks, in-service mathematics teachers improve the use of their MTSK, particularly in terms of their KoT and KMT (Montes et al., 2021). However, more research is necessary to deepen our understanding of how PTs could develop their MTSK through the performance of training tasks. We intend explore this issue as a topic for further research.

Pre-service teachers' knowledge of students' misconceptions and difficulties related to functional thinking: a German and Slovak comparison

Kerstin Frey[1], Ute Sproesser[1], Matej Slabý[2] and Ingrid Semanišinová[2]

[1]Ludwigsburg University of Education, Germany; ute.sproesser@ph-ludwigsburg.de;

[2]Pavol Jozef Šafárik University, Faculty of Science, Institute of Mathematics, Košice, Slovakia

Functional thinking, as the ability to relate two or more quantities, is relevant throughout schooling and in everyday life. Regardless of its importance, student misconceptions and difficulties are empirically well documented. As part of their professional knowledge for teaching, pre-service teachers need to be aware of these misconceptions and difficulties in order to teach accordingly. The presented paper reports an intervention study investigating German and Slovak pre-service teachers' knowledge of what misconceptions and difficulties their future students might have. The intervention involved a university course for pre-service teachers designed in the context of the Erasmus+ project FunThink to support their future students' functional thinking. The results indicate a positive development in pre-service teachers' knowledge of students' misconceptions and difficulties in both countries but also indicate system-related differences between the two countries.

Keywords: Functional thinking, functions, misconceptions and difficulties, pre-service teachers, teacher knowledge.

Introduction

Functional thinking, known as a way of thinking that is typical for functions, describes a way of thinking in relationships, interdependencies and changes (Vollrath, 1989). In this manner, it plays a crucial role in everyday life and mathematics education. Despite its relevance, studies have empirically shown that students have many misconceptions and difficulties[1] (M&Ds) with this topic (e.g., Leinhardt et al., 1990; Sproesser et al., 2022). For mathematics teachers, it is important to be aware of these possible M&Ds students face as part of their mathematical knowledge that is required for effective teaching. With this knowledge in mind, teachers can plan their lessons accordingly, dealing adequately with such M&Ds and, hence, impacting their students' learning. In this context, one of the outputs of the Erasmus+ Project FunThink was, inter alia, designing a university course for pre-service teachers (PSTs) to develop their professional knowledge for teaching functional thinking.

The study presented in this article is embedded in a more extensive study investigating the PSTs' professional knowledge for teaching functional thinking and how it develops throughout this university course. This article focuses on one item of the used test instrument that addresses students' M&Ds from the German and Slovak PSTs' perspective. The research focuses on what M&Ds the PSTs know related to functional thinking before and after participating in the described course.

[1] Misconceptions and difficulties are used in line with Leinhardt et al.'s work (1990) which serves as a base for this study.

Theoretical Background

Functional thinking

Functional thinking can be described as thinking in relationships, interdependencies and changes (Vollrath, 1989). As the name and this description state, functional thinking is closely related to the topic of functions. To deal with functions in a meaningful way, students should acquire four aspects of functional thinking throughout schooling, namely the input-output aspect, the covariation aspect, the correspondence aspect, and the object aspect (Pittalis et al., 2020). In addition to these aspects, students need to be able to master algebraic prerequisites, to use and change between different representations, as well as to relate functions with real-world situations in the sense of modelling (Vollrath, 1989). In the following, we will describe how functional thinking is implemented in the German and Slovak curricula in order to equip students with the mentioned competencies.

In Germany, the concept of function is formally introduced in grade 7 or 8, depending on the type of school. Prior to this, different representations such as tables and graphs and informal tasks such as describing and continuing patterns are thematised in primary and lower secondary education. After the formal introduction of functions, different function classes are taught, starting with proportional and linear functions. Higher-order processes such as concatenating and differentiating functions are introduced in upper secondary education (Kultusministerkonferenz [KMK], 2022). In mathematics classrooms, the correspondence aspect is often emphasised, and the covariation aspect is somewhat neglected in teaching in Germany (Malle, 2000).

In Slovakia, the concept of function appears implicitly in grade 7 in the context of direct proportionality. In grade 9, the concept of linear function is continued with an emphasis on the input-output and correspondence aspects. The covariation aspect is not sufficiently covered or is missing in textbooks for lower secondary school (Krišáková & Slabý, 2022). Later, in upper secondary school, students learn the function definition and different classes of elementary functions, including their properties. Most Slovak teachers use older textbooks to teach functions because the new textbooks are methodologically different from the way teachers are used to teaching. This is one of the possible reasons why the correspondence and object-oriented aspects predominate in teaching.

The above descriptions indicate that teaching and learning functional thinking are complex and that, apparently, not all four aspects are evenly supported in (German and Slovak) mathematics classrooms. Besides other factors, such an unbalanced implementation of functional thinking aspects in the classroom can be a reason for students' M&Ds. In the next paragraphs, we will describe typical student M&Ds related to functional thinking.

Misconceptions and difficulties related to functional thinking

M&Ds among students are empirically well documented (e.g., Leinhardt et al., 1990; Sproesser et al., 2022). Some reasons for these M&Ds might be the abstract character of functions, the necessity to acquire the four aspects, multiple formal prerequisites such as understanding the variable concept, or the need to use and to change between different representations (inter alia but not restricted to the change between mathematical and situational representations when modelling real-world situations by mathematical functions). For the presented research, we use the work by Leinhardt and colleagues

(1990) as a base. Leinhardt et al. (1990) describe the following eight categories of M&Ds: What is and is not a function, linearity, continuous versus discrete graphs, representations of functions, concept of variable, notation, correspondence, relative reading and interpretation. Examples and brief descriptions for each category will be provided in the methods section of this paper.

Being aware of these possible M&Ds among their students is required for teachers to plan their lessons accordingly and to support student learning. Therefore, in the next section we will describe the connection of M&Ds and teachers' professional knowledge.

Professional knowledge for teaching functional thinking

It is well known that teachers have a decisive influence on their students' learning (e.g., Yoon et al., 2007). In this manner, PSTs need to develop comprehensive knowledge to teach their future students appropriately. As the present research relates to teacher knowledge on typical student M&Ds, we will demonstrate in the following exemplarily, how this knowledge is reflected in two models of teachers' professional knowledge that are well-recognized in mathematics education: For example, within the framework *Mathematical Knowledge for Teaching* (MKT), knowledge about typical M&Ds is described as a core element of the PCK subcategory *knowledge of content and students* (KCS) (Ball et al., 2008). Similarly, within the model *Mathematics Teachers' Specialised Knowledge* (MTSK), knowledge of students' M&Ds is part of the PCK subcategory *knowledge of features of learning mathematics* (KFLM) (Carrilo-Yañez et al., 2018).

Both models of teacher knowledge reflect the relevance for (future) teachers to know about typical M&Ds. However, research shows that teachers' knowledge of M&Ds is heterogeneous and often not sufficiently pronounced, what makes it difficult to prevent or adequately react to such M&Ds (Sproesser et al., 2020). Moreover, the study of Hubenakova et al. (2021) indicates that system-related particularities such as curricular requirements and typical culture-related teaching traditions can cause differences in teacher knowledge related to M&Ds. The project underlying this study aims at fostering German and Slovak PSTs' professional knowledge for teaching functional thinking by a university course. In this paper, we report and compare PSTs' corresponding knowledge and describe how it developed through participation in this course. The research question is: What M&Ds in the field of functions do German and Slovak PSTs know before and after participating in a course to support students' functional thinking? The corresponding research will be described in the following.

Method

Participants and context

The PSTs participating in this research chose the university course on supporting students' functional thinking as part of their lectures in didactics of mathematics. The course was developed within the FunThink project by German and Slovak partners inter alia and took place in the winter semester of 2022/23. It consisted of about 14 sessions (90 minutes each) focusing on the following topics: meaning and relevance of functional thinking, functional relationships and functions, aspects of functional thinking, the role of representations and representational changes, typical misconceptions and difficulties in the field of functional thinking (rather in the context of other topics such as "representational changes and corresponding difficulties"), development of functional thinking and

its embedding in the curriculum. In addition, the PSTs tried out, developed and reflected learning environments to foster students‘ functional thinking. Smaller variations between the implementation in the two countries were possible due to national requirements, but the general concept was identical.

In Germany, 14 PSTs of Ludwigsburg University of Education (11 female, 3 male), 22-34 years old, participated in this study. The course was offered as part of the master’s degree and participation was possible starting in the last semester of the bachelor’s degree. All participants are studying to become primary, secondary, or special education teachers and one of their main subjects is mathematics. Prior to this course, they all completed courses in mathematics and teaching mathematics.

In Slovakia, the study involved 13 PSTs from Pavol Jozef Šafárik University in Košice (9 female, 4 male) aged 22-23 years. All participants are first-year master's students and have a bachelor's degree in mathematics combined with another subject. They are studying to become teachers for lower and upper secondary schools. So far, they had courses in school mathematics and general teaching but with no pedagogical focus. Due to a country-specific adaption and contrarily to the German PSTs, the Slovak PSTs solved several content knowledge items related to functions before answering the PCK test presented below.

Test instrument, data collection, and coding scheme

The data was collected using a paper-pencil test in the first and last session of the course. Participation in the study was voluntary and not related to any grading. The test consisted of 8 to 17 items, again depending on local variations, and was developed within the FunThink project. The items focus on the PSTs’ knowledge of functional thinking and its teaching. The research presented in this paper focuses on the following item only: What learning difficulties and misconceptions do you expect when teaching functions? Use as many examples as possible to depict your answer.

For data analysis, a coding scheme was developed using qualitative content analysis, which allowed for both an inductive and deductive approach (Mayring, 2015). The deductively formed categories mainly focus on Leinhardt et al.’s (1990) classification of M&Ds. The PSTs’ answers were coded individually in each country, which led to modifications in the coding scheme. A joint discussion with colleagues from Germany and Slovakia, inter alia, resulted in the final coding scheme. To ensure consistency in coding between the countries, unclear examples were translated into English and discussed until consent was reached. The final coding scheme complemented by descriptions of PSTs responses (last row) is displayed in Figure 1 and will be briefly described in the following.

#	Code	Description	Example
1	F/N	No differentiation between what is and what is not a function	Misclassification of a graph as a function – assigning two x-values to one y-value.
2	LIN	**Linearity:** Overgeneralisation of properties of linear functions	Students connect two points by straight lines without paying attention if a linear function is appropriate.
3	1REP	**Representation of functions:** M&Ds related to one form of representation	Students are not able to draw a graph
4	LREP	**Linking representations:** M&Ds related to linking representations	Two formulas of functions and two graphs are given and students are not able to assign which graph belongs to which formula.
5	MOD	**Modelling:** M&Ds related to modelling	Students are not able to interpret graphs correctly (example, if they relate the shape of the glass to a graph of the function of the height of the water in the glass versus time when the water is poured evenly into the glass).

6	VAR	**Concept of variable:** M&Ds related to the concept of variable	Students are not able to understand how the values of variables can change in a given formula.
7	NT	**Notation:** M&Ds related to function notations	Lack of awareness that f(x) is another notation for y.
8	CvsD	**Continuous vs discrete graphs:** students cannot differentiate between continuous and discrete graphs	If the student draws a graph from the table, he does not connect the resulting points (e.g., pouring water into a glass of 100 ml - continuous graph).
9	1A	**Input-output aspect:** M&Ds related to the input-output aspect	Students are not able to assign input-output values.
10	2A	**Covariation aspect:** M&Ds related to the covariation aspect	Students are not able to determine from the table how x varies with f(x).
11	3A	**Correspondence aspect:** M&Ds related to the correspondence aspect	Students are not able to find the formula based on the provided data.
12	4A	**Object aspect:** M&Ds related to the object aspect	Student are mistaken about the types of functions if they are not indicated in their basic form.
13	GEN	**General:** M&Ds not related to the concept of functions	The student does not know how to start solving the problem.
14	Oth+	**Other meaningful answers:** M&Ds related to functional thinking that cannot be classified in any other category	Students do not know the rules for modifying expressions with powers, logarithms...
15	Oth-	**Meaningless or incomprehensible answers:** unclear answers	Misunderstanding of parents and their comments on student's learning.
16	BLK	**No answer or I do not know**	-

Figure 1: Coding scheme (adapted from Slabý & Semanišinová, accepted)

Categories 1, 2, 6, 7, and 8 are taken directly from Leinhardt et al. (1990) without modification. Categories 3 to 5 were derived from Leinhardt et al. (1990) adding further differentiation concerning dealing with representations. This differentiation includes changing representations, which causes difficulties for many students (Sproesser et al., 2022). Categories 9 to 12 are based on the four aspects of functional thinking as described by Pittalis et al. (2020). The last three categories (13-15) include rather general, other meaningful answers, and incomplete or incomprehensible answers. If a PST did not provide an answer or stated that they do not know possible M&Ds, code 16 was used.

Results and Discussion

The results will be presented for each country individually in the following. The numbers in the lowest line refer to the number of PSTs that mentioned each category; they do not relate to how often a PST mentioned one category. The numbers in the last column indicate how many meaningful categories (i.e., without "OTH-" and "BLK") a PST referred to in the pretest (grey) and in the posttest (black).

Figure 2 displays the German results. Most PSTs mentioned equally many or more M&Ds in the posttest than in the pretest. Only two PSTs mentioned less M&Ds in the posttest (GER4, GER14). The biggest changes can be observed for the categories of modeling (MOD) and representation of functions (1REP). This can be explained by the relevance of both these categories in connection to functional thinking (Vollrath, 1989) and a corresponding thematisation during the course.

Figure 3 indicates the responses provided by the Slovak PSTs. Most PSTs mentioned more M&Ds in the posttest compared to the pretest. Only one PST (SK9) mentioned equally many M&Ds in both tests and two PSTs (SK5 & SK8) mentioned fewer M&Ds in the posttest. Comparably big

improvements can be observed for the categories VAR, NT, and A4. Rather general and not function-related M&Ds answers decreased from pre- to posttest. In regard to the aspects of functional thinking, it can be observed that the PSTs focused only on the correspondence and object aspect (A3 & A4) in the pretest. In the posttest, these two aspects were also the dominant aspects, but A1 and A2 were also mentioned. This might be due to the previous training the PSTs underwent as described above.

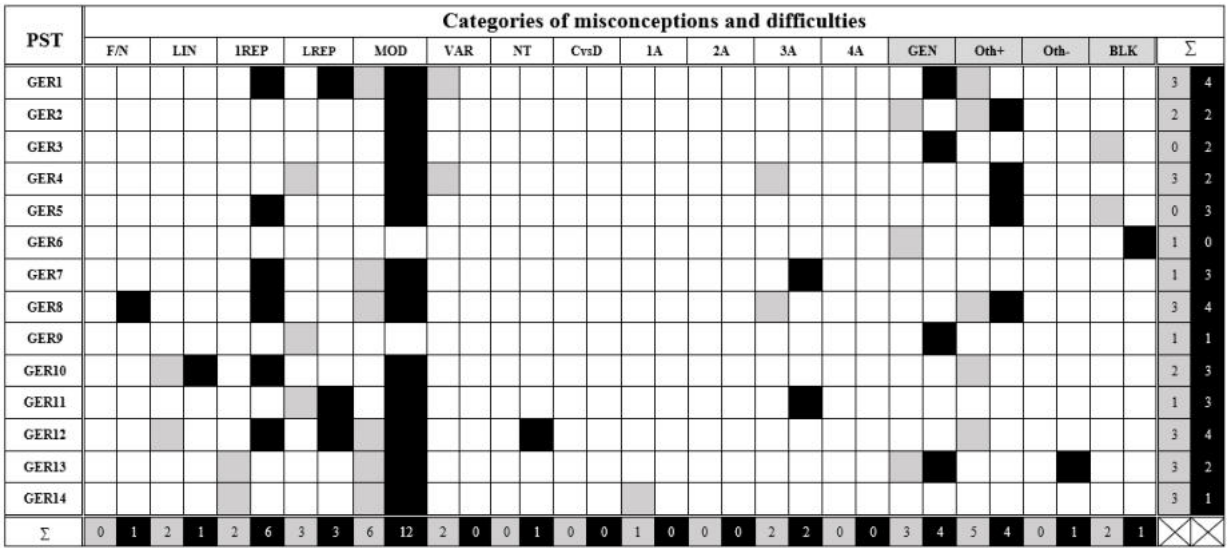

Figure 2: Mentioned M&Ds by German PSTs

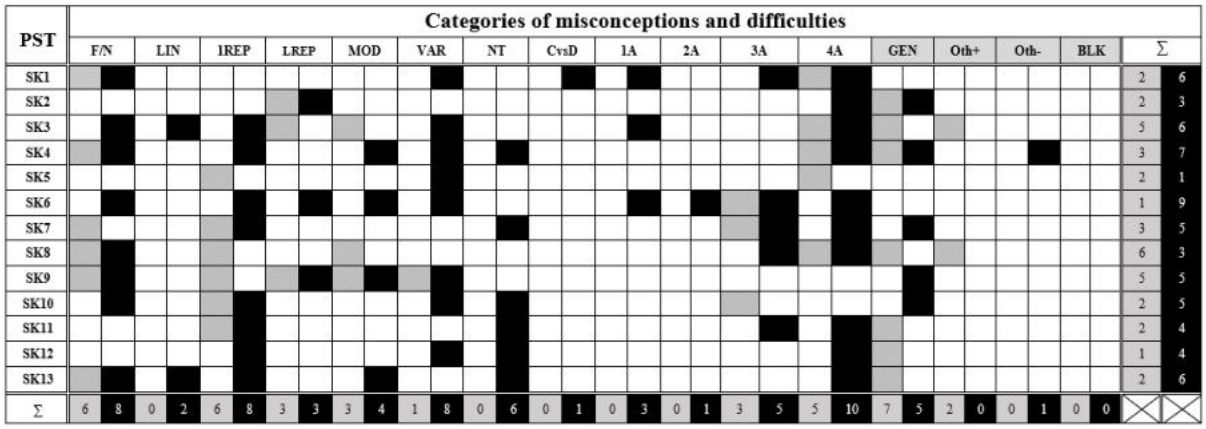

Figure 3: Mentioned M&Ds by Slovak PSTs

When comparing the German and Slovak results, it can be noted that in both countries the number of mentioned M&Ds increased from pre- to posttest. Concerning the individual categories, the German and Slovak PSTs focused mostly on different M&Ds. In the pretest, the dominant category observed for the German PSTs was Oth+, whereas in the posttest MOD was mentioned mostly. The Slovak PSTs mostly focused on F/N in the pretest and on F/N, VAR, NT and 4A in the posttest. A possible explanation for the differences between the countries might be the use of different project-related learning environments in the course that were chosen to best fit local curricula. The category 1REP was frequently mentioned in both countries. This might be because M&Ds related to representations are well documented (Sproesser et al., 2022). Yet, it appears surprising that changing representations

(LREP) was focused less often as this appears to be even more complex than mastering single representations. In total, the Slovak PSTs named more M&Ds in the pre- and posttest (36 & 65) compared to the German PSTs (28 & 36), even though the German sample included one PST more. This might be explained by the fact that the Slovak PSTs had to solve several content knowledge items before answering the PCK question on M&Ds, what might have posed difficulties for them and therefore possibly made them more sensitive for potential student problems. In this manner, it would be interesting to also have a closer look at previously attended university courses and the differences between the used learning environments to find further possible explanations. Limitations of this study are the relatively small sample size and slight variations between the German and the Slovak courses. In order to clarify if the found particularities and differences between German and Slovak participants are systematic, further research should include larger samples.

Conclusion

The results indicate that most PSTs' knowledge of students M&Ds with regard to functional thinking increased after participating in the described course in both countries which can be interpreted as a positive effect in regard to their professional knowledge (Ball et al., 2008; Carrillo-Yañez et al., 2018). This is even more remarkable since M&Ds were treated in the course rather secondary and in the context of other topics. Differences in the implementation of functional thinking in mathematics classrooms in Germany and Slovakia are obviously also reflected in PSTs' knowledge, which might also but not exclusively be moderated by differences in the learning environments and the university course. Hence, this study indicates that cross-country research is crucial, as it is obviously not possible to transfer the results from one country to another generally. Such country comparisons can also serve as inspirations in the sense of identifying and cumulating best practices of different countries, e.g., with regard to the implementation of functional thinking in the classroom.

Exploring strategy flexibility and adaptivity in multidigit multiplication: a study with Austrian in-service primary teachers'

Martina Greiler, Tanja Lobnig and Almut Thomas

University College of Teacher Education Carinthia, Klagenfurt, Austria;
martina.greiler@ph-kaernten.ac.at

Understanding teachers' strategy flexibility and adaptivity is crucial as their expertise shapes students' mathematical thinking and flexibility – key goals in primary education. This study examines the strategy repertoires and perspectives on adaptivity of 55 in-service primary teachers in Carinthia, Austria. Participants solved single-digit by two-digit multiplication problems and explained their reasoning for strategy selection. Results show a strong preference for decomposition strategies, with compensating and doubling used less frequently. On average, participants used 2.6 strategies. Teachers justified choosing the easiest strategy based on subjective criteria (e.g., familiarity, easy to understand, apply) rather than on task-based adaptivity. When evaluating a student's mathematically correct but non-adaptive strategy (5×13=5×20–5×7), responses varied: 38% considered it advantageous, justifying their evaluation from a pedagogical rather than mathematical view.

Keywords: Strategies, flexibility, adaptivity, multidigit multiplication, in-service primary teachers' knowledge.

Introduction

The development of strategy flexibility is an important goal in primary mathematics education, as emphasised in curricula and policy documents in Austria, Germany and worldwide (e.g. BMBWF, 2009). However, research highlights low levels of strategy flexibility among students, especially in traditional educational settings (e.g. Heinze et al., 2009; Torbeyns et al., 2017). Comparing strategies and exploring numerical relationships can significantly increase strategy flexibility (e.g. Green & Rathgeb-Schnierer, 2020; Greiler-Zauchner, 2022; Smedt et al., 2010). Teachers' expertise in strategy flexibility is crucial for fostering students' flexible mathematical thinking. Research highlights the significant impact of teacher knowledge on instructional quality and student achievement (Copur-Gencturk & Tolar, 2022; Hill et al., 2005; Kunter et al., 2013).

In this study, we investigate the strategy flexibility of Carinthian in-service primary teachers (IPTs) in single-digit by two-digit multiplication tasks. The study focuses on the two key constructs of strategy flexibility: first, the ability to know and use multiple strategies for these tasks, referred to as strategy repertoire. Second, we examine teachers' ability to select the most appropriate strategy for a given task, referred to as strategy adaptivity going beyond a purely task-based perspective by considering additional dimensions that may constitute strategy adaptivity for teachers.

Strategy repertoire in multidigit multiplication

Strategy flexibility, as defined above, involves the knowledge of multiple strategies. Depending on how numbers are handled, strategies can be categorised as (1) sequential strategies, (2) decomposition strategies and (3) varying strategies (Hickendorff et al., 2019). Sequential strategies involve repeated addition, e.g. 5×24=24+24+24+24+24. Efficiency increases with doubling, e.g. 24+24=48,

48+48=96, 96+24=120. Decomposition strategies use the distributive property of multiplication over addition and are classified according to how the factors are split. For example, 25×7 can be calculated as (20+5)×7=20×7+5×7 (by decades) or as 25×(4+3)=25×4+25×3 (by non-decades). Varying strategies adjust numbers and/or operations, including compensating, e.g. 19×8=(20–1)×8=20×8–1×8, or doubling and halving, e.g. 5×24=10×12 using factorization and the associative property. Another varying strategy exploits halving relationships, e.g. finding 5×24 by halving the product of 10×24.

Research on strategy repertoires and their use for multidigit multiplication among in-service and pre-service primary teachers (PPTs) is limited. A few studies have been conducted in different countries in and around Europe: Turkish IPTs predominantly preferred the standard algorithm for problems such as 15×19 and saw no need for alternative strategies, some of them even had difficulties understanding them (Aylar-Çankaya, 2020). Similar patterns were observed among Greek PPTs, with the majority relying on mental representations of the written algorithm for two-digit multiplication and only a small proportion using alternative strategies such as decomposition (Lemonidis et al., 2014). The study found that 44% of PPTs lacked strategy flexibility in the sense that they were unable to use different strategies appropriately depending on the multidigit multiplication problem. A study of Romanian PPTs found that more than a quarter of participants did not use any strategies beyond mentally following the standard algorithm, while more than a third used only one or two strategies, mainly decomposition (Baranyai et al., 2019). A study of Norwegian PPTs found that 59% of PPTs also used decomposition for mental multidigit multiplication (Månsson, 2023). Despite socio-cultural differences, a common trend shows reliance on standard algorithms and limited strategy flexibility, with decomposition as the main alternative.

Perspectives on strategy adaptivity

The concept of adaptivity as the ability to select the most appropriate strategy, is interpreted differently in the literature. Some researchers conceptualise adaptivity primarily from a task-based perspective, meaning that the appropriateness of a strategy is determined by the specific characteristics of the mathematical problem (e.g. Blöte et al., 2001; Heinze et al., 2009; Hickendorff, 2018). In the context of multidigit multiplication, this perspective favours strategies such as doubling for factors such as 4 or 8 and compensating when a factor is just below a multiple of ten (e.g. 19×8). Doubling and halving is particularly effective when one factor is even and the other is a convenient number, such as 5, 15, 25 or 50. Similarly, halving the product of 10 is advantageous when 5 is a factor. In contrast, decomposing by decades is often seen as a universal strategy, especially when no specific task characteristics suggest a more adaptive approach.

However, children do not always prefer task-specific strategies, even when they can use them. Instead, they tend to favour strategies with which they are familiar or feel more comfortable (e.g. Greiler-Zauchner, 2022). Further evidence suggests that task-specific strategies, although having the fewest and the easiest steps, are not necessarily easy for all students, as they require a strong understanding of numbers and numerical relationships (Hickendorff, 2022).

These considerations support a broader conceptualisation of adaptivity. In this sense, Verschaffel et al. (2009) define adaptivity as the ability to select and use the most appropriate solution strategy for

a given mathematical task, for a specific individual, in a particular sociocultural context. These different perspectives on adaptivity may lead to different justifications for why a particular strategy is considered most appropriate for an individual – a key focus of this study. In particular this study explores teachers' perspectives on adaptivity, which may also be influenced by pedagogical considerations.

Research question

Primary teachers' expertise in strategy flexibility and adaptivity has a significant impact on their teaching practices in arithmetic. Existing studies on IPTs' repertoires and the use of multiplication strategies have predominantly been conducted in specific geographical settings (e.g. Greece). Research is needed to see if these findings apply to other European countries, including Austria. Furthermore, teachers' perspectives on strategy adaptivity have been under-researched. Little is known about the criteria teachers use to judge the appropriateness of strategy choices. To address these research gaps, the study is guided by the following research questions:

1. What is the range and frequency of strategies used by Carinthian IPTs when solving single-digit by two-digit multiplication problems?
2. What criteria do Carinthian IPTs use to determine which multiplication strategy is the easiest?
3. What criteria do Carinthian IPTs use to evaluate the appropriateness of a student's chosen strategy for a given multiplication problem?

Method

An online questionnaire, designed as a self-assessment tool, was administered to 55 Carinthian IPTs in 2021 and 2022 (53 female, 2 male). The IPTs were volunteers enrolled in a professional development course for the promotion of mathematical competences, which aims to improve teachers' understanding of mental multiplication according to new curricula and standards and to provide them with validated teaching materials to support their classroom practice. The teaching experience of the 19 teachers who provided information ranged from 3 to 41 years. Data collection took place at the beginning of the first online session in autumn 2021 and 2022. The original questionnaire consisted of five questions assessing content and pedagogical content knowledge related to two-digit multiplication, with an estimated completion time of 30 minutes:

In Question 1a, participants were asked to solve the multiplication problems 17×4, 5×24 and 19×6 in various ways in order to assess their repertoire of strategies. The answers were analysed and categorised according to established strategy types (Greiler-Zauchner, 2022; Hickendorff et al., 2019). In Question 1b participants had to justify in a written report which of the strategies from Question 1a they found easiest and why. Their responses were categorised according to different dimensions of adaptivity (task-based and subject-based), with subject-based arguments further classified inductively based on the content of the responses. Question 2 presented a scenario in which a student *Verena* used the 5×20–5×7 strategy – inappropriate from a task-based perspective – to solve 5×13 for her homework. Participants evaluated Verena's choice of strategy in a written report. In the first round of analysis, responses were categorised according to whether they considered the strategy

to be inadequate, advantageous or neutral. The justifications within the *inadequate* category were further classified inductively based on their content.

Results

Question 1a: IPTs' repertoire of multiplication strategies

The multiplication strategies used by the 55 IPTs for the 17×4, 5×24 and 19×6 problems were categorized into sequential strategies (repeated addition and doubling), decomposition strategies (by decades and non-decades), varying strategies (compensating, halving the product of 10, doubling and halving), the standard algorithm and erroneous strategies. Figure 1 shows the frequency of the strategies used: Decomposing by decades was the most frequently used strategy, with 89% (49 participants) using 10×4+7×4 for 17×4 and 71% (39 participants) using 5×20+5×4 for 5×24. Compensating was common for 19×6, with 80% (44 participants) using 20×6–1×6.

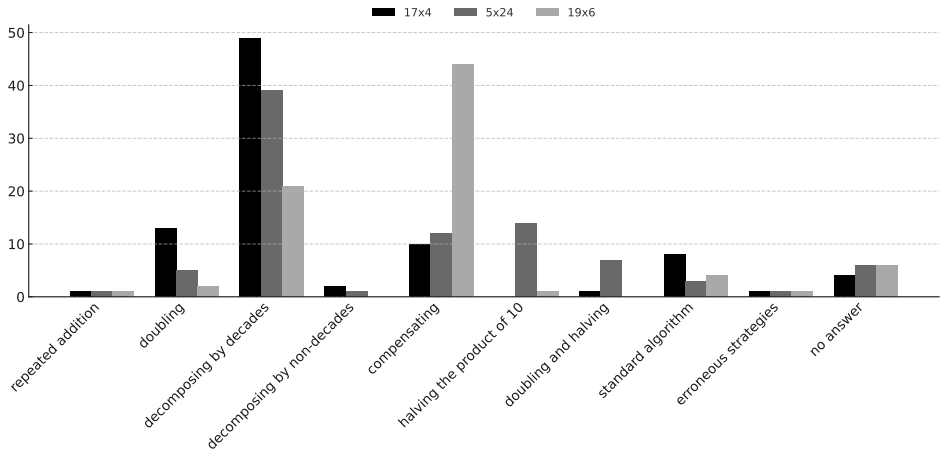

Figure 1: Frequency of multiplication strategies for 5×14, 4×16 and 19×6

Less common strategies included doubling, used by 24% (13 participants) for 17×4, halving the product of 10, used by 25% (14 participants) for 5×24 and doubling and halving, used by 13% (7 participants) for 5×24. A small number of participants used erroneous strategies (1 participant) or gave no answer (4–6 participants, depending on the problem). The standard algorithm was chosen by 3 to 8 participants, depending on the problem.

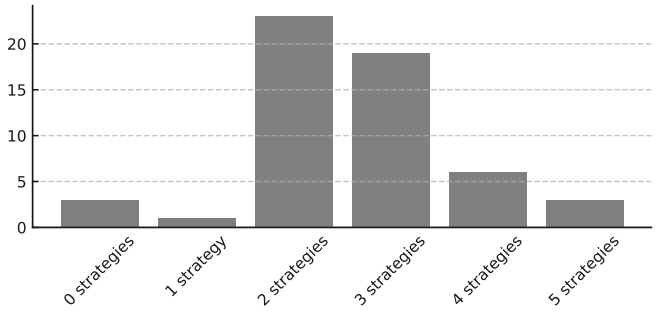

Figure 2: Number of different strategies used per person

Figure 2 shows the distribution of participants by the number of strategies used. The most common approach was the use of two strategies, observed in 42% (23 participants), with 16 favouring a combination of decomposing by decades and compensating. Three strategies were used by 35% (19 participants), most often adding either doubling or halving the product of 10 to the two main strategies. Fewer participants used four or more strategies (9 participants), while 5% (3 participants) provided no answer and 2% (1 participant) used only one strategy.

Question 1b: IPTs' justification of the easiest strategy

Question 1b asked participants to justify why they considered their chosen strategy the easiest. However, 11 participants mentioned a strategy as the easiest without giving a reason. In addition, 2 participants referred to number manipulation in their answers, which did not include a justification. 13 participants gave justifications for adaptivity, some with multiple responses (total: 19). When these justifications were categorised, five distinct reasoning patterns emerged. Table 1 provides an overview of these categories, along with translated examples of participants' responses.

Table 1: IPTs' justifications of the easiest strategy

Category	Reasoning/Example		Frequency (N=19)
Fast	IPT59:	For me, the second method [compensating] is the easiest because it's the fastest.	31.58% (6)
Familiar	IPT17:	In my opinion, strategy 1 [doubling] is the easiest because the kids are already familiar with doubling.	21.05% (4)
Easier to understand and apply	IPT15:	I find the method above [compensating] the easiest because I think it's simpler for kids who have trouble multiplying large numbers.	15.79% (3)
Frequently used	IPT58:	It is used most frequently.	15.79% (3)
Less prone to error	IPT36:	This strategy has less error potential.	15.79% (3)

Notably, none of the participants justified their choice based on task characteristics. Instead, the most frequently cited criterion was *fast*, mentioned by six participants (31.58%), who associated the easiest strategy with the one that could be performed the fastest. The rest of the answers were distributed among the categories of familiarity (4), easier to understand and apply (3), frequently used (3) and less error-prone (3). It is also worth noting that 53% (29 participants) did not answer this question. This may indicate that they overlooked the second part of the question.

Question 2: IPTs' evaluation of Verena's strategy choice for 5×13

In Question 2, the IPTs were asked to evaluate Verena's strategy for solving 5×13, which she approached by calculating 5×20–5×7. Although this strategy is mathematically correct, it is less appropriate compared to other strategies such as decomposing or halving the product of 10. The responses fell into three categories: (1) 54% (30 participants) found the strategy inappropriate, (2) 38% (21 participants) found it advantageous and (3) 4% (2 participants) were neutral. Two responses could not be categorized. Within the first category, the responses were further grouped according to the reasons given. 22 IPTs also suggested an alternative calculation strategy, most commonly

decomposition. Table 2 gives an overview of the categories and sub-categories and provides examples of the participants' responses, translated into English.

Table 2: IPTs' responses categorized with examples

Category	Reasoning/Example	Frequency (N=55)
Strategy considered inappropriate		
- due to the absence of relevant task features	IPT220: The multiplicand is closer to 10, so it would be more sensible for Verena to calculate as follows: 5×10=50, 5×3=15, 50+15=65.	11% (6)
- due to other reasons (e.g. error-prone, existence of easier methods)	IPT35: Too cumbersome with sources of error; subtraction is more prone to error here…	27% (15)
- without further explanation	IPT203: Correct, but cumbersome.	16% (9)
Strategy considered advantageous	IPT07: Verena calculated advantageously! Many children are not yet capable of this! IPT25: Excellent method; Verena thinks very complexly.	38% (21)
Neutral evaluation	IPT55: Creative method.	4% (2)
Answer not categorizable		4% (2)

Summary and Interpretation

This study investigates the strategy repertoires and adaptive reasoning of Austrian in-service primary teachers (IPTs) when solving single-digit by two-digit multiplication problems. The results indicate a strong preference for decomposition strategies, particularly those based on decades. Compensating was frequently used, especially for the 19×6 problem, where task-based features make it advantageous. However, other task-based strategies, such as doubling, halving the product of tens, or doubling and halving, were used less frequently, especially for the 17×4 and 5×24 problems. The standard algorithm was rarely used, probably because of the small numbers involved and the numerical characteristics of the problems. On average, participants used 2.6 different strategies, indicating a broader use of different strategies and less reliance on the standard algorithm compared to studies conducted in other countries, as discussed in the theoretical section.

Regarding the criteria used by the Carinthian IPTs to determine which multiplication strategy was the easiest, the results show that the teachers investigated did not focus on task-specific characteristics but justified their choice mainly on subjective criteria such as: quick, familiar, easier to understand and use, frequently used or less error-prone. The criteria used to evaluate the appropriateness of a student's chosen mathematically correct strategy, which does not follow the principles of task-based adaptivity (5×13 = 5×20–5×7), also illustrate the diversity of teachers' perspectives on adaptivity. Nevertheless, 38% of teachers found it advantageous, often citing its complexity or creativity and

appreciating the complex solution. In contrast, only 11% considered it inappropriate because of insufficient task relevance.

These findings show that IPTs' perspectives on adaptivity in these tasks are largely not aligned with a task-based view. Instead, their reasoning often reflects instructional and pedagogical considerations, such as encouraging student creativity, supporting higher order thinking, or minimising errors. This is an indication that teachers do not always justify their choices from a strictly mathematical perspective, which needs to be taken into account when interpreting the results. Given these tendencies, professional development programs should aim to strengthen teachers' task-based reasoning while also integrating subject-based and socio-cultural perspectives into discussions on strategy selection. The small sample size limits the generalizability of the findings and further research is needed to explore their applicability in different educational contexts.

An investigation of TPACK using a 3D Techno-pedagogical integration matrix in the context of mathematics teaching

Tuğba Hangül Demirci[1] and Hatice Akkoç[2]

[1,2]Marmara University, Ataturk Faculty of Education, Istanbul, Türkiye;
tugba.hangul@marmara.edu.tr

This study uses a three-dimensional Techno-Pedagogical Integration Matrix (3D-TPIM) to re-conceptualize TPACK. Our case involved a senior pre-service mathematics teacher (PMT) in a teacher preparation program. The data consisted of a video recording of his lesson in a real classroom setting. The video was analyzed using the 3D-TPIM. The x-axis represents the sub-codes of the richness of the mathematics dimension of the Mathematical Quality of Instruction (MQI) framework. The y-axis represents levels of the MQI sub-codes. The z-axis represents the levels of technology integration using the SAMR (Substitution, Augmentation, Modification, and Redefinition) model. The findings indicated that the PMT used technology mainly at the augmentation and modification levels for linking representations and mathematical sense-making. We will discuss the theoretical and practical implications of our conceptualization of TPACK using the 3D-TPIM.

Keywords: SAMR model, Mathematical quality of instruction, 3D techno-pedagogical integration matrix, Pre-service mathematics teachers, TPACK.

Introduction

One of the critical issues in teacher education research has been the type of knowledge needed to successfully incorporate technology into the teaching of any subject matter and how this knowledge should be evaluated or developed. Mishra and Koehler (2006) call this *Technological Pedagogical Content Knowledge* (TPACK). In recent years, the framework has faced criticism for overlooking contextual factors (referred to as contextual knowledge, or XK, by Mishra, 2019, and XTPACK by Brianza et al., 2022) and for lacking a domain-specific focus in its approach (Voogt et al., 2013).

Building on our previous study (Akkoç & Hangül, 2023), this study also emphasizes TPACK as a domain-specific knowledge, treating it as a core area rather than focusing on the framework as a whole. We propose an alternative interpretation of TPACK tailored to mathematics and its pedagogy, moving away from a generalized model that downplays the importance of subject content. By integrating the Mathematical Quality of Instruction (MQI) framework, our conceptualization highlights the significance of the subject matter (mathematics). We aim to examine a PMT's TPACK through the lens of this new conceptual framework, as detailed below. Our research question is: "What is the PMT's TPACK through the lens of the 3D-TPIM?"

Conceptual Framework

The present study uses a three-dimensional Techno-Pedagogical Integration Matrix (3D-TPIM) to re-conceptualize TPACK. We developed this model to design the content of the Teaching Practicum I-II courses, analyze PMTs' TPACK, and monitor their development. The MQI sub-codes originally have levels. In our previous studies (Akkoç, Hangül & Çeziktürk, 2022; Akkoç & Hangül, 2023), we only included its categorical sub-codes without their levels and utilized a 2D-matrix: one of the axes

represented the richness of the mathematics dimension of the MQI framework which has six sub-codes: *mathematical sense-making, explanations, mathematical language, patterns and generalizations, linking between representations, and multiple procedures or solution methods* (Hill, 2014). The other axis represented the levels of technology integration using Puentedura's (2020) SAMR (*Substitution, Augmentation, Modification,* and *Redefinition*) model. This study includes the levels of the MQI adhering to its original version and formed a 3D-TPIM for a more in-depth examination. This current study adds the levels of the sub-codes of the richness of the mathematics dimension (*not present, low, mid, high*) as the third axis (See Figure 1). Utilizing this 3D-TPIM, we seek to examine the TPACK of a PMT in a real classroom setting. Below, we present our conceptual framework further.

Mathematical Quality of Instruction (MQI)

MQI is an observational rubric that provides a framework for analyzing mathematics instruction in five domains: *the richness of the mathematics, common core aligned student practices, errors and imprecision, working with students and mathematics,* and *classroom work is connected to mathematics* (Hill, 2014a). *The richness of the mathematics* dimension aims to determine the depth of the mathematics in the instruction within six sub-codes: *explanations, mathematical sense-making, linking between representations, patterns and generalizations, multiple procedures or solution methods,* and *mathematical language* (Hill, 2014b). The code of *explanations* focuses on the question of "why". For instance, why is an answer true/false, why is a solution method appropriate/inappropriate, and why does a procedure work/not (Hill, 2014b)? The code of *mathematical sense-making* is expressed to seize the connections between mathematical ideas (Hill, 2014b). The code of *linking between representations* examines how teachers connect between different representations of a mathematical concept (Hill, 2014b). *Patterns and generalizations* code is about whether a mathematical generalization is developed (Hill, 2014b). *Multiple procedures or solution methods* code is concerned with looking for multiple procedures of a problem type or multiple solution methods of a problem (Hill, 2014b). The code of *mathematical language* focuses on the teacher/students' fluency in mathematical language (Hill, 2014b). We used these six sub-codes on the *x*-axis and their levels (*not present, low, mid, high*) on the *y*-axis of the 3D-TPIM.

SAMR Model

SAMR model evaluates the level of technology integration in the classroom (Puentedura, 2010; 2020). It defines four sub-levels in two primary levels: *substitution* and *augmentation* (at the *enhancement* level), *modification* and *redefinition* (at the *transformation* level). Technology acts as a direct tool substitute with no functional change at the *substitution* level, while at the *augmentation* level, it acts as a direct tool substitute with functional change. The use of technology permits a substantial task redesign at the *modification* level. At the *redefinition* level, new tasks emerge that would not have been possible without technology. We also added not using technology as another level when PMT did *not use technology* for specific purposes. We represented these five levels on the *z*-axis of the 3D-TPIM.

Methods

We considered a single case study appropriate for an in-depth investigation of TPACK with a 3D-TPIM. Although the 3D-TPIM offers a quantitative approach by determining TPACK with three-dimensional coordinate points, how these points are determined needs to be examined qualitatively to increase the study's validity. The participant was a senior PMT (male) enrolled in a four-year mathematics teacher preparation program at a state university in Türkiye. We chose this PMT because he used technology in his teaching. He was a senior PMT, so he attended various courses such as technology-enhanced mathematics teaching. We collected data in the context of the Teaching Practicum II course. It was a 10th-grade class in a Science High School with twenty students. The data consists of a lesson on trigonometric functions using a modelling activity using GeoGebra. The classroom had a central screen, and students did not have their own devices to work with GeoGebra.

The 33-minute lesson video was divided into three segments following the MQI perspective. While determining the segments, the beginning and end of the teaching activities were considered. In this way, we ensured that each segment formed an integrity within itself. This study will only present the findings of Segment 1. We first determined whether the sub-codes (*mathematical sense-making, explanations, mathematical language, patterns and generalizations, linking between representations,* and *multiple procedures or solution methods*) of the MQI's *richness of the mathematics* component exist in the relevant segment. Then, sub-code levels (*not present, low, mid, high*) were determined. In the next stage, PMT's use of the technology was analyzed by considering the SAMR levels. Accordingly, in the 3D-TPIM, the *x*-axis shows the MQI-richness of the mathematics sub-codes, the *y*-axis shows their levels, and the *z*-axis shows SAMR levels (See Figure 1). We coded the segment independently based on the 3D-TPIM. The initial agreement between the first and second researchers was 0.67, but all disagreements were resolved through discussion to enhance validity.

Findings

This study only presents the findings from the analysis of Segment 1 (between 00.00 and 08.49 minutes of the video). In this segment, the learning goal that PMT focused on is as follows: Graphs of functions of the type $f(x) = a.cos(bx + c) + k$ and the effects of the coefficients on the graph are discussed.

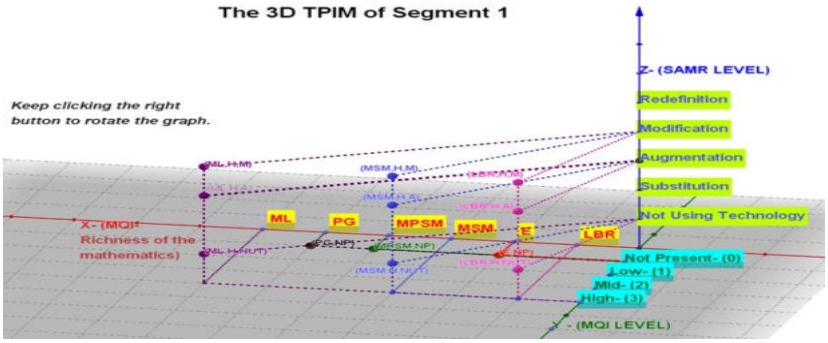

Figure 1: The 3D TPIM of Segment 1 (Click here for a dynamic version)

In line with this objective, worksheets containing different trigonometric functions and graphs were distributed to the students to evaluate their prior knowledge and to remind them about the subject. He

opened GeoGebra software on the smart board and showed the algebraic and graphical representations of functions on the worksheets. He showed many different functions, their transformations, and graphical representations with GeoGebra and explained them. As shown in Figure 1, the MQI codes detected in Segment 1 were *mathematical language*, *linking between representations*, and *mathematical sense-making.*

Mathematical language

During Segment 1, the PMT used mathematical language intensively and fluently and supported students in using mathematical language. For this reason, *mathematical language* was coded at the *'high'* level in this part of the lesson. During this process, PMT utilized either technology (at the *augmentation* and *modification* levels) or the worksheets distributed to the students. The findings are given as coordinates for the *mathematical language* sub-code in Figure 1 are *(ML, H, NUT), (ML, H, A),* and *(ML, H, M).*

The point *(Mathematical Language, High, Not Using Technology)* represents cases where the PMT used *mathematical language* at the *'high'* level without integrating technology into his teaching. While explaining the functions (such as $y = cos\,x$, $y = 1 + cos\,x$, $y = 2cos\,x$, $y = -cos\,x$, $y = cos\,3x$, $y = 1 + 2cos\,x$) and their graphs in the worksheets, PMT used mathematical language intensively by mentioning many different concepts fluently since he did not make any extra drawings on the board.

During his lesson, he used mathematical terminology such as "$cos\,x$ equation, translation, lower bound, symmetry, period, and trigonometric functions" correctly and fluently, using the worksheet in about 1.30 minutes. According to the MQI framework, the *mathematical language* sub-code is coded as *'high'* when the teacher uses mathematical language intensively in the discourse or makes the terminology more understandable to remind students of mathematical meanings (even if the teacher does not use language intensively) (see, Hill, 2014b).

The point *(Mathematical language, High, Augmentation)* represents cases where the PMT used *mathematical language* at the *'high'* level by integrating technology into his teaching at the *augmentation* level. Regarding the *mathematical language* sub-code, we observed that the PMT could use mathematical terminology intensively in a short time by explaining the algebraic and graphical representations of many different $cos\,x$ functions using GeoGebra. However, since he did not use the slider tool, we considered the technology used at the *augmentation* level of the SAMR model (see Figure 2a & 2b). In this context, the relevant section of the lesson showing the contribution of technology to the *mathematical language* sub-code is as follows:

> PMT: What if I multiply the $cos\,x$ function by 2? It would have to expand…Yes, the upper and lower intervals have expanded. So, what if I multiply x by a number? Its period should change (He drew the function $f(x) = 2cos(2x) + 1$ using GeoGebra). Yes, this time, I've shrunk it. What I'm actually changing here is the period.

As shown above, using GeoGebra, he obtained the function $f(x) = 2cos(2\,x) + 1$ and used mathematical terminology such as "period" to explain how the graph changed.

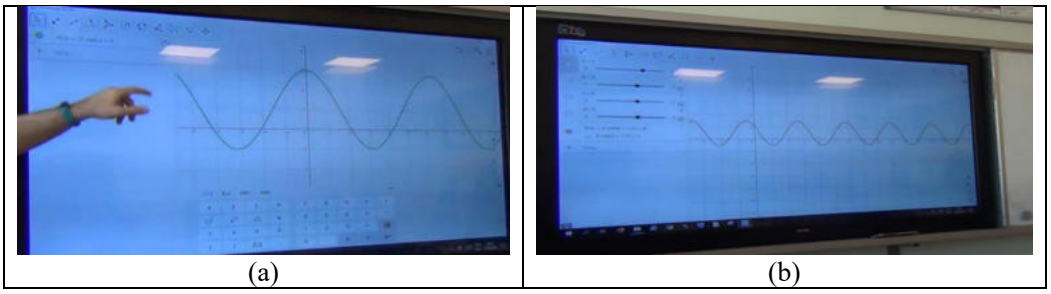
As explained above, we observed that PMT drew many different functions in GeoGebra (without using the slider tool) in a short time and used mathematical language intensively in his explanations

about them, reminding the students of the meaning of the concept of period to make the terminology more understandable. For this reason, *mathematical language* was coded at the *'high'* level, and this finding was shown in the 3D-TPIM as the point *(ML, H, A).* In the analyses of other sub-codes related to the use of technology, the graphical drawings made without using the slider tool in GeoGebra were similarly coded at the *augmentation* level.

The point *(Mathematical Language, High, Modification)* represents cases where the PMT used *mathematical language* at the *'high'* level by integrating technology into his teaching at the *modification* level. PMT expressed the function as $(f(x) = a.cos(bx + c) + d)$ using the slider tool in GeoGebra and obtained a different cosine function when he moved the slider. The task that PMT expects from his peers by using this feature is to make inferences about how the change in the coefficients of the cosine function changes its graph. In this process, similar to the dialogue above, the *mathematical language* reached at the *'high'* level. In this respect, in the analyses of other sub-codes related to the use of technology, obtaining different functions by using the slider tool in GeoGebra was coded as the *modification* level. For this reason, this finding is shown with the point *(ML, H, M)* in the 3D-TPIM. All these findings imply that technology contributes positively to the intensity of using mathematical language.

Linking between representations

Linking between representations, another code we identified in this part of the instruction, was also at the *'high'* level. The PMT used the periodic function's algebraic, verbal, and graphical representations and established the connection between them (see Figure 2a & 2b). Since more than one type of representation was used together and connections were established, the code level was determined to be *'high'* in this context. In this process, the PMT either did *not use technology* or used technology at the levels of *augmentation* or *modification*.



(a) (b)

Figure 2: A screenshot of GeoGebra activity

The point *(Linking Between Representations, High, Not Using Technology)* represents cases where the PMT linked different representations at the *'high'* level without integrating technology into his teaching. On the worksheets he distributed to his peers, he focused on algebraic and graphical representations of functions. He made connections between them through the graphical drawings on the worksheet.

The point *(Linking Between Representations, High, Augmentation)* represents cases where the PMT linked different representations at the *'high'* level by integrating technology into his teaching at the *augmentation* level. Using GeoGebra, he explained the cosine function by showing different types of

representations (algebraic, graphical). In the process in which he drew the graphs one by one without using the slider tool, the level of technology use was determined as *augmentation* (see Figure 2a).

The point *(Linking Between Representations, High, Modification)* represents cases where the PMT linked different representations at the *'high'* level by integrating technology into his teaching at the *modification* level. The use of technology was at the level of *modification* (see Figure 2b) in the process in which PMT used the slider tool in GeoGebra to help students make mathematical inferences from different functions and their graphs (e.g., concluding that the function $f(x) = cos\, x + 1$ shifted up by 1 unit compared to the original function). Here, since the PMT made explanations about how the change in the algebraic representation of the cosine function affected its graphical representation (see PMT's explanations in the (*MSM, H, M)* section for detailed information), *linking between representations* was coded as the *'high'* level in this part of the lesson. This finding was shown in the 3D-TPIM as the point *(LBR, H, M)*.

Mathematical sense-making

The last code in Segment 1 is *mathematical sense-making*. In this context, the PMT emphasized making sense of the cosine function, which is a periodic function, through its algebraic and graphical representations. In other words, since making sense of how the function's graphical representation changes as its algebraic representation changes continues throughout the segment, the level of this code was coded as *'high'*.

The point *(Mathematical Sense-making, High, Not Using Technology)* represents cases where the PMT focused on *mathematical sense-making* at the *'high'* level without integrating technology into his teaching. He targeted sense-making by concentrating on the relationships between cosine functions and their graphs on the worksheet. According to the MQI framework, the *mathematical sense-making* sub-code of this segment is coded as *'high'* when it comes to making sense of the relationships between mathematical ideas and their representations. While answering the questions in the worksheet, the PMT explained how changes in the algebraic representation of the $cos\, x$ function affect its graphical representation and how the period of the function changes. For this reason, *mathematical sense-making* was coded at the *'high'* level in this part of the lesson, and this finding was shown in the 3D-TPIM as the point *(MSM, H, NUT)*.

The point *(Mathematical Sense-Making, High, Augmentation)* represents cases where the PMT focused on *mathematical sense-making* at the *'high'* level by integrating technology into his teaching at the *augmentation* level. PMT sketched the graphs of cosine functions in GeoGebra without using the slider tool and expressed their relationship (see Figure 2a). PMT entered the $cos\, x$ function in GeoGebra and explained how the change in the algebraic representation of the function affects its period. Therefore, this part of the lesson coded as *mathematical sense-making* at the *'high'* level. The technology usage level was coded as *augmentation* since it explained the relationships of the functions obtained by applying different transformations to the cosine function without using sliders in GeoGebra (see Figure 2a). This finding is shown as the point *(MSM, H, A)* in the 3D-TPIM.

The point *(Mathematical Sense-Making, High, Modification)* represents cases where the PMT focused on *mathematical sense-making* at the *'high'* level by integrating technology into his teaching

at the *modification* level. PMT has shown how a change in the algebraic representation of the cosine function affects its graphical representation and the relationship between them through the slider tool in GeoGebra (see Figure 2b).

A sample of the expressions he used while making his drawings in Figure 2b is presented below:

> PMT: Let me have constants *a,b,c,d.* (In the meantime, he created four sliders between -5 and 5 in GeoGebra.) Let me retake the cosine function. (By writing $(f(x) = a.cos(bx + c) + d)$ I add a constant d. Look, as the number we multiply gets larger, it expands; as it gets smaller, it shrinks.

As understood above, PMT utilized technology at the *modification* level to help students make sense of periodic functions. This finding is shown in the 3D-TPIM as the point *(MSM, H, A).*

Discussion

This study aimed to examine PMT's TPACK in the context of MQI in a real classroom using the 3D-TPIM. The findings showed that the PMT used technology for *mathematical sense-making* and *linking between representations* at the *augmentation* and *modification* levels. The findings also revealed that the effective use of *mathematical language* supported technology-enhanced instruction. *Mathematical sense-making, mathematical language,* and *linking between representations* sub-codes were found to be at the *'high'* level when using technology. In addition, using technology at the *augmentation* and *modification* levels not only helped the PMT regarding the sub-codes mentioned but also increased the levels of these sub-codes. In this respect, we argue that using technology in teaching contributes to improving the mathematical quality of instruction.

The *substitution* and *redefinition* levels of the SAMR model, explanations, multiple procedures and solution methods, and patterns and generalizations sub-codes of MQI were not observed in the lesson segment. Analyzing the first 08.49 minutes of the instruction, which constitutes the introductory part, may have played a role in obtaining this finding. For example, the *"explanations"* sub-code was encountered in the second and third segments, where the participant elaborated on the concepts. The mentioned sub-codes and the *substitution* level were present in other segments. The lack of equipment such as tablets, mobile phones, and laptops in the hands of the students may have been a factor in the absence of the *redefinition* level. In using technology at the *redefinition* level, students need to experience the process of self-discovery through technology (Kihoza et al., 2016). The relevant literature shows that teachers have difficulty using technology at this level (Akkoç & Hangül, 2023).

This study proposed a 3D version of the TPIM that was initially two-dimensional (Akkoç et al., 2022; Akkoç & Hangül, 2023). With the third dimension, the z-axis (MQI sub-code levels), the revized matrix provided a more nuanced picture of TPACK. The levels of the MQI sub-codes were also used to operationalize the MQI framework following its original form to contribute to using both theoretical frameworks by demonstrating the impact of MQI in examining TPACK.

We suggest that the 3D-TPIM can be used to determine the development of pre-service teachers or teachers in intervention studies since it offers a quantitative approach. Similarly, teacher educators could systematically employ 3D-TPIM framework to analyze instructional practices, diagnose pedagogical challenges, and monitor teachers' or PMTs' professional growth over time. Finally, other

components of the MQI will be added to the *x*-axis of the 3D-TPIM to investigate lessons involving different PMTs or experienced teachers and covering different mathematical topics in future studies.

Preservice teachers' self-perceptions about their knowledge for teaching

Hulya Kilic[1] and Fatma Aslan-Tutak[2]

[1]Yeditepe University, Türkiye; hulya.kilic@yeditepe.edu.tr

[2]Bogazici University, Türkiye

Teacher training programs are crucial for supporting teacher candidates' professional development but candidates' beliefs, perceptions and motivations about teaching and learning are likely to influence how much they are benefited from the opportunities provided in those programs. In this paper, we aimed to explore how preservice mathematics teachers' self-perceptions about their knowledge for teaching varies with respect to some variables. We collected data from a total of 749 elementary and secondary mathematics preservice teachers from 10 universities via Self-perception about Teacher Knowledge scale. Preservice teachers' self-perceptions varied with respect to their universities, year at the program (junior vs senior students), teaching experiences and commitment to teach after graduating from their programs.

Keywords: Teacher knowledge, self-perception, teaching experience, becoming a teacher.

Introduction

Teacher training is one of the hot topics of educational specialists' and policymakers' agenda since many studies point out the fact that quality in education can be achieved and sustained by leveraging quality of teachers in terms of their knowledge and skills for effective teaching (Darling Hammond, 2020). The structure, coverage and dissemination of teacher training programs vary with respect to countries' vision, culture, needs, policies, economics and so forth, however, equipping candidates with knowledge of subject matter to be taught and subject-specific pedagogy of teaching and learning are common for any teacher training programs (Cochran-Smith et al., 2015; Kleickmann et al., 2013). For instance, mathematics teacher candidates are basically given opportunities to learn about and/or make practice about mathematics, how to teach mathematics and tailor their instruction according to readiness and needs of students in those teacher training programs.

For effective mathematics teaching, teachers should be equipped with strong mathematical and pedagogical knowledge for teaching accompanied with well-developed teaching skills. Ball and her colleagues (2008) described such knowledge as *mathematical knowledge for teaching* (MKT) as a composition of six knowledge types categorized under subject matter (SMK) and pedagogical content knowledge (PCK). In terms of SMK, they noted that a teacher should know about the fundamentals of mathematics, relationships between mathematical concepts, facts, and procedures as well as their connections with other disciplines and real life. They described PCK as knowing about effective and appropriate ways of teaching mathematics (knowledge of content and teaching (KCT)), how students learn mathematics including their difficulties and misconceptions in math (knowledge of content and students (KCS)) and coverage and aims of math curriculum identified for a specific grade level (curriculum knowledge (CK)). Studies revealed that many mathematics teacher education programs

somehow offer courses aiming to address and foster candidates' knowledge and skills about these components of MKT (Cochran-Smith et al., 2015).

Besides opportunities given at teacher training programs for developing professional knowledge and skills, teacher candidates' intrinsic and extrinsic motivations, beliefs and thoughts about teaching and learning are likely to influence their performance in those programs as well as after they begin to work as a teacher at schools (Baumert & Kunter, 2013; Charalambous, 2015; Fray & Gore, 2018). When preservice teachers are dedicated to be a teacher, have higher level of self-efficacy beliefs and perceptions about their teaching abilities, perceiving teaching as a valuable profession and so forth, they become more eager to learn how to be a *good* teacher and improve their teaching skills (e.g., Barış Pekmezci & Dağdeviren Ertaş, 2024; Fray & Gore, 2018). More specifically, preservice teachers feel more confident about their knowledge and skills as they do their practicum at schools or have some informal teaching experiences (Clark et al., 2015; Ferguson et al., 2023). However, studies revealed that preservice or in service teachers may lack of well-developed teacher knowledge and skills even though they possess high level of motivation for teaching and self-perceptions of themselves as a teacher (e.g., Odysseos & Pittalis, 2023). Therefore, in our study, we aimed to explore how preservice mathematics teachers perceive their knowledge for teaching and whether their perceptions are compatible with their actual performance on a short test consisted of items measuring their knowledge.

In this paper, however, we wanted to discuss how preservice teachers' (PSTs) self-perceptions about their knowledge for teaching, specifically their MKT, varied with respect to their teacher training programs, year at the program, overall academic achievement in the program, informal teaching experience and willingness to work as a teacher after completing the program. We would also discuss having teaching experience and commitment to become a teacher nourished PSTs' self-perception about which MKT component more. Moreover, we would talk about stimuli behind PSTs' choice of teaching as a profession.

Methods

Participants

In this study we used convenient sampling such that we asked our colleagues whether they would inform their junior (Year 3) and senior (Year 4) preservice teachers from elementary and/or secondary mathematics education program about the study. In Türkiye, elementary mathematics PSTs are trained to teach grades from 5 to 8 (middle school), while secondary mathematics PSTs are supposed to teach grades from 9 to 12 (high school). Both elementary (EMT) and secondary (SMT) mathematics teaching are 4-year bachelor programs administered under faculty of education. The candidates take common core mathematics and pedagogy courses in the first two-years of the program but later they begin to take area-specific departmental courses. They complete a total of 144 hours of practicum at relevant schools in their last year while taking some other courses at the university. We collected data from 749 PSTs (551 female, 198 male) from 10 universities such that three of them are ranked at top 10 public universities on teacher education according to Turkish Higher Education Council (HEC) ranking system which is based on students' scores obtained from university entrance exam (UEE) and two of them were foundation (private) universities offering elementary mathematics

teaching program (see www.yokatlas.gov.tr). Moreover, there are 12 universities offering SMT programs and 86 universities offering EMT programs such that UEE scores of SMT programs are generally higher than EMT programs in Türkiye.

Data collection and analysis

We revised our earlier *Self-perception about Teacher Knowledge* scale (Kilic, 2015) which consisted of 24 items with 5-point Likert type style. Based on our expertise, experiences in our earlier studies and relevant literature, we added four new items to strengthen the items having respectively lower item-loading in the previous study and asked participants to give a point between 1 and 10 (from least to most) to indicate how much they agreed about given statements. After eliminating cross-loading items, we obtained a 24-item scale with 5 factors (Chi-square/df=3.446, GFI=.905, CFI=.942, RMSEA=.061) and .91 as reliability coefficient. We named the factors as pedagogical knowledge (PK) (4 items), knowledge of content and teaching (KCT) (10 items), knowledge of content and students (KCS) (4 items), curriculum knowledge (CK) (2 items) and subject matter knowledge (SMK) (4 items) based on Ball and colleagues' MKT model (see Ball et al., 2008). Sample items from each factor is given below in Table 1.

Table 1: Sample items from self-perception about teacher knowledge scale

Item	Factor
I can use appropriate teaching strategies according to students' needs	PK
I can prepare tasks to support students' mathematical thinking skills	KCT
I have a repertoire of students' possible misconceptions in mathematics	KCS
I know about the order of topics with respect to grade levels identified in official math curriculum	CK
I have a strong content knowledge in mathematics	SMK

For ease of interpretation, we categorized PSTs' perceptions about their knowledge based on their total scores obtained from the scale as follows: A score between 210 and 240 refers to very high, 170 and 210 is high, 130 and 170 is moderate, 90 and 130 is low and below 90 is very low self-perception about teacher knowledge. We also used a 15-item form to collect some demographic information about participants including their GPA, teaching experiences and willingness to work as a teacher after graduation. Almost all items in the form, they were given options to select (e.g., their year in the program) which fitted to them and we used that data to classify the participants for further analysis. There were a few items asking them to write their answers (e.g., which grade levels they had teaching experiences) and we used that data to calculate frequencies of given answers.

Results

In this study, we applied *Self-perception about Teacher Knowledge* scale to elementary (EMT) and secondary (SMT) mathematics preservice teachers to collect data however we preferred to analyse some of the findings separately for further discussion. We initially looked at whether PSTs' perceptions varied with respect to which program they enrolled and we found that there was no significant difference between EMT and SMT preservice teachers' self-perceptions ($t_{747,.05}$=-1.022, p=.307). As seen in Table 2, both EMT and SMT mathematics preservice teachers' perceptions about

their knowledge was "high" according to our classification. Although there were some EMT preservice teachers with having low level of perception, almost all SMT preservice teachers had at least moderate level of self-perception about their teacher knowledge.

Table 2: Descriptive analysis of self-perception about teacher knowledge scale

	N	Min	Max	Mean	Std. dev.
EMT					
Year 3	336	109	236	176.05	25.2
Year 4	320	101	240	185.92	23.25
Total	**656**	**101**	**240**	**180.86**	**24.75**
SMT					
Year 3	44	131	215	181.27	20.30
Year 4	49	121	227	185.73	22.50
Total	**93**	**121**	**227**	**183.62**	**21.49**

We analysed how EMT and SMT preservice teachers' perceptions about their teacher knowledge varied with respect to their universities, the year in the program, academic achievement (GPA) and teaching experiences as shown in Table 3. We found that universities, year in the program and teaching experience led significant variance among EMT preservice teachers' self-perceptions but not for SMT preservice teachers'.

Table 3: Analysis of preservice teachers' self-perceptions about their teacher knowledge

	Yes	453	182.58	25.10			80	183.09	20.86		

Notes: 1)"PubUniv" refers to public universities and "PriUniv" refers to foundation universities. 2) Each type of university is ranked according to Turkish HEC ranking system of universities in terms of students' UEE results. 3) SMT program are only offered in PubUniv1, PubUniv2, PubUniv3 and PubUniv7.

EMT preservice teachers who were from top 3 universities in our list indicated very close mean scores and their self-perceptions were significantly higher than PubUniv5 and PriUniv 2 according to post hoc analysis results. Moreover, the effect size of this difference can be accepted as at moderate level

(Muijs, 2011). Although SMT preservice teachers from the highest ranked public university revealed the highest mean score among all participants, their mean score did not vary significantly from other universities offering SMT program. In terms of the year at the program, senior preservice teachers were feeling more confident about their teacher knowledge as expected. The difference between EMT preservice teachers was significant with a modest level of effect size while it was not the case for SMT preservice teachers. We observed that as SMT preservice teachers' academic achievement score (GPA) got higher, they felt more confident in their knowledge but such difference was not significant as seen in Table 3.

Among 656 EMT preservice teachers 453 of them (69%), among 93 SMT preservice teachers 80 (86%) of them noted that they had some kind of teaching experiences in the form of tutoring (approx. 63%) or part time teaching at a private institution (approx. 8%) or being a volunteer in faculty-school collaboration programs (<1%) or taking a part in community service studies (approx. 4%). Almost half of EMT preservice teachers (approx. 51%) noted that they had experience with middle school students while 29% of them had experience with either both primary and middle school students or middle school and high school students. SMT preservice teachers mostly had experience with high school students (35%) or both middle school and high school students (40%).

We observed that EMT preservice teachers with teaching experience perceived themselves as possessing higher knowledge for teaching in comparison to ones who did not have such an experience while it was not the case, even conflicting, for SMT preservice teachers as seen in Table 3. However, the effect size of such difference between the groups was small. We further analysed on which component of MKT that teaching experiences led a variance between the groups. EMT preservice teachers with teaching experiences revealed higher self-conception about their CK ($t_{654, .05}$=2.643, p=.008, d=.223), KCS ($t_{654, .05}$=2.242, p=.025, d=.189), and SMK ($t_{654, .05}$=2.025, p=.043, d=.171) as well as PK ($t_{654, .05}$=2.626, p=.009, d=.222) with respect to ones who did not have such experiences. Although PSTs with teaching experiences noted higher self-perception about their KCT (M=7.87, SD=1.11), it was not significantly higher than from PSTs with no teaching experience (M=7.71, SD=1.13).

Because PSTs had high self-perceptions about their teacher knowledge, we wondered whether they wanted to work as a teacher after graduating from their programs. Approximately 91% of EMT and 90% of SMT preservice teachers declared that they wanted to work as a teacher. Those of EMT preservice teachers had higher self-perception about their teacher knowledge with respect to ones who did not want to ($t_{643, .05}$=2.264, p=.024, d=.336) where the effect size of such variance was at modest level. In terms of MKT components, EMT preservice teachers revealed higher self-conception about their KCS ($t_{643, .05}$=2.883, p=.004, d=.227) and KCT ($t_{643, .05}$=2.164, p=.024, d=.336) as well as PK ($t_{643, .05}$=2.170, p=.030, d=.323) with respect to ones who did not want to do teaching. We did not observe such a difference among SMT preservice teachers.

We also looked at the distribution of PSTs with respect to their universities, year at the program, GPA, and teaching experiences in terms of commitment to teach after completing their programs. Approximately one third of PSTs who wanted to work as a teacher were from top 3 universities in our sample while approx. half of them from the last 3 public universities. In line with this finding,

approx. 58% of PSTs who did not want to work as a teacher were from top 3 universities while 26% of them from the last 3 public universities. Moreover, both junior (approx. 90%) and senior (approx. 94%) PSTs were very dedicated to work as a teacher when they completed their program. Similarly, 95% of PSTs with GPA between 3.00-4.00 and 90% of preservice teachers with GPA between 2.00-3.00 expressed their desire to work as a teacher. Furthermore, approx. 72% of PSTs having some sort of teaching experiences noted that they wanted to work as a teacher when they accomplished their program.

We asked for stimuli behind PSTs' choice of working as a teacher or not when graduate from the program. Among the others, the most popular answers for working as a teacher were i) to like teaching as a profession (approx. 38%), ii) to had been enrolled to the program to become a teacher (approx. 14%) and iii) to like mathematics and kids (approx. 15%). The PSTs noted that they did not want to work as a teacher because i) they realized that teaching is not congruent to themselves, ii) teachers are getting low salaries and iii) they want to do another job (approx. 20% each).

Discussion

In this paper, we wanted to discuss how preservice mathematics teachers' self-perceptions about their teacher knowledge varied with respect to some factors including the program and universities they enrolled, year at the program, teaching experience, desire to work as a teacher after graduation. We found that being enrolled in EMT or SMT program did not make a difference in PSTs' perceptions but other factors led differences with statistically small or moderate level of effect sizes.

The preservice teachers of EMT programs from the highest-ranking universities revealed significantly higher self-perceptions about their knowledge for teaching. Those universities were the oldest universities with faculty of education in Türkiye whose graduates are accepted as well-qualified teachers or educators of the country. Therefore, PSTs might feel that their EMT or SMT programs are designed in a way to support their professional development and they would become well-qualified mathematics teachers in the field. Because those universities accept candidates who perform very well at university entrance exam, PSTs' self-conceptions about themselves might be valid since these PSTs' SMK and PCK tend to be higher than their peers in other universities (Kleickmann, 2013). From SMT preservice teachers' lenses, their teacher training programs and universities enabled them similar opportunities for development of their professional knowledge and skills as different from their EMT preservice teacher peers. Additionally, the number of participants from SMT programs was comparably lower than EMT programs which possibly had an effect on the results of statistical analysis, that is, even though there a difference between their mean scores, it was not significant. Furthermore, the reason behind the lowest mean obtained from EMT preservice teachers from recently established public university might be the PSTs' suspicious about the quality of their program or coverage of their courses or proficiency of their instructors or all. However, SMT participants were from old public universities which carry out the program for decades.

As expected, senior PSTs' self-perceptions about their knowledge for teaching was higher than junior PSTs because they had already taken more courses about teaching mathematics (Ferguson et al., 2023). However, PSTs' academic achievement (GPA) did not make any significant difference in their

self-perceptions. PSTs might think that no matter how they are performing in their courses, their programs are already designed to improve their professional knowledge and skills.

For EMT preservice teachers having a teaching experience led a significant difference in terms of self-perceptions while it was not the case for SMT preservice teachers. Seemingly, EMT preservice teachers thought that they learned from their practice more than theoretical knowledge provided in their programs (Ferguson et al., 2023) as opposed to studies showing that PSTs' self-perception about their teaching abilities gets lower as they have more practice in teaching (e.g., Clark et al., 2015) which probably was the case for SMT preservice teachers in our sample. On the other hand, as we expected, working closely with students enabled PSTs to perceive themselves as possessing the knowledge of mathematics they are teaching (SMK), coverage of the math curriculum (CK), how students learn mathematics and their possible difficulties and misconceptions (KCS) and appropriate teaching strategies and methods (PK) in comparison to PSTs with no teaching experience. Moreover, EMT preservice teachers with teaching experience desire to work as a teacher when they graduate more than PSTs with no teaching experience. They perceived that they were well-equipped in terms of KCS, KCT and PK which can be thought as critical components of PCK for effective teaching.

Most of PSTs aimed to work as a mathematics teacher when graduate from their programs because they were mostly intrinsically motivated to be teachers as noted by other studies (Fray & Gore, 2018). The PSTs stated that they like teaching, mathematics and kids and their training programs provide opportunities to improve their professional knowledge and skills. However, approx. one third of PSTs from top 3 universities declared their intention to work as a teacher when they complete the program while approx. 58% did not want to. Even though these universities were thought as the pioneers in teacher training, low salaries and facilities given for teachers in Türkiye might be the reason for changing their career plans for those PSTs (Fray & Gore, 2018). Indeed, job opportunities after graduating from teacher training programs is getting a serious treat for achieving and sustaining quality in teacher training and school education in long run in Türkiye.

Briefly, PSTs thought that their teacher training programs provided enough opportunities to learn about and make a practice for being a mathematics teacher and they wanted to do their job when they accomplish their programs. Moreover, they are learning from their informal teaching experiences which is likely to contribute to development of their PCK. Although PSTs' self-perceptions about their knowledge for teaching should be confirmed by data based on their actual performance on a knowledge test to discuss the quality of their teacher training programs, we can conclude that teacher training programs are providing similar opportunities for PSTs and candidates are mostly satisfied with those given opportunities. Thus, they want to work as a teacher when they graduate from their programs even though their salaries will be lower than other professions.

The Theory of planned behavior as a tool for linking beliefs and knowledge within the MTSK model

Monika Krišáková and Veronika Hubeňáková

Pavol Jozef Šafárik University in Košice, Faculty of Science, Košice, Slovakia;
monika.krisakova@upjs.sk

The Mathematics Teacher's Specialised Knowledge model (MTSK) is the inaugural model to incorporate teachers' beliefs alongside their knowledge. However, most studies utilising this model address either knowledge or beliefs in isolation. This study proposes a framework for elucidating the reciprocal relationship between them through the Theory of Planned Behaviour (TPB). In the paper, we demonstrate connections between the beliefs of pre-service teachers (PSTs) and three subdomains of the MTSK model: Knowledge of Topics (KoT), Knowledge of Mathematics Teaching (KMT), and Knowledge of Features of Learning Mathematics (KFLM) in the context of functional thinking development.

Keywords: Teachers' beliefs, teachers' knowledge, MTSK model, Theory of planned behaviour.

Introduction

A number of researchers have highlighted the interrelated nature of teachers' knowledge and beliefs, and their concomitant impact on the quality of teaching (e.g., Thompson, 1992; Charalambous, 2015). The frequently used model *Mathematics Knowledge for Teaching* (MKT) (Ball et al., 2008) was the subject of criticism precisely because it did not include the teacher's beliefs in any way. The newer model *Mathematics Teacher's Specialised Knowledge* (MTSK) (Carrillo-Yañez et al., 2018) sought to address this issue. However, even when beliefs have been incorporated into the model, only few papers (utilising the MTSK model) have explicitly discussed both knowledge and beliefs (e.g., Vasco & Climent, 2017).

One of the reasons for studying beliefs is to gain insight into their potential influence on human behavior. In this regard, the Theory of Planned Behavior (TPB) (developed by Icek Ajzen, 1991) may be a useful theoretical framework to consider, as it has been applied in a range of research areas and has demonstrated efficacy in linking beliefs and behavior, or the intention to engage in a specific behavior. It is also being employed with increasing frequency in the design and evaluation of interventions aimed at modifying behavior (Ajzen & Schmidt, 2020). According to Bosnjak et al. (2020, p. 352) "the TPB is one of the most applied theories in the social and behavioral sciences." This prompts the question of whether there are any connections to be made between the two models under discussion here, namely MTSK and TPB. The following research question is therefore posed: what are the connections between the various areas of MTSK knowledge and beliefs from the perspective of TPB? As the topic influences the content of teachers' knowledge and teachers' beliefs about teaching and learning such a topic (Carrillo-Yañez et al., 2018), we limit our response in this paper to functional thinking and its development.

This study was conducted as part of the FunThink Erasmus+ project, which aimed to enhance functional thinking from primary to upper secondary school. The project's objective was to develop

functional thinking, which can be defined as a mode of thinking that is oriented towards relations, dependencies, and changes. This involves the ability to identify, generalise, and abstract relations between co-varying quantities, to represent these relations through language, symbols, and graphs, and to utilise generalised representations in problem-solving situations (Pittalis et al., 2020).

Theoretical background

MTSK model

The MTSK model (Carrillo-Yañez et al., 2018) is an analytical tool designed for examining the complexity of teachers' knowledge. It consists of three main parts: *Mathematical Knowledge* (MK), *Pedagogical Content Knowledge* (PCK) and Beliefs. MK consists of the subdomains: *Knowledge of topics* (KoT), *Knowledge of the structure of mathematics* (KSM) and *Knowledge of practices in mathematics* (KPM). PCK includes three further subdomains: *Knowledge of mathematics teaching* (KMT), *Knowledge of features of learning mathematics* (KFLM) and *Knowledge of mathematics learning standards* (KMLS). Beliefs are divided into two types, *Beliefs about mathematics* and *Beliefs about mathematics teaching and learning*. They are placed at the centre of the model to emphasise the reciprocity between them and the other subdomains. Given the restricted length of the paper, we provide a brief overview of the three subdomains KoT, KMT, and KFLM, as we will use them to illustrate the connection between the "knowledge" subdomain of MTSK and beliefs.

KoT describes what a teacher should know about the content of the mathematics they teach. It comprises four categories: (1) *Definitions, properties and foundations* includes knowledge of the relationships between concepts and properties within the subject unit, (2) *Procedures* includes knowledge of different procedures for solving problems within the subject, including their critical evaluation in terms of conditions of use, (3) *Registers of representation* includes the ability to use different representations to discuss a concept and to solve problems, (4) *Phenomenology and applications* includes knowledge of the different contexts in which the topic can be applied.

KMT concerns knowledge about the teaching of mathematics and includes the following three categories: (1) *Theories of mathematics teaching* which can be applied to the design of learning opportunities, (2) *Teaching resources (physical and digital)* that can be used for specific mathematical content (3) *Strategies, techniques, tasks and examples* (their potential or limitations for teaching specific mathematical content).

KFLM focuses on understanding how mathematics is learned. KFLM contains four categories: (1) *Theories of mathematical learning* is knowledge of theories of the cognitive development of the pupil, (2) *Strengths and weaknesses in learning mathematics* that pupils have or might have in relation to the mathematical content, (3) *Ways pupils interact with mathematical conten*t is knowledge of pupils' strategies, and (4) *Emotional aspects of learning mathematics,* which includes awareness of the emotional and motivational aspects that influence pupils' engagement and success.

Theory of Planned Behavior

To conceptualize beliefs, we will use the Theory of Planned Behavior (TPB) (Ajzen, 1991). The TPB describes how do beliefs influence the *Intention* to conduct a behavior of interest, and subsequently

with consideration of *Actual (or Perceived) behavioral control*, they influence particular behavior (Figure 1).

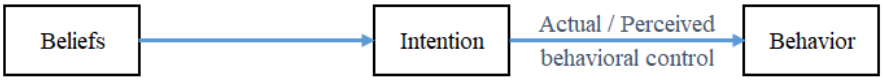

Figure 1: Simplified version of the TPB

The TPB is applicable if the behavior of interest can be defined in terms of its *target*, the *action* involved, the *context* in which it occurs, and the *time* frame. Each of these elements can be defined at varying levels of specificity or generality (Ajzen & Schmidt, 2020). For example, to study the implementation of inquiry-based learning in mathematics education may define the behavior such as "using inquiry-based learning to introduce the concept of a linear function".

Ajzen (1991, p. 189) assumes that "people can hold a great many beliefs about any given behavior, but they can attend to only a relatively small number at any given moment", these are *salient beliefs.* The TPB distinguishes between three categories of salient beliefs. Simply said, there are beliefs about the usefulness and/or pleasantness of the expected outcomes, beliefs about other people beliefs and beliefs about one's capacity to control the behavior. In the model, we can find them as *Behavioral beliefs*, *Normative beliefs* and *Control beliefs.* For the next analysis, we need to understand these categories. Figure 2 shows the structural TPB model as it is currently conceptualised.

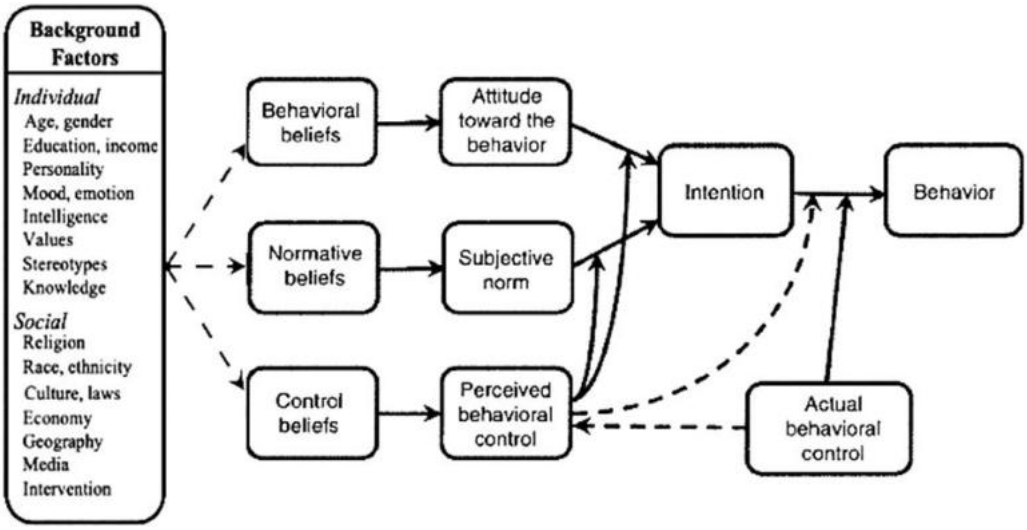

Figure 2: Theory of Planned Behavior with background factors (Ajzen, 2019)

As we can see, the core of the model is a causal chain of effects that begins with the formation of salient beliefs. A *behavioral belief* is the subjective probability that the behavior will produce a given outcome (*instrumental behavioral beliefs*) or experience (*experiential behavioral beliefs*). For example, the belief that if pupils discover something on their own, they understand it better. Behavioral beliefs are theorized to create positive or negative *attitudes toward behavior*. These beliefs answer the question "What do I think about a given behavior?". A *normative belief* is the subjective probability that a significant referent (e.g., leadership, parents, pupils) encourages performance of the behavior or is likely to perform the behavior him- or herself. Normative beliefs contribute to the

overall perceived social pressure to engage in the behavior (*subjective norm*). These beliefs answer the question "What do I think others think about a given behavior?". *Control beliefs* are related to the perceived presence of factors that may facilitate or impede performance of the behavior, such as required skills and abilities, availability or lack of time, money, and other resources. For example, the belief that I can't manage group setting in the classroom. Control beliefs answer the question "Can I perform a given behavior?". They determine the *perceived behavioral control* which refers to people's perceptions of their ability to perform a given behavior. It relates to a specific context and not to a general predisposition, so it usually varies in different situations. Perceived behavioral control is assumed to moderate the influence of attitude and subjective norm on behavioral intention. The *actual behavioral control* is assumed to moderate the effect of intention on behavior. Usually, knowledge about actual behavioral control is limited, therefore perceived behavioral control is used as a proxy to aid in the prediction of behavior (see Figure 2). As for background factors, they also influence intentions and behavior indirectly by their effects on salient beliefs. The dotted arrows in the diagram indicate that there is no necessary connection between background factors and beliefs. Whether or not a particular belief is influenced by a particular background factor is an empirical question (Ajzen & Schmidt, 2020).

Methods

One of the intellectual outputs of the FunThink Erasmus+ project is a course designed for pre-service teachers (PSTs). Data collection occurred at Pavol Jozef Šafárik University in Košice, Slovakia, during the autumn of 2023. This mandatory course consisted of 26 teaching hours, attended by 19 PSTs (grades 5-13), and was placed in the first semester of their master's studies. For them, it was the first course focused on the didactics of mathematics. The PSTs experienced different learning environments based on the principles of inquiry, digital tool use, embodiment and situatedness. They observed and reflected on classroom recordings, discussed pupils' solutions and potential misconceptions.

Each PST submitted two lesson plans: one at the beginning of the course (the pre-lesson plan) and another at the end of the course (the post-lesson plan). Both plans focused on introducing the concept of a linear function, which is part of the Slovak grade 9 curriculum. For the post-lesson plan, PSTs revised the pre-lesson plan by making necessary adjustments and adding comments to explain their changes. Additionally, the post-lesson plan was included in the final assessment. The aforementioned lesson plans were collected as data for our research purposes; however, they were not implemented in actual classroom settings. The pre-service teachers had no prior experience of teaching, although they had started participating in classroom observations in the autumn of 2023. Moreover, eight PSTs were interviewed at the beginning of the semester, and seven of them were also interviewed at the end. Participants were selected based on their pre-lesson plans. All participants were informed about the scientific and developmental objectives of the research.

The semi-structured interviews were transcribed and subsequently analysed together with the lesson plans using content analysis methods (Krippendorf, 1989), examining the PSTs' statements and comments to identify evidence of their knowledge and beliefs. The data were coded by both authors independently using Atlas.ti software. Various MTSK and TPB constructs were used as codes.

The coding was then compared. In this paper, we present data analyses from three PSTs where the clear connections between the models were visible.

Results

Our analysis of the interviews and lesson plans revealed several interesting links between knowledge and beliefs from the perspective of TPB. We describe them in the next paragraphs. The lesson plans reflect the behavioral *Intentions* of PSTs in introducing the concept of a linear function.

KFLM forming behavioral beliefs

Firstly, we identified multiple instances where the Knowledge of Features of Learning Mathematics led to the formation of a belief, which was subsequently integrated into the lesson plan. We will provide two examples.

Example 1: The course addressed the issue of misconceptions that can arise when the concept of a linear function is not adequately taught and learned. Student Nina illustrated how this knowledge, classified as KFLM, influenced her post-lesson plan.

> Nina: In the post-lesson plan, I tried to be more mindful of misconceptions that could immediately arise among the pupils. In the pre-lesson plan, I only started with a task that involved an increasing linear function. In the post-lesson plan, I incorporated a decreasing function as well, so that from the start, it was clear for pupils that not everything is increasing. [...] I hadn't really thought about that in the pre-lesson plan – that I should be careful there.

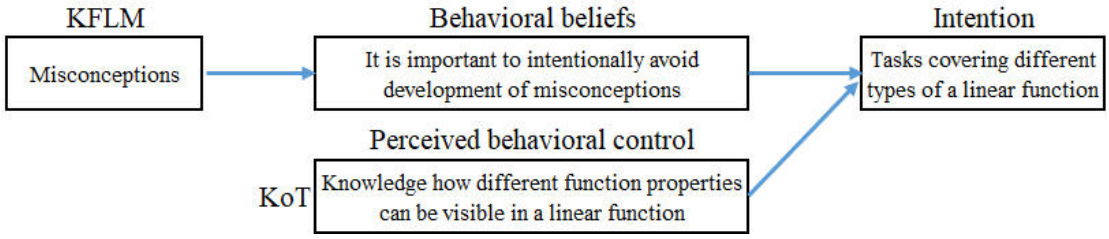

Figure 3: Beliefs as a knowledge (KoT) activator

As Figure 3 describes, Nina's statement indicates that the modification to the lesson plan was not solely a consequence of KFLM growth. She also provided an argumentation based on Knowledge of topics (KoT). Without knowledge about the different properties which linear functions can hold, it would not have been possible for her to choose appropriate tasks. Therefore, in this case, KoT can be considered a perceived behavioral control.

Example 2: During the course, PSTs were introduced to the concept of function as described by Pittalis et al. (2020), which also serves as a basis for developing pupils' functional thinking. Sára demonstrated how this knowledge was applied in the creation of her post-lesson plan.

> Sára: I really liked when we talked about those aspects of the concept of function. It was only then that I realized how that understanding was evolving. That in the beginning pupils seriously can't understand the function. Until they understand input-output, until they can find some kind of connection, [...] and that teaching the functions not only helps to learn the functions, but to learn, even to go through the whole process, those individual aspects.

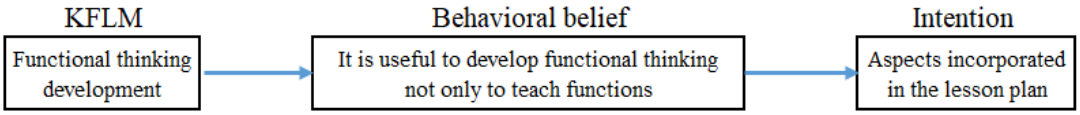

Figure 4: Knowledge (KFLM) as beliefs builder

From Sára's statement, we can infer that her decision to modify the lesson plan was informed not only by her understanding of the development of functional thinking but also by her belief that fostering functional thinking is a fundamental objective of mathematics education.

Limited content of knowledge as a perceived behavioral control

The next example is somewhat antithetical to the preceding Example 1. Here, PST articulated a behavioural belief that was not substantiated by the requisite knowledge. This contradiction resulted in a lesson plan that did not sufficiently meet the expectations for structure and goal fulfilment. It is from the beginning of the semester.

Example 3: Some of the PSTs, including Sára, were interviewed after they were present at the classroom observations. At these observations she could see inquiry-based teaching and she came up with the following thoughts:

Sára: I really liked it when I went to observe the class for the first time. Teacher gave group work, and it wasn't like she dictated the formula for combinations and said, "This is how it will be, apply it to the examples." That's what I experienced. But she gave the pupils three examples so they could discover the formula based on those examples. She called it inquiry-based learning, and it was such a shock for me, like, "Aha, there's a higher purpose," and she started talking about how she leads them to explore. Then they had that "Eureka" moment, realizing they had discovered something, and it wasn't just about memorizing the formula, but they came up with it themselves. […] I think I still don't fully understand what inquiry-based learning is, but I think the conclusion of my lesson plan is somewhat inquiry-based. Pupils can play and experiment there, and it's not just about receiving information, but they are also involved in the process of creating those functions.

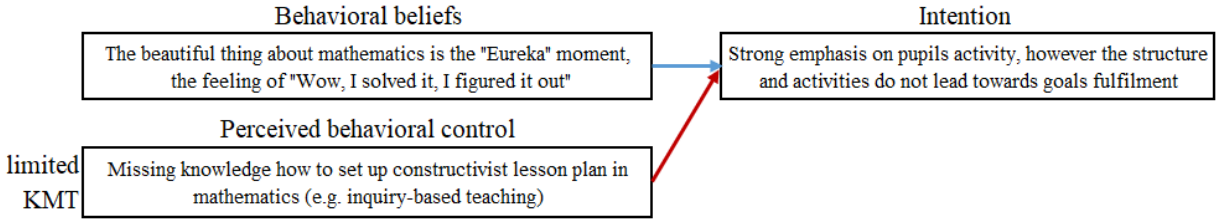

Figure 5: Limited knowledge (KMT) as a barrier of beliefs

As pinpointed in Figure 5, Sara's behavioral beliefs, also derived from an interview, led to a positive attitude toward constructivist teaching. Because she was unfamiliar with this type of teaching in mathematics, she was unable to develop a pre-lesson plan properly. Therefore, in this case, limited Knowledge of Mathematics Teaching (KMT) about the constructivist approach in mathematics, was perceived behavioral control.

Similarly, we found examples where limited KoT (real-life application of functions) restricted PST Jana from incorporating real-life problems into her lesson plan. Even though, her behavioral beliefs were quite clear about it.

Control beliefs in opposition with behavioral beliefs

Increased Knowledge of Mathematics Teaching (experience, examples and theory behind inquiry way of teaching) has led to the development of new salient beliefs. The following illustration demonstrates that these beliefs can potentially be in conflict and mutually constraining.

Example 4: The PSTs were exposed to the practice of inquiry-based teaching during the course and classroom observation. These experiences led to the formation of new behavioral beliefs, which subsequently resulted in the development of positive attitudes. However, in case of Jana, these positive attitudes appeared to be overridden by strong perceived behavioral control formed by her control belief. This perceived control regarding time pressure occurred for Jana in both interviews.

Jana: But I always have this feeling that anything that's somehow different or extra, like when we covered inquiry-based learning, it's great, it's nice, everything's good, but I'm not sure if it won't take up too much of my time. Like, if it might steal time from the lesson. I'm not sure if the allocated time is really suited for it.

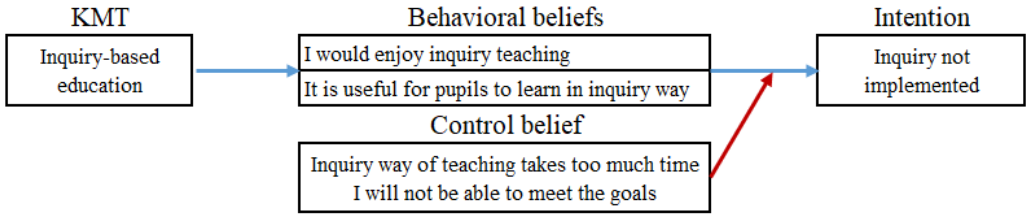

Figure 6: Control beliefs moderate behavioral beliefs

The other control beliefs that emerged from the other interviews were related to KMLS (a lack of experience with how topics are scaffolded) or KFLM (pupils' reactions and the specific needs of the particular class).

Discussion and implications for future research

Returning to our research question – *What are the connections between the various areas of MTSK knowledge and beliefs from the perspective of TPB?* – our findings reveal three distinct types of these links. Firstly, beliefs can prompt teachers to utilize the knowledge they already possess (Example 1). The second type is that knowledge can serve as a foundation for the formation of beliefs (Example 2). Another type of connection occurs when limited knowledge acts as a perceived behavioral control, preventing beliefs from being fully integrated into a lesson plan (Example 3). It is also worthy of note that Example 4 demonstrated how control beliefs moderate the influence of attitude on behavioral intention. Concerning normative beliefs, the PSTs only discussed the pupils, and did not mention other relevant referents. This could be a crucial factor influencing the resilience of newly acquired beliefs once they are put into practice, especially when parents, colleagues, and management come into play. These observations are deemed crucial for designing courses for PSTs, as further work to link the two models is believed to be beneficial.

Promoting and unpacking pre-service teachers' thinking about students with exceptional difficulties in learning mathematics in the context of a university course

Philipp Larmann[1], Leonie Horsch[1] Samira Reitmann[1] and Matthias Ludwig[1]

[1]Goethe University Frankfurt a.M., IDMI MATIS I, Germany; larmann@math.uni-frankfurt.de

In this paper, we present a qualitative study that unpacks pre-service teachers' thinking about students with exceptional difficulties in learning mathematics after they attended a specially designed university course on the topics of diagnosis and support with both theoretical input and practical application. The theoretical construct of subjective theories and the corresponding methodology was chosen for this study as it integrates knowledge and beliefs and thus provides the most detailed view of pre-service teachers' thinking. Our results show that pre-service teachers exhibit complex and adequate thinking about students with exceptional difficulties in learning mathematics after participating in the course, which contrasts with previous research on pre-service teachers. These findings provide a strong mandate for the large-scale implementation and research of similar courses to the one presented in this paper.

Keywords: Pre-service teachers' thinking, teacher education, learning difficulties, subjective theory.

Introduction

Previous studies have demonstrated that many pre-service teachers at the end of their university degree and thus at the end of their mathematics didactics training deviate greatly in their thinking about children with exceptional difficulties in learning mathematics from the desired perspectives and views on how to overcome the problems those students face (Larmann & Ludwig, 2023; Larmann & Ludwig, 2024). Often, the causes of exceptional difficulties are explained by purely personal factors and concrete actions for a more precise diagnosis of individual problems can hardly be named (Larmann & Ludwig, 2024; Gaidoschik et al., 2021). This is a major problem, as the number of children worldwide who are developing exceptional difficulties in learning mathematics is constantly increasing. The last Pisa study showed that, on average, 30% of children in Year 9 do not reach the minimum standards in mathematics, which represents an average increase of 10% since the previous survey (OECD, 2023).

Based on these findings, the Mathe.Kind project was launched at Goethe University Frankfurt, in the context of which a course for pre-service teachers was developed that is designed to prepare them for precisely this challenge and can be easily adapted by other teacher training institutions. With the present study, we now want to unpack the pre-service teachers thinking about students with exceptional difficulties in learning mathematics after participating in this course. Furthermore, we would like to know to what extent areas can be identified in which their thinking continues to deviate strongly from scientific theories on how to deal with children with exceptional difficulties in learning mathematics. To achieve this, we again utilize the theoretical construct of subjective theories to ultimately gain new indications for the adaptation of teacher education.

Exceptional difficulties in learning mathematics

As already mentioned, the OECD (2023) describes the problem that more and more students are no longer meeting the minimum standards in mathematics. These students have not been able to acquire basic mathematical skills over a longer period of time and are therefore severely disadvantaged in their ability to continue learning. By definition, they can thus be summarized under the term students with exceptional difficulties in learning mathematics (Gaidoschik et al., 2021), which, unlike the terms dyscalculia or learning disorder, extends its focus from the purely individual level to the student's entire learning process also including external influences from school and the socio-economic context in the consideration of the development of difficulties (Baiti et al., 2024). In most cases, these difficulties manifest themselves early on in basic mathematical competences. The understanding of natural numbers, the understanding of the decimal system and the understanding of arithmetic operations. Without an in-depth comprehension of these contents of primary school education, more advanced topics such as fractions or algebra cannot be understood and, in the best case, mastered through the use of familiarized strategies (Prediger et al., 2019). In order for teachers to face these challenges at primary and secondary level, they need a wide range of knowledge and an adequate thinking about causes, diagnostic possibilities and ways of preventive lesson design and support that enables them to provide assistance to affected students in overcoming their existing learning hurdles.

The Mathe.Kind university course

However, it seems that pre-service teachers largely do not have adequate ways of thinking about these topics (Larmann & Ludwig, 2024). For this reason, the Mathe.Kind project was established at the Goethe University Frankfurt with an associated university course, which could be chosen as an optional specialisation and is now offered in the second year for a maximum of 14 pre-service teachers per semester.

The underlying idea of the course is that pre-service secondary mathematics teachers meet once a week over the course of a full semester with a student with exceptional difficulties in learning mathematics from grade five to seven, identifying their individual problems and providing individualized support in a total of 12 sessions. The semester is organized in such a way that the course supervisor first contacts schools in the vicinity of the university and asks the available mathematics teachers to pass on an information and registration letter to parents of eligible children. The parents contacted can then register their children in the Mathe.Kind project, whereupon an approximately one-hour interview takes place between the course supervisor and the student in which the student's existing competence gaps are recorded and a decision for the inclusion into Mathe.Kind is made. For this purpose, the session is videotaped and then analysed by the course supervisor. Once all students participating in the project have been determined, two pre-service teachers are assigned to each student, thus forming a permanent support team for the rest of the semester. Before the support team meets for the first time, however, there are two full-day (8 hour) inputs for the pre-service teachers in which they are specifically prepared for the subject area of pedagogical diagnostics. Furthermore, they plan their own diagnostic interview with the student based on the protocol of the initial interview, which forms the basis for the first meeting with the child. The aim of this first

meeting is the detailed identification of existing competences that are important for the area of mathematics that is to be developed in the subsequent support and thus to obtain as precise a picture as possible of the child's mathematical foundation on which to build.

Before the weekly support program starts, the pre-service teachers receive a further one-day input, which provides an introduction to the topic of individual support. As every meeting of the support team is recorded on video, it is possible in the accompanying seminar during the semester to not only address other relevant topics in the area of support, such as the use of materials, language support or conversation training, but also to analyse video sequences from the support sessions in the plenum. This is always done using guiding questions that are thematically linked to the contents of the accompanying seminar. At the end of the semester, the pre-service teachers carry out a final diagnosis, the aim of which is to visualize the successes achieved by the child and to show which next steps need to be taken in order to close existing competence gaps. A final report is compiled on the basis of this diagnosis, which is presented to the respective child and their parents in an individual meeting.

Several factors that are crucial to change and promote ways of thinking were taken into account when designing this approach in the seminar. Firstly, it is important that the pre-service teachers' existing ideas about how to act are incorporated (Trevors, 2023; Dann, 1989), which is achieved by having them plan the diagnostic and support sessions independently. By subsequently reflecting on the procedure in the seminar and comparing it with the seminar content, a confrontation of the previous with new and more adequate ways of thinking and perspectives on students with exceptional difficulties in learning mathematics is then achieved (Trevors, 2023; Dann, 1989). It is important that this process of confrontation and ultimately change takes place in a practically relevant way, so that it becomes apparent that the new knowledge is better suited to overcome challenges, which is ensured by the continuous work in the support teams (Dann, 1989).

Subjective theories

The theoretical construct we have chosen to visualize pre-service teachers' thinking about students with exceptional difficulties in learning mathematics is that of subjective theories. Subjective theories are defined as the totality of a person's cognitions about a particular topic that contain at least implicit argumentation structures and fulfil the functions of explaining, predicting and guiding the person's behaviour and thus the functions of objective (scientific theories) for that person (Groeben & Scheele, 2000). The word totality allows us to include knowledge as well as attitudes or emotions into the understanding of those theories. If one follows this construct and transfers it to the educational context, this means that all professional actions of a teacher and thus also the interaction with students with exceptional difficulties in learning mathematics are based on patterns of thinking, knowledge and the structures organizing that knowledge (Dann, 1989). This construct differs from other constructs such as attitudes, beliefs or knowledge in the sense of TPACK or MTSK in that an integrated approach is chosen in which particular emphasis is placed on the connections between the contents of the various subjective theories. The more complex and adequate these argumentation structures and contents are, the more positive the effect on the success of teachers' actions (Dann, 1989), which is why a lack of fit between the subjective theories of pre-service teachers and teaching-relevant topics should give reason for adjustments to pre-service teacher trainings.

Research Questions

The following research questions arise from the above-mentioned motivation to unpack the thinking of pre-service teachers on how to deal with students with exceptional difficulties in learning mathematics:

RQ1: How do pre-service teachers' subjective theories on dealing with children with exceptional difficulties in learning mathematics who have attended a specialized training seminar on this issue look like?

RQ2: What areas in the subjective theories of those pre-service teachers can still be identified that differ from scientific research on students with exceptional difficulties in learning mathematics?

Methods

To answer the research questions, a qualitative interview study was conducted with four pre-service teachers who had taken part in the seminar course described above and who agreed to participate in the elaborate methodological structure. The methodology followed that of the Research Programme Subjective Theories (RST) (Groeben & Scheele, 2000), which was also used in the previous studies (Larmann & Ludwig, 2023; Larmann & Ludwig, 2024). The procedure is divided into four main steps, which we briefly present below, and which are described in the dialogue-consensus procedure of the RST (Groeben & Scheele, 2000). All interviews within the framework of the procedure were conducted by trained personnel who were not involved in the seminar in order to enable the interviewees to speak freely and without fear of negative judgement.

The first main step was a problem-centred semi-structured interview (Witzel, 2000), which aimed to capture the contents of the subjective theory. The interview was supported by a short questionnaire previously completed by the pre-service teacher, on the basis of which the introductory questions were generated. It is important in this step that the pre-service teacher can communicate their own personal view of the issue without the interviewer specifying exactly which aspects of the topic they should talk about. To this end, questions were asked about specific problem situations that may arise in the classroom. In the second main step, the interview was then analysed using a summative, qualitative content analysis (Mayring, 2022). For this purpose, the interview was first transcribed and divided into units of analyses. These units were then paraphrased and generalized in order to link them to didactic concepts (Mayring, 2022). The generalizations were then summarized in categories, which were then given a label that was as close as possible to the pre-service teacher's own phrasing. These labels were then written down on cards, the so-called content cards (Kindermann & Riegel, 2016). In the third main step, the subjective theories of the pre-service teachers were reconstructed with the help of a structure-formation-technique (Groeben & Scheele, 2000). For this purpose, the content cards are first validated, discarded or modified by the pre-service teacher and then related to each other using so-called structure cards. These structure cards symbolize different relationship structures between the content cards and thus represent the argumentation structures of the subjective theory. The result is a so-called structure image, which is a graphic representation of the subjective theory and is analysed in the fourth main step. The analysis was carried out in three sub-steps following the so-called Siegen variant (Kindermann & Riegel, 2016). Firstly, clusters were identified

that formed larger, related content areas in the subjective theory. These clusters were labelled and compiled into a rough cluster map. In the second step, these individual clusters were then analysed with their content and argumentation structures. This involved analysing not only the content and structure maps, but also the comments made by the pre-service teacher during the second interview on the individual content areas (Kindermann & Riegel, 2016). Finally, the clusters were placed in relation to each other, resulting in a detailed cluster map that depicts the subjective theory both descriptively and graphically (Kindermann & Riegel, 2016).

Results

In the following, we will briefly describe the subjective theories of the four participating pre-service teachers (PT 1 to PT 4) based on the detailed cluster maps. An exemplary detailed cluster map of PT 1 can be viewed in its entirety in Figure 1.

In his subjective theory, PT 1 describes dealing with children with exceptional difficulties as a chronological process from problems occurring in the classroom to diagnosis and support. Various causes for the development of difficulties are mentioned and a special focus is placed on a lack of competences in the mathematical content of the primary level. The diagnostic interview is the preferred method for identifying competence gaps and it is made clear that individualized support can only succeed on the basis of detailed diagnostics. Although individualized diagnostics are seen as a challenge, according to PT 1, there are even greater risks associated with not using them. Accordingly, PT 1 weighs up different forms of diagnosis. For individualized, but also supportive lessons, PT 1 refers to forms of teaching and materials that enable the respective student to discover new content themselves. To this end, lesson preparation and the teacher's own knowledge of methods and possible problems are regarded as fundamental. PT 2 attributes dyscalculia and mathematical difficulties to a lack of mathematical understanding and believes that targeted diagnosis and promotion of basic competences can help. For PT 2, the aim is to develop basic math concepts and strategies to enable long-term learning. A diagnosis-led and understanding-orientated approach is also mentioned for successful support. One of the main difficulties for PT 2 is reconciling large group sizes at school with individualized support. Poor teaching and a lack of support at home are identified as causes of persistent problems. PT 2 emphasizes the importance of teacher competence and in-service training.

PT 3 emphasizes in his subjective theory the importance of prerequisites such as attitude towards mathematics, basic ideas and prior knowledge that influence exceptional difficulties in learning mathematics. He takes a critical view of routine and memorized knowledge and demands that teachers take into account the heterogeneity in the classroom. A positive atmosphere during diagnosis, suitable tasks and careful evaluation are essential for him. He sees support as a long-term, individualized process in which cooperation with the students' parents is important. PT 3 sees the process as a challenge, but adequate support is at the centre of his considerations in the classroom. For PT 4, diagnosis and support are also central components of his subjective theory. He names various signs of difficulties, such as overwhelm, poor grades or disruptive behaviour. Quick intervention by the teacher is essential when these warning signs occur, as otherwise more long-term difficulties can arise. PT 4 emphasizes the importance of basic concepts and building on previous knowledge when providing support. Support should continue to be individually customized and not be limited to

current topics. For PT 4, open tasks and an error-friendly atmosphere are important for diagnosis. Cooperation with parents and strengthening the student's self-confidence in the classroom are also crucial for PT 4.

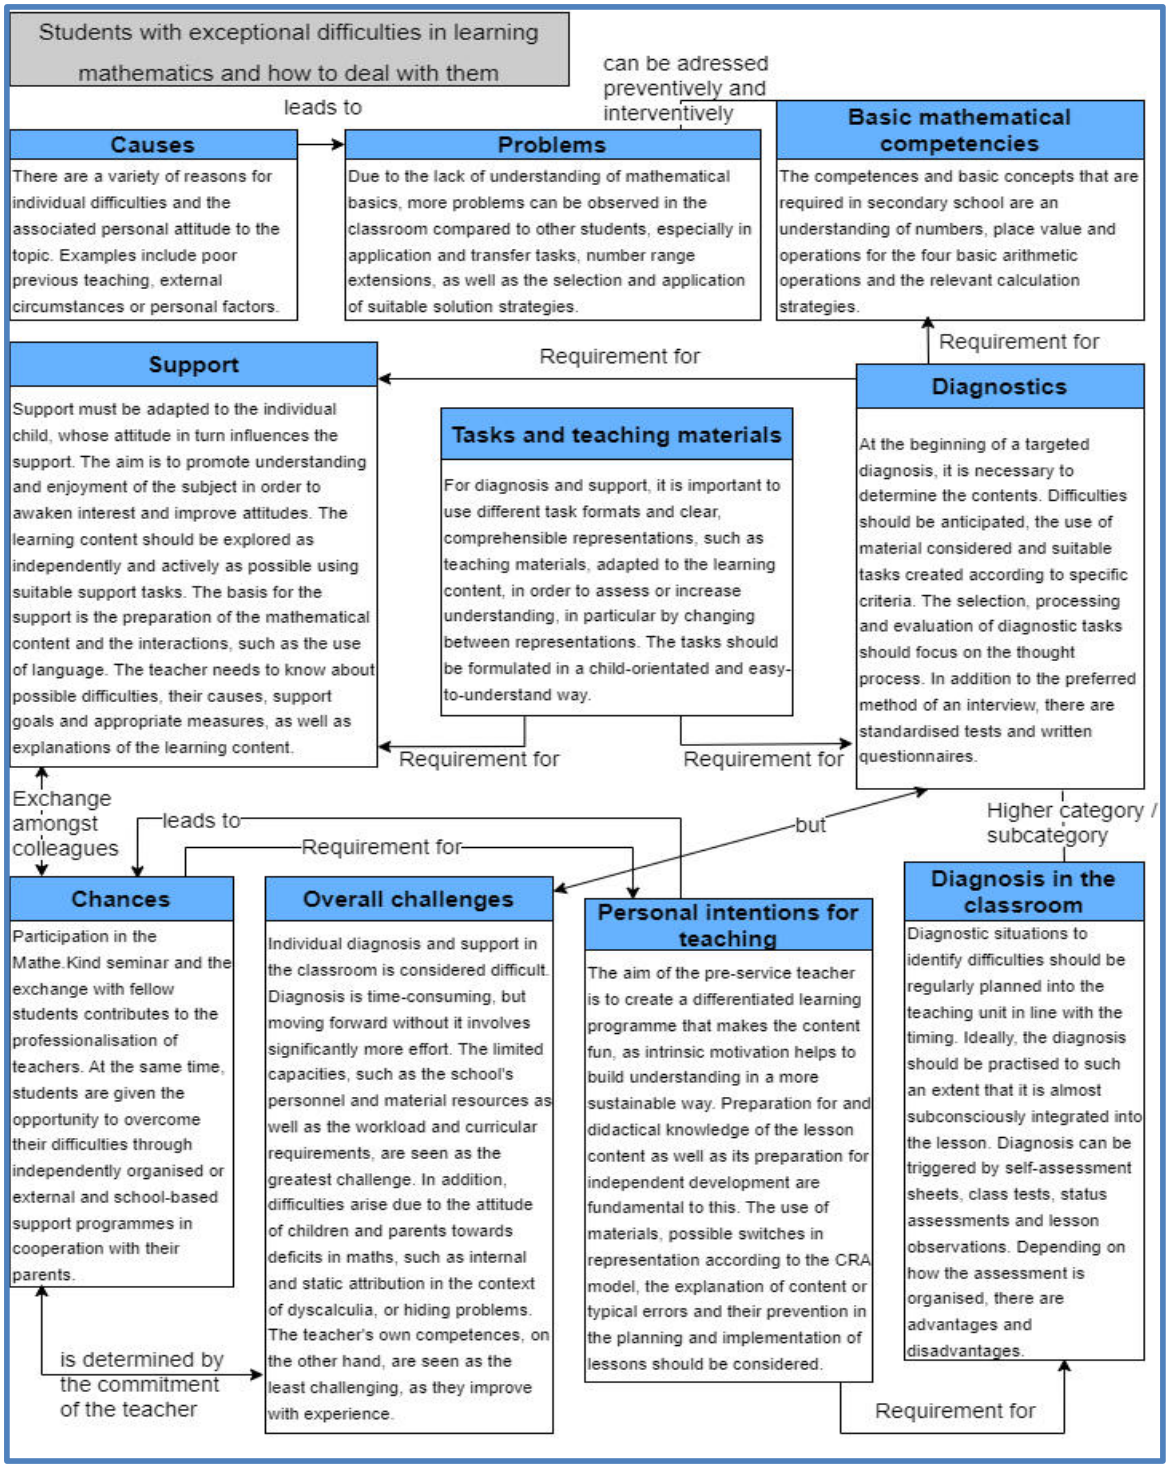

Figure 1: Exemplary detailed cluster map of the subjective theory of one of the participating pre-service teachers

Discussion and conclusion

The subjective theories of the pre-service teachers described above include many aspects that were not included in earlier studies (Larmann & Ludwig, 2024). When looking at causes, there is a strong focus on the mathematical content of the primary school level, which means that purely motivational and individual factors are pushed into the background. The social environment and previous schooling play a major role, which is why we can speak of a much broader way of thinking about the causes of exceptional difficulties in learning mathematics (Baiti et al., 2024). In all subjective theories, the area of diagnostics functions as a key focus alongside support. Within the clusters describing diagnostics, it is not just a list of possible methods, but a combination of possible approaches, materials and tasks needed for the diagnostic approaches as well as teacher behaviours that can help to reveal students' thinking on mathematical concepts. The focus on the diagnostic interview as the preferred method paired with less time-consuming methods for everyday teaching, such as observing students solving work assignments or making them complete short tests, speaks in favour of a tendency towards process-oriented diagnostics, which Gaidoschik et al. (2021) describe as desirable.

However, it is not only the contents of the subjective theories that can be perceived as positive. We also recognise a change in the argumentation structures between the different clusters. Support and diagnostics in particular are strongly interwoven in all of the subjective theories analysed and are mutually dependent. In general, diagnosis is seen as a necessary prerequisite for support, without which it is hardly possible to constantly adapt support to the individual needs of the child (Prediger et al., 2019). In addition, although all students recognise that dealing with students with exceptional difficulties in learning mathematics is challenging, they consider their diagnostic and support skills to be adequate, which was also not found in previous studies (Larmann & Ludwig, 2023; Larmann & Ludwig, 2024). It is also interesting that all pre-service teachers view the role of traditional extracurricular tutoring as critical, although this was neither part of the Mathe.Kind course nor discussed in any other way during the support sessions. They particularly criticised the lack of work on the students' actual problems and the fact that it is merely a treatment of symptoms, which may help in the short term but does not facilitate long-term learning. However, adequate extracurricular support is seen as desirable and helpful, which is also in line with the literature. (Gaidoschik et al., 2021).

In summary, it can be said that the pre-service teachers participating in the Mathe.Kind course have a predominantly adequate subjective theory of how to deal with students with exceptional difficulties in learning mathematics. With regard to our second research question, no areas could be identified in which the pre-service teachers' ways of thinking deviated strongly from scientific knowledge about dealing with those students. This may indicate that the described seminar can contribute to preparing pre-service teachers for corresponding tasks in everyday school life and to fostering their knowledge and thinking. In order to record the effect of the seminar on the subjective theories of the pre-service teachers more precisely, the next step will be to conduct a pre-test-post-test study with all course participants since these results can not be generalized based on the small sample size and the method.

Inconsistencies in the process of posing problems for use in class by pre-service teachers

Juan Pedro Martín[1], Ángeles Chico[1], Isabel Pascual[2], Miguel Montes[1]

[1]University of Huelva, Spain; miguel.montes@ddcc.uhu.es

[2]University of Sevilla, Spain

This study is framed in a research project, in which we explore the professional competence of posing problems for use in class. Specifically, we analyse the processes involved in formulating and solving problems in the output of 72 pre-service primary teachers who were asked to pose a two-stage problem based on the multiplication of fractions. By means of a methodology based on constant comparison, three types of inconsistencies were identified: inconsistencies between problem statement and numerical solution; inconsistencies between problem statement and diagrammatic solution; and inconsistencies between numerical and diagrammatic solutions. The results suggest that the pre-service teachers tend to solve the mental image of the problem they think they have formulated rather than the actual problem given in the problem statement.

Keywords: Problem posing, Teacher education, Pre-service primary teacher, Inconsistency.

Introduction

It is widely recognised that problem solving should be both vehicle and objective of mathematics education (NCTM, 2020). Consequently, teachers need to be competent formulators of suitable classroom problems (Kilpatrick, 1987). Nevertheless, there are gaps in the research into problem posing which need to be addressed, especially with regard to the process of posing problems itself (Cai et al., 2022).

In this paper we note that during the process of devising problems for use in class there may occur a disconnect between the aimed for and the actual formulation. We consider such disconnects from a non-judgemental perspective, with the sole aim of advancing our understanding of the elements at play during this process. To this end, we carried out a study of the output of 72 pre-service teachers (PST) in a problem posing task involving the multiplication of fractions, which required them to formulate a problem, provide the solution, and explain the decisions made during the process. In the subsequent analysis of the responses, a number of the problems stood out for presenting a disconnect between what was intended and what was actually produced, which we refer to as inconsistencies. We describe a framework for categorising the inconsistencies identified during the problem posing process. The long-term goal of this work, extending beyond the scope of this paper, is to use these inconsistencies as pieces of evidence providing an insight into the mechanisms used by the pre-service teachers to devise, evaluate and vary problems, given the fundamental role that solving them plays in this process. Here, however, we limit ourselves to answering the following research question: What inconsistencies can be identified in the pre-service teachers' formulations of problems involving fractions?

Theoretical background

Problem posing by teachers and pre-service teachers has received considerable attention from the mathematics education research community (Crespo, 2003; Tichá & Hospesová, 2013; Montes et al., 2024). Notwithstanding, the processes involved in posing problems remain an under-researched area (Cai, et al. 2022), particularly with regard to the stages a problem goes through, and the heuristics the poser uses in developing their problem. In broad terms, the problem-posing process follows a cycle of formulation, solution, and revision of the problem statement, which goes through various iterations before being presented to the pupils. The cycle involves certain elements on the part of the teacher, such as mathematical and pedagogical knowledge (Tichá & Hospesová, 2013), which are directed towards the achievement of a specific teaching objective (Montes et al., 2024).

The cycle, with its constituent stages, has been studied by various researchers (e.g., Cruz, 2006; Baumanns & Rott, 2022). Cruz (2006), proposes a model in which the goal is an explicit element, making it especially interesting in terms of exploring the processes involved in the teacher's problem-posing. For their part, Baumanns and Rott (2022), identify five types of activities – situation analysis, variation, generation, problem-solving, and evaluation – which combine to generate a descriptive model of the stages involved. The model establishes the interrelation between the different activities which are carried out during the process, generating a series of sequential stages. In the course of each of the stages, the problem poser produces different outcomes (provisional problem statements and solutions, evaluations of the suitability of the problem, and so on). This paper focuses on the coherence of the outcomes, in particular the phraseology of the problem statement, and the stated solution, noting discrepancies that can occur between what is written in the problem statement and what is affirmed in the solutions provided.

Methods

This paper forms part of a larger project aiming to deepen our understanding of the processes involved in posing problems for use in class by pre-service primary teachers from an interpretative perspective. The study was conducted with a group of 72 pre-service primary teachers coming to the end of their second year, having followed a course in teaching numbers and arithmetic, including aspects of fractions. They were given a task to formulate a two-stage problem, one involving addition and the other multiplication (Figure 1). Participants were asked to give informed consent. Data was coded as PST 1.X, meaning X the number of student in alphabetical order. During the course, the pre-service teachers had practised problem posing for themselves, and the need to go through the process of solving the problems as a means of checking the problem statement had been reiterated on several occasions.

Devise a problem in which there is at least one addition and one multiplication of fractions.

a. What kind of fraction does the problem result in?

b. Solve the problem representing the fractions graphically.

c. Identify potential errors and points of difficulty for the pupils, in terms of both visual and arithmetic aspects.

Figure 1: Task presented to the pre-service teachers

The objective of the larger project entailed analysing the pre-service teachers' outputs in the search for key features of the problem-posing process. In the course of the analysis, various inconsistencies in this process became apparent, which offered a means of gaining insight into the features we were looking for. Given the limitations of space, this paper focuses solely on the inconsistencies, taking a non-judgemental position with the aim of illustrating critical points which can arise in the course of problem posing. Of particular importance is the recognition that although one might be in possession of certain items of knowledge, it does not necessarily follow that these will be deployed consistently.

Analysis of the inconsistencies using an emergent procedure based on the constant comparison method (Bryman, 2001), grouped them into three types, which were triangulated by external researchers. The three groups were: (i) inconsistency between the problem statement and the numerical solution; (ii) inconsistency between the problem statement and the diagrammatic solution; (iii) inconsistency between the numerical and the diagrammatic solutions. Examples of each type of inconsistency are given below in order to illustrate the inconsistency involved and suggest the possible causes.

Results

Table 1 presents a summary of the frequency of occurrence of the inconsistencies, from which it can be seen that their occurrence among the pre-service teachers' problems is very high.

Table 1: Quantitative summary of the occurrence of inconsistencies

	Absolute frequency	Percentage
Inconsistency between problem statement and numerical solution	28	38.9%
Inconsistency between problem statement and diagrammatic solution	33 (plus 26, without a graphical solution)	45.8% (plus 36,1% without a graphical solution)
Inconsistency between numerical and diagrammatic solutions	56	78%
No inconsistencies	16	22%

In the next section we give a detailed description of the key features and defining mathematical characteristics of examples from each of the three groups of inconsistencies. We will show the problems in Spanish, translated to English, in order to let the readers see the original information.

Inconsistency between the problem statement and the numerical solution

This group of inconsistencies are characterised by the disconnect between the problem statement and the numerical solution to the problem. A clear example of this kind of inconsistency is the response of pre-service teacher PST1.64, whose problem statement and numerical solution are given in Figure 2. He adds 7/12+11/12 to put all the slices together, and supplies a meaning for this fraction in terms of the part-whole relationship between the uniform slice and the total number of slices, although he fails to make explicit the correspondence between the total slices and the unitary item they represent, the cake. Subsequently, as seen in Figure 2, he expresses the idea of 'half' not through the natural idea of division into two, but through the arithmetic transformation of multiplying by a half, which he explains as "this is the way you obtain half of a fraction".

Problem: Pablo made a cake and afterwards there were 7 slices left out of 12. His mother made another cake and this time there were 11 slices left out of 12. When they got home, they put all the pieces of cake together, bearing in mind that they were all the same size. The next day, the family ate half of the slices. How many slices were left, bearing in mind the size of the cake is twelve slices?	
	7/12+11/12=18/12 First of all, the slices are joined together by adding the fractions. […] Then, after obtaining the fraction 18/12, in other words, 18 slices, the family ate half of them. To carry out this operation using fractions it is necessary to do the operation using ½, since this is the way you obtain half of a fraction. 18/12 x 1/2=18/24=9/12

Figure 2: Problem set by PST 1.64 with their solution (original with translation on right)

On the other hand, the PST's intention is to work with fractions, and in this regard, he clearly aims to meet the parameters of the task. However, he appears not to have thought through the nature of the problem he poses, which can be solved more directly with natural numbers. This illustrates a potential disconnect between the posed problem and the solution, in that the solution does not address the problem as it is actually posed, but rather the problem as it is interpreted through the filter of fractional thinking, thus introducing an overly complex approach to the problem.

Problem: On Maria's birthday, there are two cakes. From the first one they eat 2/13 parts, and from the second 3/13 parts. How many pieces do they eat between the two cakes? If they had eaten twice as much, how many pieces would they have eaten?	
	In order to know how many pieces they eat between the two cakes, you use addition: 2/13+3/13=5/13 They eat 5/13 pieces

Figure 3: Problem set by PST 1.43 with their solution (original with translation on right)

In this problem (Figure 3), the pre-service teacher uses two terms, "parts" and "pieces", interchangeably to refer to a fraction. It can be assumed that she considers 2/13 parts in terms of a part-whole relationship in which the numerator represents the number of parts eaten and the denominator the total number of parts. In the problem statement, the questions ask about "pieces" that are eaten. Beyond the interchangeability of the terms, we can again see the arithmetical application of fractions in a context where it is mathematically unnecessary. The solution adds together two fractions to arrive at the conclusion that 5/13 pieces (of cake) have been eaten. This confirms the assumption above that a part-whole relationship underpins the problem, although, a literal interpretation of the phrase "5/13 pieces" takes the piece as the whole and a subdivision of the piece as part.

Inconsistency between the problem statement and the diagrammatic solution

This type of inconsistency involves a lack of connection or coherence between the problem statement and the visual representation of the solution to the problem. We illustrate this group of inconsistencies with the problem statement and visual representation by the pre-service teacher PST1.5 (Figure 4).

Problem: My grandfather bought $\frac{2}{5}$ of a cake, but as there were a lot of us he bought $\frac{2}{6}$ more of a cake. When he got home, he realised that he needed $\frac{2}{3}$ more of each total fraction of the previous amounts. What fraction of cake does my grandfather finally need?	
Figure 4: Problem set by PST1.5 with corresponding diagrammatic representation

We can see that this pre-service teacher first addresses the addition of fractions, in compliance with the task, with a inconsistency between the magnitude of each unit corresponding to the items to be added together as well as the unitary concept underlying the result. In other words, the setter does not seem to consider what wholes are being represented by the problem. This referential ambiguity is reinforced by the accompanying diagrammatic representation. Rather than present a visual representation of the problem and its solution, the PST draws two diagrams representing the fractions to be added, alongside a third representing the result. Underneath, she writes the fraction 66/60, without giving any clear indication of where it comes from. This fraction is then reduced to 11/10, this time without an accompanying diagram. In the second part of the problem, the PST carries out the multiplication of 11/10 x 2/3, and with it completes the solution, although the text of the problem statement, as written, seems to suggest that this should be added to the amount they already have. The treatment of this problem is very much like that of the first example, in which the pre-service teacher carries out the operations they had in mind to solve the problem rather than the actual problem they had formulated.

Inconsistency between the numerical and the diagrammatic solutions

In this type of inconsistency, there is a divergence in the reasoning underlying the pre-service teacher's solutions as represented in the numerical and visual registers, which in one extreme case results in two different solutions. In the example below (Figure 5), there are inconsistencies both between the problem statement and the two solutions, and between the solutions represented in the two registers, numerical and visual.

Problem: On my birthday, my friend Carlos ate 1/3 of the cake and my friend Lucía 2/5. How much did they eat between the two of them? Afterwards, my grandfather ate ½ of the rest. How much did they eat between all of them?	
	We need to find the least common multiple (l.c.m)=5x3=15. 1/3+2/3=5/15+6/15=11/15 is what Carlos and Lucía ate [Corresponding division sums included] To work out what my grandfather ate of the rest we need to multiply 11/15x1/2=11x/15x2=11/30 is what my grandfather ate of what Carlos and Lucía had left. 11/15+11/30=22/30+11/30=33/30 is what they ate between all of them
	[Diagram representing the addition of fractions] The shaded parts are what they ate The total of what Carlos and Lucía ate we multiply by ½, which my grandfather ate

Figure 5: Problem set by PST1.7 with corresponding numerical and visual representations

The numerical procedure is technically correct, in arithmetic terms, although the result, implying that more was eaten than there was originally, does not make sense. With respect to the accompanying diagram, it incurs the same inconsistency identified previously – the relative size of the parts representing the two fractions is not taken into account, and likewise the addition of these two amounts is carried out without reference to the actual elements of the problem to which they correspond. Observing the solutions provided in the two registers, numerical and visual, we can see that although in the numerical register the PST recognises the need to apply a procedure to make the size of the parts the same, he fails to do this in the visual register. Further, in the visual representation the pre-service teacher finishes the procedure with the product of 11/15 by ½ (which he does not explain, but simply provides a representation of the fraction, again with no reference to what it represents), whilst in the numerical representation the procedure finishes with the calculation of the total amount eaten.

Final reflections

Formulating problems for use in class requires the teacher to use the process of solving the problem posed (by the problem statement) as a means of revising the problem statement itself (Baumanns & Rott, 2022), or at least to think carefully about the solution the problem statement implies. The strategies required, and the stages through which the problem-posing process goes through require close investigation (Cai et al., 2022), as well as specific training. In particular, this study highlights three types of inconsistencies produced by pre-service teachers in the problem-posing process.

These inconsistencies suggest that pre-service teachers tend not to use problem-solving as a tool for evaluating the problems they devise. Indeed, we have found that in some cases the PSTs appear to solve the problem they thought they had formulated, but not the actual problem corresponding to the text of the problem statement (e.g., the first problem). In this respect, we consider that when they formulate a problem, pre-service teachers generate a "problem image" (in a similar sense that Tall and Vinner, 1981, refer to a concept image), and then solve the problem image rather than the stated problem. This is especially evident when pre-service teachers choose to tackle problems that can be solved using natural numbers by using structures associated with fractions.

Also worth noting is that the difference in occurrence of inconsistencies between the problem statement and the numerical resolution compared with those between the problem statement and the diagrammatic solution suggests that the mechanisms for connecting the problem statement with the solution as a means of reviewing the problem formulation might differ according to the register in question. Nevertheless, the aim of this study is not to identify areas where knowledge is lacking among pre-service teachers, but rather to illustrate the need to explore the finer details involved in the process of problem posing (Cai et al., 2022), which can feed into teacher education programmes and enable PSTs to develop the professional competence in formulating problems they need.

Characteristics of teachers' lesson observations: A comparison of in-service and pre-service teachers' gestures

[3]Naruto University of Education, Naruto, Japan

This study focuses on lesson observation, which is a key teacher activity in a lesson study. Although previous studies have described the act of observation by particular individuals in particular contexts, there has been limited scientific discussion on teacher expertise that the lesson observation is based on, or how such expertise is formed. Based on the Anthropological Theory of the Didactic, this study addresses the research question: What praxeological equipment is used for lesson observations? Thus, questionnaire evidences for pre-service and in-service teachers were conducted and all praxeologies extracted from them were used as a reference model to analyse teachers' observational activities. In conclusion, the commonalities/differences in observation tendencies between pre-service and in-service teachers, according to years of teaching experience, as well as the relationship between mathematical content-related praxeology and other ones are discussed.

Keywords: Lesson observation, lesson study, anthropological theory of the didactic, praxeological equipment, praxeological reference model.

Introduction: *Problématique* on teachers' lesson observations

Lesson study has been widely known as the Japanese traditional approach to teachers' professional development process (e.g., Fujii, 2014; Takahashi & McDougal, 2016), and it is also disseminated internationally (e.g., Clivaz, 2015; Rasmussen, 2016). However, most of the research studies have focused on a teacher or a group of teachers who work as lesson practitioners through lesson study. Teachers participating in a lesson study can be viewed from two different positions. On the one hand, teachers take a position in which they engage in lesson design and lesson implementation. For this position, the infrastructure of the lesson study practice as the superstructure is considered a *lesson plan*. On the other hand, teachers take another position in which they engage in *observing the lesson* concerned. Post-lesson discussion is considered a sharing setting for both position teachers. Although lesson study has received growing attention from educational researchers, one of the underexplored areas is how the teachers observe and learn the lesson during lesson study. To better explain lesson study as a collaborative setting, it is worth including lesson observation as the object of study and then we explore a way to reveal teachers' activities and knowledge during the observation (Shinno & Yanagimoto, 2020). Some previous studies have described teachers' observation work focusing on particular individuals, in particular, contexts, as to 'what' and 'how' other teachers as such participants observed. Nevertheless, there has been inadequate discussion on the didactic or paradidactic gesture (Miyakawa & Winsløw, 2019) that work of lesson observation is.

It is noteworthy that traditionally, Japanese teachers' lesson observations have in most cases relied on training experience. Less experienced teachers tend to take a form similar to that of the Japanese

‘道 (*dou*)’ culture, which “means ‘way’ and it implies the training process to follow” (Hirabayashi, 2006, p. 57) to acquire ‘observational skills’ and ‘teaching skill’ similar to ‘veteran’ teachers by participating in many lesson study sessions. A similar situation can be identified in student teachers in pre-service teacher-training programmes. In lesson observation activities at school (including watching videos), most pre-service teachers only focus on superficial behaviours of practicing teacher and students in the classroom; for example, what the teacher and students said and wrote. We assume that lesson observation is a professional activity which may vary according to observers’ mathematical and didactic knowledge of ‘what’ and ‘how’ to observe. Thus, ‘observing a mathematics lesson’ is an activity beyond simply ‘seeing what’ but also ‘seeing why’. There are several educational studies on lesson observation in Japan, and these studies have described or prescribed ‘observation viewpoints’ and ‘observation methods’ for supporting teachers’ professional development. However, none have attempted to elucidate lesson observation as the object of study with theoretical underpinnings. To contribute to the existing studies in this field of research, this study attempts to adopt a scientific approach aiming to theoretical framing teachers’ observation activities as a phenomenon, that is interpreted as ‘human observation of the lesson’ within our theoretical framework: the Anthropological Theory of the Didactic (hereinafter ATD).

Theoretical framework, research question, and research context

Theoretical framework

Lesson study or classroom observation is an everyday practice in Japan, however, that may not always be the case in other countries. On the other hand, even in Japan, almost all cases of such phenomena have traditionally been described empirically, where it has not been clear who the observer is and by whom such acts of observation are described. Especially, lesson observation is not only a matter for the personal observer, but also for the institution concerned. Therefore, we begin by describing ‘lesson observation’ in terms of *cognitive algebra*, as used in ATD (Chevallard, 2019; Chevallard & Bosch, 2020). This is because such an approach allows us to better understand the object of study with the following questions. That is, the question arises as to who is responsible for the act of ‘observing a lesson’, who is the one when we say ‘he/she observed a lesson’, and by whom is the statement judged to be so? We use the notion of instance to clarify this ‘who’, as follows. In order to clarify these points, we describe lesson observation as didactic or paradidactic phenomena using the cognitive algebra.

The actions of one teacher implementing a lesson and other teacher(s) observing it are denoted as follows: An entity with position p in institution I is called an instance (I, p). The teacher instance (hereinafter $\hat{\jmath}$) expects the relationship $R(x, o)$ of x to the didactic stake o to be learned by the learner position (p) in the classroom institution (I) to approach the $R_I(p, o)$ (relationship that position p as a learner in I should have for o) is expected to approach:

$$\hat{\jmath} \vdash R(x, o) \cong R_I(p, o).$$

If the relation of x to o at the beginning of the lesson $(t = 0)$ and at the end of the lesson $(t = 1)$ are $R(x, o)_{t=0}$, $R'(x, o)_{t=1}$ respectively and $\bar{R} = R_I(p, o)$, the evaluation instance (hereinafter observer or $\hat{v}$) estimates the degree of attainment between $R(R')$ and $\overline{R}$, i.e. $\varphi(R, \overline{R})$ and $\varphi(R', \overline{R})$, as either:

$$\hat{v} \vdash \varphi\left(R, \overline{R}\right) \begin{matrix} < \\ \approx \\ > \end{matrix} \varphi(R', \overline{R}). \qquad (\#1)$$

Note that any observation by $\hat{v}$ will be determined by the reference instance (hereinafter $\hat{w}$):

$$\hat{w} \vdash [\hat{v} \vdash \varphi\left(R, \overline{R}\right) \begin{matrix} < \\ \approx \\ > \end{matrix} \varphi(R', \overline{R})]. \qquad (\#2)$$

When regarded in this way, the purpose of this study described above can be translated as follows: *when $\hat{v}$ observes a lesson, what praxeological equipment of $\hat{v}$ is judged to be used by $\hat{w}$?* (Q_0)

The praxeological equipment (hereinafter PE) is explained as follows. The ATD contains a theory of human action whose beginning point is the notion of a type of tasks T (and the notion of task t of type T, which is denoted by $t \in T$). The realisation of task $t \in T$ requires the use of a technique τ_T relating to T. The ordered pair made up of a type of tasks T and a technique τ relating to T is denoted by $[T/\tau]$ and is called the praxis block. Any technique requires an explanatory or supporting comment, called technology, denoted by θ. The technology θ is itself coupled with a justifying discourse at a higher level, which is the theory, denoted by Θ, of the technique τ. The ordered pair made up of the technology θ and the theory Θ is denoted by $[\theta/\Theta]$: it is the logos block. Any praxis block $[T/\tau]$ supposes a logos block $[\theta/\Theta]$ with which it forms a praxeology $\wp = [T/\tau/\theta/\Theta]$. Hence, the praxeological universe of $\hat{\imath}$ is defined by $\Omega^{\blacklozenge}(\hat{\imath}) \stackrel{\text{def}}{=} \{\wp / R(\hat{\imath}, \wp) \neq \emptyset\}$ and $\hat{\imath}$'s praxeological equipment by $\Gamma^{\blacklozenge}(\hat{\imath}) \stackrel{\text{def}}{=} \{(\wp / R(\hat{\imath}, \wp)) / \wp \in \Omega^{\blacklozenge}(\hat{\imath})\}$. (Extract from Chevallard & Bosch, 2020).

When the relations in #1 are denoted by $R(\hat{v}, \varphi)$ and the relations in #2 by $R(\hat{w}, R(\hat{v}, \varphi))$, the following are the key questions: Where do these relations emerge from? What are they born of? What is their genesis? These can be answered using the notion of praxeology.

Research question

The following research question (RQ) is formulated as a partial solution (first step) to Q_0.

RQ: *What PE is used for lesson observations in $\hat{v}$?*

RQ seeks to identify the PE ($\Gamma^{\blacklozenge}(\hat{v}) = \{\pi(\hat{v})_n | n \in \mathbb{N}\}$) that $\hat{v}$ uses to observe the lesson practice by $\hat{\jmath}$ (or $\hat{\jmath}$'s didactic gesture $\delta_{\hat{\jmath}}$), where $\hat{v}$ includes in-service and pre-service teachers. Thus, it attempts to identify the characteristics of the lesson observations of the two groups. This requires a praxeological reference model (cf. Corica, 2020) by $\hat{w}$. This research project can be translated as finally aiming to construct such a REM, but since this paper is a case study as part of the data resource for this purpose, we denote it as a PE of $\hat{w}$ ($\Gamma^{\blacklozenge}(\hat{w}) = \{\pi(\hat{w})_n | n \in \mathbb{N}\}$).

Research context

To address RQ, the following context is established in this study. The context is designed to compare the lesson observations of pre-service and in-service teachers, as both might carried out lesson observation activities differently.

For pre-service teachers, in a university class included in the teacher education programme, they watched a video of a lesson ('Written subtraction', primary school Grade 2) and were asked to write a report in which they answered the following questions.

Q_{pa}: What did you observe in the lesson?
Q_{pb}: Why did you observe it?
Q_{pc}: How did you observe the facts and what did you extrapolate?

However, in-service teachers (primary school) were not asked to observe a common lesson but were provided the following questions in which they were asked to reflect on the lesson studies in which they had participated.

Q_{ia}: What do you focus on when you observe a lesson?
Q_{ib}: Why do you intend to observe it?
Q_{ic}: How many years of teaching experience do you have?

It does not mean that such a setting is necessarily appropriate to address our research end. Rather, especially in the case of in-service teachers, they had already experienced many lesson studies, and we attempted to mine for their recognitions from such experiences.

Then, $\Gamma^{\blacklozenge}(\hat{w})$ denotes all the findings from these questionnaires, with which $\Gamma^{\blacklozenge}(\hat{v})$ is analysed.

Result

The $\pi(\hat{w})_n$ were extracted by organising the key words from the descriptions in the questionnaire survey. Both pre-service and in-service teachers responded with regard to more than one $\pi(\hat{w})_n$. Table 1 presents the results of the percentage (%) of the total number of responses for each category, divided by the number of pre-service teachers ($N = 37$) and in-service teachers ($N = 19$).

Table 1: Pre-service and in-service teacher observation items

$\Gamma^{\blacklozenge}(\hat{w})$	$\pi(\hat{w})_1$	$\pi(\hat{w})_2$	$\pi(\hat{w})_3$	$\pi(\hat{w})_4$	$\pi(\hat{w})_5$	$\pi(\hat{w})_6$	$\pi(\hat{w})_7$	$\pi(\hat{w})_8$	$\pi(\hat{w})_9$
	blackboard	things prepared	organisation	questioning	assistance	speaking style	interaction	appearance	mathematical content
Pre-service	16	7	51	21	28	2	26	26	14
In-service	21	0	16	68	47	0	26	79	26

Table 2 presents similar proportions contrasted by the years of experience of the teachers (Experienced ≥ 10 ($N = 14$), Non-experienced < 10 ($N = 5$)).

Table 2: Experienced and non-experienced teacher observation items

$\Gamma^{\blacklozenge}(\hat{w})$	$\pi(\hat{w})_1$	$\pi(\hat{w})_2$	$\pi(\hat{w})_3$	$\pi(\hat{w})_4$	$\pi(\hat{w})_5$	$\pi(\hat{w})_6$	$\pi(\hat{w})_7$	$\pi(\hat{w})_8$	$\pi(\hat{w})_9$
E ≥ 10	40		40	80	60		40	60	0
N < 10	14		7	64	43		21	86	36

The following are the provisions for each $\pi(\hat{w})_n$ based on the actual response descriptions. All these descriptions were expressed in Japanese and translated into English by the authors.

[$\pi(\hat{w})_1$] *Writing on a blackboard*: Regarding $\pi(\hat{w})_1$, both pre-service and in-service teachers commonly indicate to 'view the flow of the lesson at a glance'. While pre-service teachers tend to write abstract statements such as 'summarising diagrams and formulae to strengthen students' understanding', in-service teachers often describe clearly their intentions, such as 'how they organise

the lesson, including the objectives, summary and reflections' and 'whether they describe the student's thinking and the contents to be taught'.

[$\pi(\widehat{w})_2$] *Things to be prepared*: For $\pi(\widehat{w})_2$, responses were found only among pre-service teachers, and their attention was focused on the students' interest according to the pros and cons of the preparation.

[$\pi(\widehat{w})_3$] *Lesson organisation*: $\pi(\widehat{w})_3$ contains two different but related issues. One concerns time allocation or management and the other concerns the status of each lesson phase. With regard to the former, we found not only pre-service teachers' descriptions of, for instance, 'I was concerned about which stage in the lesson took more time', but also in-service teacher's description of 'I am not good at it, it is a challenge for me'. With regard to the latter, pre-service teachers were particularly involved in Japanese structured problem-solving lessons, answering questions such as 'how is teaching conducted according to individual differences?' and 'it takes time to refine and elaborate (*neriage*)'.

[$\pi(\widehat{w})_4$] *Teacher's questioning*: For $\pi(\widehat{w})_4$ as well, there are some differences in the way pre-service and in-service teachers are described, with in-service teachers generally being more specific in their descriptions. Pre-service teachers described 'how the teacher implements the lesson with a focus on dialogue with students', 'how the teacher supports the students' learning', and 'to understand the progress of the students' learning'. However, in-service teachers pay attention to 'student's inspiration, how they want to tell their friends, what they are thinking about', 'whether the students understand the questions to achieve the aim/whether they are trying to connect the students' ideas', and 'whether the questions are simple and easy for students to understand'.

[$\pi(\widehat{w})_5$] *Teacher's assistance*: For $\pi(\widehat{w})_5$, both pre-service and in-service teachers described relatively similar ways. Pre-service teachers provided answers such as 'to know how to respond to a wrong answer', 'what type of assistance is desirable in the context of understanding' and 'in a whole-class atmosphere [students] can present themselves or correct their trajectory and lead to an answer'. In-service teachers also need to ask themselves, 'what type of words of assistance, and how to connect them to the subsequent development? and what steps can be taken to raise the level of the activity?' and 'how is the students' goal picture envisioned?' Teacher's assistance has a special role in SPS. It may be a gesture specific to Japan. Therefore, it is distinguished from $\pi(\widehat{w})_6$ and $\pi(\widehat{w})_7$.

[$\pi(\widehat{w})_6$] *Teachers' speaking*: $\pi(\widehat{w})_6$ is found in only one pre-service teacher. The description includes 'tone and loudness of voice, strength of explanation and nomination', which have a highly pedagogical aspect.

[$\pi(\widehat{w})_7$] *Teacher and student interaction*: $\pi(\widehat{w})_7$ relates to the way teachers and students interact in lessons; all descriptions provided by pre-service teachers are of teacher-student interaction: 'whether there were any attempts to facilitate the smooth running of the lesson', 'she gave advice to children who seemed to be having difficulties', 'they rephrased or supplemented in easy-to-understand words', 'the teacher asked the students to pay attention', 'the students took the initiative by having them write on the blackboard and explain in front of everyone', 'active comments (by the students) make the lesson easier to understand and give them new perspectives', and 'a good response reduces afraid and increases speaking out'. In contrast, more than half of the descriptions of in-service teachers relate to

the way in which students interact with each other: 'I want to aim for lessons that strengthen learning through students' interaction', and 'whether they are learning and enhancing each other's peers, and whether their comments connect and strengthen each other's ideas'.

[$\pi(\widehat{w})_8$] *Students appearance*: For $\pi(\widehat{w})_8$, the pre-service teachers watched the video lesson, they were limited to the range of what they could capture on the screen. Consequently, their descriptions were limited to abstract statements such as 'did the learners actively participate?' However, in-service teachers reflectively described their direct lesson observations (lesson study); therefore, descriptions specifying concrete objects of observation (students' notes and utterances) were conspicuous. They are all regarded as a means of understanding the students' changes in the lesson as if they were lesson teacher themselves: 'are the students writing their thoughts, what types of notes are they taking?' In addition, some respondents paid attention to the students' facial expressions, with descriptions such as 'the moment their expressions change, I can feel how the students are feeling' and 'whether the students are engaged in the lesson in a lively way'.

[$\pi(\widehat{w})_9$] *Mathematical content*: The intent of the description of $\pi(\widehat{w})_9$ was different for pre-service and in-service teachers. For pre-service teachers, the reason for focusing on a mathematical topic is to improve the way of teaching: 'as simple an introduction as possible made it easier to engage with the lesson' or 'to facilitate students' understanding, [the teacher] attempted to repeat it many times and provide them the opportunity to expand on the problem and think about it'. In contrast, the intentions of in-service teachers are uniformly associated with the purpose of the lesson: 'Are the aims of the lesson being met, and are they adequate?' and 'what have the students learnt and what have they been able to do?'

Discussion and Conclusion

Comparison between in-service and pre-service teachers

When the pre-service and in-service teachers groups are combined, all praxeologies, $\pi(\widehat{w})_1 \sim \pi(\widehat{w})_9$, are described in some way, and as a whole, it can be said that they observe the lesson from the same perspective regardless of their teaching experience. However, many students used $\pi(\widehat{w})_3$, that is, *lesson organisation* (51%), in which they were interested in observing the allocation of time for each phase of the lesson, the learning process they spent the most time on, the smooth progress of the lesson, and the allocation of time to attract or keep students engaged in the lesson. They observed with interest and stated that they wanted to learn the skills they needed to become teachers. Furthermore, regarding $\pi(\widehat{w})_5$, that is, *teacher's assistance* (28%), which was used by several students, there were descriptions of how to respond to mistakes, to respond to individual differences, to proceed according to the lesson plan, to make everyone involved and interested in the lesson. Regarding $\pi(\widehat{w})_7$, that is, *teacher and student interaction* (26%), they observed how the teacher's behaviour was related to the students' learning, in particular how it led to creating an atmosphere of easy participation in the lesson and how a good response would encourage everyone to speak up without afraid of mistakes. In addition, $\pi(\widehat{w})_8$, that is, *students appearance* (26%), was described as an image of students who were motivated to learn, such as their attitude to expressing their thoughts and the ordinary state of the class.

Characteristics of teachers with less than 10 years of teaching experience

In-service teachers were asked to describe their teaching experience using a questionnaire. The results revealed that teachers with less than 10 years of teaching experience tended to differ from more experienced teachers. It was rather similar to the characteristics of the pre-service teachers, particularly $\pi(\widehat{w})_3$, they focused on the lesson structure and attempted to observe not only the time management but also the way the task was presented as a learning flow. Further, they described how they wanted to learn about the actual situation of the students as $\pi(\widehat{w})_8$ about their learning discipline or didactic contract (Brousseau, 1997), the way they talk, the type of thoughts they write, and whether they are proactively engaged in the lessons because they can observe a glimpse of their daily teaching. This is similar to pre-service teachers' descriptions of whether students concentrated on the lesson. Compared with those with more than 10 years' experience, although they focused on the same $\pi(\widehat{w})_4$, that is, *teacher's questioning*, teachers Es (≥10) described 'whether the questioning is to get closer to the aim', 'whether the questioning is aimed at strengthening the students' thinking', and 'whether the questions were designed to facilitate the students' thinking'. whereas teachers Ns (<10) described 'I want to know if the questions were simple and straightforward', 'I would like to know it because I am not good at', and 'I want to learn so that I would not talk for too long'. Thus, the Ns are aware of their own issues with lesson organisation and questioning in their daily lesson observations and are attempting to learn how to improve them by themselves.

The relationship between $\pi(\widehat{w})_9$ and other praxeologies

Pre-service teachers' descriptions were based on the fact that the questionnaire was administered after they had watched the actual lesson video, therefore, they wanted to know 'what type of teaching is appropriate for learning how to think?', 'what is the mathematical ability to provide logical explanations?', and 'what is the process for proceeding to applied problems?'. Their focus is on observing how the problem is solved and how the problem is developed, and there is minimal relationship between $\pi(\widehat{w})_9$ and other praxeologies. However, in-service teachers' descriptions related to $\pi(\widehat{w})_9$ include 'is the aim adequate?' and 'what is being learned?' together with 'is the board writing structured in such a way that the learning of the period can be viewed at a glance?', 'is the questioning adapted to the learning of the period and the actual situation of the students?', 'is the questioning adapted to the aims of the period?', 'how is the assistance provided according to the individual differences in the students' activities?' The respondents answered that they observe the mathematical content in relation to other praxeologies: $\pi(\widehat{w})_1$, $\pi(\widehat{w})_4$, $\pi(\widehat{w})_8$ or $\pi(\widehat{w})_5$.

Answer to research question (RQ) and theoretical open questions

To answer 'RQ: What PE is used for lesson observations in $\hat{v}$?', we set up an evaluation instance $\widehat{w}$ of $\hat{v}$ and PE of $\widehat{w}$, $\Gamma^{\blacklozenge}(\widehat{w}) = \{\pi(\widehat{w})_n | n \in \mathbb{N}\}$, as the praxeological reference model to identify PE of $\hat{v}$, $\Gamma^{\blacklozenge}(\hat{v}) = \{\pi(\hat{v})_n | n \in \mathbb{N}\}$. This way, the PE used for the lesson observation of $v_0 \in \hat{v}$ can be denoted from $\widehat{w}$'s viewpoint, e.g. $\Gamma^{\blacklozenge}(v_0) = \{\pi(\hat{v})_i | i \in \{1,2,5\}$. $\Gamma^{\blacklozenge}(\widehat{w})$ was extracted using a questionnaire survey and is therefore, as a matter of course, insufficient. However, we are convinced that the procedural or methodological validity of identifying $\Gamma^{\blacklozenge}(\hat{v})$ could be argued. Further theoretical work is required on how $\Gamma^{\blacklozenge}(\widehat{w})$ needs to be elaborated in the future, in particular for the judgement (⊢) in #2.

Three-fold meta-didactical conflict. LSA and teacher education

Serena Monica[1] and Federica Ferretti[1]

[1]University of Ferrara, Faculty of Mathematics, Ferrara, Italy; serena.monica@edu.unife.it

This research aims at investigating the presence of the three-fold meta-didactical conflict, comprising the relationship between teachers and large-scale mathematics assessments, in the context of Italian upper secondary school. The study involves both in-service and prospective secondary school teachers. The conflict is theoretically framed within the MTSK Model. The data collected show some inconsistencies with the national results and confirm the presence of the conflict in the population involved. This study contributes to the research line that uses data from large-scale assessment as tools for enhancing teacher education and improving teaching and learning processes.

Keywords: Type Teacher education, secondary school teachers, MTSK model, three-fold meta-didactical conflict, Large Scale Assessment.

Introduction

As highlighted by literature, from the macro-phenomena emerged through Large Scale Assessment - LSA, with an opportune and conscious integration in teacher education, it is possible to improve teachers' knowledge and skills (Campbell & Levin, 2009; Ferretti & Santi, 2023). On the one hand, the analysis of the results of LSA can be useful for teachers to reflect on teaching-learning processes, as well as on the possible strengths and weaknesses of specific teaching choices; on the other hand, precisely through the interpretation of macro-phenomena emerged in LSA by prospective and in-service teachers, information can be obtained on the possible weaknesses related to their specialized knowledge. As argued by Adler (2000), mathematics teacher education should focus on resources, understood as tools that enable them to refine mathematical activity in the classroom. In this perspective, macro-phenomena emerged in the INVALSI (National Institute for the Evaluation of the Education and Training System) standardized assessment can determine relevant observations on the specialized knowledge of teachers, to be able to subsequently construct a model of intervention for teacher education, that such as Mellone and colleagues claim is a "highly desirable" outcome (Mellone et al., 2017, p. 8). Our study moves within the strand of research that links large-scale assessments with teacher education and, in particular, is grounded in the Arzarello and Ferretti's construct of the *three-fold meta-didactical conflict* (2021). This conflict arises from the comparison between the context of a mathematics class and the general school context and, as the name suggests, consists of three components concerning the discussions on teaching and learning processes. The present study aims to explore this meta-didactical conflict and involves in-service and prospective secondary school mathematics teachers. The survey tool used is a questionnaire consisting of questions about eight selected 10^{th} school grade Italian LSA INVALSI items. Each question allows for the investigation of the presence of the conflict's components consistently with the domains of the Mathematics Teacher Specialized Knowledge (MTSK) model (Carrillo-Yañez et al., 2018). As we will discuss in the following sections, teachers and prospective teachers' knowledge and beliefs are interpreted and framed with some sub-domains of the MTSK model.

Three-fold meta didactical conflict

The *three-fold meta-didactical conflict* is a construct consisting of three components and it arises from the comparison between the classroom reality and the national context. The contextualization of this meta-didactical conflict arises from the analogy between the small context of a mathematics classroom and the general national school context, which the research is considering. In the analysis of classroom interactions, it is common to observe what is referred to as "incommensurable discourse" (Sfard, 2008) between teacher and students: it often happens that - in the communicative processes of classroom teaching practices - students and teachers use the same words but with different meanings, without being aware of the differences. Conflicts are generated which, if not made explicit and overcome, can have serious consequences for the success of teaching/learning processes in the classroom. These incommensurable languages have also been identified between mathematics teachers and large-scale assessments and identify the so-called "*three-fold meta-didactical conflict*" (Arzarello & Ferretti, 2021). The conflict is meta-didactical as it concerns discourses on educational processes such as assessment, student skills and errors, etc. and not mathematical concepts as theoretical constructs. The three components that characterize the construct are the following ones:

(i) *the perception of the difficulty of the questions*. This component relates to the fact that teachers perceive the difficulties of the LSA mathematics test questions in a very different way to the national level data. The perception and, therefore, the estimation of item difficulty, is not part of the metrological validity of a test, but part of a broader issue that aims to investigate teachers' awareness of possible obstacles to correct student resolution of an item;

(ii) *the awareness of the causes of the errors*, this component concerns the interpretation of the causes of errors that are widespread nationwide and framed by researchers with some of the most internationally recognized constructs of mathematics education;

(iii) *the perception of the purpose of the questions*, a consequence of the two previous components, which concerns the contradictory way in which the teachers interpret the purpose of the questions in relation to their usefulness for teaching and, above all, learning goals.

On the one hand, the three components are specific and focused on targeted skills, while on the other hand, they closely intersect as a possible representations of the teacher's specialized knowledge. In line with Ferretti, Martignone and Viola (2023), we will interpret the data with reference to the three components of the meta-didactical conflict by relating them to the PCK sub-domains of the Carrillo MTSK Model.

The research objectives from the MTSK model perspective

The knowledge and beliefs of mathematics teachers bring into play during their profession is the focus of much recent research and most of these studies highlight how mathematics teachers' knowledge model is a useful tool for organizing also initial teacher education (e.g. Montes et al., 2013). Especially, from Shulman definition of the two macro-categories, Subject Matter Knowledge and Pedagogical Content Knowledge, several models have been developed, including the model by Carrillo-Yañez and colleagues (Shulman, 1986).

The Mathematics Teacher's Specialized Knowledge (MTSK) model, outlined by Carrillo-Yañez and colleagues in 2018, coordinates two broad areas of knowledge, Mathematical Knowledge (MK) and Pedagogical Content Knowledge (PCK), placing the teacher's beliefs at the center (Carrillo-Yañez et al., 2018). The first group is related to a mathematics teacher's own knowledge in terms of a scientific discipline within an educational context and is further divided into three sub-domains: *Knowledge of Topics* (KoT), *Knowledge of the Structure of Mathematics* (KSM), *Knowledge of Practices in Mathematics* (KPM). The PCK areas, that will be focused on in our study, represents knowledge related to the mathematical content in terms of teaching-learning processes and is composed by: *Knowledge of Mathematics Teaching* (KMT), which determines knowledge of mathematics teaching theories, resources, materials and technologies, but also knowledge related to strategies for introducing and representing content and concepts; *Knowledge of Features of Learning Mathematics* (KFLM), related to the ability to predict students' reactions: their detectable errors and difficulties on specific topics and, in general, their interactions with mathematics, taking into account all aspects, including affective ones; *Knowledge of Mathematics Learning Standards* (KMLS), i.e. knowledge of the national curriculum and international documents of all school levels. Beliefs about mathematics and its learning and teaching are at the core of the model, precisely to emphasize the reciprocity between beliefs and knowledge domains. *Beliefs on Maths* include all the beliefs and preconceptions that teachers have about mathematics, based on their own education and the *Beliefs on Maths Teaching and Learning* are built on teachers' personal and professional experiences (Carrillo-Yañez et al., 2018).

The connection between these facets of the teachers' specialized knowledge and reflections on macro-phenomena revealed in INVALSI tests to comprehend some of the critical aspects of teacher education is the basis within which the questionnaire and the entire research were developed. Our research aims to characterize Arzarello and Ferretti's *meta-didactical conflict* further, both by investigating its presence at secondary school level and also with prospective teachers, and by framing it theoretically with the MTSK Model.

Methods

The research involves a population of 62 interviewees, made up of 18 secondary school prospective teachers, including some master's degree students in mathematics on the teaching program and other PhD students in mathematics education and 44 in-service teachers, from new hires to teachers with more than fifteen years of experience. All data queries are selected from an online database, Gestinv (2024), where it is possible to search the INVALSI items from 2008 to the present. The survey was administered anonymously in a telematic way via Google Forms. The design of the questionnaire was guided by the identification of macro-phenomena that emerges with reference to INVALSI mathematics items for secondary school considered suitable for the investigation of the starting assumptions. Four items (D21 s.y. 2017, D15 s.y. 2011, D28 s.y. 2010, D5 s.y. 2016, Gestinv, 2024) make up the basis of the research on the first component of the *three-fold meta-didactical conflict*, of which two with a high percentage of incorrect answers (above 60%) and two with a low percentage of incorrect answers (below 55%) respectively. Therefore, regarding this component of the conflict, situations were proposed in reference to both questions with very low and very high percentages of correct answers at national level: this is another innovative element compared to the meta-didactical

conflict foundation research, which only investigated the first component with reference to questions with low correct answer percentages. The remaining four items (D22 s.y. 2011, D14 s.y. 2011, D14 s.y. 2013, D24 s.y. 2017, Gestinv, 2024) from the foundations of the survey for the second component and scored a very low percentage of correct answers at national level - less than 35%. Each question is followed by targeted, open-ended questions and closed-ended questions on a Likert scale of 1 to 4. The first closed-ended question "In your opinion, how difficult do you think the following item is for students at the end of the second class of the second-grade secondary school?" makes it possible to investigate the participants' perception of the students' difficulty of the items. This survey seems to relate to the concept of PCK in the MTSK model. The PCK required of teachers in identifying the correct level of difficulty considers both the knowledge inherent to teaching, KMT, and that one relating to the characteristics of learning, KFLM. The relationship between perception and knowledge of learning is fundamental to identify the appropriate level of difficulty that students perceive in the problem solving. The teacher must, therefore, be familiar with learning techniques and understand the way in which each student can tackle a problem. At the same time, knowledge of the transmission systems, with the possible difficulties that can be generated, is strongly related to the teacher's awareness. In the following figure (Figure 1), we show the representation of this priori analysis of the first component of the meta-didactical conflict involving the different sub-domains of the PCK.

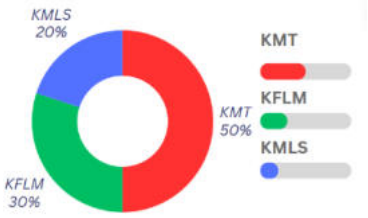

Figure 1: First component – PCK sub-domains

The open-ended question "In your opinion, which is the most chosen wrong option(s) and why?" is, on the other hand, useful for analyzing the level of awareness of the causes of errors. Also in this case the knowledge and beliefs involved concern all three sub-domains of the PCK. In particular, the factor relating to the learning process (KFLM) appears more relevant. This component seems to highlight the fundamental importance of the interpretative effort required of the teacher; the skill of the teacher to understand and to analyse the error brings into play different type of knowledge, as noted in this a priori analysis depicted by following graph.

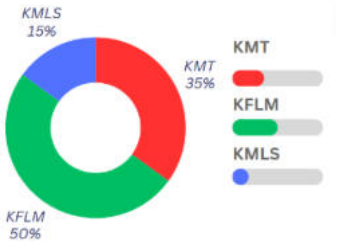

Figure 2: Second component – PCK sub-domains

The questions “On a scale of 1 to 4 how suitable do you think this item is for assessing the learning of students at the end of second class of second-grade secondary school?” (for prospective teachers and in-service teachers) and “On a scale of 1 to 4, how habitually do you use items like this in your assessment tests?” (for in-service teachers) are aimed at defining the rank of perception of the purpose of the items. This component arises directly from the two components described above. Indeed, to construct a definitive view on the usefulness of a problem for assessment purposes, an in-depth analysis is required, related both to the objective difficulty of the questions and to the subjective difficulties experienced by the students. Consequently, it is possible to frame the latter component in relation to the PCK. In this case, the KMLS seems to appear predominant. The teacher initially provides his/her own conception of the question by means of his/her specialized knowledge of teaching and learning. Subsequently, the teacher expresses his/her perception of the purpose of the problem, exclusively through the contextualisation of that in relation to the grade and to the student's curriculum.

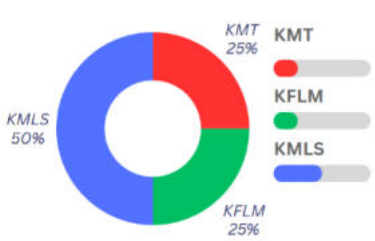

Figure 3: Third component – PCK sub-domains

In all components of the meta-didactical conflict, beliefs seems to play a role. The awareness of the causes of errors can be influenced by each teacher's personal conceptions of both mathematics and even more on teaching and learning; each teacher identifies with the student and provides reflections that may arise, in part, from their own experience and from their own beliefs. Especially if a teacher prefers a reproductive approach, they will have a different perception from those who implement a productive approach.

Data analysis and discussion

In this section we will analyse, by way of example, the results of questions about two INVALSI items that allow us to delve deeper the teachers’ perception of the difficulty and the awareness of the causes of the errors. This is part of a broader study on each item of this research where results are also obtained on the perception of the purpose. Following it is presented one of the considered items (Figure 4) about which teachers are asked to estimate the students’ difficulty in solving it without knowing the INVALSI results of the percentages of error. The item requires a *conversion* (Duval, 2006), the semiotic transformation of a representation from the graphic register to the numerical register. The percentage of the wrong answers is higher than 65% (Figure 5) and the most selected wrong options are answers A and D.

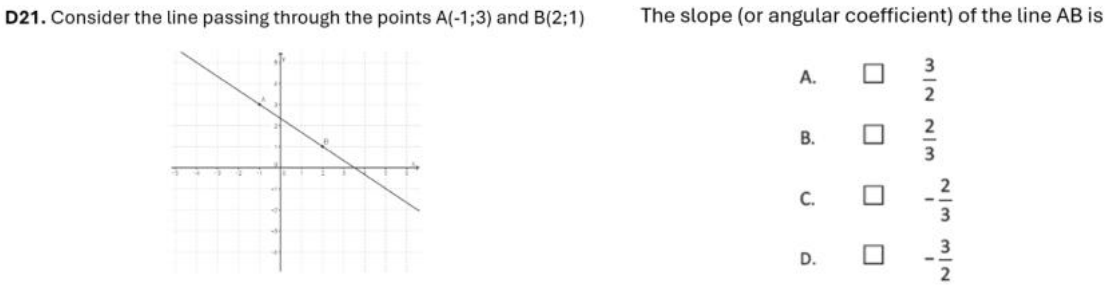

Figure 4: Item 21, grade 10 Mathematic INVALSI test 2017 (Translated by the authors, Gestinv, 2024)

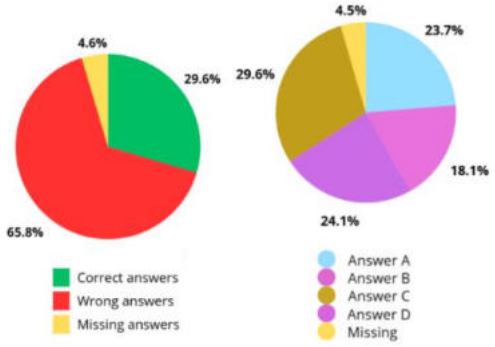

Figure 5: Percentage of choice of each option, item 21, grade 10 Mathematics INVALSI test 2017 (Gestinv, 2024)

Teachers are asked to estimate the degree of difficulty on a scale from 1 (*very easy*) to 4 (*very difficult*). In Figure 6 it is possible to see the answers of the population involved.

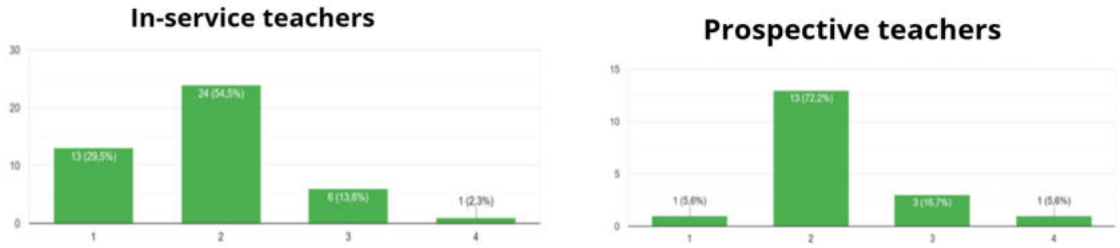

Figure 6: Percentage of choice - question on item 21 (Figure 4)

As highlighted in the Figure 6, the perception of the difficulty of the item appears in contrast with the national results (Figure 5): despite only about 29% of the students gave the correct answer, the majority of the population involved in the experiment (almost 85% of in-service teachers and almost 80% of prospective teachers) considered the question *easy* or *very easy*. This symbolises a possible criticality in the teachers' specialized knowledge, with reference to the PCK and, in particular, with regard to the KFLM sub-domain (Figure 1).

The other item considered (Figure 7) is about the awareness of the causes of the errors. In order to solve the item, it is necessary to carry out a *treatment* in Duval terms (2006), the semiotic transformation from a representation to another in the same numerical register.

D24. The expression $\left(a-\frac{1}{a}\right)^2$ can be written as

A. ☐ $a^2+\frac{1}{a^2}-2$

B. ☐ $\frac{a^4+1}{a^2}$

C. ☐ $a^2-\left(\frac{1}{a}\right)^2$

D. ☐ $\frac{a^2-2a+1}{a^2}$

Figure 7: Item 24, grade 10 Mathematic INVALSI test 2017 (Translated by the authors, Gestinv, 2024)

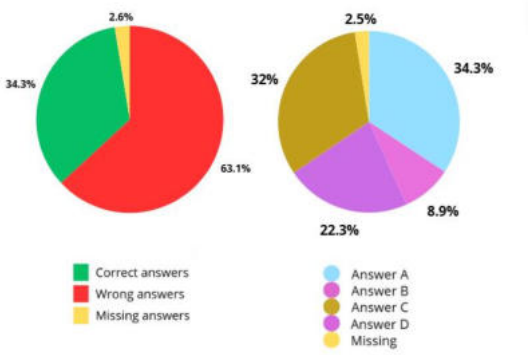

Figure 8: Percentage of choice of each option, item 24, grade 10 Mathematics INVALSI test 2017 (Gestinv, 2024)

In this case the percentages of the correct answers (34,3%) were reported on the questionnaire. Answers C and D respectively are selected by 32% and 22,3% of the national sample of students, showing difficulties in the management of treatments, in particular errors in splitting the square of the binomial in the first case and the failure of the lowest common multiple in the second case. In reference to the open-ended question about the choice of the most common wrong answer 50% of the population involved selects the answer C and about the 20% choose the answer B and D. The results about the erroneous options represent a possible critical element to reflect on regarding the teachers' specialized knowledge, with reference to PCK as in Figure 2.

Conclusion and further directions

In this paper we show some results of a broader work about the three-fold meta-didactical conflict on a population of in-service and prospective teachers. We frame the three components of the conflict with a priori analysis related to PCK sub-domains of the MTSK model, strengthened by the results obtained from the data related to the 10th grade INVALSI items considered. The answers collected represent inconsistencies between the perception of the population involved and the national students' results. In particular, this work not only confirmed the presence of the components of the three-fold meta-didactical conflict in the secondary school context considered but also defined some new characterizations. The data obtained are a possible starting point for some reflections on the teachers' specialized knowledge. The definition of the theoretical framework is currently in the process of refinement, facilitated by an expansion of the model, while also exploring the potential for a network of theories. The mainly further direction would be to contribute to the construction of an updated

model for teacher education that considers the difficulties of this conflict related to specialized knowledge.

Mathematics teachers' identity in the prison context

Gabriella Pocalana[1], Silvia Regola[2] and Agnese Ilaria Telloni[3]

[1] University of Pavia, Department of Mathematics, Italy; gabriella.pocalana@unipv.it

Within the Learning Mathematics in Prison project, we analysed the identity of mathematics teachers working in a prison context, with a specific focus on their motivations, goals and perceived role. Through the qualitative analysis of the interviews to four teachers working in different Italian school prisons, we derive that their professional identity is more strictly related to their role of educators in a prison context than to their role of mathematics teachers. This is also reflected in their perceived professional development needs, which are prevalently connected with the management of situations connected with the prison context rather than to the teaching of disciplinary contents.

Keywords: Mathematics education, prison education, teacher identity, teacher views.

Introduction and theoretical background

In this paper, we aim to explore the identity of mathematics teachers working within prison contexts, with a particular focus on their motivations and perceived roles. Teacher identity is a crucial concept in sociocultural research, understood as a dynamic and situated phenomenon constructed through discourse (Lerman, 2006; Sfard, 2008). Exploring teacher identities in prison settings is relevant as it sheds light on the pedagogical challenges and opportunities these environments present (Novek, 2019). Prison schools are institutions offering students (minors or adults) opportunities to obtain educational certifications and fostering both human and professional growth. Prison schools focus on lower secondary education and early years of upper secondary education. Collopy (2003) defines teacher identity as a "constellation of interconnected beliefs and knowledge about subject matter, teaching, and learning, as well as personal self-efficacy and orientation towards work and change" (p. 289). Expanding on this, Ponte and Chapman (2008) describe it as a teacher's professional self, reflecting a form of social identity. According to Holland et al. (2001), identities are closely linked to self-understandings that individuals articulate to themselves and others. Sfard and Prusak (2005) frame identities as "a collection of stories about persons" (p. 16), highlighting the role of communication in shaping and expressing one's identity. Bjuland et al. (2012) advocate for a narrative-based approach to analyzing teacher identity, emphasizing its construction within specific contexts (Hodgen, 2011). Narratives collected during interviews, as noted by Dalby (2017), provide authentic and credible insights into how teachers perceive and articulate their identities.

The notion of a stable identity trait contrasts with the socio-cultural view that sees social interactions as fundamental in shaping identity. In this framework, identity is constructed through narrative, making it socially situated, ever-changing, and uniquely created by the individual for each specific situation. As Holland et al. (2001) suggest, a narrative approach allows researchers to develop a more reliable analysis of identity, recognizing that it is uniquely constructed within the narrative context, by the individual, for the situation. In interview settings, therefore, the identity presented is

specifically constructed for the researcher, yet it maintains authenticity and credibility within this narrative framework.

Professional identity can be broadly understood as the aspect of identity that individuals develop in relation to their profession or occupation. Adopting a narrative perspective, in this case, means that teachers' personal accounts are essential for a comprehensive understanding of their professional identity (Dalby, 2017). This study focuses, in particular, on the professional identity of mathematics teachers working within prison contexts, a topic that, to the best of our knowledge, has not been specifically addressed in the literature.

Methodology

Data collection

The study has been conducted as a part of the PRIN projects LeMP (Learning Maths in Prison). This project aims to develop guidelines and educational materials for teaching mathematics in prison. It involves experts in Mathematics Education, Special Education, and Pedagogy from five different universities, and mathematics teachers working in prison schools in three different Italian regions.

We collected data by conducting individual semi-structured interviews, lasting about an hour each, with four mathematics teachers working in three prison schools, who participated on a voluntary basis. All the interviewees work with highly diverse groups of students, varying in age, educational, and cultural backgrounds, and characterized by high turnover rates. Caterina has a degree in Ecological Sciences, taught for 4 years in CPIA (Provincial Centers for Adult Education), and has now been teaching at the juvenile detention center for 4 years. Anna has a degree in Geological Sciences, with 21 years of experience in middle school, 4 years in CPIA, and two years in an adult prison. Salvo holds a degree in Biology, has a PhD and research experience in Neuroscience, with 2 years of experience in an adult prison. Camilla holds a degree in Marine Biology and has 20 years of experience in middle school and 4 years of experience in adult prison. None of them have received specific training for teaching, neither in a usual context nor in a prison context.

All the interviews were conducted online by two authors who took turns: one asked the questions, and the other took notes. They have been video recorded and fully transcribed. In drafting the questions of the interview, we chose to explore three predetermined categories: role of the school and the teacher in the prison context; teachers' goals and motivation for teaching in a prison context; teachers' perceived professional development (PD) needs. Our research interest was particularly focused on mathematics, so we investigated whether and how the role of mathematics emerged also from the answers to general questions. Otherwise, we prompted teachers to specify the answers in relation to mathematics.

In particular, the following questions constituted the plot of the semi-structured interview: *1)What led you to teach in prison? 2) In your opinion, what is the purpose of school in prison? 3) What is the role of the teacher in prison? 4) What significance do you think learning mathematics has for students in prison? 5) What is the main objective you set for yourself when teaching mathematics in prison? 6) What has been your educational and work path? 7) In what way, in your opinion, does your*

background influence your way of teaching? 8) Where would you like to continue your professional career in the future? 9) Do you feel you have any specific professional development needs for doing your job at your best?

Data analysis

We focus our analysis on teachers' answers to the questions of the interview related to the categories under scrutiny: role of the school and the teacher in the prison context; teachers' goals and motivation for teaching in a prison context; teachers'perceived PD needs.

We conducted a qualitative analysis of the collected data, categorizing the emerging themes based on qualitative content analysis principles (Cho & Lee, 2014). First, the three of us individually classified all responses according to the three pre-determined categories mentioned above and created new categories suitable for the data not fitting in with the pre-determined ones. In the second phase, we compared our findings to reach a consensus.

From our analysis, it emerged that the first two pre-determined categories (role of the school and the teacher in the prison context, and teachers' goals and motivation for teaching in a prison context) were very much intertwined, while a new category emerged: teachers' vision of mathematics. Even though a clear-cut division cannot be made between the first two categories, in the presentation of the results we divide them according to this criterion: in the first one we classified the themes prevalently related to the school in prison as an institution, while in the second one we classified the themes related to the single teachers, to their personal beliefs, goals and motivations.

Results

Role of the school and the teacher in the prison context

The teachers' declarations essentially focus on two values of the prison school, an educational one and an ethical one. The first value, mainly relevant for the teacher who worked with students in compulsory school age, is linked to the opportunity of providing continuity to the educational path undertaken before the detention (Caterina: "*the role of prison school is allowing students to continue their studies and facilitate the dialogue with the external schools*"). In this perspective, prison school is perceived as a hinge between the life before imprisonment and the next life, i.e. as an environment where students build conditions for a "*second chance*" (Camilla) once they leave prison. The teachers agree that it is very important to avoid school drop-out and "*do not miss the students again*" (Salvo), taking into account their previous experience of failure, not only in the scholastic field. According to Caterina, "*the relationship of trust with the teacher [...] is a glue for the students in prison, who had already had many failures".* The other value of prison school felt as a fundamental one by the teachers involved in the study is that concerning the "*personal redemption and social lift*" (Anna). The students have the opportunity of entering in touch with "*the beauty, the goodness of knowledge and human relationships*" (Camilla). In this sense the teacher is a figure guiding them to discover, to be curious and learn without being judged; he/she provides students with engaging challenges and offers support to overcome them, so fostering the regaining self-confidence and trust in the others. For example, Salvo declares that "*teaching mathematics in prison could give a great contribution for students: by overcoming [disciplinary] obstacles, they have the opportunity of finding themselves".*

Through the didactics, the prison school plays an ethical role: hopefully students find new impulses and interests, get used to collaboration avoiding conflicts and benefits from the exchange with the peers and the teacher. Consequently, students have the opportunity to find in school experience an opportunity for personal growth that goes beyond achieving disciplinary goals.

Motivation for teaching in a prison context

For all the teachers of our sample, entering the prison school system often occurs by chance, driven by curiosity, a desire to experiment, and the search for new stimuli.

A commonly shared experience among teachers is the need to open up to relationships, separating the incarcerated individual from the crime they have committed. This relationship requires empathy and brings forth a range of emotions, like compassion (Anna: "*When you're able to separate [...] the crime, which you obviously reject, from the person who committed it, who is a human being and therefore made a mistake, well, [...] in the end I connected with them and became super attached*"). The outcome of this interaction is an exchange, leaving teachers with something "*that stays with them*". Due to this openness, educators experience a strong sense of fulfilling a social role and feel that they can be important to their students. From one perspective, they aim to offer opportunities for change and personal growth, broadly guiding students and enhancing their self-confidence. However, they also feel the need to reaffirm their role as teachers and educators, distinct from psychologists and social workers.

All the interviewees set the goal to manage the reality of failure: an experience their students have often encountered, both academically and personally, and a potential outcome of the prison education process. Another recurring theme in the teachers' statements is the concept of challenge, seen as a motivation for self-improvement, both from the students' perspective - facing academic and cognitive obstacles - and from the teachers' perspective, as they navigate a context where engaging all students is essential yet difficult.

From the point of view of their motivations to teach in a prison context, some teachers are prompted by the willingness to follow their personal interests (curiosity about neuroscience, better empathy with older individuals, fascination with the prison context), while others focus on the benefit they can offer (expressing affection and love, knowing that "*you mean so much to them*"). All the interviewees express appreciation for the reduced bureaucratic and curricular constraints in prison education (fewer external pressures such as parental involvement or stringent assessments) and the smaller class sizes compared to standard schools. These aspects contribute to their desire to continue teaching in this environment.

Teachers' vision of mathematics

As a general observation, we can state that, even when responding to questions where a reference to mathematics would be expected, the teachers do not often speak about the subject in itself. Instead, they all mention the contribution that learning mathematics has on the imprisoned students' mindset. Camilla and Caterina refer to this in terms of the development of problem-solving skills. Caterina emphasizes "*developing reasoning ability, the capacity to find a solution*" and the importance of "*structuring the mathematics lesson as a question*". Anna and Salvo speak about fostering "*open-*

mindedness", focusing on logical structure and the ability to look beyond appearances. Salvo highlights the possibility for students to evaluate and choose among different procedures: "*I present them with different methods and then let them choose. I show them that switching to another method might have advantages, and then they decide*".

Concerning instrumental understanding or relational understanding of mathematics (Skemp, 1976), only Salvo and Camilla express themselves in such a way as to bring out one of the two approaches, while in the other interviews more aspects emerge that suggest the first approach (e.g. the reference to mathematical procedures and techniques), but also some aspects that suggest the other (e.g. a certain attention to diversifying representations). Terms such as "*operations*", "*calculations*", "*rules*", "*techniques*", and "*errors*" appear in most interviews, often marginally. However, Camilla frequently refers to these concepts throughout her interview, mentioning "*expressions*" eight times, "*calculations*" twice, "*rules*" three times, and "*fractions*" three times. All the interviewees mention the use of problems in their teaching practice. Camilla specifically mentions problems in the context of geometry, while the others attribute a more general and significant role to problem-solving. Salvo's interview also shows a desire to go beyond the execution of simple exercises, for example when he says: "*we don't want them to be simply self-sufficient in very simple mathematical tasks, [...] but we also want to get them used to opening their minds, to approaching slightly larger problems*".

All the teachers report - sometimes only after prompting - that their students, especially those with a migrant background, perform mathematical procedures and representations of mathematical content differently, due to previous educational paths, work experiences, or other factors. Viewing different procedures as an obstacle may indicate a procedural understanding (Skemp, 1976). Camilla remarks that "*when an expression has rules, you can't ... more or less the procedures are the same*".

Another recurring theme is the relationship between mathematics and language, primarily understood as formal and symbolic language. Camilla aims to "*show them that this formal language, in the end, makes sense*". This aspect is particularly significant for Salvo, who identifies a strong connection between mathematics and language, emphasizing them as human characteristics. He also raises linguistic challenges in definitions, especially in a multicultural context: "*Mathematical language is somewhat universal, but when concepts like perimeter, area, and volume appear in geometry, these are mountains for them [foreign students]*".

The connection between mathematics and reality is only partially recognized. Anna mentions this connection only concerning geometry: "*They like geometry because it has practical applications, helping them better understand reality*". Conversely, Camilla feels that this link is lacking in mathematics, except for topics functional to the sciences, attributing this as one of the main difficulties in teaching mathematics: "*If I could only teach science, I would feel much better in prison. And maybe just include a bit of mathematics when needed*".

Some teachers recognize mathematics as particularly important as a prerequisite for further studies. Anna notes: "*I see mathematics as laying the foundations to enable them to continue their studies*", while Camilla states: "*When I realize that someone in the class will continue studying, I try to make them engage with mathematics because it will be useful to them*".

All teachers address difficulties in learning mathematics, described in terms of "*effort*", "*obstacle*", and "*complexity*". However, according to Caterina and Salvo, this is a positive aspect in the prison context because it allows students to face challenges and gain satisfaction from overcoming them. In contrast to the deprivations of the prison environment, mathematics can offer a stimulating opportunity for mental escape. Caterina observes that "*it can provide opportunities to think, offering problems that help the student escape from reality, from daily life, and distance themselves from immediate problems*".

Overall, we can say that the teachers' perception of mathematics appears closely tied to the context in which they teach.

Declared professional development needs

From the responses to the question about the PD needs that the participants feel they have, a predominance of references to issues related to the prison context emerges. Far fewer are the references to PD needs related to specific didactic approaches to teaching mathematics.

Salvo refers to a need for PD on effective approaches for teaching mathematics to adults or individuals from different cultures ("*Professional development tailored to the type of individuals, meaning it should take into account their age, which [...] always involves a range of different ages. It should also consider, [...] the diversity of cultures and the different systems for using mathematics in various regions*"). Camilla emphasizes the need for PD to prepare more engaging math lessons that can capture the interest of students in prison, without using technologies forbidden in prison. She also mentions the need to learn to linguistically simplify the instructions for people who do not have a strong knowledge of Italian. These requests by Salvo and Camilla regard needs related to the prison context but also specifically referred to the disciplinary content.

In all other cases where this category emerges, the stated needs are related to issues of managing problematic situations at a relational level with or among the imprisoned students. This is likely because the teachers have not received any specific psychological training, which makes them feel unprepared to handle situations that significantly differ from those in an external school.

For example, Anna would like to learn more tools for emotionally handling relationships with women who are depressed because they are separated from their children. Caterina also expresses a need for PD to manage situations of low motivation to study among students who are depressed and, at times, drug-addicted. Caterina mentions a PD need related to conflict management and the dynamics that concern the lives of the students in prison. She also mentions the study of body language to understand what students do not express verbally ("*Methodologies… Yes, regarding disciplinary issues, but also, for example, being able to understand what is not said, such as aspects related to gestures*"). Finally, she highlights the need for language training, especially in Spanish and English, to conduct lessons according to the CLIL (Content and Language Integrated Learning) methodology.

The fact that the PD needs expressed by the teachers in our sample mainly concern issues related to the prison context seems consistent with an identity that is more connected to their role as educators of prisoner students rather than as teachers of a specific subject.

Concluding discussion

Our analysis allows us to note that two of the predetermined categories - role of the school and the teacher in the prison context, and teachers' goals and motivation for teaching in a prison context - are very much intertwined. This result suggests us that the identity of the teachers of our sample is strictly bound with the role that they attributed to school in a prison context, in general terms and not in relation to a specific discipline. These findings are aligned with those of Stevens (2015), who highlighted that, for the majority of the teachers in her study, the prevalent motivation to work in prison contexts was the willingness to work with "disadvantaged youth" and that "youth corrections is the perfect career for them" (p. 27).

This prevalent identity as educators in prison context is also confirmed in the analysis of their declared PD needs, which are more focused on managing prison-related situations rather than addressing discipline-specific issues in mathematics. This is also probably because they feel inadequate to fulfill a role that is more suited to a psychologist, as they lack training in this area. However, they recognize that the context demands it, and on the other hand, they appreciate taking on this role, which involves a form of affective rehabilitation of their students. These findings relate to the prison teachers' identities identified by Wright (2005). In particular, the teachers involved in our studies seem to have what Wright calls *settlers* or *cultural mediator* identities. Indeed, the first type of prison teacher "*makes commitment to stay [in prison] ... erasing attributes from the home culture that inhibits his or her integration in the new culture"* (p. 30); instead, the prison teachers who are cultural mediators "*make enormous efforts to pull the outside (the community, its norms and practices) into the school"* (p. 31). Coherently, the teachers' view of mathematics emerged from the interviews is primarily contextual, emphasizing what the subject can represent for incarcerated students in a broader sense, rather than its intrinsic disciplinary value.

From these results, we can conclude that the teachers' identity emerged in this study is more strongly aligned with their role as prison educators than with their role as mathematics teachers. This conclusion is similar to that drawn by Dalby (2017) in her study on teachers at adult vocational schools. Dalby found that they "often identified themselves more strongly with being a Further Education teacher than with being a mathematician" (p. 14).

We acknowledge that this study has limitations, including the small number of participants and the fact that none of them have a specific background in mathematics, holding degrees in other scientific fields. Future research aims to expand the study by including a larger sample of mathematics teachers working in prison contexts, possibly incorporating participants with a mathematics degree. This will allow us to explore potential differences in their views on mathematics, their specific teaching objectives, and the role they perceive mathematics to play for students in prison.

Towards European measures for upper secondary teacher students' mathematical content knowledge

Ottavio G. Rizzo[1] and Carl Winsløw[2]

[1]University of Milano, Italy; ottavio.rizzo@unimi.it

[2]University of Copenhagen, Denmark

We report on initial experiences with developing and trialling items to test school-relevant mathematical knowledge of prospective upper secondary level teachers in Europe. We give examples of how trials led us to reject or retain items, and our current rationales for developing and selecting items. Further perspectives and motivations for this line of research are outlined.

Keywords: Mathematical content knowledge, European upper secondary teacher education.

Introduction

Throughout the world, students' mathematical knowledge is routinely evaluated using written items, both in formative and summative assessment. A similar approach to evaluate teachers' mathematical knowledge is less common. It could be seen as sensitive or even offensive by teachers. A third case, that is somewhat intermediate, is that of pre-service teacher students. At universities, their mathematical knowledge is also commonly evaluated at written exams.

In an international context (with 17 countries), a comparative assessment of teacher students' knowledge was carried out by the TEDS-M study for prospective primary and lower-secondary level teachers of mathematics (see next section). A seed project (called "Knowledge for Teaching Upper secondary Mathematics", KTUM) was approved by the 4EU+ alliance to develop a similar approach within several European universities (located in Czech Republic, Denmark, France, and Italy), to develop a shared model of the mathematical content knowledge that is deemed relevant in the participating universities for students close to qualifying for upper secondary — as opposed to primary and lower secondary as in TEDS-M — teaching.

The motivations for the project were as follows:

- Within the EU, teachers who are qualified to teach in one country can teach in another: for linguistic and regulatory reasons, this is not (yet?) a common occurrence, but it shows the importance of knowing if the teachers get somehow similar or different "basic knowledge" and, potentially, of developing common European qualification standards in major and shared school disciplines like mathematics.
- The difference between national education systems is reflected in a wide array of organisations of pre-service teacher education. For example, in Denmark and Italy, most or all of the university study is in (pure) mathematics, although with some options to take courses in didactics; only later do those who wish to become teachers attend a professional course on pedagogy and practice. In France, after a generic bachelor's degree (typically in mathematics), future teachers take a master's degree specifically oriented towards the profession of teaching.

In the Czech Republic, both the bachelor's and master's degrees are oriented towards the profession, including the mathematics components.

- Moreover, different hiring processes — national competitive contests (Italy, France) vs. direct hiring by schools (Czech Republic, Denmark) — also contribute to different motivations and settings for developing profession-oriented knowledge.

It is natural to ask if these significant systemic differences are somehow reflected in students' capacity to cope with "basic knowledge" questions, directly related to the mathematics taught in secondary school. In this paper, we report on first attempts to develop and testing an inventory of such questions across countries in the European Union.

Theoretical Framework and Research Questions

There have been many attempts to develop measures of mathematics teacher knowledge, particularly in the US (e.g., Hill et al., 2008), but also internationally (Krainer et al., 2015). Such studies naturally seek to focus on elements of teacher knowledge that correlate with measures of efficient teaching, when controlling for other factors (for an overview, see Winsløw, to appear). To summarise, early results suggested that there is no simple correlation between the sheer amount of academic mathematics courses completed by teachers, and the results or knowledge gain of their students. However, deep knowledge of the mathematics to be taught, as well as knowledge about how to teach it, are promising categories in terms of their impact on teaching quality and student achievement. These categories of knowledge have been theorised in various ways, giving rise to categories such as MCK (mathematical content knowledge) and MPCK (mathematical pedagogical content knowledge), as used in the TEDS-M study (Tatto, 2015). Quantitative studies operationalise these categories in test inventories. Most studies have been focused on primary and lower secondary school teacher knowledge and education, and none has so far focused on MCK and MPCK resulting from upper secondary teacher education in the European context as we do in this paper. We used an adaptation of the subdomains of MCK from TEDS-M, summarised in Table 1, while including also some items which would be classified as MPCK in that study (meaning that the item specifically addresses teaching). In particular, the categories are adapted to the upper secondary level as shown in Table 1, while including also some items which would be classified as MPCK in that study (meaning that the item specifically addresses teaching).

Given these categories, we have worked with the following research questions, focused on methodology for developing test items corresponding to the categories:

1. What kinds of items are proposed by representatives of European universities, when asked to provide input to an MCK/MPCK test for future upper secondary school teachers?
2. How did students from the four universities do on them initially (according to category and country, are there any apparent differences)?

Concerning 1., the main sources of items have been exams given in teacher-oriented courses at the participating universities, subsequently adapted and revised for small-scale pilot experiments (cf. the next section) in order to provide first answers for 2. that could illustrate the kinds of result one might obtain with larger and more carefully sampled groups of respondents.

Table 1: MCK framework: subdomains and content areas (adapted from Tatto, 2013, p. 13)

Subdomain	Content Areas
Numbers	Number sets (e.g. rational); Induction; Number Theory
Geometry	Geometric shapes; Geometric measurements; Analytic Geometry
Algebra	Algebraic expressions; Algebraic equations; Vectors, Matrices
Functions	Equations; Algebraic and Transcendental functions
Data and Chance	Data processing and interpretation; Probability
Analysis	Continuity; Limits; Differential calculus; Integral calculus

Context and methods of KTUM

4EU+ is an alliance between eight European universities who share the goal "to create one comprehensive research-intensive European University through a new quality of cooperation in teaching, education, research and administration" (4EU+, 2024). Members from four participating universities — University of Milan, University of Copenhagen, Charles University Prague, University of Paris–Sorbonne — joined in a one-year programme (November 2023 to October 2024) called *Knowledge for Teaching Upper-secondary Mathematics* (KTUM) to explore the feasibility of sharing parts of the respective teacher training programmes, focusing on a definition of common framework of MCK and MPCK across the four programmes.

Each of the four universities offer a different model for pre-service teacher training; here we consider a typical path for a student to qualify for teaching mathematics at the upper-secondary level, noting that these are not necessarily the only paths for prospective teachers. In particular, in all the participating universities except Paris, it is also possible to study mathematics as a minor. All four universities follow the Bologna model, with a 3-year bachelor programme (B) followed by a 2-year master programme (M).

Milan U.: B and M in mathematics. A mathematics education track is available in M, but it is not compulsory. This is followed by a 60 ECTS course in pedagogy, mathematics education, school regulations, etc. Students qualify for teaching either mathematics or mathematics and physics.

Copenhagen U.: B and M in mathematics. The programme normally includes a minor, so students qualify for teaching two subjects. During their first year of teaching, teachers must pass a 20 ECTS nationally organised course on pedagogy, subject teaching, school regulations, etc.

Charles U., Prague: B and M in mathematics education. Periods of practicum are included in the programme.

Sorbonne U., Paris: B in Mathematics, followed by a M in mathematics education which includes practicum and elements of Pedagogy.

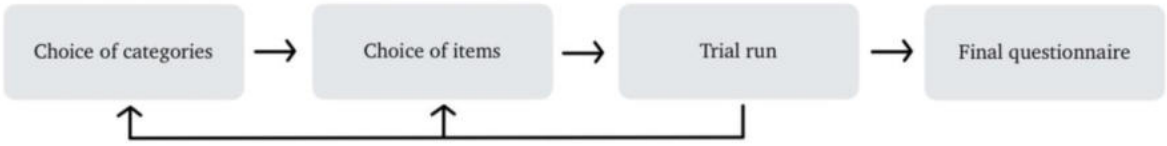

Figure 1: Development cycle of the questionnaire

The main objectives of KTUM were to map out the details of these paths, and then to develop a questionnaire to evaluate the knowledge of mathematics content (see next section) of students at the end of their master's programmes. The second step was not straightforward, and it relied both on the first step and on feedback from the trial runs of the questionnaire (Figure 1).

It was expected that the curricula in the four countries differ on points like whether or not synthetic geometry is emphasised or not. It surprised the authors of this paper to learn that, in the Czech Republic, differential and integral calculus is no longer part of the upper secondary curriculum. Nevertheless, since essentially all the concerned students in the Czech programme will also have taken courses in analysis, and analysis is a major topic in upper secondary school in the remaining three countries, it was agreed that this domain should be part of the questionnaire. As an example of more detailed differences, which affected our selection of items in the end, was whether teacher students could be expected to know the rational root theorem or not. The principle was to include only items that could be solved by knowledge taught in all four programs.

Each national group initially proposed 5-7 items based on their experience and practice of assessing MCK and MPCK. These items were mostly taken or adapted from exams in teacher-oriented courses, from national contests and standardised tests (INVALSI tests), etc. The KTUM team then met for three days in Prague, working in mixed groups (people from different universities) to discuss these first items, propose new items to cover missing areas or aspects (especially MPCK), and to fine tune the resulting inventory of items in terms of balance and formulation. Many items were discarded because some national group did not find them appropriate for their students.

The first phase was entirely conducted in English, being the only language mastered by all members of KTUM. The second phase required the items to be translated into the four relevant languages (Italian, Danish, French, Czech): since French is mastered by most members of KTUM, the French translation was used to double check translation issues. One example of these issues is the difference between "dot product" and "scalar product": in English, the latter typically refers to any symmetric bilinear form, while the former refers to the standard scalar product on $\mathbb{R}^n$. In, say, Italian, only the latter expression is used: "dot product" should then be translated as "prodotto scalare standard" (standard scalar product).

The group collaborated on a common LaTeX file hosted on OverLeaf, and special routines to deal with international text were developed by the first author: in order to minimise the risk of inconsistencies in the different localisations, it was deemed paramount that the mathematical part was not part of the localisation, and that the LaTeX machinery should be transparent enough to be usable by project members with little, or no, previous LaTeX experience (see Figure 2).

```
\en{Find} \it{Trova}\da{Bestem et tal}\cz{Najděte } \fr{Trouver  } $x$
\en{such that }\it{tale che }\da{ så }\cz{ takové, že }\fr{  pour que }
$\left(\sin(1/x)\right)^{-1}$
\en{has 128 digits}\da{har 128 cifre}\cz{má 128 číslic}\fr{s'écrive avec 128 chiffres}\it{abbia 128 cifre}.
```

Figure 2: Example of localised LaTeX code

At the end of the first phase, 14 items (most with several questions) were selected and administered to a group of 17 volunteer students: four from each of Milan, Prague and Paris, and five from Copenhagen. The students did the test in the same room in Milan, and after the test, a thorough follow up discussion with them was organised (also to let them know how to solve all items). The sample of students was far from being statistically significant or random as they were volunteers. All except the Milan students would presumably have been motivated by a paid trip to Italy. Still, the students' performance and assessment of the items was believed to be valuable for the further development of the item inventory.

Based on the first results and student input, nine of the fourteen initial items were selected (with some rearrangement and shortening). All questions were adapted to closed (multiple-choice) format, using the open answers from the first test as a source of (further) distractors. These questions were then pilot tested with 105 students (i.e., most students in the teacher training track, plus 17 Italian temporary teachers with a minor in Mathematics and enrolled in an alternative qualification programme) in Autumn.

Initial test items

As mentioned above, 14 items were selected for the first trial: 6 involved the domain Numbers, 7 Algebra, 3 Geometry, 2 Functions, 2 Data and Chance, 3 Analysis. Here, the total is greater than 14, since most items contain several questions which could be in different domains). Considering all questions, 17 involved the domain Numbers, 8 Geometry, 15 Algebra, 8 Functions, 3 Data and Chance, 6 Analysis. For the first trial test, students were given three hours. This allowed to experiment several items, mostly with open response questions. However, for a large-scale test, a shorter test time would be more realistic. Therefore, at any rate, some items or questions had to be dropped.

A main principle was to discard questions that were done correctly by all, or by none (or very few) of the students (so they had little or no discriminatory power). For example, in Figure 3, we have three apparently similar questions which test students' MPCK. The first one was selected by three (out of 17) students, the second was selected by half the students (IT: 1/4; DK: 0/5; CZ: 2/4; FR: 3/4), and the last one by none. We retained to two first options.

The second answer illustrates the mutual dependency of MCK and MPCK: during the follow-up discussion, we learned that the students who had not marked this exercise simply did not know the

relationship between logarithms and number of digits (MCK). So MCK clearly influences MPCK. The piece of MCK concerned is useful to circumvent difficult actual calculations and relates to intrinsic and historically crucial aspect of logarithms. The fact that Danish students did not know this might be related to the extensive use of computers in Danish upper secondary school. By contrast, that 3 of 4 French students marked the second exercise could be caused by the fact that French high school students are expected to solve exercises with as little help as possible from technical tools. Thus, differences in (relevance of) MPCK may also lead to differences in MCK.

Emma wants to select exercises that can be solved by using logarithms and their properties. Mark all the exercises that are relevant for her.

- ◯ Find x such that $(\sin(1/x))^{-1}$ has 128 digits.
- ◯ How many digits has 3^{280}?
- ◯ How many digits has the integer part of $\sin(3^{280})$?

Figure 3: A question on choosing exercises (extract)

We expected the questions in Figure 4 to be quite doable for master's level students in Mathematics or Mathematics Education, with the only difficulty being in the writing of a proper proof using one of the various possible arguments. All the Czech students answered the first question of item 13 correctly, while none of the French, one Italian and one Danish did so. However not a single student gave correct answers for the first question of item 14, and no student gave mathematically rigorous answers to the second questions. Both items were discarded.

13. For which natural numbers n does the equation $x^n + x + 1 = 0$ have at least one real solution? Explain your answer.
14. For what natural numbers n does the equation $x^n + x + 1 = 0$ have at least one rational solution? Explain your answer.

Figure 4: Questions that were too difficult

Initial test outcomes

We now analyse the data from the first pilot. The sample set is not yet large enough for any meaningful psychometric analysis (like Rasch models). We still consider rough trends in the shares of correct answers to the questions of some interest. In Table 2 we present the results by country and MCK subdomains (Cf. Table 1). For each subdomain D, the first column represents the percentage A_C^D of correct answers for students of country C; while the second column shifts the data in such a way that the average value in each column is zero and that the average results of different universities is zero: i.e., it represents the difference between A_C^D and the expected number, given the average number A^D of correct answers to the subdomain, the national average A_C, and the total average: $(A_C^D - A^D) + (A_C - A)$. This number provides a rough measure for areas in which the respondent groups over- or underperformed, given their overall performance.

We notice that the Italian students with a Maths minor performed significantly worse than all the other groups, despite having at the very least one year and a half of teaching experience, which hints

to a significant effect of majoring in Mathematics. It is interesting to notice that the Danish students, who are majoring in pure Mathematics, present results similar to the Czech ones, which are majoring in Maths Education.

We now ignore the Italian students with a Math minor: the variation in differential scores is much more contained in the shown pilot results than in the first trial, which should reflect a choice of items which do not discriminate on the difference in mathematical content in the four universities. Nevertheless, the Algebra subdomain show little variation on expected scores: this is an interesting factoid that could hint to the subdomain receiving a similar approach in different countries. The highest differential scores are presented by the Italian students in Analysis and by the French students in Data & Science: this could possibly follow from the previous attendance to classes focusing on the teaching, respectively, of Analysis and of Data & Chance.

Table 2: Results from the first trial test: raw data and difference from centred values.

	Size	Numbers		Geometry		Algebra		Functions		Data & Chance		Analysis		Total
IT	12	82%	*8%*	82%	*0%*	51%	*0%*	71%	*-7%*	56%	*0%*	71%	*9%*	**71%**
IT-M	17	47%	*0%*	51%	*-5%*	55%	*4%*	27%	*3%*	24%	*-5%*	34%	*-1%*	**44%**
DK	17	55%	*-8%*	70%	*-1%*	70%	*3%*	35%	*-4%*	45%	*1%*	55%	*4%*	**59%**
CZ	42	63%	*3%*	75%	*6%*	67%	*2%*	34%	*-3%*	37%	*-6%*	42%	*-7%*	**57%**
FR	33	67%	*-2%*	73%	*-5%*	70%	*-3%*	50%	*5%*	61%	*10%*	62%	*4%*	**66%**
Avg		**52%**		**64%**		**45%**		**60%**		**49%**		**36%**		**53%**

Plans and potentials for continuation

A new round of tests will need to be administered to (different) students in 2026; students minoring in Mathematics (where feasibile) should also be tested. If results were shown to be stable, a definitive item inventory to be employed at large scale, involving more universities and, possibly, more European countries.

In a similar way to TEDS-M, the relationship between the structure of teacher education programmes and results on the test can then be assessed on the short term. On the medium term, we could envision studying the connection to results in teaching (say, two years after graduation); while on the long term it will be possible to investigate the year-to-year performance gains of the teachers' pupils (controlling for other variables like socio-economic-cultural context of families and schools). The long-term goal of the project could include the establishment of an upper secondary level extension of TEDS-M, tailored to inform common policies and development in Europe.

Conclusion

The main outcome achieved so far consists in the possibility and methodology of developing items that can be used across different European programs and systems, by adaptation and trials that result in a test inventory with real discriminatory power and reflecting expert knowledge in the area. Of course, without demonstrating correlation with teaching quality in some sense, this consensus remains limited in value for policy making; however, experience from decades of effect studies gives some reason for optimism in this regard, as does the relative ease by which expert consensus was achieved, both on and within the categories of MCK shown in Table 1, and in regard to the composition of the second inventory of items that is now to be experimented.

Despite the sample size of respondents so far involved, the hypotheses thus generated are still of some interest, given that no similar evidence is available.

We also emphasise that the Czech students, who are the only one who are not enrolled in a pure mathematics degree, show results very similar to the Danish students who, on the other hand, are not offered a Maths education track. This, too, is an interesting factoid that should be explored in a statistically significant sample set and could inform policies regarding this major systemic difference. We also note that a major difference separating the Danish programme from the rest is the limited external motivation (like a national competition) and opportunity they have to attend courses focusing on MCK (and MPCK) closely related to upper secondary school mathematics.

Perceptions of mathematical creativity: The case of one teacher in a special education class

Maya Ron-Ezra[1, 2] and Esther S. Levenson[1]

[1]Tel Aviv University, Tel Aviv, Israel; maya.ronezra@gmail.com

[2]Achva Academic College, Israel

Teachers' perceptions of creativity can significantly shape their practice and influence students' creativity. This case study explores the perceptions of one special education teacher, examining the alignment between those perceptions and classroom practices. An interview revealed that the teacher focused on herself and how she expresses creativity, with less emphasis on the student's ability to express creativity. However, observations of her mathematics lessons showed that her practice had the potential to occasion mathematical creativity among her students.

Keywords: Teacher's perceptions, mathematical creativity, learning disorders.

Introduction

The ability to think creatively is inherent in every person, regardless of their cognitive abilities (OECD, 2017). In mathematics classrooms, encouraging mathematical creativity strengthens connections between mathematical topics and expands knowledge (Levenson et al., 2018). In this study, we presume that students with learning disorders (LD) have the potential to express mathematical creativity when provided with the right conditions, highlighting the importance of creating such opportunities. Because teachers play a key role in fostering creativity, their beliefs influence whether and how they do so (Levenson, 2013). Examining teachers' perspectives can reveal which approaches they adopt or should adopt to support students' mathematical creativity, especially considering that special education (SE) teachers do not necessarily receive specific training in mathematics. This study explores the perceptions of one SE teacher regarding mathematical creativity and how those perceptions are reflected during her mathematics lessons in her SE class.

Theoretical background

Creativity has been recognized as essential for success in the twenty-first century, and consequently, various aspects of fostering creativity among students are attracting interest. Within the field of mathematics education, several studies have examined expressions of mathematical creativity in different ages (Elgrably & Leikin, 2021) as well as tasks that encourage mathematical creativity (Levenson, 2013; Ron-Ezra & Levenson, 2023). Despite this, few studies have looked at mathematical creativity among students with LD.

Mathematical creativity is usually measured according to three components: *Fluency* refers to creating many ideas or solutions while working on a task. *Flexibility* involves approaching a task from different directions, producing solutions of various types, and associated with divergent thinking, which enables switching between different topics (Levenson et al., 2018). *Originality* refers to generating unique or innovative ideas (Elgrably & Leikin, 2021). Tasks that can encourage mathematical creativity may provide vague instructions that do not specify the method of solution,

enabling a variety of answers or solution strategies, and are called open-ended tasks (Levenson et al., 2018), or multiple-strategies tasks (Ron-Ezra & Levenson, 2023). Despite the importance of including such tasks in class, teachers tend to find it difficult to recognize their potential (Chiu, 2009). This study will examine if a SE teacher is aware of such tasks and teaching methods and if she implements such tasks in her SE class.

Mathematics teachers' perceptions affect their choice of teaching practices and the opportunities they create for their students. Likewise, teachers' perceptions regarding creativity can affect whether they choose tasks that encourage expressions of mathematical creativity and have implications for fostering creativity in the classroom (Levenson, 2013). Previous studies have investigated teachers' perceptions of creativity, not specifically related to mathematics. A review of such studies conducted by Andiliou & Murphy (2010) showed that teachers believe creativity can be developed, but often limit it to gifted students and the arts, struggling to identify less obvious creative students. Another study revealed that both general education and special education (SE) teachers consider themselves creative (Kasirer & Shnitzer-Meirovich, 2021). However, SE teachers prioritize fostering creativity, likely due to smaller class sizes and less pressure to meet standard curricula. They also display more originality in their teaching methods, tailored to students' unique needs (Kasirer & Shnitzer-Meirovich, 2021).

Mathematics teachers' perceptions of mathematical creativity are shaped by their views on the nature of mathematics. Some view it as a rigid, procedure-based subject, while others see it as fostering problem-solving and creativity. Pre-service primary teachers often believe that mathematical creativity involves teaching creatively with diverse resources and real-life examples (Bolden et al., 2010). Lev-Zamir and Leikin (2012) found that while elementary and middle school teachers hold positive perceptions of creativity in mathematics and related tasks, they do not always effectively implement these tasks to foster mathematical creativity in the classroom. High school teachers may recognize the importance of fostering mathematical creativity but are unsure how to achieve it in practice (Shriki & Lavi, 2012).

Lev-Zamir and Leikin (2012) noted that teachers hold two different conceptions of classroom mathematical creativity: a teacher-directed conception and a student-directed conception. The teacher-directed conception means that creativity is attributed to the teacher's work and the actions he takes (such as choosing tasks, conducting a conversation, or solving problems), which makes teaching creative (Lev-Zamir & Leikin, 2012). The student-directed conception of creativity refers to the teacher's perception of the mathematical creativity exhibited by the student while performing a task. A student's creativity can be manifested in asking questions, using a variety of strategies, developing his own methods for approaching problems, and exploring ideas (Bolden et al., 2010). Shriki and Lavi (2012) pointed out inconsistencies between teachers' claims and their actions. On the one hand, teachers claim that they develop mathematical creativity by encouraging students to solve problems in different ways; on the other hand, possibly because of time constraints, such practices are limited or non-existent. As for SE mathematics teachers, few studies have examined how their perceptions regarding mathematical creativity are reflected in their SE classes.

Consequently, the aim of the case study presented here is to examine the perceptions of one SE teacher regarding mathematical creativity and whether there is an alignment between the teacher's stated perceptions and the way in which mathematics lessons are conducted in her SE class.

Method

This study employs a case study methodology, allowing for an in-depth exploration of the teacher's perceptions of mathematical creativity and how her actions in the classroom encourage creativity among her students with LD. Through interviews and lesson observations, the study focuses on a specific situation, providing a detailed understanding of how one teacher fosters mathematical creativity in her classroom.

Niri (a pseudonym), the special education teacher in this study, has been teaching students with special needs for 19 years. While she received general training in special education, she had no specific training in mathematics. Her extensive experience, ability to engage students with mathematical tasks, and skill in selecting appropriate challenges made her a suitable focus for this study. The students in her class had been diagnosed with LDs and, due to significant gaps, mainly in reading, writing, and comprehension, as well as the need for support, were placed in a SE class. Yet, they followed the general education mathematics curriculum. According to Niri, their mathematical progress was slow, requiring many examples and repetitions, though not significantly below age expectations. All students and their parents consented to participate in the study, which was approved by the Chief Scientist of the Ministry of Education and the university's ethics committee.

The research tools included a semi-structured interview with Niri and observations of seven mathematics lessons in her class. The semi-structured interview with Niri took place three months after the beginning of the school year and was recorded and transcribed by the first author. The interview questions included: "How does creativity manifest itself during mathematics lessons?", "Is there a need to encourage mathematical creativity in a SE class?", "How can students with special needs be encouraged to express mathematical creativity?" In addition, Niri was presented with a task considered to encourage mathematical creativity because of its many solution paths (Figure 1). After presenting the task, Niri was asked: "Are you familiar with such tasks?" and "Can this type of task be used during a lesson in a SE class?"

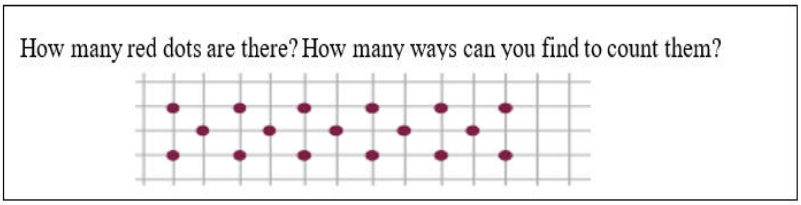

Figure 1: A creativity-promoting task (Bicer & Bicer, 2023)

Following the interview, seven observations were conducted during mathematics lessons where Niri taught the entire class. Each lesson was recorded using a stationary video camera at the back of the room, capturing the classroom setting, the teacher, and the students. The interview data were analyzed through repeated readings, identification of key concepts, and organization into themes (Patton, 2014). These themes were then examined through the "lens" of mathematical creativity, with

particular focus on Lev-Zamir and Leikin's (2012) distinction between "teacher-directed creativity" and "student-directed creativity." Out of the seven recorded lessons, two were selected for detailed analysis because they contained clear examples of student engagement and creativity. The analysis focused on the teacher's actions that encouraged creativity and examined how students expressed mathematical creativity, with an emphasis on fluency, flexibility, and originality.

Findings

This section presents Niri's perceptions of mathematical creativity and examines its expressions in her SE class by analyzing two mathematics lessons.

Niri's perspectives of creativity that arose from the interviews

The concept of mathematical creativity, as defined in the literature on mathematics teaching (e.g., in Elgrably & Leikin, 2021) was not familiar to Niri. She stated, "The definition of creativity is unclear; it isn't clear to me what you researchers are thinking about." Even when she was presented with a task thought to encourage expressions of mathematical creativity (Figure 1), she said that she was not familiar with such tasks and therefore does not give them to her students. She added: "It would have been nice if someone had given me things like that," demonstrating her willingness to experiment and expand her knowledge on encouraging mathematical creativity in the classroom. She continued, "A task like that would awaken children's curiosity and motivation." Without explicitly recognizing the potential of such a task to occasion mathematical creativity, Niri recognizes that such a task could attract the attention of students and make mathematics interesting for them.

Despite stating that she is not familiar with a formal definition of creativity, she does have implicit perceptions of what is meant by mathematical creativity. Niri explains that in her view, she demonstrates mathematical creativity by using mathematical games and instructional manipulatives for illustration purposes: "I use manipulatives. I use the computer. I offer them all the options available." Niri considers herself a creative teacher; in her opinion, the variety of activities she initiates during her lessons in the SE class are an expression of her creativity. She notes: "I look at it from the perspective of how I teach. I teach in all kinds of special ways and make the lessons creative." Her statements indicate a teacher-directed conception of creativity.

When discussing the subject of mathematics, Niri perceives creativity in mathematics when it is connected to other topics and everyday experiences. In her opinion, creativity in mathematics is manifested by finding connections between mathematical subjects and real-life examples. She described a history lesson in which she incorporated mathematics and said: "It is very important for me to include mathematics in all disciplines. I believe this is something that opens them (to new directions). This can also be defined as creativity." She also claims that her mathematics lessons are conducted creatively since she improvises and draws connections to everyday life. She adds: "I take a certain subject (in mathematics) and show them how it is in real life, which is also a type of creativity. I think outside the box and bring a lot of manipulatives and teaching aids, and I show them how they work in many ways." Once again, Niri emphasizes the importance of providing a variety of teaching methods during mathematics lessons.

Throughout the interview, Niri focuses on the ways in which she demonstrates creativity, and not on expressions of mathematical creativity among her students. Following Niri's descriptions of her teaching, the researcher tries to guide her, asking whether her students also display this variety: "So, the children can show it (their solutions) in several different ways?" Niri appears to dismiss this, saying: "Not necessarily," and goes back to focusing on creativity as a characteristic of the activities *she* implements in the SE class which make *her* teaching creative.

Niri does recognize that students in the present era are required to demonstrate creativity, which is reflected in their ability to express a different line of thought and to show a variety of solution strategies while using different representations (Transcription 1).

Transcription 1 – part of the interview with Niri: mathematical creativity in students

Researcher:	What would you consider an expression of mathematical creativity in a child?
Niri:	When he shows me a different way, when he thinks in a different way. When he calculates in a different way, he can use objects to show me another way to see the calculation, see the number.
....	
Niri:	I think you must have creativity in everything, because this is where the world is heading, not to robots, but rather, anyone who is more creative is more successful in the world in my opinion.
Researcher:	What does it mean, more creative?
Niri:	More original, innovative, brings new ideas to people around him and manages to see things in a different light and think outside the box.

The terms "original" and "innovative" are common in the field of mathematical creativity, but when Niri is asked to explain their meaning and provide a concrete example from the class, she is unable to do so. Subsequently, she states that she feels she does not give many tasks that encourage mathematical creativity, in which the students must work independently and demonstrate a range of appropriate solution strategies. When the researcher explains what is meant by fluency as a component of creativity, Niri's expresses reservations about students with special needs, saying that "In SE you will find it (fluency) very limited, especially in young students."

Mathematical creativity in the classroom

During Niri's mathematics lessons, expressions of mathematical creativity (fluency, flexibility, and originality) were observed among the students. In this part of the findings, we focus on two lessons: one centered around the "decimal system" and the other on "long addition and subtraction" and present examples of activities Niri carried out that had the potential to encourage creativity among her students, alongside examples of her students' expressions of mathematical creativity.

In both lessons, Niri used open-ended questions and instructions, allowing students the flexibility to provide answers in their own way. In the lesson on the decimal system, Niri wrote the number 792 on the board and asked the students to represent it. The open-ended instruction she gave was: "I'm writing a number on the board, and each of you will explain to the class, however, you like, what this number is." This instruction allows students to work independently in a variety of ways. The students start working immediately, apparently familiar with this type of instruction. At the class level, students demonstrate fluency by proposing different representations of the number 792, including an addition sentence (700 + 92 = 792), a verbal representation ("7 hundreds, 9 tens, and 2 units"), a

representation using base-ten blocks, and more. At the individual level, each student produces only one representation of the number, without switching between different representations. Moreover, the teacher does not encourage individual students to find more than one representation. Consequently, neither fluency nor flexibility are seen at the individual student level.

Similarly, in the lesson on long addition, Niri asks the students to represent the number 32. However, in this case, the open-ended question she presents (Transcription 2) stimulates a conversation that leads to a few answers. The students respond to the question and create together several ways of representation, which indicates fluency and flexibility at the student level as well.

Transcription 2 – a conversation between Niri and her students during the lesson on long addition and subtraction

Niri:	In order to explain what three tens mean, how can I draw three tens?
Student 1:	Circles.
Niri:	Circles? (starts drawing circles on the board)
Student 2:	Lines, lines (referring to a tens block which he calls a line).
Student 3:	Three (meaning, to draw three rectangles representing the three tens).
…	(Niri erases the circles and draws a rectangle divided into ten parts).
Student 2:	And you can also do units (meaning, to represent the number through units).

In this lesson, the teacher's open question invites the students to come up with a flow of ideas for representation. Student 1's idea was not accepted by the teacher. Student 2's idea, although not worded with the correct terminology, was understood to refer to the rectangle of the tens block, which looks like a line. Building on Student 2's response, Student 3 added that three of those "lines," meaning rectangles, would be necessary to represent 3 tens.

In both lessons, students use classroom resources to respond, while Niri encourages them to explore other manipulatives: "Is there another way? Something in the class to represent it?" She leaves the choice to the children without specifying an item, fostering flexibility and making students comfortable selecting tools that assist them. For instance, in a long addition lesson, the teacher invites two students to solve 32 + 77 on the board, while others use a teacher-designed navigation card to guide their solution or work in their notebooks. Meanwhile, one student, who struggles with writing, solves the problem using base-ten blocks.

Discussion and conclusions

The first research question sought to examine one SE teacher's perceptions of mathematical creativity. The teacher, Niri, appears unfamiliar with the concept of "mathematical creativity" as described in the research literature. Like other teachers (Chiu, 2009), she does not recognize tasks that are designed to occasion mathematical creativity. When the researcher explains to her the notion of fluency as it is used concerning creativity, she implies that her students' LDs and their young age could make it difficult for them. Regarding flexibility, although Niri does not use this term explicitly, her perception of mathematics as a subject that can be connected to other subjects and to everyday experiences, is in line with how researchers suggest promoting flexible thinking (Levenson et al., 2018). Finally, Niri specifically mentions original thought in relation to creativity but cannot recall an instance of original thinking in her SE mathematics class.

Niri demonstrates a teacher-directed conception of creativity (Lev-Zamir & Leikin, 2012). In her view, teaching methods such as using various means of representation, demonstrating different strategies, and creating connections to everyday life make her a creative teacher (Bolden et al., 2010). Yet, by demonstrating a variety of solutions, she is, although inadvertently, promoting mathematical creativity among her students (Levenson et al., 2018). In fact, she emphasizes that students can express themselves through different representations and suggests that this can lead to originality. In general, Niri considers creativity important and even mentions how students demonstrate creativity by showing her a "different way."

Regarding the relationship between Niri's perceptions of mathematical creativity and the way mathematics lessons were conducted in her SE class, a few differences were observed. While in the interview Niri claims to be unfamiliar with tasks that encourage mathematical creativity, the teaching methods she uses in class include elements that promote expressions of mathematical creativity (Kasirer & Shnitzer-Meirovich, 2021). A gap is evident between Niri's positive views on mathematical creativity and her pedagogical knowledge of how to implement tasks that encourage students to express creativity (Chiu, 2009). Niri does not mention using open-ended questions and instructions to encourage mathematical creativity among her students, but in practice, she incorporates this method into her lessons. Using open-ended questions and instructions (Levenson et al., 2018) allows students to choose the solution strategies that suit them (Ron-Ezra & Levenson, 2023), which aligns with researchers' views on flexibility and originality (Levenson et al., 2018). However, Niri does not encourage each student to solve a problem or represent a number in multiple ways. In the lessons observed, fluency and flexibility can be seen at the class level, but not at the individual level. Furthermore, Niri does not attempt to facilitate a discussion that might help students find connections between different representations, which could lead to collective creativity (Molad et al., 2020). Rather than examining mathematical creativity as a primary focus, the study identified creativity components within Niri's words and practices, focusing on behaviors and expressions instead of using creativity as the main analytical framework.

In conclusion, this case study highlights the gap between a special education teacher's willingness to promote mathematical creativity and her knowledge of how to do so. A key limitation is that students' creativity may be restricted because the teacher does not model fluency, flexibility, and originality in her task solutions. Additionally, the case study design limits generalizability, and it would have been insightful to observe whether the teacher herself demonstrates the expected creativity. While the findings cannot be generalized to all SE teachers, they provide insight into how conceptions of mathematics, creativity, and SE are interconnected. A key conclusion is the need for teacher training to encourage mathematical creativity by fostering personal engagement with tasks and self-expression.

Teachers' beliefs regarding the knowledge they need to teach word problems in middle school

Iris Schreiber

Kibbutzim College of Education & Bar-Ilan Universit , Israel; iris.schreiber@smkb.ac.il

This paper describes a part of research on several aspects of teaching word problem-solving. It involves 57 middle school mathematics teachers and focuses on teachers' beliefs regarding the knowledge they need to teach word problems: What do teachers believe is essential for them to know?. Teachers rated the importance of various knowledge components based on the framework by Deborah Ball et al. (2009), which includes common content knowledge, specialized content knowledge, knowledge of content and teaching, and knowledge of content and students. Teachers generally believe that specialized content knowledge and knowledge of content and students are the most essential for them. However, they prioritize different aspects within these components, considering some more important than others. These findings could influence teachers' guidance and training.

Keywords: teachers' knowledge, beliefs, word problems, middle school

Introduction and theoretical framework

Beliefs shape how people see the world and may influence their attitudes and performance (cross, 2009). Many studies have dealt with teachers' beliefs and suggested various definitions for this concept, such as perceptions, attitudes, opinions, worldviews, and more. They also refer to beliefs regarding different aspects of the mathematics teaching profession: beliefs about students, about teaching, about mathematics, about the role of learning mathematics, and more (Goldin et al., 2009). The present study is based on Voss' definition of beliefs as psychologically held understandings and assumptions about objects that are felt to be accurate and influence people's interactions with the world (Voss et al., 2016). Teachers' beliefs may affect their relationships with students and how they teach, i.e., their pedagogical decisions and overall effectiveness, ultimately shaping students' learning experiences (cross, 2009; 2015; Lau, 2021).

Teachers' beliefs about their required knowledge may influence their teaching, so it is essential to test it and design their training accordingly. This study addresses the knowledge components defined by Deborah Ball and colleagues (Ball et al., 2008), which defined four main knowledge components: Common Content Knowledge (CCK) is a type of mathematical knowledge required even for non-teachers. For example, knowing how to calculate and solve exercises and problems. Specialized Content Knowledge (SCK) is content knowledge unique to teaching. For example, knowing how to solve a problem in a variety of ways, knowing how to connect different representations to an exercise or a problem and understanding the theoretical principles behind them, and knowing how to examine an unconventional way of solution, i.e., whether it is correct and whether it will work in other cases. Knowledge of Content and Teaching (KCT) combines content knowledge with teaching. For example, knowing how to choose examples suitable for presenting a topic and examples ideal for deepening it, knowing different representations to teach a problem, and evaluating each representation's advantages and disadvantages for teaching the problem. Knowledge of Content and

Students (KCS) combines content and students' knowledge. For example, knowing common student errors and possible reasons for these errors, knowing whether a given example might interest and motivate students, and knowing what is easy and difficult for a specific population of students.

Some studies examined the relationship between teacher knowledge and teachers' beliefs. For example, Drageset (2010) examined teachers' beliefs related to what mathematics is (for example, "Mathematics means finding the correct answer to a problem") or what is essential for students to know (for example, "The ability to explain their answers"). He focused on CCK and SCK but not on what essential knowledge teachers should acquire, and the other elements of knowledge mentioned in Ball's theory were not tested. Also, he did not ask what is the most important when combining several aspects corresponding to the same knowledge component. Other researchers (Kim, 2018; Lui & Bonner, 2016; White et al., 2005; Yang et al., 2020) examined beliefs in three domains: general beliefs about mathematics, such as what is the nature of mathematics or what is the beauty in mathematics; beliefs about learning mathematics, such as what is essential in learning mathematics- the way to the solution or the correct answer; and beliefs about theories of mathematics teaching, such as constructivist, traditional and technological. These studies found a correlation between beliefs and knowledge. However, they did not systematically test beliefs regarding knowledge components defined by Ball (Ball et al., 2009). They did not test beliefs about the need for, or the importance of, each knowledge component.

Since knowledge is specific to each topic, a particular topic was chosen for this research: word problem-solving. Word problem solving is a central topic in mathematics curricula for all ages at all stages of education worldwide. Curricula and various studies emphasize the importance of problem-solving as a subject that connects everyday life problems with mathematical models, combining several concepts, developing a high level of thinking and creativity, and enabling the students to apply various skills they have learned. Also, there are many different strategies for solving word problems using multiple tools - arithmetic, algebraic, graphic, and more (Ministry of Education in Israel, 2013; NCTM, 2000; Verschaffel et al., 2020).

Despite the variety of problem-solving strategies, mathematical word problem-solving is considered a complex subject for students, which causes many errors and difficulties, which may be related to reading, calculating, algebra, and more (Pongsakdi et al., 2020). Given students' difficulties in this topic and the various teaching strategies, teachers' knowledge of this subject is fundamental. Hence, it is essential to test teachers' beliefs about what is important to know to teach the subject effectively. Knowing teachers' beliefs may lead to better preparation of guidance and professional development programs.

The research question is: What are the teachers' beliefs regarding the knowledge they need to teach word problems?

Methods section

Participants: Fifty-seven teachers teach mathematics in middle schools in Israel. All the teachers specialized in mathematics as part of their academic studies - 40 teachers with a bachelor's degree (B.Ed or B.A degree) and 17 teachers with master's degrees (M.Ed or M.A degree). Teachers' seniority varied from 1-2 years of experience to 25 years of experience: 21 teachers are novice

teachers, with seniority of up to 5 years, and 36 teachers are experienced teachers, with seniority of 10 or more years.

Research tool: An electronic questionnaire was built for this study. A preliminary study was conducted with 12 teachers who answered these questionnaires, and reliability was examined for each questionnaire. Cronbach's coefficient alpha was calculated using the pilot data, yielding an acceptable reliability score: $\alpha = .79$. The teachers received 14 statements in the questionnaire concerning the knowledge required for a math teacher to teach word problems. There were no time limits for answering the questionnaire, and it took a very short time—about 5 minutes. The statements addressed each of the four knowledge components according to Ball's framework. The teachers were asked to rate their beliefs regarding the degree of importance they attributed to each knowledge component that appeared in the statement. The rating was done on a Likert scale between 1 and 5, where 1 is "I believe it is not important at all to…." and 5 is "I believe it is important to….". Example for a statement related to CCK: "Know how to solve a word problem"; Example for statements related to SCK: "Know how to link different representations to a word problem" or "Understand the theoretical principles behind each representation"; Example for a statement related to KCT: "know how to choose appropriate examples for presenting the topic" or "know how to choose appropriate examples for deepening students' knowledge"; Example for a statement related to KCS: "know what common errors students make in solving a certain problem" or "estimate how difficult a given problem is for certain students". The statements appeared without classification (it was not written for each statement to which type of knowledge it belonged) and in random order, so not all the statements belonging to the same type of knowledge appeared in sequence. After the teachers rated their beliefs about the importance of the various knowledge components, they were asked to say which of the knowledge components they believed was the most important for mathematics teachers.

It is important to note: (A) The findings described in this paper are part of a wider study that examined teachers' knowledge, and the associated beliefs and self-efficacy. In the study, for each statement of beliefs, there was a corresponding statement of self-efficacy, and there was a question that tested teachers' knowledge. Therefore, only 14 statements were given, to avoid a questionnaire that was too long or tedious. (B) A key factor in solving word problems is the verbal aspect, which is one of the main factors in students' difficulties. Teachers were asked about students' difficulties in the study and were able to indicate these difficulties in the part that tested knowledge. In this part that deals with beliefs about the knowledge components, the types of difficulties that children have were not explicitly mentioned. Teachers were asked about the importance of knowledge that deals with students' difficulties without being limited to a specific difficulty. (C) Correlations were examined between the teachers' responses and their seniority, and between the teachers' responses and the training they received for teaching mathematics. Since no significant findings were found related to teacher training, and differences were also found between veteran and new teachers, I will not address the findings related to education and training.

Results

In the first part of the questionnaire, the teachers received 14 statements and rated each according to the importance they attribute to it. Each statement represents a specific aspect of a particular

knowledge component. Generally, all the statements were rated highly, ranging from 3 to 5. None of the teachers rated any statement with a level of importance between 1 and 2. According to the responses provided by the teachers (Table 1), the teachers prioritize certain statements over others within the same knowledge component. For instance, in Knowledge of Content and Teaching (KCT), teachers considered one statement the most important in the questionnaire. In contrast, another statement in KCT was rated as one of the five least essential statements.

Table 1: The number of teachers who gave each rating for each statement, the mean, and the standard deviation.

Knowledge component	Statement: "I believe it is important..."	No. of teachers that ranked each level			M (sd)
		3	4	5	
CCK	To know how to solve a problem	2	22	33	4.544 (0.559)
	To use terms and notations correctly	4	22	31	4.474 (0.525)
SCK	To know how to solve a problem in various ways using different representations	2	17	38	4.632 (0.546)
	To be able to evaluate the plausibility of students' claims	3	16	38	4.614 (0.58)
	To know how to link representations to underlying ideas	2	16	39	4.649 (0.541)
	To know how to modify tasks to be either easier or harder	8	13	36	4.491 (0.722)
KCT	To know which examples are most suitable to start teaching with	2	11	45	4.737 (0.509)
	To know which examples are most suitable to promote students' understanding of the content	1	22	34	4.579 (0.523)
	To be able to evaluate the instructional advantages and disadvantages of representations used to teach a specific problem	6	20	31	4.439 (0.67)
KCS	To know students' common errors and misconceptions	5	14	38	4.579 (0.642)
	To know the reason for students' common errors and misconceptions	2	20	35	4.579 (0.555)
	To be able to predict what students will find interesting and motivating	8	18	31	4.404 (0.716)

	To be able to anticipate whether students will find a problem easy or hard	1	21	35	4.596 (0.521)
	To be able to interpret students' emerging and incomplete thinking	5	16	36	4.544 (0.645)

Table 1 shows that the statement given the highest rating was one regarding KCT ("To know which examples are most suitable to start teaching with"). Other statements rated higher than the others are related to SCK ("To know how to link representations to underlying ideas"). Two statements were given the lowest rating: the first regarding KCS ("To be able to predict what students will find interesting and motivating") and the second regarding KCT ("To be able to evaluate the instructional advantages and disadvantages of representations used to teach a specific problem").

After the teachers rated each statement, they were asked to indicate which knowledge component they believed was the most important for mathematics teachers. The findings of this question (Table 2) show that teachers believed that the most essential knowledge component is KCS. The second knowledge component that they believed is essential is SCK.

Table 2: The number and percentage of teachers who rated each knowledge component as the most important one

Knowledge component	The statement	Believe this knowledge component is the most important	
		Number	percentage
CCK	Knowing how to solve a problem and use terms and notations correctly	2	3.51
SCK	Knowing to solve the same problem in different ways, linking the various representations, and knowing the meanings of the representations	21	36.85
KCT	Knowing how to choose examples and representations and knowing how to evaluate their advantages and disadvantages	12	21.05
KCS	Knowing what is easy or difficult for specific students, being able to anticipate student errors, and knowing the reasons for these errors	22	38.59

Table 2 shows that there is not one knowledge component the teachers believe is significantly more important than the others. It also indicates that the teachers believe the components of knowledge that are not common content knowledge are significantly more critical to their work, especially

specialized content knowledge and knowledge of content and students. The teachers seem to believe that the importance of these two knowledge components is significantly higher than the other two.

Examining the Pearson correlation coefficient between seniority and beliefs, it was found that there is no correlation between seniority and beliefs in the importance of specialized content knowledge or the belief in the importance of knowledge of content and students. However, a significant correlation was found regarding the other two knowledge components: experienced teachers were more prone to believe in the importance of common content knowledge ($r(55)=0.537$, $p<0.01$) and knowledge of content and teaching ($r(55)=0.265$, $p<0.05$).

Discussion and conclusions

This research focused on investigating the specific beliefs of middle school teachers related to the knowledge they require to teach word problems effectively. This study is particularly notable because it delves into the teachers' perspectives on the importance of different knowledge components outlined by Deborah Ball. What sets this research apart is that it examines the teachers' beliefs about these knowledge components in the specific context of word problems. Additionally, the study produced insightful and valuable findings.

The first meaningful finding is that teachers indicated that the most critical knowledge components were SCK and KCT. Previous studies found that teachers have partial knowledge of these knowledge components and lower self-efficacy regarding them (Schreiber & Filo, 2019; Visochansky & Schreiber, 2023). This may be due to past situations that the teachers had previously experienced in classrooms, where they had felt that they lacked the tools or knowledge necessary to deepen the student's understanding and problem-solving abilities. The fact that the teachers were aware of the importance of these knowledge components highlights the need to strengthen and expand their knowledge concerning these components and highlight the importance of teachers' training and guidance (Van-Inger et al., 2016). Because the teachers attribute importance to these components, they might be perceptible and willing to learn and improve their knowledge.

The second important finding is that teachers did not consider all aspects of a specific knowledge component equally important. Some aspects were highly rated in each knowledge component, while others were rated low. This suggests that further investigation is needed into the knowledge components and their different aspects as they are taught in teachers' training. Those involved in training or guiding teachers should examine, in each knowledge component, the aspects that teachers believe are less significant. If these aspects are indeed important, teachers must be shown their significance. If not, these aspects should be given less attention, allowing other aspects of the same knowledge component to take priority.

The third meaningful finding is the difference between novice and experienced teachers. The more experienced the teacher is, the more he recognizes the importance of common content knowledge and knowledge of content and teaching. This may stem from experience in situations in the classroom where the teacher discovered that he lacked content knowledge and realized that it is essential to have a thorough and good knowledge of the content. This also may impact teachers' professional development and guidance.

The study's limitations are its relatively limited scope, the small number of participants, only middle school, and the small number of questionnaire questions. It would be suggested that more factors, such as knowledge and self-efficacy in various mathematical topics, be tested thoroughly in primary school and high school and that more participants be obtained. Research done in the past testified that there was once a gap between teachers' beliefs and actual performance (Leatham, 2006; Lev-Zamir & Leikin, 2013). Therefore, it is essential to investigate in the future both teachers' beliefs regarding the elements of knowledge that are important to them and the knowledge they acquire when they come to teach a new or unfamiliar subject.

Specialised mathematical knowledge in the scope of geometric isometric transformation translation and its impact on teacher's levels of Interpretive Knowledge

Caroline Silva[1] and Miguel Ribeiro[1]

[1]State University of Campinas, Brazil; cmribas78@gmail.com

We discuss the specialisation of mathematics teachers' knowledge in the scope of geometric isometric transformation translation, considering the Mathematics Teacher's Specialised Knowledge and Interpretative Knowledge. Students and teachers reveal difficulties in such topic which makes it a good subject for discussion. 14 mathematics teachers participated in a Professional Development context focusing on developing teacher's knowledge and here we focus on the knowledge (written, oral and gestural) revealed when discussing an Interpretative Task. The results pinpoint to connections between teachers mathematical specialised knowledge in the context of translation and the interpretation performed (IK levels).

Keywords: Mathematics Teacher's Specialised Knowledge, Interpretative Knowledge, Interpretative Task, geometric isometric transformation translation.

Introduction

It is expected that mathematics teachers' practices allow developing students' mathematical thinking and understanding the diversity of topics they have to deal with, and the connections among them. Such practice, starting from what the students know and how they know it, requires a specialised knowledge which is perceived here in the sense of the Mathematics Teacher's Specialised Knowledge – MTSK conceptualization (Carrillo et al., 2018) and the Interpretative Knowledge – IK (Jakobsen et al., 2014). Among the diversity of mathematical topics in which students reveal difficulties, we focus on Geometric Isometric Transformations and here we give a special look at translation considering the students' (e.g., Flores & Yanik, 2016) and teachers' (e.g., Gomes, 2012) difficulties. In that sense we address the following research question: which mathematical specialised knowledge do mathematics teachers reveal when participating in a Professional Development context and how is it related to the interpretation performed (IK levels)?

Teacher's Specialised and Interpretative knowledge

Both students and teachers reveal difficulties in geometric isometric transformation translation. Students' difficulties involve: (i) perform the translation (especially with polygonal figures and when the translation vector is parallel to one of its sides), considering the length of the vector as the space between the figure and the image (Godino & Ruíz, 2002); (ii) establish the distance between the corresponding points of the figure and the image during the process (Sünker & Zembat, 2012) as equivalent to the magnitude of the translation vector (Flores & Yanik, 2016). Teachers' difficulties include determining the magnitude of the translation vector mistakenly associating (as students do) the magnitude of the translation vector with the space between the figure and its image (Gomes, 2012).

Considering that teacher's knowledge is related to student's learning and results, understanding the specificities of teachers' knowledge is fundamental to contribute to design and implement Tasks for Teacher Education and Professional Development contexts leading to improve students' understanding, knowledge and, in consequence, results. In order to develop such student's knowledge and understanding we perceive as fundamental to assume as a starting point what the students know and how they know it so that we can "move" them to a state of knowing and for doing so it requires from teachers a specialised mathematical knowledge grounding which we name the Interpretative Knowledge (Jakobsen et al., 2014). Such mathematical specialised knowledge (MK) is perceived here as part of the Mathematics Teacher's Specialised Knowledge – MTSK (Carrillo et al., 2018).

The MK is comprised by three subdomains, and even considering that all of them are equally important, here we focus on Knowledge of Topics (KoT) which is composed by four categories: (i) procedures; (ii) definitions, properties and foundations; (iii) registers of representation; and (iv) phenomenology and applications. From these we address special attention to procedures and foundations.

Procedures (which we term as KoTp) includes teachers' knowledge on the different ways of doing mathematics to solve a problem or calculation, considering: how it is done; when it can or cannot be done; why it is done that way; and the characteristics of the result obtained (e.g., Carrillo et al., 2018). In the topic of translation, it includes knowing the different steps for adding the translation vector to "each point of the figure" to obtain the corresponding point in the image. Foundations (KoTf) refers to the knowledge of the set of fundamental mathematical attributes that mathematically support the existence of the topic and connect concepts (Reyes & Sosa, 2019). It is, therefore, a subset of properties and it includes, for example, knowing that the translation vector and its properties is one of the foundations of translation (in Portuguese we use three words – direção, sentido, magnitude).

The content of teacher's mathematical specialised knowledge grounds the interpretation performed to student's productions and, thus, the teacher's interpretative practices. Such practices are related with teachers' Interpretative Knowledge – IK (Jakobsen et al., 2014) which refers to a deep and wide mathematical knowledge that enables teachers to support students in building their mathematical knowledge starting from their own reasoning and productions, no matter how non-standard or incorrect they might be. IK completes the knowledge of typical errors or solution strategies, with the knowledge of possible source for typical or atypical error and the knowledge of possible use of errors (Di Martino et al., 2020). At the moment IK comprises three levels which are intertwined with the interpretative practices performed (Mellone et al., 2017): (i) Evaluative interpretation: a process through which the teacher determines congruence between student's productions and the mathematical scheme of correct answers (s)he has; (ii) Interpretation for the educational design: the manner in which the teacher designs educational steps based on the work produced by the students; (ii) Interpretation as research: teacher's willingness and ability to revise his/her mathematical formalization in order to ensure that it is coherent with students' productions (even when these seem in conflict with the traditional mathematics taught in school).

Teachers' Interpretative and Specialised knowledge does not naturally develop over the course of years of work experience, but it is something that requires a special attention from an educational

point of view (Ribeiro et al., 2013), and for doing so it is required to design and implement educational contexts with such an aim. Contributing for such development we have been developing Interpretative Tasks – IT (Mellone et al., 2020) aiming at assessing and developing teachers' IK, and for each IT we devise a research question, focusing on a specific mathematical topic – in this specific case the geometric isometric transformation translation. Each IK is comprised by three parts: Preliminary Part, with focus on teachers' mathematical specialised knowledge; Part I starts from a conceptualized task for students to develop their mathematical thinking and understanding on the topic (usually a problem), and a set of questions for teachers, where one of them is frequently related to "*anticipate possible correct and incorrect students' productions to the task and which mathematical knowledge grounds the associated reasoning*"; Part II considers, usually, some students productions to the task (written, videos, transcripts) and includes some questions requiring teachers to reveal their IK.

Context and method

This paper is part of a broad research project on teachers' knowledge and mathematical practices in which one of the focuses is Geometrical Thinking. Here we focus on interpretative and specialised knowledge of 14 mathematics teachers (upper and lower secondary) participating in the context of a professional development program (40 hours – nine meetings) aimed to access and develop teachers' IK and particularly in one IT on the space of geometric isometric transformation translation. Participating teachers had between one and 26 years of experience teaching mathematics at lower and upper secondary (students aged 11 to 18 in Brazil). All teachers had a degree on mathematics teacher education (four years). Data collection includes audio and video recordings of teachers' discussions in small groups (of three or four) and during the plenary discussion as well as teachers' productions to the IT. Here we focus on Part I of the IT. The task for students pursues the aim of developing students understanding the set of procedures to perform translation of polygonal and non-polygonal figures as well as some properties of translation. The first question to teachers is to solve the students' task without thinking in a teaching context. Part II includes three student's productions directing the focus of attention to the mathematical thinking grounding the student's errors and the teacher's knowledge to devise ways to overcome such difficulties. Due to space constrains, we present part of the IT on translation with the questions on which we focus our attention (Figure 1).

Teacher knowledge in the scope of translation

Preliminary Part

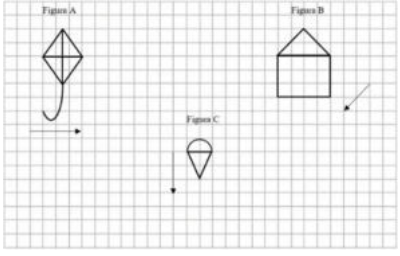
[...].

Part I

Task: Changing places…

(You should always explain your reasoning by describing the process you use to answer the question. For doing so you can use diagrams, words, calculations, ...)

1. Represent the figure (image) in each situation, according to the arrow:



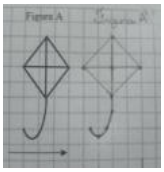
[...].

1. Consider the previous task:
   i) Solve the task by yourself (without thinking on a teaching context).

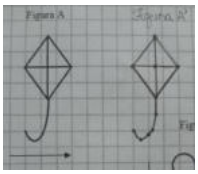
[...].

Part II

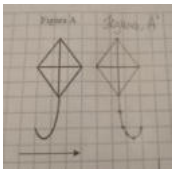
1. Teacher Josi implemented the previous task in her 7th grade classroom. She received different responses and as she was participating in one of the professional development contexts of CIEspMat she decided to take these productions to discuss them with the other participants.



Paula's production



Laura's production



Maria's production

a) For each of the students' productions, indicate whether you consider them mathematically correct (adequate) or not, justifying the mathematical reasoning shown.

[...].

Figure 1: Part of an Interpretative Task in the scope of translation

Each one of these productions were included as they allow discussing specific student's difficulties. Here, for space constraints, we focus on Laura's production because it has allowed a large span of knowledge revealed. Laura's production brings to front the students' difficulties in establishing the distance between each point of the figure and the corresponding point in image as equivalent to the magnitude of the translation vector. Preliminary Part was answered individually and Parts I and II (distributed separately), in groups of three or four (G1 to G4). After that, a collective discussion took place – having as a starting point the participants' production. Teachers' productions (written and oral) were transcribed, and the dialogues were complemented with teacher's gestures.

To identify teacher's specialised knowledge, the written productions were transcribed *ipsis litteris*, and for the analysis we used the MTSK categories (KoTpn and KoTfn are used to identify the knowledge revealed on procedures and foundations (*n* increases sequentially for each one separately). For IK, after transcribing the productions, we have identified (colored red) keywords associated to each level of IK (incorrect; partial correct; correct) considering the three categories presented by Mellone et al., (2017) and from the analysis a new category for the interpretative practice emerged (misinterpretation, corresponding to interpret as correct a mathematical incorrect student's production). For identification we used a set of symbols after the acronomous (*; **; []) where * is associated to an inadequate mathematical knowledge, ** when it is incomplete and [] absence of evidence of knowledge required to interpret the student production.

Analysis and discussion

From the four teachers' groups only two (G1 and G2) performed the translation correctly. G3 correctly performed the translation of the polygonal component of Figure A, but didn't provide the translation of the curved component. G4 performed an incorrect translation using six distance length measurement units for the translation vector magnitude instead of four (Table 1).

Table 1: Teachers' productions for the question "*Represent the figure (image) in each situation, according to the arrow*" focusing on Figure A

Group	Teachers' Productions			
G1		*G1*	*Transcription*		117	Aline	This point here must move four.	
	118	Joice	That's it.	
	119		[Aline counts according to the squares of the grid].	
	120	Aline	One, two, three, four.	
G2		*G2*	*Transcription*		166	Marcia	So, is this one going to come here?	
	167	Jorge	His vertex there.	
	168	Marcia	Here? One, two, three, four. Here more or less?	
	169	Jorge	That.	
	[…]			
	176	Jorge	That's it. You can now close the drawing above.	
G3		*G3*	*Transcription*		50	Igor	We can name the point, name each point	
	51	Igor	and place a "line".	
	52	Telma	You have to make the stitches.	
	53	Igor	And do A', B'.	
G4		*G4*	*Transcription*		42	Luana	I think that only the distance has to be the same,	
	43	Luana	if we are going to transfer the kite here, how many? Two	
	44	Luana	little squares? And answer and put it right here.	
	45	Luana	[Luana points to figure A and the place where its image	
	46	Luana	would be located on the task sheet].	

G1 reveals [117 – 120] knowing that the translation procedures consist of choosing crucial point on the figure and moving them, counting the sides of the squares on the grid according to the unit of distance measurement indicated by the vector magnitude, obtaining the corresponding image points (KoTp1**). This is a particular case of procedures for translation requiring to know the need to consider the three properties of vectors (direction, sense and magnitude) and adding the vector to fundamental points of the figure to obtain its corresponding image points [(KoTp2)].

Teachers in G2 employ similar procedures as G1, but explicitly chooses the vertices of the figure to be translated [167], so that they can later be joined, and the image is obtained [176]. This involves knowing that in polygons it is enough to translate the vertices, taking into account the translation vector and its properties, and then join them by straight line segments (KoTp3). Similarly to the first two groups, G3 [50 – 53], reveals knowing that for translating a figure it is enough to carry out the transformation of some of its points, naming the points [vertices] of the figure by Latin capital letters and their correspondents in the image using that same letter added by an apostrophe (KoTp4).

At G4 teachers reveal they know that it is necessary to maintain the distance between all points in the figure and the corresponding points in the image [42], but they incorrectly use six length units for the translation vector magnitude instead of four (KoTf1*), not establishing a relationship between this distance and the magnitude of the translation vector provided. Translation is a topic for students at grade 7 (12–13 years old) in the Brazilian context, but G4 performed the same students' common mistake, disregarding the magnitude of the translation vector (Flores & Yanik, 2016). It reveals an

inadequate knowledge on the three foundational properties of the translation vector – direction, sense and magnitude [(KoTf2)].

When interpreting Laura's production (Part II), G1 and G2 considered the production incorrect, while G3 and G4 assumed it was correct.

G1: Laura → incorrect, despite maintaining the size of the drawing, it did not correctly shift according to the vector.
G2: Laura → Mathematically there was misconception because she used the vector as the distance between the figure and the image and not as the translation of the corresponding points.
G3: Laura's production: Analysing the image, we noticed that the student used the limit on the right to start the entire transformation, (except) for this reason she performed the activity correctly.
G4: Laura's production: We consider Laura's production to be correct, as the student created the image with sense, direction and distance.

G1 and G2 carry out an evaluative interpretation (IK level 1). G1 identifies some indication of the student understanding (*despite maintaining the size of the drawing*) associated with knowing that in translation the dimensions of the figure in the image are maintained, and G2 focus on describing the error in the production (*used the vector as the distance (...) points*).

G3 and G4 provided an interpretation characterized as a misinterpretation (IK level 0), since they assume a production that is mathematically inadequate as correct – reveal similar difficulties as those of students (Gomes, 2012). Even if G3 identify one of the student's errors (*the student used (...) transformation*), revealing knowing to identify the students' mistake of associating the translation vector to the oriented segment that joins a point in the figure with a point closer to the image (Flores & Yanik, 2016), they interpret the production as correct. G4 does not consider the three properties of the vector (direction, sense and magnitude) and that needs to be considered in the translation of a figure, as they consider the student's production correct (*as the student (...) distance*); however, Laura did not use the magnitude of the vector provided, being this – not using all the translation vector properties – a common students' difficulty (Sünker & Zembat, 2012).

In Table 2 we associate the content descriptors of revealed knowledge to the interpretative practices.

Table 2: Synthesis of the interpretative practice carried out associated with the revealed knowledge and the adequate knowledge based on the evidence of the groups

Evidence	Revealed knowledge	Adequate knowledge	Interpretative practice and level of IK
G1: incorrect, despite maintaining the size of the drawing, it did not correctly shift according to the vector.	Know that during translation the dimensions of the figure in the image are preserved and that the properties of the translation vector must be considered to carry out this transformation.		Evaluative interpretation: Interpret as incorrect a student's production that, despite maintaining the dimensions of the figure in the image, does not move it according to the vector provided, indicating the error in the production. **(IK level 1)**
G2: Mathematically she had a misconception	Know that in translation it is the magnitude of the translation vector that		Evaluative interpretation: Interpret as incorrect a student's production that

because she used the vector as the distance between the figure and the image and not as the translation of the corresponding points.	determines the distance between each point in the figure and its corresponding point in the image.		considers the vector as the distance between the figure and the image and not as the distance measurement between the original and transformed points, making the error in the production explicit. **(IK level 1)**
G3: the student used the limit on the right to start the entire transformation, (except) for this reason she performed the activity correctly.	Know that students make the mistake of identifying the translation vector as the oriented segment that joins a point in the figure with a point closer to the image.	Know that performing the translation disregarding the magnitude of the translation vector as corresponding to the distance between each point in the figure and its corresponding point in the image is mathematically inadequate.	Misinterpretation: Interpreting as correct a student's production that is mathematically inadequate. The error consists of using the right-hand limit of a figure to apply the vector and start the translation. **(IK level 0)**
G4: Laura's production was correct, as the student created the image with sense, direction and distance.	Know that when translating a figure, it is necessary to consider the same sense, direction and distance to translate all its points and obtain the image.	Know that when translating a figure, it is necessary to consider the same direction, sense and distance to translate all its points and obtain the image, these properties being determined by the properties of the translation vector and that they all need to be considered.	Misinterpretation: Interpreting as correct a student's production that is mathematically inadequate and that obtains an image through translation, disregarding the magnitude of the translation vector provided. **(IK level 0)**

Some final comments

Developing teachers' IK is fundamental for promoting interpretative practices beyond evaluative, requiring, thus, developing teachers specialised mathematical knowledge in each mathematical topic, such as translation. We found that the content of teachers' MK impacts the type and level of interpretative practice and knowledge – low level of MK constrains teacher's interpretations. A new category emerged related with the so-called mistaken interpretation, which was associated to a level 0 of IK (it's important to notice that this does not mean absence of knowledge), as it does not refer to the "common" evaluative interpretation, which at least points out the student's error (level 1). The mistaken interpretation grounds on teacher's MK and reflects his/her insufficient mathematical specialised knowledge to interpret a mathematically incorrect student's production, and so, even with a minimal level of MK, teachers assume they can interpret the students' productions, independently of the level of mathematical elaboration of such production. In that sense one open question to further discuss refers to identify and define the content of specialised MK levels. Another further research path to follow, considering the PD context in which data has been gathered concerns to focus the attention on the IK development and on the factor sustaining such development – not only by solving IK tasks but also due to the context of preparing, implementing tasks to their students and selecting student's productions to elaborate IT for the PD colleagues.

Preservice and inservice teachers' understanding of the concept of function: The case of motion problem

Ingrid Semanišinová and Matej Slabý

Pavol Jozef Šafárik University, Košice, Slovakia; matej.slaby@upjs.sk

This paper analyses the knowledge of inservice mathematics teachers (ISTs) and preservice mathematics teachers (PSTs) regarding the concept of function. The study is grounded in the Mathematics Teachers' Specialised Knowledge (MTSK) model (Carrillo et al., 2018) and involves 9 ISTs and 19 PSTs. A set of mathematical tasks served as the research tool, implemented through a three-part process: (1) individual task solving, (2) group task-based interviews, and (3) a joint task-based interview. This paper focuses on two motion problems, examining both written solutions and recorded discussions. The analysis reveals the specific knowledge mobilised by ISTs and PSTs when solving function-related mathematical tasks.

Keywords: Functions, inservice teachers, preservice teachers, mathematical tasks, motion problem.

Introduction

Since the 1980s, research interest in the knowledge and expertise of both PSTs and ISTs has grown significantly. Understanding and analysing their knowledge is essential for improving it. This paper focuses on functions and functional thinking, one of the most important areas of mathematics education. However, numerous studies have highlighted the persistent difficulties students face with functions (e.g., Ostermann et al., 2018; Leinhardt et al., 1990).

To analyse the specialised knowledge mobilised by PSTs, we chose the Mathematics Teacher's Specialised Knowledge (MTSK) model (Carrillo et al., 2018). This model adopts an interpretative approach, emphasising the understanding of knowledge as it is used or developed, rather than evaluating it. It consists of the domains Mathematical Knowledge (MK) and Pedagogical Content Knowledge (PCK), each further divided into subdomains that enable a detailed analysis of mathematics teachers' knowledge. The model also includes an important third domain, which brings together the teacher's beliefs about mathematics and the teaching and learning of mathematics.

We employed specific mathematical tasks as a research tool, recognising that while solving such tasks is central to student learning, it also fosters teachers' professional growth beyond mathematical knowledge (Zaslavsky & Leikin, 2004, p. 30). Some of our findings also stem from the international FunThink project, which shares the vision that strengthening functional thinking from primary to upper secondary education can enhance mathematics learning.

In this context, we pose the following research question: What specific knowledge do ISTs and PSTs mobilise when solving mathematical tasks related to the concept of function?

Theoretical background

Research suggests that tasks fostering functional thinking should engage learners in multiple solution approaches and help identify misconceptions (e.g., Zaslavsky & Leikin, 2004; Leinhardt et al., 1990). In movement-related tasks, for instance, common misconceptions involve continuity and linearity

(Leinhardt et al., 1990). Students often struggle to determine whether a graph should be represented as continuous or discrete, making errors in both directions – interpreting continuous data as discrete and vice versa. Their tendency to overgeneralise linearity may stem from learning linear functions first and extending their properties to other elementary functions. Ronda (2015) emphasizes that teaching functions should focus on recognising invariant properties across different representations and understanding their contextual advantages and limitations. Therefore, incorporating tasks that require transitions between multiple representations can be beneficial. Pittalis (2020) further highlights the importance of addressing the four key aspects of functions – input-output assignment, covariation, correspondence, and functions as mathematical objects – when designing tasks. In motion problems, in particular, covariational reasoning plays a crucial role in effective mathematical modelling (Thompson, 2011). These theoretical foundations guided the development of our research tool, which consists of a set of tasks, as detailed below.

The MTSK model was selected to analyse the specialised knowledge mobilised by ISTs and PSTs. As mentioned earlier, this model comprises two main domains: Mathematical Knowledge (MK) and Pedagogical Content Knowledge (PCK). This paper focuses on one subdomain of MK – Knowledge of Topics (KoT) – and two subdomains of PCK: Knowledge of Features of Learning Mathematics (KFLM) and Knowledge of Mathematics Teaching (KMT). These are examined through PSTs' approaches to solving mathematical tasks related to functions. This aligns with Zaslavsky & Leikin (2004), who argued that solving and discussing mathematical tasks is one of the most effective ways to reveal teachers' knowledge.

Method

As part of the FunThink project, we developed a course for PSTs focused on linear functions to enhance teachers' functional thinking. The course is available at www.funthink.eu. Our research involved four groups: two pilot groups (whose results are not reported here) and two research samples of PSTs and ISTs, whose results are analysed in this study.

The first research sample comprised ISTs who participated voluntarily as part of their professional development within the national IT Academy project. The training, conducted from April to June 2022, spanned five full-day sessions over two months. Nine middle school ISTs (two men and seven women) aged 28 to 52, each with at least four years of teaching experience, took part. All held a master's degree in mathematics combined with another science subject.

The second research sample included 19 PSTs (2 men and 17 women) aged 22–23, enrolled in the first year of a full-time master's programme at Pavol Jozef Šafárik University in Košice during the 2023/2024 academic year. All had completed a bachelor's degree in mathematics combined with another subject. As part of the compulsory course *Didactics of Mathematics*, they attended 26 lessons across 13 sessions (lasting 90 minutes). The course aimed to develop PSTs' specialised knowledge of functions according to the MTSK model, with a particular focus on functions and linear functions.

Our research was conducted using the Task-based interview method (Goldin, 2000). It consisted of three parts. In the first part, both research samples were given a set of tasks to complete at home and send electronically to the lectors. The set of tasks was chosen to cover equally the different

representations of functions, the connections between them, the 4 aspects of the concept of function, and the different actions that the task requires of the solver, as suggested by Leinhardt et al. (1990).

This paper focuses on Task 1 and Task 2 (see Figure 1) from the set of mathematical tasks. Both tasks are grounded in real-world contexts and, based on Leinhardt's (1990) classification of learner actions, primarily fall into the categories of construction and prediction tasks. Task 1 connects table and graph representations of a function, while Task 2 links. Task 1 is taken from a Slovak mathematics textbook for upper secondary schools as one of the introductory tasks to introduce the concept of function. It emphasizes the input-output aspect of functions. However, to connect the given table to its graphical representation, students must identify the type of change and predict the function's behaviour. This requires covariational reasoning, which is crucial for mathematical modelling, particularly in motion-related contexts (Thompson, 2011). Additionally, recognising invariant properties – such as the function's non-increasing nature, its non-elementary classification, and its continuity over the defined domain – includes the object aspect of function understanding. Task 2 is a standard mathematics problem commonly found in Slovak textbooks. An analysis of these two tasks through the lens of the MTSK model highlights specific areas of knowledge that they help develop (see Table 1, columns 1 and 2).

Task 1. In order for an artificial Earth satellite to move in a circular orbit, it must reach a certain minimum velocity, called the initial space velocity. The table below shows some pairs of the numerical value of the velocity v (km/s) as a function of the numerical value of the distance d (in hundreds of km) of the satellite from the Earth.

d	0,5	1	2	3	4	5	6	7
v	7,6	7,4	6,9	6,5	6,2	5,9	5,7	5,4

Construct the graph of the function given by the above table.

Task 2. Alex has bought a new car with 80 km on the odometer. However, this is about to change as he is going on a long journey tomorrow. Describe how (table, graph, equation) if his average speed is 70 km/h.

Figure 1: Task 1 and 2 from the set of tasks

In the second part of the research, ISTs and PSTs were asked to work firstly in groups of three (four) and discuss the tasks from the set, focusing on three questions:

1. Do you think this task is important for teaching mathematics? If yes, why? If no, why?

2. What are the advantages and disadvantages of this task?

3. Which task would be difficult for the students and why?

The questions above focus on the subdomains of KMT and KFLM of the MTSK model. However, in answering the questions, teachers were also concerned with KoT, so we included the KoT subdomain in our analysis as well. After the group discussions, we had a joint discussion with the ISTs and PSTs. All discussions were recorded.

After data collection, we first analysed the written solutions submitted by the ISTs and PSTs for Task 1 and 2. We then coded the group and joint discussions according to the observed knowledge within the MTSK model. Both authors coded the data separately. We then had checked each other's assigned codes and agreed on the final version of the coding.

Table 1: Knowledge mobilised by the Task 1 and 2

		PSTs	ISTs
K o T	Function definition	x	
	Domain and range of a function	x	x
	Definition of a linear function	x	x
	Properties of functions (monotonicity, continuity, boundedness...)	x	x
	Cartesian coordinate system and the points in it	x	x
	Representations of functions (graph, verbal description, table, formula)	x	x
	Linking function representations	x	x
	Function notation	x	x
	Applications of function (mathematical modelling, cross-curricular relations)	x	x
	Elementary functions	x	
	Formal definition of the function concept (notation; unambiguity...)		
K F L M	Difficulties in understanding the concept of function		x
	Difficulties in plotting points on Cartesian axes (function does not always pass through the origin	x	
	of the coordinate system; different scales of x-axis and y-axis...)	x	x
	Students' attitude towards the abstraction of the concept of function	x	
	Knowledge of misconceptions (generalisation of the properties of linear functions; interpretation of		
	a graph of a situation as a picture of the situation...)	x	x
	Variety of strategies in solving the problem (use of different aspects of the concept of function; use		
	of different representations)	x	x
	Potential of the task for teaching	x	x
	Students' emotional aspects to the task (reluctance to solve problems, dislike of mathematics,...)	x	
K M T	Logical consistency of definitions, procedures and tasks during the teaching process	x	x
	Use of digital technologies to teach functions		
	Use of everyday situations to teach functions		x
	Use of examples and counter examples to teach functions		
	Awareness of different ways of representing situations (table, graph, rule, verbal description)	x	x

Results

In Figure 2 we can see the different types of solutions that appeared for PSTs (see Figure 2, graphs A to D) and ISTs (see Figure 2, graphs E and F) to Task 1. All PSTs plotted points on the Cartesian coordinate system and connected the points. In eight cases the PSTs plotted a graph, which some PSTs described later in the discussion as a decreasing linear function (see Figure 2, graph A). 7 PSTs plotted a graph that visually looked more like an exponential decreasing function (see Figure 2, graph B). In graph C, we can see a typical misconception about the swapping of the x and y axes (Ostermann, 2018), which PST Simone made in several tasks. Only PST Dana (see Figure 2, graph D) solved the task in multiple ways with appropriate comments. On the other hand, two of the nine ISTs did not connect the points in the graph (see Figure 2, graph F) because they did not find the correct way to connect them, and 7 ISTs connected the points in the graph (see Figure 2, graph E).

If we look at the values in the table in Task 1, we see that the values do not decrease by the same constant. However, most PSTs have visualised this function as a linear function. We assume that they have not gone back to the table to link the two representations. In the discussion below, the PSTs discuss whether the points should be connected or not.

Episode 1. Discussion about the continuity of the graph of a function.

27	Simone:	I didn't know whether to connect the dots or not.	*[KoT]*
28	Mary:	I think the dots should be connected.	*[KoT]*

29	Simone:	But since it's about speed... I would probably connect the dots. It probably wouldn't make sense if it wasn't connected. *[KoT]*
30	Hannah:	It depends... that distance... I won't jump from distance one to distance two. This is also so intuitive for the students for sure. *[KoT]*
31	Simone:	By the fact that it is a movement in time... so it should be connected.
32	Lector:	And how do I know how to connect those two points side by side? *[KFLM]*
33	Mary:	The satellite could be going very fast and suddenly it would slow down. But, as we can see, we tend to draw it straight (a straight line). *[KoT]*

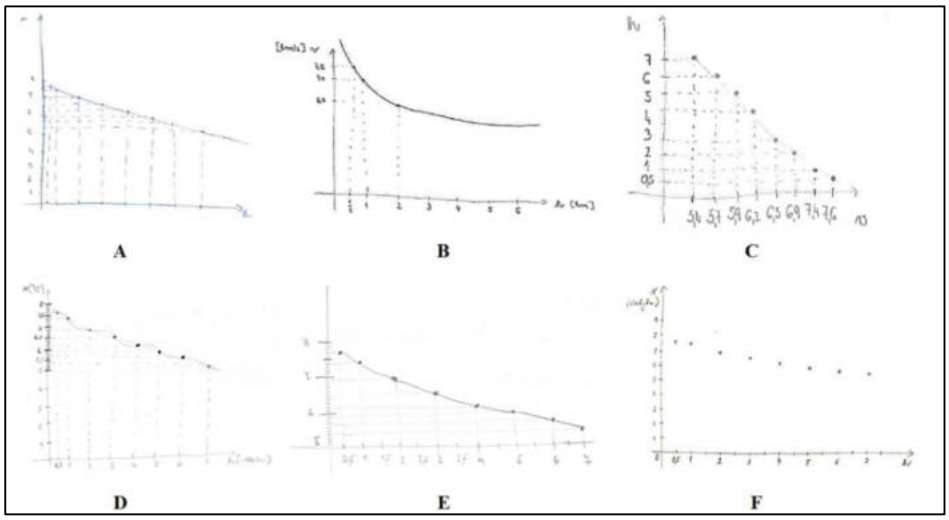

Figure 2: Different ISTs and PSTs solutions to Task 1

Dana is the only one who connected the points in two different ways, claiming in her solution that there are an infinite number of them (solutions) and stating in her comment that she cannot construct an unambiguous graph of the given function because of the information about uniform motion (see Figure 2, graph D). In the discussion, Mary adds her by mentioning that we tend to draw the graph as a linear function (replica 33), which is also her solution. Simone, who swapped the axes in her solution (see Figure 2, graph C), was unsure all the time (replica 27) whether or not to connect the dots in Task 1. In the following discussion, Rose admitted that she had not thought at all about how to connect the dots (replica 15). She connected the values and, thanks to an inaccurate sketch, produced a graph of a linear function. Dana even doubts whether it is a function or not (replica 18).

Episode 2. Discussion of the linearity of the function and whether it is a function.

15	Rose:	I think it is simple. I don't see anything complicated about it. And I think they would do exactly what I do... a straight line. *[KMT]* And they wouldn't think twice about it. Maybe... I don't know... but I don't think they would think about it. *[KFLM]*
16	Dana:	Even if you look at the table now, if you think about it, you can see that if this distance changes by 1 and the speed changes by 0.4, and here it's only 0.3. *[KFLM]* Now it shouldn't be linear. And there's also some rounding in there. *[KoT]*
17	Lector:	So, is it a graph of a function?
18	Dana:	Yeah... it's a function, isn't it? (uncertain) *[KoT]*

However, Dana adds that it cannot be a linear function, and although there may have been a lot of rounding, it is clear from the table that it is not an elementary function. Looking at the graph of the function, Hannah argues in replica 10 that even if we cannot describe the dependence by a rule, it

must be a function. Simone is still convinced that it must be an elementary function because the task assignment says that it is the graph of a function (replicas 12 and 14). She automatically associates the graph of the function with the elementary functions.

Episode 3. Discussion on whether this is some elementary function.

10	Hannah:	The task is good for uncovering misconceptions. Maybe with these non-linear functions they think it's not a function, I can't write a formula. But the dependence function is there, I just don't know how to describe it with this formula.	*[KFLM]* *[KMT]*
11	Lector:	That is, does the graph or table represent some elementary function?	
12	Lenka:	I think it's going to be something. But I don't know what.	*[KoT]*
13	Simone:	And I think again that it won't be any elementary function. I don't know.	*[KoT]*
14	Mary:	But… the assignment is: construct the graph of the function.	

In contrast to the PSTs, the two ISTs produced a solution where the points in the graph were not connected, outlining a discrete graph (see Figure 2, graph F). The seven ISTs in Task 1 sketched a continuous graph (see Figure 2, graph E), which in several cases visually resembled a linear function. The decision not to connect the dots stems from the following group discussion, where in replica 1 Greta claims that the function is "strangely decreasing". In replica 5 Greta is trying to make sense of at least some information, looking for something to help her, but she cannot make sense of her own thoughts. Replicas 6 and 7 show the ISTs' "problems" with the task, as they found no relationship (linear pattern) and thus no discernible pattern between the values in the table in Figure 2 of Task 1. In replica 8 it even seems that IST Viera sees only one solution to the task as she claims that the students would clearly connect the dots with a ruler.

Episode 4. Discussion on how to connect the dots.

1	Greta:	…that satellite. I didn't connect the dots, because this was so weird to me.	*[KoT]*
2	Vera:	I didn't connect dots because it didn't look like any elementary function. It was going down so strangely at the beginning.	*[KoT]*
3	Greta:	That's where the assignment took me into uncertainty. I can't really picture the movement or why it jumps like that.	*[KoT]*
4	Michael:	I connected the dots. It's not linear or anything, it's a stretched indirect proportionality, I think. But I've connected it.	*[KoT]*
5	Greta:	I don't think it's the proportionality, because...	*[KoT]*
6	Vera:	I didn't even know how to connect the dots.	*[KoT]*
7	Greta:	This is so unclear. I didn't know what to base it on.	*[KoT]*
8	Vera:	Students would be able to construct a graph, right? They would have played a bit with the ruler.	*[KFLM]*
9	Greta:	Basically, that's all they were supposed to do and nothing else.	*[KFLM]*
10	Vera:	The only problem would be... Connect the dots? Don't connect the dots?	*[KFLM]*
11	Greta:	I mean, the movement is continuous, but we don't know if...	
12	Vera:	In the beginning, there's a little curve.	
13	Greta:	The points are arranged irregularly; it jumps up and down. For me it's unclear. I would be insecure as a student, but also as a teacher.	*[KFLM]*

In the joint discussion, Jodie replies that she would definitely connect the dots because they are rounded values (the distance is in hundreds of kilometres per hour), and this can skew the measured data (replica 8). Emma argues that it is necessary to connect them because the satellite is not jumping from point to point, but it is a movement (replica 10).

Episode 5. Discussion about the continuity of the graph of a function.

6	Michael:	I connected the dots.	*[KoT]*
7	Patrick:	I also connected the dots.	*[KoT]*
8	Jodie:	Me too. Otherwise, it's in the hundreds of kilometres. I mean, there's already up and down with these units.	*[KoT]*
9	Vera:	Negligible rounding.	*[KoT]*
10	Emma:	But it (satellite) just doesn't jump from one point to another.	*[KoT]*

In contrast to Task 1, in Task 2 neither the PSTs nor the ISTs hesitated and, with the exception of two PSTs, drew a graph of the linear function, automatically assuming uniform motion of the car throughout the journey. They clearly connected the points with a half line and did not consider how the graph would behave between the points. IST Viera adds: "Sometimes we have to model things even though we know it won't be like that in everyday life". In this task, the ISTs were aware that we can't describe everything exactly with a graph, so it is necessary to adapt the graph of a function to a given situation and to discuss with the students why we do it this way. However, they didn't use this reasoning in the situation in Task 1, where they could not link it to a known elementary function.

Analysis of the PSTs' and ISTs' interviews subsequently revealed which knowledge was mobilised during the solution and subsequent discussion of Tasks 1 and 2 (see Table 1, columns 3 and 4).

Discussion and Conclusion

In order to answer the research question formulated above we will discuss which specific knowledge have been mobilised within two tasks dealing with motion situations. Concerning the KoT subdomain, we see that in both cases the ISTs and PSTs are mainly concerned with the continuity and properties of the Cartesian coordinate system within Task 1. The ISTs paid most attention to the continuity of the function, but one can often sense the uncertainty in their words. Two ISTs did not connect the points in the graph because they were not sure how to connect them. The ISTs tried to find out if their claims were correct and asked for solutions to the task. On the other hand, the PSTs were more confident in their statements. All PSTs connected the dots in the diagram. Dana suggested a number of ways to connect the dots, which another PST also considered. On the other hand, there were almost no doubts between ISTs and PSTs about whether and how to connect the dots in the situation described in Task 2.

In the KFLM subdomain, the more dominant student’s interaction with mathematical content. The ISTs tended to focus on how they would solve the task and only marginally mentioned the learners' problems with the task. In contrast, the PSTs focused their attention on the learner, apparently in preparation for their future profession. A strong aspect for both groups is motivation. Both groups perceived the tasks in terms of cross-curricular relationships. On the basis of their solutions to the task, they outlined a number of misconceptions that might be manifested in students.

From the perspective of the ISTs, the Task 1 is not important to teach because they think it hardly practise anything. They would use better tasks that give nice values to construct the graph of a function. The PSTs see the potential of the task to solve some misconceptions (linearity, generalising properties of a linear function, continuous vs. discrete graphs). They consider it an advantage to label the dependent and independent variables differently than the traditional labelling: the independent variable is labelled h instead of x, the dependent variable is labelled v instead of y. The ISTs showed knowledge of lesson organisation, reflecting on the time needed and the form of the students' work.

We think that the inclusion of these two tasks in the PST and IST courses is appropriate for teacher training. In our research sample, it helped to reveal misconceptions centred on connectedness and linearity. Discussing the tasks in groups and together has the potential to help participants to identify potential gaps in their knowledge and consequently to develop their specialized knowledge. Although this research has some limitations (e.g. the research sample was from one region and), we believe that such an analysis is an important starting point for designing professional development courses for ISTs and for PSTs in order to develop teachers' and thus their students' functional thinking.

Impact of an academic intervention on prospective teachers' mathematical world views during their transition to university

Felix Woltron

University of Vienna, Faculty of Mathematics, Vienna, Austria; felix.woltron@univie.ac.at

Numerous studies have examined the impact of mathematical world views on teachers' classroom practices in recent decades. A particular focus has been placed on the possibility of changing those beliefs. In light of these findings, this study explores the impact of an academic intervention on the mathematical world views of 30 prospective teachers during their first semester at university. Using a longitudinal design, participants' beliefs were evaluated via a standardized questionnaire at the beginning and end of their first semester. The quantitative analysis shows significant shifts. Dynamic mathematical beliefs increased, while static mathematical beliefs decreased. These findings suggest that targeted interventions during the transition from school to university can have an impact on the mathematical world view of prospective teachers.

Keywords: Mathematical world views, beliefs, teacher education, beliefs change

Introduction

The transition from school to university can be challenging for many students, including those who study mathematics. Therein, the new didactical approach provides students with more autonomy and self-regulated learning (Gueudet, 2008) and therefore may cause a shift from previous experiences (Geisler & Rolka, 2020). In particular, keeping in mind potential cultural differences, the emphasis on math application tasks with a strong focus on modelling (ibid.) and proofs (Vollstedt et al., 2014) at university level can be seen as examples of this change. High drop out and subject change rates illustrate the difficulties involved in this transition (Geisler & Rolka, 2020). Consequently, students in their first weeks at university require specialized support. Based on Geisler and Rolka's (2020) analysis of how beliefs affect the transition from school to university, this study focuses on how students develop their mathematical world views while attending a specific designed course during their first semester. This leads to the following research question:

How do prospective teachers' mathematical world views change as a result of a specific course focused on the transition from school mathematics to university mathematics during their first semester?

Theoretical Background

Beliefs

Over the last few decades, research on mathematics education has increasingly focused on (prospective) teachers' beliefs (Eichler et al., 2023; Philipp, 2007; Skott, 2015; Thompson, 1992). According to research conducted on mathematical beliefs, teachers' epistemological views influence students' motivation to learn, their learning strategies, and their performance (Beumann & Geisler, 2022; Eichler & Erens, 2015), along with their likelihood of dropping out or switching subjects (Geisler & Rolka, 2020).

According to Safrudiannur and Rott (2019, p. 2), there is no consensus regarding an explicit definition (Beswick, 2005, p. 39) of beliefs (see also Skott, 2015). This article uses Philipp's (2007) interpretation of beliefs, which he defines as “psychologically held understandings, premises, or propositions of the world that are thought to be true”. To analyze prospective teachers' beliefs, the present study utilizes the theoretical framework of "mathematical world views" by Grigutsch et al. (1998). The authors developed four aspects which categorize teachers' beliefs-cluster concerning the nature of mathematics and are known as a teacher’s “mathematical world view”. These four aspects can be defined as follows by Eichler et al. (2023, p. 1493):

- The formalist aspect represents beliefs implying that (school) mathematics is characterized by a strongly logical and formal approach.
- The schema aspect represents beliefs implying that (school) mathematics is a set of calculation rules and procedures to apply to routine tasks.
- The process-oriented aspect represents beliefs implying that (school) mathematics is a creative activity consisting of problem-solving using different and individual ways.
- The application-oriented aspect represents beliefs implying that the utility of mathematics for real-world problems is the main aspect of the nature of (school) mathematics.

According to Grigutsch et al. (1998), there is a significant correlation between formalist and schema aspects, or between process-oriented and application-oriented aspects. Thus, according to Viholainen et al., (2014), the first two aspects of mathematics are considered as "static", whereas the last two are considered as "dynamic" nature of mathematics.

Based on Geisler and Rolka (2020, p. 605) "[...] beliefs which do not fit to university mathematics [...]" can lead to dropping out of mathematical teacher training. Therefore, it is critical to clarify which beliefs of prospective teachers are beneficial as well as how to change hindering beliefs to enhance the likelihood of a successful study path. A study conducted by Geisler and Rolka (2020, p. 599) showed that dynamic beliefs of prospective mathematics teachers negatively predicted their intention to drop out. Moreover, dynamic views on mathematics, as well as on teaching and learning mathematics, are generally considered beneficial for learning (e.g., Ostergaard, 2024). The mechanisms through which teachers' beliefs change pose a challenge (Liljedahl et al., 2012). There is wide consensus that a long-term strong impact is required for sustained shifts in (teachers’) beliefs (e.g., Philipp, 2007; Levin, 2015). In this research approach, the transition from school to university is seen as such a strong impact that, accompanied by a specific lecture with a focus on the question "What is mathematics?", can lead to a change of beliefs.

Intervention

In order to implement the specified intervention, the mandatory lecture "Aspects of Mathematics" of teacher training program at the University of Vienna was selected because of its curricular requirements (https://ssc-mathematik.univie.ac.at/im-studium/studiengaenge/bed-uf-mathematik/curriculum-studienplan/)

In this lecture, which is based on the book "Panorama der Mathematik" by Loos et al. (2022) the guiding questions addressed were epistemological in nature (e.g., "What is mathematics?", "How do mathematicians acquire knowledge, and how do they know that they are correct?"). In addition, based on the explicit-reflexive methodology of belief teaching (see McComas et al., 2020), reflexive phases

were utilized to allow students to become aware of their mathematical world views and to question them based on the content discussed. As a result, the course consisted of a combination of lectures on specific topics and reflection/discussion-sections in small groups of approximately four prospective teachers.

Method Section

Sample

As part of a longitudinal study, 30 prospective teachers were surveyed with an online questionnaire regarding their mathematical world views within their first and last "Aspects of Mathematics" lecture.

Data Collection and Analysis

The longitudinal design was evaluated with quantitative analysis. Within the pre- and the post survey, the participants filled out an online questionnaire, which consist of 37 closed items on a five-point Likert-scale (5 = "totally agree"; 4 = "agree"; 3 = "neutral"; 2 = "disagree"; 1 = "totally disagree") taken directly from Grigutsch et al. (1998)'s questionnaire regarding the mathematical world view. In Table 1, sample items are presented for each of the four aspects, as well as the number of used items for each aspect and the internal consistency based on Cronbach's α values (pre-survey-participants). To determine whether the four mathematical world views were accepted or rejected, the (overall) arithmetic mean of the individual arithmetic means of the total values resulting from the four subcategories and their items embedded therein was calculated. The ordinal scaled data were interpreted as quasi-metric (Blömeke et al., 2008). This part of the analysis concludes with a comparison of the collected central tendencies with the Wilcoxon-test for related samples (longitudinal design).

SPSS-28 was used for this evaluation.

Table 1: Quantitative data collection and analysis

	Formalist aspect (F)	**Scheme aspect (S)**	**Process aspect (P)**	**Application aspect (A)**
Sample item	A fundamental component of mathematics is the application of logical rigor and precision, also known as objective thinking.	Mathematics consists of learning, understanding, and applying.	In most cases, in mathematics there is more than one way to solve a problem.	Mathematics helps to solve daily tasks and problems.
Number of items	10	8	9	10
Cronbach's α	0.738	0.720	0.739	0.768

Results

Cronbach's alpha values (Table 1) for all mathematical world views are higher than 0.7, which is considered sufficient in terms of internal consistency (Taber, 2018).

In Table 2, the descriptive statistics for each subcategory are presented. For the interpretation of the arithmetic means an equidistance scale was used which is derived from the Likert-scale range 1 to 5. Accordingly, we got: 1 to 1.8: strong disagreement (--); 1.8 to 2.6: disagreement (-); 2.6 to 3.4: neutral (~); 3.4 to 4.2: agreement (+); 4.2 to 5: strong agreement (++)

Table 2: Descriptive statistics of mathematical world views ($\overline{x}$ = arithmetic mean)

Sample		F	S	P	A
Pre $N = 30$	$\overline{x}$	3.68	3.43	3.82	4.09
	interpretation	+	+	+	+
	standard deviation	0.53	0.59	0.54	0.59
Post $N = 30$	$\overline{x}$	3.17	2.83	4.04	4.11
	interpretation	~	~	+	+
	standard deviation	0.71	0.78	0.57	0.46

These findings concerning the descriptive statistics of the longitudinal study show that the prospective teachers agree with all world views simultaneously within the pre-test. Participants at the end of their first semester agree only with the dynamic aspects of mathematics and have a neutral attitude towards the static view. Across all sample groups, the application-oriented aspect has the highest level of agreement, while the scheme-oriented aspect has the lowest one.

In light of the controversy regarding the use of parametric or non-parametric evaluation methods for evaluating Likert scales (De Winter & Dodou, 2010), and the presence of some outliers in the data, Wilcoxon-tests have been used to assess whether participants might have shifted their mathematical world views in response to their experiences during their first semester studying mathematics. The analysis of the longitudinal design (Wilcoxon-test) indicates that accept the application-oriented aspect, all other mathematical world views show (highly) significant changes with moderate ($0.3 < r < 0.5$) to strong ($r > 0.5$) effect sizes due to the scale of Cohen (1992) (F: $p < 0.001; r = 0.67$ / S: $p < 0.001; r = 0.67$ / P: $p = 0.022; r = 0.42$).

Discussion

Using a similar questionnaire (Laschke & Blömeke, 2013) to the one used in the present methodology, Geisler and Rolka (2020) examined whether students' beliefs could be interpreted as indicators of exam achievement and dropout risk as well as how students' beliefs about the nature of mathematics change during their transition from school to university. Their findings differ from those of this study: Geisler and Rolka (2020) analysed that prospective teachers' dynamic beliefs decline during their transition, whereas static ones remain stable. The present study evaluated significant changes and the trend of favoring dynamic aspects, which can be interpreted as positive, since dynamic world views are regarded as negative predictors of a student's intention to drop out (Geisler & Rolka, 2020). Kuklinski et al. (2018) conducted a similar study with the aim of increasing students' dynamic beliefs and found a weak decrease in static beliefs but no changes in dynamic views. There was no attempt to force the measured trend in favor of dynamic views on mathematics within the presented intervention. According to the theoretical background section of this paper, the purpose of the lecture in discussion was to facilitate the transition from school to university and to provide prospective teachers with the opportunity to reflect on their mathematical world views.

The measured output concerning beliefs can be viewed as a beneficial support for a successful transition from school mathematics to higher mathematics since it can be interpreted as providing benefits to learning (Ostergaard, 2024) and preventing students from dropping out.

Moreover, the measured significant changes in the mathematical world views are not consistent with similar evaluations at the University of Vienna. According to Woltron (2023), a quasi-longitudinal design over the entire course of study (12 semesters) reveals a stability of beliefs, especially within the mathematical world view. Additionally, this would accord with the common interpretation of beliefs as stable or slowly evolving (Geisler & Rolka, 2020). The present study illustrates that, in accordance with Liljedahl et al. (2007), it is possible to achieve significant changes in beliefs by designing learning environments that are embedded in specific situations that can facilitate a change in beliefs, i.e., which enable a strong impact (Eichler et al., 2023). Combining the mentioned particular situation of the transition from school to university with specific courses appears to facilitate the change in beliefs.

Conclusion

In spite of its strengths, this study has some limitations. Whenever Likert scales are used, there is always the possibility of favouring responses that are correlated with social desirability (Kreitchmann et al., 2019). Predefined (fictitious) contexts can mitigate this problem, but qualitative analysis is time-consuming and therefore not feasible for large sample sizes. It would be useful to conduct further studies to examine the change in students' mathematical world views due to special intervention within the first semester qualitatively by interviewing participants who attend the final exams and those who drop out earlier in the semester. Furthermore, a control group could be analyzed to gain a deeper understanding of how the lecture actually impacts mathematical world views. This missing criteria for an intervention study can also be seen as a limitation of the methodology. Students' transition from school to university is a special stage in their lives that is affected by a variety of factors. In this regard, it should be noted that significant changes in mathematical world views are

not solely attributable to the intervention mentioned above. In addition, all participants in this longitudinal study are volunteers. Students who drop out or are about to drop out are often the focus of research in the transition phase, where a volunteer sample appears to have a significant effect. During this particular phase of the study, volunteer sampling may create a bias towards higher-achieving students (Di Martino et al., 2023, p. 25).

The purpose of this study was to investigate how students' mathematical world views may change during the first semester as prospective teachers. An intervention in a specific situation (transition from school to university) resulted in a decrease in static beliefs and an increase in dynamic beliefs. These findings have implications for both university and school courses, both of which provide learners with the opportunity to broaden their understanding of this scientific discipline, keeping in mind cultural differences. Besides the approach described in the intervention, further methodologies for implementing such interventions can be found in the context of "Nature of Science" research (see McComas et al., 2020). In addition, the results show that, taking into consideration the limitations mentioned, the used method of combining special situations (e.g., transition, first practical experiences (Woltron & Götz, 2023), etc.) and specific intervention can be a possible approach to the difficulty of “changing beliefs”.

Elementary preservice teachers' knowledge in creating alternative word problems: A guide for mathematics educators

Fatimah Ahmad

Kuwait University, Kuwait; fatimah.ahmad@ku.edu.kw

Keywords: Word problem, Mathematical knowledge for teaching, Preservice teachers.

Introduction

Hill et al. (2008) incorporated Shulman's (1987) pedagogical content knowledge ideas into a framework of mathematical knowledge for teaching. Ball et al. (2008) suggested that more work is needed to identify how different types of knowledge are utilized in the act of teaching mathematics. Examining aspects of knowledge that are integrated in the daily practice of teaching mathematics has important implications for developing and enhancing methods courses. Mathematics teachers engage in several kinds of work, including identifying, examining, selecting, and creating mathematical problems. Word problems (WPs) are a common type of math problem found in curriculum materials; additionally, there are decades of research on WPs, their importance for student learning, and the challenges in solving them (Pongsakdi et al., 2020). However, little is known about WPs through the lens of mathematics teacher knowledge. In this study, I examine elementary preservice teachers' (PSTs) knowledge in creating alternative WPs. An alternative WP maintains the same conceptual challenges as the original, so students succeed or struggle with both for identical reasons. Creating alternative WPs is a complex, multi-step process requiring PSTs to categorize problems, identify operations, examine numbers, and apply creativity.

Methods

Data was collected from eight PSTs enrolled in an elementary methods course in a public university in Kuwait. The PSTs completed a task in which they were instructed to create two alternative WPs for a given WP: one tailored for girls and another for boys, along with explaining their reasoning. The task was designed to serve two purposes: (1) to explore potential underlying gender biases, which is the focus of a separate paper, and (2) to evaluate the quality and originality of the WPs, which is the primary focus of this work. An example of a given WP is: *Fatima has 18 flowers and 4 vases. She want to put 6 flowers in each vase. Did she use all the vases? Explain your answer.* A total of 29 WPs were analyzed following Lincoln and Guba's (1985) constant comparison method. Allowing for a systematic comparison of the WPs characteristics to answer the question: What are the characteristics of WPs created by PSTs?

Results and discussion

I focused on mathematical and linguistic characteristics drawn from Daroczy et al.'s (2015) work.

Mathematical characteristics

In half of the cases, the PSTs were unable to select new numbers for their WPs. That said, maintaining the numbers as in the original WP did not always lead to having a solvable problem. For example,

PST 2.1 wrote: “Sara visited a cosmetics center and bought 36 lipsticks and 27 eye shadow palettes. Note that she has 140 KD. How much does she have left after buying what she needs?” Two of the numbers represent the quantity of the items, while the third represents the total amount of money, making the problem unsolvable, the error was having different units for the numbers. Unsolvable problems were also present due to having missing numbers, such as the total. Inattention to the property of numbers and to how computations are carried out reduced the difficulty level of the WPs compared to the original WPs. For example, having a one-digit number instead of a two-digit number, a straightforward addition without a carry over, and a division with no remainder.

Linguistic characteristics

All the PSTs created a context that differed from the original WPs. However, several linguistic errors were noted. Missing important verbal cues transformed WPs from having one solution into open WPs with multiple answers. Several PSTs did not use any of the words indicating a division problem. Others who used the words “distribute” or “share” failed to write that that was done equally. Another error was writing a story without a question. In other cases, the question did not match the context of the problem. PST 3.5 wrote, “You have four boxes and each contains four mixed cookies, and you share the cookies equally with 16 people in your family. How many rocks will each one of you get?” In conclusion, identifying aspects of PSTs’ knowledge in creating alternative WPs and reporting examples of their work and errors provide a guide for mathematics educators in preparing PSTs and enhances professional development experiences.

Teachers' knowledge and beliefs about assessment in mathematics: initial evidence from a national survey of teachers' formative needs

Giorgio Bolondi[1], Maria Chiara Cibien[2], Federica Ferretti[2], Alessandro Gambini[3] and Francesca Martignone[4]

Keywords: standardised assessment, assessment, teachers beliefs, teachers knowledge

Introduction

This contribution aims to illustrate the first results of the National Project "*Mathematics standardized assessment as a tool for teachers' professional development*", that aims to develop theoretical and operative tools to utilize the results of mathematics national assessments INVALSI to support teachers' professional development. It also seeks to promote a formative use of INVALSI materials and related good practices in schools, both at the institutional and classroom levels. The impact of standardized assessment is traditionally top-down: survey results influence public opinion, which in turn affects policymakers who act on the system's structure at different levels; only at a final stage do surveys and their results have an impact on local teacher action. The innovative idea of our project is to provide tools for a bottom-up approach in which theoretical frameworks/test/results are used immediately by teachers, to implement formative assessment and individualized instruction. In recent decades, research has been conducted to create a bottom-up dynamic which starts with a conscious use of frameworks, released items and results by the teachers. Some conditions should be fulfilled, such as the connection between assessment and curriculum, which should be perceived by teachers, as assessment is a key component of their identity and practice (Hannula et al., 2016; Ferretti & Santi, 2023). Our research aligns within this line of thought, aiming to develop a model for pre- and in-service mathematics teachers based on the effective use of standardized assessments (Ferretti et al. 2020). As a preliminary step, an anonymous questionnaire was used to survey teachers' beliefs, knowledge and needs regarding assessment and standardized assessment. This investigation provides crucial insights for designing the model and serves as the starting point of our research.

The first stages and findings: the administration of the questionnaire

In the first phase of the project, we investigated mathematics teachers' knowledge and beliefs about standardized assessments, particularly INVALSI tests and data. This phase involved the design and administration of a research questionnaire, structured into six distinct versions, considering the possible differences between pre- and in-service teachers (e.g., in terms of training and experience), as well as the school level at which the participants teach or will teach (primary, low secondary, and high secondary school). A total of 131 teachers responded to it. The questionnaire is intended to examine three main macro-variables: the mathematical and teaching knowledge of the participants

(including how they interpret INVALSI items and their outcomes in relation to mathematical content); the affective factors related to teaching practice (such as the perception of their competence in mathematics and mathematics teaching, and how assessment is perceived); the beliefs and knowledge about the purposes and possible uses of standardized assessment in mathematics, formative assessment, and awareness of mistakes (e.g., the interpretation of the causes of mistakes identified in the macro-phenomena of standardized assessment) (Bolondi & Ferretti, 2021; Ferretti et al. 2023). The data collected highlight several phenomena: regardless of school level and experience, teachers seem unable to correctly interpret the most common mistakes, and, in some cases, there is also inconsistency between teachers' perceptions of item's coherence with the ministerial guidelines and their purpose in relation to the teaching practices they adopt. We consider these phenomena as teachers' formative needs, understood as the necessity for development to refine their knowledge and competencies in the context of standardized assessment. These results can therefore serve as a starting point for designing new activities to be integrated into the aforementioned professional development model for teachers.

Alternatively certified mathematics teachers' perceptions, experiences, and commitment to continue teaching

Evan McClintock

University of Colorado Denver, United States; evan.mcclintock@ucdenver.edu

Keywords: Teacher certification, teacher motivation, teacher persistence, mixed methods.

Introduction and theoretical perspective

There is a need to study alternatively certified teachers (ACTs) to address a growing teacher shortage, as more teachers earn their credentials via alternative certification programs (Richter et al., 2022). In Germany and the U.S., researchers have explored connections between ACTs' intentions and commitment to continue teaching, job satisfaction, and experiences (McClintock, 2024; Richter et al., 2022). The current study focuses on alternatively certified mathematics teachers (ACMTs) in the U.S. and investigates their commitment to continue teaching. Research question: How do ACMTs' perceptions and experiences relate to their self-ratings of their commitment to continue teaching?

Situated Expectancy-Value (SE-V) theory (Eccles & Wigfield, 2020) and Job Demands-Resources (JD-R) theory (Bakker & Demerouti, 2017) are coordinated to frame the study. SE-V theory explains individuals' decisions about engaging in and persisting with an activity (e.g., teaching), and JD-R theory explains a dynamic system of job-related and personal factors that impact occupational well-being (e.g., burnout). Coordinating SE-V theory with JD-R theory helps explain aspects of being a teacher that affect ACTs' decision to persist in teaching or leave the profession (McClintock, 2024).

Instrument, population, data collection, and methods

The current mixed methods study examined ACMTs' commitment to continue teaching. Participants, 47 early career ACMTs, freely volunteered. The instrument, an electronic survey, included a self-rating question (0-100) and an open-ended question about commitment to continue teaching. No personally identifiable data were collected, and participants' rights were protected. Qualitative analyses included initial coding, modified holistic coding, and theming (Saldaña, 2013). ACMTs clustered into groups according to their self-rating level of commitment. Holistic profiles were developed for each group, thus qualitizing quantitative data (Onwuegbuzie & Leech, 2021).

Results

The clustering resulted in three distinct groups of ACMTs: high (90-100), medium (61-89), low (0-60). Holistic profiles for each group's commitment to continue teaching included a characterization of the group and a researcher generated first-person narrative from codes with highest frequencies.

High commitment profile (self-ratings between 90-100)

This group of 15 ACMTs is characterized by noting job affordances and personal resources. The researcher generated first-person narrative is: *I love teaching, and it is a great fit for me. I believe it's important for my community and the larger society. Teaching is fulfilling and allows me to work with kids. Doing something I'm good at is rewarding. There is no job I would rather have, and I'm excited for each new day.*

Medium commitment profile (self-ratings between 61-89)

This group of 18 ACMTs is characterized by noting job affordances, job limitations, personal resources, and job demands. The researcher generated first-person narrative is: *I'm not so sure teaching is the career for me. I see positives about teaching, and I've put a lot into becoming a teacher. I truly love teaching math. I like seeing my students learn, but the downsides of the job are tough. I feel conflicted about continuing to teach.*

Low commitment profile (self-ratings between 0-60)

This group of 14 ACMTs is characterized by noting job limitations, stress, workload, feeling neglected, job affordances, and an intention to leave teaching before retirement. The researcher generated first-person narrative is: *Teaching isn't the best fit for me. The negative aspects of the job far outweigh any positives. The pay is too low compared to the hours, and switching careers would allow me to earn more. Being a teacher is not what I thought it would be. I feel neglected, stressed, and overworked. I don't see myself doing this much longer.*

Discussion and conclusion

ACMTs' commitment to continue teaching connects to their valuations of teaching, experiences on the job, and personal resources. Results from the current study are consistent with results from a larger study (McClintock, 2024), involving 368 ACTs across different disciplines. In each study, the profiles represent roughly one-third of the participants suggesting there may be common challenges to retaining ACTs, regardless of discipline. Importantly, ACMTs' confliction about staying in the career connects to their commitment (e.g., loving to teach math may not be sufficient to stay).

Developing prospective kindergarten and primary teachers' specialized knowledge through tasks for teacher education in the scope of operations with natural, integers and rational numbers

Sandra Menezes[1], Miguel Ribeiro[1], Maria Mellone[2] and Arne Jakobsen[3]

[1]State University of Campinas – UNICAMP, Brazil [2]University Federico II of Naples, Italy; maria.mellone@unina.it [3]University of Stavanger, Norway

Keywords: Tasks, teacher education, mathematics teachers specialized knowledge, numerical thinking.

Some initial ideas and discussions

Students' knowledge is frequently constrained to the mechanical execution of algorithms, often characterized by the mere application of predefined rules. This approach typically lacks a deeper comprehension of the mathematical problem faced, focusing instead on procedural proficiency of arithmetical algorithms or the retrieval of memorized procedure (Bessa & Costa, 2017). However, a deep understanding of arithmetical operations necessitates an appreciation of their inherent complexity and cognitive demands, supporting in this way the development of numerical understanding and meaning (Anghileri, 1989; Park & Nunes, 2001).

The National Common Curricular Base (BNCC) in Brazil (BRASIL, 2018), which serves as the guiding document for the national curriculum, stipulates that multiplication should be introduced starting in Grade 2 (for students aged 7–8). However, research indicates that foundational notions of multiplication can, and indeed should, be addressed as early as kindergarten. These discussions should extend beyond the view of multiplication as merely repeated addition of equal addends, encompassing its various conceptual meanings (Anghileri, 1989; Park & Nunes, 2001). To address the challenges teachers face in practice—such as the operational difficulties students often exhibit—it is critical to move beyond the mechanical application of rules and algorithms. Instead, emphasis should be placed on fostering mathematical reasoning. This involves teaching the four operations with a focus on understanding their meanings, integrating problem formulation and resolution, and attributing appropriate significance to each step of the algorithms that students are expected to master. To achieve this, it is essential for teachers to develop their specialized knowledge, as such expertise has been shown to have the greatest impact on students' comprehension and performance (Nye et al., 2004).

Given that teachers' practice is inherently rooted in the use of tasks (e.g., Mason & Johnston-Wilder, 2006), it follows that tasks should also serve as the foundational element in Teacher Education contexts for the development of teachers' professional knowledge. In this framework, tasks are considered essential both as tools and as frameworks for designing effective Teacher Education contexts. Recognizing the distinct nature of teachers' practices compared to students' learning processes, we adopt a specific structure for tasks in Teacher Education. This structure creates a meaningful context for the development of teachers' knowledge and practices, enabling them to engage in experiences that mirror those they are expected to provide for their students (Ribeiro, 2020). In order to contribute to the area of task design and the development of teacher's knowledge, this project aims to discuss the structure and characteristics of the Tasks for Teacher Education (TTE) (Ribeiro, Almeida & Mellone, 2021) and how these tasks influence the development of prospective kindergarten and primary teachers' knowledge, particularly in the area of arithmetical operations. The framework for this teachers' knowledge is grounded in the Mathematics Teacher's Specialized Knowledge (MTSK) model (Carrillo et al., 2018).

Context and method

Data has been collected in a course for thirty-nine prospective kindergarten and primary teachers (PPTs) through the implementation of an itinerary of eight TTE focusing on the four operations typically addressed in primary education. Data collection includes written productions to each TTE, narratives about their lived experiences and the expected changes in their future teaching practices, as well as audio and video recordings of all discussions with the prospective teachers. For the analysis, we are focusing on the content of the MTSK categories and on the core characteristics and properties of the different TTE that may maximize the development of PPT's specialized knowledge.

Some expected results

The expected outcomes are: understanding the influence of the TTF for developing prospective teachers' specialized knowledge, obtaining a set of specialized knowledge descriptors in the topic of operations, identifying levels of knowledge revealed to enquiry the content of such levels.

Overview

The Topic Working Group 21 (TWG21) on Assessment in Mathematics Education was established at CERME 10 in Dublin (2017) to promote communication, cooperation, and collaboration among researchers interested in assessment across all educational levels and contexts. A central aim was to integrate insights from mathematics education research into assessment practices.

During the current conference, the working group discussions brought to light a variety of interconnected themes that reflect the richness and complexity of assessment in mathematics education. First, formative and summative assessment were framed as two sides of the same coin, each contributing in different but complementary ways to understanding and supporting student learning. The presentations reflected a wide range of methodological approaches - both quantitative and qualitative - demonstrating the diversity of perspectives and tools used in current research. The international composition of participants further enriched the dialogue, offering opportunities to learn from different national and cultural contexts.

A strong focus was placed on the role of student-teacher interaction within assessment processes, particularly regarding feedback. The integration and development of digital resources for assessment was also central, highlighting both their potential and the practical challenges they pose. Discussions emphasized the importance of teachers' professional knowledge in assessment, underlining the need for targeted teacher education. Participants also reflected on the types of mathematics that are assessed. Theoretical and curricular perspectives were a key to framing many of the contributions, with several participants examining the influence of theoretical frameworks and curriculum structures on assessment choices and interpretations. The distinction between quantitative and qualitative feedback was discussed in relation to its effect on students' engagement and learning. Finally, a critical theme concerned the implementation of research findings into practice, including how assessment results - particularly from diagnostic activities - can be used to both enhance teaching and support students' learning trajectories in meaningful and actionable ways.

The sessions

The first session began with an introductory moment devoted to mutual acquaintance among participants and an overview of the group's structure and organization. It was followed by two presentations focusing on the **use of technology in classroom assessment**, specifically from the perspective of teachers. Saralar-Aras and Tütüncü discussed how middle-school teachers in Turkey perceive the role of digital tools in enhancing classroom assessment practices. The qualitative study suggests perceived benefits, such as increased students' participation and efficient use of time, as well as teachers'access to detailed analyses of students' mistakes. At the same time, some challenges are reported, such as additional workload for preparation and limited access to technology. In particular, the use of technology for summative assessment purposes is still perceived as demanding. Chen, Bos, Doorman and Drijvers examine how mathematics teachers integrate digital technologies into formative assessment practices, drawing on the theoretical frameworks of instrumental orchestration and formative assessment with technology. The study is based on the analysis of 12 award-winning lesson videos from China, considered examples of best practice. The findings highlight that the effectiveness of technology largely depends on teachers' pedagogical choices. However, the use of exemplary lessons introduces a notable limitation, as they may not reflect the typical dynamics of everyday classroom practice. The subsequent discussion addressed the issue of what is needed by teachers to implement digital-assisted technology.

The second session showcased **how assessment can be used for various purposes**. The paper by Pilet and Grugeon-Allys examines how standardized assessment can be turned into a tool that helps education professionals to manage heterogeneous learning in the classroom. Using an example from middle school algebra, they show how mathematical didactics can provide a method for interpreting the results of standardized assessment that is complementary to statistical methods. In the paper by Haara, on the other hand, the context is the reform of the national 10th grade oral exam in Norway. The paper presents a practice-based model for teachers' professional development in which teachers participate in planning the implementation of the new exam. Finally, Donner and Lerchenberger study the multiple-choice test format. Using the dual-process theory, they examine how multiple-choice tasks might favour superficial solving strategies, and the authors propose recommendations for the design of such tasks.

The third session focused on **diverse approaches to enhance formative assessment practices**. The study by Lemmo, Cotroni, and Polidoro builds on critiques of using written mathematics tests as formative assessment tools and it examines how a primary school teacher uses mathematical competence during test design and analysis. The teacher is able to obtain meaningful feed-up, feedback, and feed-forward, which inform both her understanding of student progress and future instructional planning. Mikite, Burgmanis, France and Namsone evaluate the effectiveness of a multi-indicator scoring approach to assess mathematical literacy through a detailed breakdown of six tasks into 17 individual items. Rasch analyses confirms the method's validity and reliability, although improvements are needed in the person separation index for better differentiation. In a different context, Hankeln, Prediger, Kroehne, and Hahn explore the use of speech input as an alternative to typed responses in digital formative assessments to assess students' conceptual understanding. The researchers observe that spoken responses are longer and incorporate multiple arguments. Responses

are especially rich when students use everyday language, which improves access to their conceptual understanding.

The fourth session explored **how formative assessment practices are shaped and reinterpreted in diverse mathematics education contexts**. Kaplan-Can and Haser analyze preservice teachers' lesson plans and interviews, revealing a range of formative strategies alongside tensions between planning and anticipated enactment. Andersson, Palm, and Winberg focus on an experienced teacher receiving individualized support to implement formative assessment during independent student work, emphasizing the value of context-specific professional development. Manzoni, Regola, and Giberti examine assessment in prison schools, showing how this unique setting fosters personalized, student-centered practices that differ from traditional summative approaches. Collectively, the papers illuminate how context matters in the enactment of formative assessment, shaping both opportunities and challenges.

In session 5 we discussed three papers, concerning **how assessment tools can better capture and support students' mathematical learning across diverse educational contexts**. Drüke-Noe and Bauer analyze statewide exit exams in Germany and conclude that tasks without aids and their standard solutions effectively target all six nationally defined mathematical competences. Point distributions align with the aim of testing basic skills. The findings highlight how these exams convey normative expectations for both teaching and assessment. Through the Erasmus+ DiToM project, Brings and colleagues developed diagnostic screening tools based on a shared framework of key mathematical skills, enabling early identification of students at risk of falling behind in key mathematical skills across European countries. The framework is based on a criterion-referenced approach, allowing test development to align with diverse national curricula. Sango's study in South Africa explores how subscore data from high-stakes assessments can help predict first-year university students' performance in mathematics. It compares different scoring methods, such as IRT and number-correct, to evaluate their impact on subdomain ranking and performance variance. The findings inform better use of test data for academic support planning.

Session 6 comprised two papers and one poster, all referring to assessment at university level. The paper by Barana, Marchisio Conte, Roman, Sacchet, Vinerean and Wondmagegne deals with a binational study in which they experimented with computer-aided assessment systems. In formative group activities university students worked on graphical calculus tasks and received a digital graphical feedback. The results show beneficial effects on reasoning that in turn enabled students to perform well in abstract tasks, too. Ramö, Myyry, Häsä and Zi examine students' choices between self-assessments and an examination and asked them to give reasons for their choice. The students justify their respective choice with reference to perceived usefulness, psychological safety and affective attitudes. Other justifications refer to learning gains, the absence of stress or the accuracy of assessment and the students seem to appreciate such a choice. In their poster, Andreas Büchter and colleagues present the results of a longitudinal study with university students. The data was collected before and after the pandemic. The tasks test mainly conceptual or mainly procedural knowledge or a combination of both. The longitudinal results reveal a substantial decline in the percentage of tasks

that were solved correctly while at the same time the percentage of unprocessed tasks rose substantially.

Focus on individual perspective

A review of past TWG21 contributions reveals that the student perspective has received comparatively limited attention. This observation led us to devote some time in our sessions to examine collaboratively the opportunities and challenges of placing greater emphasis on the learner's point of view. To build a rich understanding of the issue, we started the discussion by asking the participants what *student perspective* meant to them. Among the various contributions, one respondent emphasized the importance of enabling learners to focus on their knowledge rather than their gaps ("Students should be able to demonstrate what they know as opposed to what they do not know") while another drew attention to the subjective and situated nature of the assessment experience ("Students' experience in the moment of assessment"). These examples illustrate the diverse ways in which the student perspective can be conceptualized within assessment discourse. The discussion highlighted the highly individual nature of students' experiences with assessment, underlining the complexity of designing effective practices. Particular emphasis was placed on the value of formative assessment, especially when it incorporates both cognitive and affective dimensions of student response, supports self-regulation, and provides feedback that is meaningful from the learner's point of view. It was noted that assessment can be perceived as judgmental or appreciative, as motivating or, conversely, demotivating. For this reason, students should be given the opportunity to demonstrate what they know, rather than being assessed for what they do not know. Assessment should provide fair and valid judgments and enable active student participation. Feedback, in turn, should help students to learn from the assessment process and draw meaningful inferences from the results.

Finally, participants were invited to work in small groups, each selecting a paper to revise from the students' perspective, with particular attention to the research question, rationale, and methodology. Following this activity, they were asked to reflect on the process of reinterpreting the paper through the lens of the student perspective. The outcomes of the discussion revealed a shared interest among participants in placing greater emphasis on the student perspective within research itself. This could involve initiating research from the student's point of view or collecting more student-related data, for instance, regarding their engagement in standardized tests or their emotional responses to assessment. The ultimate goal of this shift would be to promote a more balanced distribution of responsibility and agency between teachers (or other assessors) and students (or assessed individuals) within the assessment process.

Graphical tasks with graphical feedback on limits of functions to support abstract reasoning

Alice Barana[1], Marina Marchisio Conte[1], Fabio Roman[1], Matteo Sacchet[1], Mirela Vinerean[2] and Yosief Wondmagegne[2]

[1]University of Turin, Department of Molecular Biotechnology and Health Sciences, Turin, Italy; marina.marchisio@unito.it

[2]Karlstad University, Department of Mathematics and Computer Science, Karlstad, Sweden

In the last few years, the use of automatic assessment has rapidly grown, especially in higher education. In Mathematics, computer-aided assessment (CAA) systems based on advanced computing environments make creating meaningful tasks to address higher-order thinking skills possible. This study focuses on graphical tasks with graphical feedback on limits and asymptotes of functions developed with a CAA system. They were experimented within formative group activities in two first-year university mathematics modules in Italy and Sweden. The answers to the final exam were analysed and compared with the group activity results to understand if the graphical tasks supported abstract reasoning during the exam. The results will be used to adjust the activities and improve the digital feedback provided.

Keywords: Asymptotes, computer-aided assessment, example-generation tasks, graphical assessment, mathematics education.

Introduction

In recent years, automatic assessment tools have seen significant and rapid growth, with a notable impact on higher education, given the need for scalable and efficient methods supporting remote and hybrid learning environments. In the context of Mathematics, computer-aided assessment (CAA) systems have emerged as powerful tools (Barana et al., 2021). These systems, often built on advanced computing environments, enable educators to create complex, meaningful tasks beyond basic calculations and memorisation. By incorporating sophisticated algorithms and interactive components, CAA systems allow for assessing higher-order thinking skills, such as problem-solving, critical thinking, abstract reasoning, and conceptual understanding (Fahlgren et al., 2021). This development is crucial in Mathematics education, where the ability to evaluate deeper cognitive processes is essential for fostering a more comprehensive understanding of the subject matter. With many CAA systems, it is possible to generate graphs and insert them into questions, answers, and feedback, so in turn to design tasks that allow students to interact with graphs, thus opening the way to different cognitive processes (Sangwin, 2015).

This study is framed within a joint research project between two universities, Karlstad University (KAU) in Sweden and University of Turin (UNITO) in Italy, about CAA in Mathematics (Fahlgren et al., 2024). The researchers developed digital tasks for formative assessment to enhance mathematical competences. During the academic years 2022/2023 and 2023/2024, tasks on calculus have been experimented within first-year university mathematics modules using graphical tasks involving limits and asymptotes of functions solved by students as group activities. The aim of this

paper is to show how the tasks were designed and to understand how working on similar tasks supported students' abstract reasoning.

Theoretical background

Computer-aided assessment is compelling in formative assessment (FA) since the enhanced Mathematical capabilities of CAA systems support using many FA strategies (Black & Wiliam, 2009). The possibility to personalise grading codes allows for the automatic grading of example-generation tasks, which ask students to provide examples of mathematical entities under certain conditions (Yerushalmy et al., 2017). Solving example-generation tasks is usually a non-routine problem-solving activity since the solution cannot be calculated through standard procedures (Watson & Mason, 2005). According to Watson and Mason (2005), the students' ability to provide different and varied examples that meet the given criteria is an index of their level of understanding. Thus, these tasks are a way to elicit evidence of students' deep understanding of mathematical entities.

CAA systems' algorithmic capabilities support the creation of graphs that can be included in the tasks. Graphs can depend on random parameters and vary at each attempt and for each student. This enables the design of graphical tasks, which are mathematics assessment items containing a graphic deemed integral to the solution process (Lowrie et al., 2011). Specifically, the graphic element contains information that needs to be decoded to solve the task. Graphical tasks are often used to foster students' sensemaking (Lowrie et al., 2012). When the topic of a graphical task is calculus, decoding the information from a graph involves analysing the representation of a function in a graphic register and translating the information into a different register (symbolic or numerical). This practice can help students make connections and enable abstract reasoning (Adu-Gyamfi et al., 2017). Abstract reasoning may be described as the ability to think conceptually, by understanding complex ideas and spotting patterns or relationships without having concrete examples to base on (Staub & Stern, 1997).

In CAA items, graphs can also play a relevant role in delivering feedback. For instance, in an example-generation task that asks students to write the expression of a function, showing the graph of one possible correct function is a way to provide implicit feedback (Sangwin et al., 2009). Students need to analyse the graphical feedback and decode the relevant information to try it again. Once again, the feedback analysis involves translating from one representation to another and vice versa. Where the solving process is more complex, the feedback could include a screencast and be proposed in the form of a silent video. Robinson et al. (2015) show that video feedback in the form of a screencast is effective according to Sadler's feedback definition (1989). In particular, it prompts action, which helps students close the gap between current and reference performance, thus developing mathematics understanding.

Method

This study aims to answer the following research question: *How does working on graphical tasks with graphical feedback on calculus in a formative group activity support abstract reasoning?* To do so, we set up international research involving students from two distinct post-secondary educational contexts: a mathematics module in the first year of a bachelor's degree in biotechnology at UNITO and a mathematics module in the first year of a bachelor's degree in engineering at KAU. In UNITO,

the module deals with basic calculus, linear algebra, and probability/statistics, while in KAU, the module only covers basic calculus. The international research group designed tasks through a CAA system that students in both countries could engage with during the course as group activities. This study is focused on one part of the group activities, which consisted of tasks about asymptotes: these results are a small part of a larger set of data under analysis. The tasks are described in Table 1. Items 1 and 3 were conceived as group tasks, while tasks 2 and 4 were individual: each student had different random parameters, which made the solution vary student by student; however, they were encouraged to discuss their solutions in groups. The group activities were eligible for UNITO students and compulsory for KAU students.

Table 1: Description of the group tasks about asymptotes

Task 1 and Task 3 – Group	**Task 2 and Task 4 – Individual**
An image represents the graph of a function. Students must use the graph to determine the analytical expression of the function. **Task 1** The image represents a function which has two vertical and one horizontal asymptotes. **Task 3** The image represents a function which has one vertical and one oblique asymptote.	Write two different functions such that they both have the following asymptotes: **Task 2** Two vertical asymptotes x=a and x=b, A horizontal asymptote y=c. **Task 4** A vertical asymptote x=a An oblique asymptote y=bx+c Note: a, b and c are random parameters
First feedback: Students can preview the graph of their response before submitting.	First feedback: Students can preview the graph of their response before submitting.
Second feedback: Students can verify their solution and, in case of an incorrect answer, watch a silent video feedback of the resolution process on another similar function.	Second feedback: The students in the group have different parameters, and they can discuss the solving process with their peers.

Tasks 1 and 3 are graphical tasks since students have to use information in the graphic register to solve them. The solution process includes translating the information into a symbolic register to provide the expression of the function. They are provided with implicit feedback that allows them to change their answer before submitting it, stimulating self-assessment. Moreover, silent video feedback emphasizes the abstract definitions for asymptotes and shows one possible solution process for those who failed the task. Tasks 2 and 4 are example-generation tasks conceived to encourage the expansion of students' example spaces by asking for two different examples, formulated using only the symbolic register; implicit feedback in the form of a graph is given before submission. The idea is that reasoning on the graphs in tasks 1 and 3 can support abstract reasoning in tasks 2 and 4.

Though different in the two modules, the final exam includes a common task about asymptotes. For UNITO students, it consists of one item among the following choices, where "ungiven" means that the asymptote(s) had to be of proper kinds and/or in the right number, but without requiring to satisfy a precise equation. The numbers in square brackets refer to how many students from KAU or from UNITO in the datasets had to answer to each choice:

Give an example of a function that has

- *(1) exactly 1 vertical asymptote and 1 horizontal asymptote* (ungiven) [220 KAU, 50 UNITO]
- *(2) the horizontal asymptotes y=a and the vertical asymptote x=b* [108 UNITO]
- *(3) at most one asymptote* (ungiven) [25 UNITO]
- *(4) exactly one vertical asymptote and one oblique asymptote* (ungiven) [14 UNITO]
- *(5) at least one asymptote* (ungiven) [4 UNITO]
- *(6) at least two vertical asymptotes x=a and x=b* [8 UNITO]

Note that an *asymptote* of a function is defined as *a line such that the distance between the function and the line approaches zero as one or both of the* x *or* y *coordinates tend to infinity*. This includes the possibility that a function coincides partly or completely with a horizontal or oblique asymptote.

During the exam sessions, students may be asked to justify their responses using limits. Similarly to tasks 2 and 4 of the group activities, the exam tasks did not include any graphs, so the required reasoning is purely abstract. In UNITO, the exam is delivered through the same CAA system used in the group activities, and items use random parameters *a* and *b* to provide variety in the students' exams. In KAU, the paper-and-pen based exam date is unique, so only Choice 1 was delivered.

Our datasets are based on KAU and UNITO students. For the UNITO ones, we considered the 209 students taking the exam between January 2023 and July 2024. For the sake of statistical significance, we mainly focused our analyses on choices 1–3, nevertheless taking into account choices 4–6 for interesting insights. For KAU students, we considered 220 of them taking the exam for a course in Mathematics in November 2022, all carrying out choice 1. For all students taking the exams, we analysed whether and how they worked on the group tasks about asymptotes to understand if the graphical group tasks with graphical feedback supported abstract reasoning during the exam.

We analysed the KAU and UNITO data quantitatively and qualitatively in the spirit of mixed-method research. Namely, the quantitative analysis involved relating the performance on asymptotes at the exam with either having taken the respective group activity (for UNITO data) or the outcome of the whole exam (for KAU data), and justifications. We categorised the justifications as entirely correct, generally correct with minor imprecisions (such as not splitting left/right or –inf/+inf limits, or saying that asymptotes can be computed only at the domain extrema), and incorrect. The qualitative analysis is devoted to the *kind* of functions students provided as answers, categorised as polynomial, homographic, higher-degree rational, and non-rational; some examples are explicitly presented to show peculiar alternatives.

Results

Let us start with the results relative to UNITO students. First, we want to establish whether taking the group activity about asymptotes, with FA including graphic tasks with graphical feedback, positively

influenced the final exam task results regarding the same topic. By considering choices 1–3, we detected a total of 102 students (56%) correctly answering the exam task, while 81 students (44%) answered incorrectly. If we subdivide them according to having taken the respective group activity or not, we found 74 correct (61%) and 47 incorrect (39%) answers among students who took the activity. In comparison, 28 correct (45%) and 34 incorrect (55%) answers were registered in relation to students who did not take the activity. The proportions between the two groups are quite different; this difference can be confirmed as statistically significant through a Fisher test for contingency tables, which yields a p-value of 0.043. This significance does not imply a causal relationship. However, it suggests that taking the group activity could have helped the students correctly solve the abstract task during the exam, given that several weeks (19–67 days; median: 35.5) passed between the activity and the exam.

We now analyse how correctly students justified their answers. By restricting our analysis to the sessions relative to choices 1–3 when we asked for justifications, we obtained a sample of 75 students relative to choices 1 and 3, of which 53 took the group activity and 22 did not. Only seven of them (all taking the activity) provided an entirely correct justification; a larger number justified their correct answer generally well but with either not splitting left/right or -inf/+inf limits (29/75: 20/53 and 9/22) or making other minor imprecisions (10/75: 7/53 and 3/22). A few students provided an incorrect justification to a correct answer (7/75: 6/53 and 1/22), while the remaining ones answered incorrectly (20/75: 13/53 and 7/22) or did not answer at all (two, both not taking the activity). We see that the best outcomes are associated with carrying out the graphical tasks with the graphical feedback in the group activities. At the same time, those who did not answer correctly gave it a try.

A subsequent analysis regards the *kind* of answers students gave when asked to construct functions with certain asymptotes. Depending on the precise task, we detected the following.

- In choice 1, most students answered with a homographic function (a ratio between a constant or a linear polynomial and a linear polynomial, not multiple of each other). However, two students provided correct answers using an irrational function 3/sqrt(x) and a higher-degree rational function $(x+2)/(x^3-1)$. Other students answered with non-rational functions such as ln(x) and arctan(x), but their answers were marked incorrect.
- In choice 2, most students answered with homographic functions, too. Other correct answers were either non-rational functions such as exp(-x)/(x-1)+3, -exp(x)/(x+1)+6, ln(x/(x+9))-9 (they also depended on which exact asymptotes were given), or higher-degree rational functions, possibly with a supplementary vertical asymptote (we did not ask for *only* $x=b$).
- In choice 3, students tended to answer with homographic functions, but in this case, their answers were marked incorrect since these functions have *two* asymptotes. The correct answers were mainly non-rational functions like ln(x) and exp(x), with a student providing the higher-degree rational function $x^3/(x-2)$. Notably, only one student chose the simplest function for this case: a polynomial. Indeed, constant and linear functions have one asymptote (themselves), while higher-degree polynomials have none. Students likely struggled with the idea of asymptotes coinciding with the function and missed that "at most one" includes "zero".
- Regarding choices 4–6, the requirement of exactly one vertical and one oblique (slant) asymptote was met by students with rational functions (second-degree numerator, linear

denominator), with the noteworthy exception of $(x^2+\text{sqrt}(x-2))/(x-3)$. The requirement of at least one asymptote brought again to homographic functions; requiring at least two vertical asymptotes, both given, was satisfied with rational functions (constant numerator, second-degree denominator). In this latter case, some incorrect answers were non-rational functions.

It can be noted that for choice 1, the functions $3/\text{sqrt}(x)$ and $(x+2)/(x^3-1)$ were both answered by students taking the group activity: all the others who answered correctly used homographic functions, showing less variety. This is also true for choice 3 and the functions $\ln(x)$, $\exp(x)$, $x^3/(x-2)$; the student answering the polynomial did not take the group activity, but non-polynomial answers, all responded by students taking the group activity, were varied. The situation is more balanced for choice 2, while little data was collected for choices 4–6. Data suggest that taking the activity might have allowed students to consider larger example spaces.

Let us now consider the results relative to KAU students. While we cannot directly relate having taken the group activity to the exam outcome, since it was a mandatory activity, we could put in relation the performance on the tasks on asymptotes with the outcome of the entire exam, where all the items concerned basic calculus and abstract reasoning. Indeed, this also allows us to detect the quota of students who were weak theoretically but were able to perform well in the exam on the asymptotes task. Of the 220 students considered, 125 (57%) managed the tasks on asymptotes well and passed the exam, but 16 of them (7%) would have failed the exam without the points for the asymptotes task, after rescaling the scores. This results in a total of 62 (28%) students performing well on asymptotes but failing the exam (46, 21%) or that would have failed it after rescaling, versus 109 (50%) managing asymptotes well and that would have passed the exam even by rescaling. About those not performing well on asymptotes, 8 (4%) passed the exam (all of them narrowly), and 41 (19%) failed the exam (with very low rescaled scores, showing low engagement in the whole course). Fisher's exact test yields a p-value of almost zero ($3.4 \cdot 10^{-9}$), while Cramer's V has a value of about 0.4, highlighting how being engaged well in tasks on asymptotes is related to having success on the exam, even by excluding the asymptotes task itself. This can indicate that participation in the group activity gave some moderately weak students more chances at the exam: working with graphical examples with automated feedback can improve even the abstract understanding needed in the written exam without computer support. Still, it remains more challenging to help very weak students.

If we extend our analysis to the justifications, 69 students provided an entirely correct one, with 5 of them (7%) failing the exam, 30 of them made minor imprecisions with 4 (13%) exam fails, 57 provided an incorrect justification to a correct answer with 31 (54%) exam fails. Thus, there is also a strong relation between having success on the exam and justifying correctly the answer on asymptotes beyond answering correctly. The ability to provide a theoretical explanation and connect it to the graphical representation suggests an improved abstract understanding. However, this improvement was not as evident in topics not addressed through group activities, as most students taking the course obtained only moderate grades in the exam, indicating a weaker understanding of other theoretical aspects. Regarding the kind of answers students gave, almost all the correct answers were expressed through homographic functions, but a student answered with the ratio of 2 third-degree polynomials. Incorrect answers included $\exp(x)$, $(x-1)^2 \cdot (y-3)^2$ (bivariate), and rational non-homographic functions.

Discussion and conclusions

The results provided some indications to answer the research question about *how working on graphical tasks with graphical feedback on calculus in a formative group activity supports abstract reasoning*. Indeed, the quantitative data can suggest that students performing the collaborative group activities concerning asymptotes were significantly more able to answer correctly and with proper justification to the respective exam question (UNITO group). In turn, students answering correctly and well justified to that exam question were significantly more able to pass a basic calculus exam, while that question was crucial for the exam success of several students (KAU group). At the same time, the qualitative data from the UNITO group show that students' answers at the exam resulted in rich example spaces, which were generally more varied for those performing the activities. This aligns with (Adu-Gyamfi et al., 2017), where connections and abstract reasoning are fostered by working on graphs in calculus. The results could suggest that the design of the group activities about asymptotes, which includes graphical tasks with graphical feedback, effectively conveyed a way of reasoning that enabled students to perform well in abstract tasks. The major limitation is that we cannot be sure these associations imply causation, and we cannot rule out possible other causes: for instance, the activities could have caught the attention mainly of already inclined students. As for future work, the first direction could be a more direct comparison between the two countries. Indeed, a relation between performance on asymptotes (either at the group activity or at the exam) and the whole exam would have been less significant for UNITO students since the course is broader than the KAU one. Conversely, for KAU students, given the compulsory activities, the performance on asymptotes at the exam can be related to their (formative) grade rather than whether they are being taken. Another direction could be administering analogous activities on different topics to activate diverse facets of abstract reasoning, thus overcoming the limitation of considering a specific topic (asymptotes). Lastly, the answers to the formative assessment tasks could be analysed to understand the students' reasoning and their common mistakes and misunderstandings. Based on this analysis, the tasks and feedback can be adjusted for higher effectiveness.

The Erasmus+ funded project "Diagnostic Tool in Mathematics (DiToM)" addresses the need for national and international diagnostic instruments to assess mathematical key skills which are necessary to acquire competencies that build on them. Given the increasing proportion of countries struggling with decreasing students' performance in mathematics (e.g. France, Germany, Spain) (Mullis et al., 2020), the project focuses on identifying students at risk of being left behind in the following and advanced mathematical content. The project consortium consists of experts from seven European countries. The theoretical framework, i.e., the concept of mathematical key skills, forms the foundation of test development compatible with the similarities and differences in national curricula. Test development is criterion-based and involves creating an item pool and country-specific diagnostic screenings derived from it.

Keywords: DiToM, screening, mathematical key skills, criterion-referenced approach

Introduction

Results from national surveys in Germany indicate an increasingly high proportion (2016: 15.4%; 2018: 24.3%) of students failing to meet the minimum standards in mathematics (Stanat et al., 2019; Stanat et al., 2022). Similar tendencies and stagnant trends can be found for several European countries in the results of the international PISA studies (OECD, 2020). Such difficulties often stem from inadequate understanding of foundational mathematical concepts, leading to persistent issues in more advanced topics (Gaidoschik, 2019). Research by Ehlert et al. (2013) underscores the necessity of a solid grasp of basic arithmetic for successful progression in mathematics education. Humbach (2009) further emphasizes that more sophisticated mathematical understanding builds upon these fundamental skills, suggesting that basic arithmetic knowledge is a critical prerequisite for mastering more complex content (Humbach, 2009). Arithmetic skills are not only a prerequisite for further learning in mathematics but also serve as a significant predictor of success in the STEM field (Nakakoji & Wilson, 2014). In the context of school mathematics, a significant connection exists between arithmetic and algebra. Algebra, as it is commonly taught in schools, can be viewed as an generalization of arithmetic principles (Nydegger-Haas, 2016). Due to this close relationship, for instance, the German core curriculum, represents these topics under a combined content area titled *Arithmetic and Algebra* (MSB, 2022). Since these domains are closely intertwined, they are similarly

structured in many curricula across different countries. Errors made by students in algebra can often be attributed, at least in part, to faulty attempts to apply or adapt previously acquired knowledge from arithmetic to new situations (Kieran et al., 1990). There is a lack of national and international diagnostic instruments for continuous assessment at an early stage of the development of that basic content in arithmetic and algebra to effectively address the growing heterogeneity.

The aim of the paper is to build on this interface and to illustrate the current status of the project, i.e. how the DiToM project (Diagnostic Tool in Mathematics) meet the gap between the theoretical framework and the development of prototypical testitems. Therefore first, the DiToM project will be presented in its essential aspects. Following this, the theoretical framework of mathematical key skills will be examined and illustrated with concrete examples. Subsequently, the understanding of screening as part of a diagnostic process will be explained. In the methodology section, the process of item-shaping for one of the screening tests (grade 6) is stated. Finally, a summary will be provided, along with an overview of the next steps in the project.

The DiToM project

DiToM is a project that started in January 2023 as part of an Erasmus+ Cooperation Partnership (DAAD; KA220-HED-1194D587). The project consortium consists of Partners from the following seven countries: Germany as the coordinating partner, France, Sweden, Italy, Greece, Croatia and Spain. The project is structured into five work packages to achieve the project goals of test development, free availability of the tests via a website and dissemination of the tests. The tests are being developed for grade levels 0, 2, 4, 6 and 8, focusing on arithmetic and algebra and will be available in 2025. The official website of the project is: https://www.ditom.org.

The focus of the diagnostic tools is on arithmetic and algebra due to their indicative nature, particularly concerning the correlations in difficulties and vulnerabilities observed in learners' mathematical performance (Humbach, 2009). Additionally, the linear and hierarchical structure of these content areas (Ehlert et al., 2013), which is a common feature among participating partner countries and their curricula, further underscores the rationale for this emphasis. The intended purpose of the tests is to provide a binary risk assessment of learners' arithmetic and algebraic skills regarding “at risk” and “not at risk”.

Theoretical Framework

When developing diagnostic instruments, both the content to be assessed and the expectations placed on that content must be considered. Nowadays, the general agreed-upon expectation is that students develop operational knowledge. Operational knowledge is defined as "the capacity to draw on mathematical tools to deal with new and potentially problematic situations, rather than merely the capacity to reproduce procedures learnt in relatively stable contexts very similar to those in which they were taught" (UNESCO, 2012, p. 17). Niss and Højgaard (2019, p. 12) define mathematical competence as the "insightful readiness to act appropriately in response to all kinds of mathematical challenges pertaining to given situations". At the same time, a purely content-based description of competence, such as "being able to add two whole numbers", generally implies implicit competencies that are expected. These considerations require a transparent understanding of the terminologies of

mathematical competence and *competencies*, *mathematical concepts* and *mathematical skills* and more precise *mathematical key skills* to be articulated within the DiToM project. In the present project phase, the following understandings of the terms can be inferred: (1) *Mathematical competencies* are understood as the "insightful readiness to act appropriately in response to a specific sort of mathematical challenge in given situations" (Niss & Højgaard, 2019, p. 12). On the one hand, there are competencies of the first category that pertain to effective handling of posing and answering mathematical questions (e.g., mathematical thinking, mathematical problem-solving). On the other hand, competencies of the second category encompass abilities that are necessary for the conduction of mathematical activities (e.g., symbols and formalism competency, communication competency). (2) *Mathematical concepts* are understood as "a researcher's articulation of intended or inferred student knowledge of the logical necessity involved in a particular mathematical relationship" (Simon, 2017, p. 123). An example of an articulation of a concept could be "Understanding the addition of two-digit numbers" in which addition is limited to a specific type of task, involving the comprehension of the relationship between two-digit numbers and the addition operation. (3) *Mathematical skill*: Establishing a suitable link between mathematical competencies and mathematical concepts can evolve into mathematical skills. They can be seen as learned and applied abilities that lead learners to use mathematical knowledge effectively in some execution or performance. For instance, "mental calculations of the sum of two-digit numbers" or "articulations of the process of calculating two-digit numbers" can be seen as mathematical skills. (4) *Mathematical key skill*: A mathematical skill can be regarded as a mathematical key skill if the lack of such skill has the potential to make further learning difficult or even impossible (Gagné & Briggs, 1974). Lacking an internalization of mathematical concepts and the corresponding mathematical competencies, learners will be unable to, for instance, grasp and employ arithmetic algorithms or comprehend the principles behind decimal number notation. In the following, basic arithmetic operations are used as an example to illustrate the concept of mathematical skills and key skills. Basic arithmetic operations (addition, subtraction, multiplication, division) are elementary for dealing with mathematics (Humbach, 2009). Particular mathematical concepts are connected with the basic arithmetic operations: (1) Understanding of the operation (like "operation sense", "mental models"), (2) number facts, (3) calculation strategies, (4) understanding and use of the algorithms and (5) estimation. Comparing the DiToM countries, these concepts or part of these concepts are established in all of their curricula. The process students use to learn number intervals may be different for different grades, but the mathematical learning process takes these concepts into account. Based on these concepts, competencies are formulated - also in curricula - which indicate the learning progress expected at certain points in time. This can take the form of processes (e.g. students select and use appropriate mathematical rules and algorithms when working on problems) or content (e.g. students discover, use and describe operational properties (e.g. invertibility) and laws of arithmetic). Often, competencies are also described from both aspects. The mathematical skills describe the combination of concepts and competencies in this field of basic arithmetic operations concerning structuring, understanding and use of different situations in this field. For example, the use and explanation of structured addition, the use of basic operations in applied situations. Mathematical key skills in this

field focus on the skills that are necessary for the further learning process. For example, grade 2 students solve addition and subtraction tasks in the number range up to 100 using arithmetic laws and decomposition strategies orally or semi-orally (also using intermediate forms) in a reflective way. Consider the following tasks (for early learners):

- **Task 1:** 25 + 34 = ___ **Task 2:** 25 + 37 = ___

Task 1 involves addition without a tens transition and is considered a key skill for grade 3, reflecting the need for students to manage an expanding number range and increasingly complex operations. Task 2 introduces a tens transition, which further challenges students and illustrates a progression in mathematical complexity. This transition in the number range up to 100 is a mathematical key skill and therefore integrally related to the transfer to operations with more complex numbers. In the development of this screening test, it is essential to determine which skills are integral to mathematical key skills and which of them may hinder further learning progress.

Screening as part of a diagnostic process

The diagnostic tools developed within the DiToM project are specifically designed as screening instruments. These screening instruments aim to identify at-risk learners efficiently and with minimal resource expenditure, thereby targeting students who require additional support to advance their mathematical learning (Tröster, 2009). The design of these test instruments ensures that they can be administered to an entire class within a single lesson, making them both time-efficient and cost-effective. Screening procedures have the aim of identifying potential risks earlier than traditional methods, thus providing an early intervention opportunity (Breitenbach, 2020). These procedures are characterized by a relatively low depth of analysis, focusing instead on capturing early indicators of developing deficits (Tröster, 2009). As a result, they are well-suited for large groups, offering an economical means of assessment that minimizes student burden. The filtering capability of these tests allows for the identification of students who may require further diagnostic evaluation, thus establishing a basis for well-founded suspicions of risk (Walter, 2020). In the context of this project, the screenings concentrate on domain-specific evaluations of mathematical concepts within arithmetic and algebra. Early indicators for these screenings are defined based on the key skills identified due to the theoretical framework. The screenings follow a 2-year rhythm to match the curricula, which in most participating countries are structured in 2-year phases. The tests are designed for use at the beginning of the first grade to assess the entrance requirements for mathematics education and continue up to grade 8, before students obtain their first school-leaving certificate. These tests are administered at the end of each two-year cycle. The primary objective is to use these screenings as a preliminary diagnostic tool to pinpoint students at risk, thereby facilitating a more detailed and targeted follow-up diagnosis for those identified.

Design of prototypical test items

The objective of this paper is to offer a theory-based and transparent explanation of the process involved in transitioning from theoretical framework regarding mathematical skills and key skills to the development of items, by giving a practical example from a test for grade 6. This section outlines

the approach used to design the tests, detailing the steps from theoretical framework to the creation of prototypical test items.

Criterion-referenced and norm-referenced approaches

In educational diagnostics, two primary approaches dominate the development of tests: norm-referenced and criterion-referenced approaches (Dunn et al., 2003). Norm-referenced assessments evaluate students in relation to their peers within a specific cohort, relying on a pre-determined distribution of performance. Such tests are commonly employed in contexts where placement or selection decisions are required (Burton, 2006). In contrast, the criterion-referenced approach assesses students' performance against a predefined set of criteria (Le Brun & Johnstone, 1994). The purpose of DiToM is to identify students at risk in mathematical key skills who require immediate support from their teachers. The diagnostic assessment in DiToM is conceptualized as a form of screening, aimed at identifying students at risk in acquiring key skills in arithmetic and algebra as outlined and defined in the theoretical framework. Consequently, the criterion-referenced approach (CRA) is most suitable for the objectives of the DiToM test. According to the CRA, learning is evaluated using a predefined set of criteria and corresponding performance standards, written descriptions of what students are expected to know and be able to do at a specific stage of education. For each key skill, these descriptions are organized into rubrics, the levels of which correspond to specific grades that may vary across countries. In this paper, the CRA is applied to the 6th grade test development as an example. The following methodological steps were undertaken: (1) Identifying relevant content: Relevant content was determined through didactic models of competency development and analyses of various national curricula. (2) Identifying corresponding mathematical skills and key skills: Mathematical skills and key skills were derived from the identified content. (3) Creation of prototypical items: Prototypical items were developed based on these key skills. (4) Item review and refinement: The prototypical items were reviewed within the consortium, contextually adapted and evaluated by a focus group of a minimum of two teachers from each participating country (n=24), leading to further refinements due to approval threshold of $\geq 80\%$ for the relevance of the item as a *key skill* (Lynn, 1986). (5) Trial of the items in order to obtain empiric data, leading to further refinements.

Exemplary execution of the test for grade 6

For the 6th grade test, three relevant content areas were identified: (1) algebra and pre-algebra, (2) proportionality and linearity and (3) technical calculations. These areas were selected based on a thorough analysis of the national curricula of the participating countries. The item review revealed that these domains cover the core mathematical content expected for 6th grade students in arithemtic and algebra. In the first step, specific mathematical skills were developed for each of these domains. These skills represent key mathematical competencies that students at this grade level are expected to acquire. In the second step, key skills were derived from these, which are considered necessary prior knowledge required for the successful development of the targeted skills (see Table 1). These key skills serve as the foundation for the development of test items and are closely aligned with the curricular expectations and competency standards of the participating countries. The absence of these key skills hinders the understanding of specific mathematical skills.

Table 1: Linking of mathematical key skills, mathematical skills and prototypical test items in the domain *Algebra and Prealgebra*

Macro Area	Lower skill (mathematical key skill)	Exemplaric item based on the key skill	Upper skill (mathematical skill)
Calculating	Calculating (numeric) - Recognize equality sign as an equivalence relation - Complete an addition or a multiplication	Find the missing numbers. a.) $3 \cdot ___ = 126$ b.) $__ \cdot 4 = 172$ c.) $24 \cdot 6 = __$	- Understanding equality - Understanding equivalence - Solving equations
Generalizing relationships	Generalizing a relation without necessarily producing a symbolic expression - Arguing or motivating an answer involving regularities	Which is the rule that can be used to continue this sequence of numbers? $256, 128, 64, 32, __$ A. Substract 32 B. Substract 128 C. Divide by 4 D. Divide by 2	- Symbolic generalization of relations
Translating	Translating between different registers of representation (iconic, arithmetic, natural language…).	Tom follows the instrutions: The number 4 is added to 5. The result is multiplied by 8. What calculation can Tom use to obtain the result? A. $5 + 4 \cdot 8$ B. $(5 + 4) \cdot 8$ C. $5 + (4 \cdot 8)$ D. $5 \cdot 8 + 4$	- Translating data to symbolic representation - Understanding the structure of an expression
Problem solving and Modelling	Solving problems and modelling relationships between known and unknown quantities in an additive and/or multiplicative problem - Solve numerically a problem that can be modelled as a linear equation	The picture shows marbles, represented by green discs, and boxes, represented by orange rectangles. There are placed on two tables. Each box contains the same number of marbles. There are the same number of marbles on each table. How many marbles are there in each box? 	- Problem solving - Representing relationships between data and unknown

Thus, the test addresses the relevant mathematical domains and ensures that the items are adapted to country-specific curricular differences while maintaining consistent diagnostic validity across the entire student population. The focus group results led to revisions and a reduction of the prototypical item pool in clear cases (less than 50% agreement among experts on an item).

Summary and Perspectives

The next steps of the project involve finalizing the prototypical itempool of the screenings for all grades. Building upon this, the diagnostic tools will be developed, piloted and adjusted until mid 2025. In DiToM, the interrelation between mathematical competencies, concepts, skills and key skills are deemed essential. Key skills are necessary for learners to proficiently engage with associated mathematical content and subsequently build upon them to develop fundamental contents based on them. Additionally, the focus on the development of screening instruments and the emphasis on CRA were essential for the ongoing work. To develop screenings that can be used in all participating countries based on these initial decision-making processes, the following approach is being pursued: Mathematical competencies are derived from the literature and then enriched with mathematical concepts of the domain of arithmetic and algebra, which can be used to develop test items. This process results in a basic prototypical item pool. The binary categorization of the screenings allows for assigning learners' performance in terms of whether key skills have been acquired or not. Based on this pool of tasks, country-specific tests are developed according to the alignment with national curricula.

Exploring instrumental orchestration practices for formative assessment through digital technology

Min Chen[1], Rogier Bos, Michiel Doorman and Paul Drijvers

[1]Utrecht University, Freudenthal Institute, The Netherlands; m.chen3@uu.nl

This study investigates how teachers orchestrate student learning by using technology as well as formative assessment practices in classroom settings, using instrumental orchestration and formative assessment with technology frameworks. Our research question is: how can teachers conduct formative assessment as part of their orchestration practices when using digital technology? This study analyses twelve videos from technology-rich mathematics classrooms in China. The results show frequencies and relations of orchestration and formative assessment practices observed in the videos, and that orchestration practices are predominantly teacher-led, involving supporting direct instruction and providing individualised feedback.

Keywords: Instrumental orchestration, formative assessment, digital technology.

Introduction

Digital technologies have greatly increased the possibilities and potential for mathematical teaching and learning as well as for formative assessment (Weigand et al., 2024). In the context of formative assessment, integrating technology not only provides teachers with immediate feedback on student progress, enabling real-time monitoring of understanding, but also aligns with pedagogical goals to make the formative assessment process more dynamic, responsive, and supportive for student learning trajectories (Dalby & Swan, 2019). However, Drijvers and his colleagues (2013) emphasise that despite the potential of digital technologies to enhance teaching and learning, their adoption by educators does not necessarily lead to improved outcomes. This suggests that simply having access to digital tools is not sufficient—what matters is how teachers use them in response to students' needs. The challenge for teachers in using technology lies not in the technology itself, but in understanding how it can be adapted to enhance student learning, highlighting the need for educators to carefully orchestrate and guide the students' learning processes.

Building on this view, while digital technologies offer new possibilities for formative assessment, their use in classrooms still relies on how teachers manage the integration of these technologies in classroom settings. To better understand this process, *Instrumental Orchestration Theory* offers a framework for analysing how teaching practices shape students' interaction with digital tools. This theory conceptualises a teacher's role in guiding students toward mastering tools and facilitating their learning process (Trouche, 2004). It emphasises how teachers can intentionally and systematically integrate digital technology into their teaching to support students' instrumental genesis, the dual process in which learners adapt tools to their needs while being influenced by the tools in their cognitive and practical activities. Teachers play an important role in orchestrating this process by designing learning environments that support the interaction between learners and tools, ensuring that instrumental genesis unfolds meaningfully (Drijvers et al., 2010). Panero and Aldon (2016) further argue that a teacher's orchestration skills, developed through the appropriation of technology use for formative assessment, are cultivated alongside the students' instrumental genesis. The relationship

between instrumental orchestration and formative assessment with technology could be synergistic, integrating digital technology to create a better way to evaluate and support student learning.

Research has explored digital technology's general capabilities, but few studies have examined the integration of digital technology into live formative assessment, highlighting a gap between ideal and practical implementations. For example, Børte and colleagues (2023) report that teachers struggle to adapt digital technology within their existing formative assessment practices, which not only results in a misalignment between digital technology and formative assessment but also creates difficulties in aligning digital technology with pedagogical methods. This misalignment leads to a missed opportunity to fully explore the potential of digital technology for student-centred learning. To address these challenges, this study investigates the relationship between digital technology, instrumental orchestration, and formative assessment in mathematics education, focusing on how formative assessment is integrated into orchestration practices when using digital technologies.

Theoretical Background

This study adopts the definition of formative assessment from Black and Wiliam, who describe it as an assessment that "elicits, interprets, and uses evidence about student achievement…to make decisions about the next steps in instruction" (2009, p. 9). This definition places emphasis on the continuous, responsive nature of assessment and highlights the teacher's role in adapting instruction based on student needs. In exploring how such processes can be supported through digital technology, this study draws on two theoretical perspectives:

Instrumental Orchestration Theory was developed to shed a light on how the integration of technology into whole-class instruction can be orchestrated in various ways. According to Drijvers and his colleagues (2010), teachers demonstrate technological tools during *Technical-demo*, explain on-screen activities to the whole class during *Explain-the-screen*, or foster discussions about on-screen content during *Discuss-the-screen*. Other orchestration types include highlighting relevant student work for whole class discussion as *Spot-and-show*, connecting digital activities to their representation in traditional mathematical formats as *Link-screen-board*, and asking *Sherpa* students to use technology to perform tasks guided by the teacher as *Sherpa-at-work* (Trouche, 2004). Furthermore, teachers' walking around to provide individual feedback that is referred to as *Work-and-walk-by* (Drijvers, 2011), and teachers' providing screen-based explanations and posing closed questions that is referred to as *Guide-and-explain*, or teachers' reliance solely on traditional board instruction without digital technology is termed *Board-instruction* (Drijvers et al., 2013).

Formative Assessment with Technology, drawing on the work of Dalby and Swan (2019), explores how digital tools can be integrated into formative assessment to support classroom teaching and learning. The framework outlines a circular process consisting of four interrelated stages: *Ask*, *Answer*, *Analyse*, and *Adapt*. The flow diagram (see Figure 1) shows how the four stages connect in practice and helps clarify how technology can be part of classroom formative assessment routines.

Taken together, these two frameworks offer complementary lenses: one emphasises how teachers manage digital tools during instruction, and the other focuses on how technology can support more dynamic and responsive assessment. This study connects these perspectives to examine how

formative assessment is shaped within technology-rich classrooms, and how orchestration practices contribute to that process.

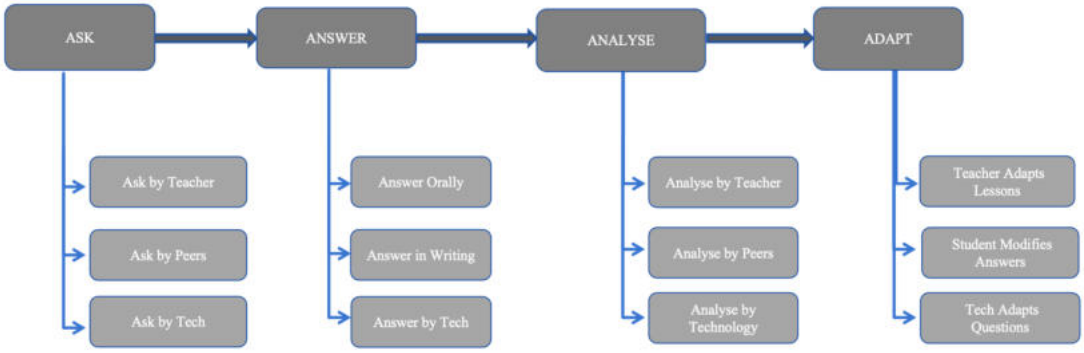

Figure 1: Formative assessment with technology, adapted from Dalby and Swan (2019)

Method

This study investigates through video analyses how secondary school mathematics teachers from Jiangsu Province, China, integrate digital technologies into their teaching practices, including interactive digital whiteboards, tablets, mathematical visualisation tools, software like Desmos and GeoGebra, and immersive technologies such as Augmented Reality. We choose twelve videos of award-winning lessons from the 2022 "*Jiangsu Province ICT-integrated High-Teaching Quality Course Competition*" for observation and analysis. These videos represent exemplary lessons, rather than typical classroom instruction, designed to demonstrate considered best practices in integrating technology within mathematics education. Thus, we expect that the videos could illustrate successful examples of technology-rich classroom practices. The research question of this study is: *How can teachers conduct formative assessment as part of their orchestration practices when using digital technology in mathematics classrooms?*

When analysing the data, we focus on understanding how the orchestration interventions employed by teachers provide them with opportunities to monitor the progress of their students and to assess their work. Initially, the identification of orchestration types was conducted using the instrumental orchestration framework (Drijvers, 2011; Drijvers et al., 2010; Drijvers et al., 2013). Subsequently, the analyses applied Dalby and Swan's (2019) framework to explore the teachers' formative assessment practices. Finally, we identified one significant event showing the potential of specific orchestration for formative assessment practice. The coding process was conducted via Atlas.TI, which is a qualitative data analysis software. The unit of analysis was defined as an *episode*, which includes the whole-class treatment of a single task within the video. These episodes were further divided into sub-episodes, if multiple orchestration types were observed in a sequence. Formative assessment instances were identified only when technology was explicitly used to evaluate student understanding, such as gathering evidence on student learning (e.g., digital polling for immediate feedback), analysing this evidence (e.g., reviewing digital submissions for accuracy), or adapting instruction based on technological results (e.g., adjusting tasks based on displayed responses).

Inter-coder reliability was established by having a second coder review three videos with predefined quotations. After an initial coding of one video, the coders reviewed discrepancies in their coding decisions. Through discussion, the coders resolved disagreements, such as whether an adaptation stage of the formative assessment process occurred during the lesson. After reaching a consensus on the coding, the second coder analysed the remaining two videos, resulting in a Krippendorff's alpha score of 0.695. This indicates moderate agreement, which is acceptable given the interpretive complexity of the videotaped classroom interactions.

Results

Table 1 provides information on the frequencies and the relationship between orchestration practices and formative assessment processes. The *Guide-and-explain* and *Work-and-walk-by* types are most prevalent, highlighting the teachers' preference for direct teaching with immediate feedback. The *Sherpa-at-work* and *Spot-and-show* types also frequently occur, though to a lesser extent. Other types are less commonly observed in the classroom settings, with some types such as *Technical-demo* and *Board-instruction* appearing only occasionally across the data (see Table 1, second column).

In the first stage of formative assessment, *Ask*, the orchestration types of *Guide-and-explain* and *Work-and-walk-by* prominently utilise teacher-led and technology-mediated questions. A notable number in Table 1 is the high engagement through technology, particularly in *Work-and-walk-by*, which shows the most frequent use of digital technology for questioning. We observed in the videos how during the *Answer* stage in orchestrations like *Sherpa-at-work* and *Work-and-walk-by* students are often invited to answer through digital technology. We noticed how the following orchestrations in the *Analyse* stage increased the depth of the analysis. *Guide-and-explain* is heavily utilised, with 51 instances of teacher-led analysis (see Table 1), demonstrating the teacher's central role in evaluating student responses. Similarly, *Spot-and-show* stands out with 17 instances of peer analysis, where student work becomes a focal point for whole-class discussion, enabling peer feedback. The *Adapt* stage, essential for completing the formative assessment loop, reveals fewer instances across orchestration types, indicating that teachers often implement the first three stages without consistently completing the adaptation phase. Notably, *Spot-and-show* emerges as a significant orchestration type in this stage, with 4 instances of prompting student rethinking and 8 instances of lesson plan adjustments based on whole-class discussion insights. However, a key observation in Table 1 is the zero instances of changes in technological resources, suggesting that digital technology may play a limited role in the adaptation process of formative assessment.

Based on the frequencies shown in Table 1, a small number of orchestration types, including *Guide-and-explain*, *Work-and-walk-by*, *Sherpa-at-work*, and *Spot-and*-show, appear more regularly and are often linked to key stages of the formative assessment process. These include teacher-led questioning (*ask*) and students' oral responses (*answer*), and in some cases, signs of teachers analysing student input and adjusting their actions (*analyse and adapt*). Other orchestration types, like *Technical-demo* and *Explain-the-screen*, are used less often and show little evidence of movement beyond the initial stages. The coding results reflect a general pattern of teacher-directed interaction with limited engagement in the full sequence of formative assessment processes.

Table 1: Frequencies of coded instrumental orchestration practices and formative assessment processes

FA practices ----- IO practices	Frequency	Ask			Answer			Analyse			Adapt		
		by peer	by teacher	by technology	in writing	orally	via technology	by peer	by teacher	by technology	changes in resources	changes to lesson plans	rethinking of students
Board-instruction	5	0	0	0	0	1	0	0	1	0	0	0	0
Discuss-the-screen	10	0	10	9	1	9	0	3	2	0	0	0	0

Total	215	0	116	107	29	68	61	31	145	31	0	22	7

Illustrative Event

The following event was chosen because it vividly demonstrates how a specific instrumental orchestration practice uses digital technologies to enhance formative assessment, exemplifying the study's findings in a technology-rich classroom setting.

In Figure 2, the teacher employed the *Spot-and-show* orchestration type to select and display examples of student work that showcased a range of solution approaches, including typical mistakes and alternative strategies. By sharing these examples with the entire class, the teacher created an opportunity for students to critically compare different strategies, identify mistakes, and discuss the underlying reasoning behind them. The teacher supported this process by asking follow-up questions and helping students explain their reasoning clearly. When errors were identified, the teacher

prompted the original students who made these answers to revise their work and articulate their thought process. This iterative process of analysis, feedback, and revision fostered a collaborative learning environment in which peer discussion played an important role. As a result, students became more engaged and took a more active role in making sense of the mathematics.

Overall, the *Spot-and-show* orchestration type supported the complete formative assessment process by enabling the teacher to monitor student progress, promote peer feedback and discussion (*Analyse*), and guide students to reflect on their understanding (*Adapt*). This continuous cycle of feedback and reflection facilitated real-time identification and resolution of misconceptions, ultimately enhancing both individual and collective learning outcomes.

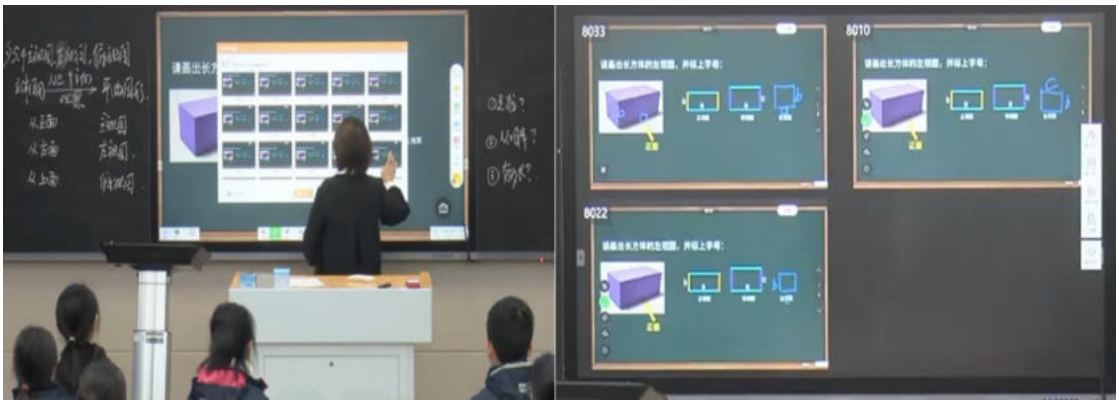

Figure 2: The screenshots of *Spot-and-show* orchestration type

Conclusion and Discussion

With this study, we investigated how teachers conduct formative assessment as part of their orchestration practices when using digital technology. The study has revealed how teachers integrated various orchestration practices at different stages of the formative assessment process.

Table 1 shows that in the *Ask* phase of formative assessment, *Work-and-walk-by* occurs most frequently. This orchestration uses technology-mediated questions to engage students. In the *Answer* phase, *Sherpa-at-work* actively involves individual *sherpa* students in solving tasks using digital technology, allowing them to showcase their problem-solving process to the entire class. In the subsequent *Analyse* stage of formative assessment, *Guide-and-explain* is used extensively in our sample videos for detailed examination of student work, demonstrating the teachers' central role in evaluating student responses and providing whole class feedback. This highlights that teachers typically lead the analysis process of formative assessment, consistent with prior findings by Panero and Aldon (2016). Although the *Adapt* phase is critical to completing the formative assessment loop, we observed that it is often not fully executed. The exception is *Spot-and-show,* where facilitating continuous observation, providing immediate feedback, fostering peer discussion, and encouraging reflection constitute a complete formative assessment process, as illustrated in the previous example. Finally, this study also shows that digital technology in our sample videos primarily facilitates interactions between the teacher and students, rather than direct student interaction with the digital technology itself. This outcome may, however, have been influenced by the choice of videos, which

focused more on whole-class practices, and the didactical configuration in the classroom. In addition, some orchestration types inherently provide more opportunities for students to engage directly with digital technologies.

This study also reveals that digital technology enables teachers to conduct prompt assessments, provide timely feedback, monitor student progress, and summarise student responses, which supports formative assessment, as noted by Dalby and Swan (2019). However, as shown in Table 1, the formative assessment process remains largely teacher initiated. This suggests a need to better balance teacher-led and student-driven contributions to formative assessment, highlighting the critical role of teachers in shaping formative assessment processes through their orchestration strategies, underscoring that the true value of digital technologies lies not only in their technical affordances but also in how they are integrated by teachers to enhance student engagement and support formative assessment (Cusi et al., 2017). However, how these orchestration strategies unfold in real-time classroom settings remains underexplored. Future research should investigate strategic orchestration of students' instrumental genesis by teachers, the collaborative design of digital technology between teachers and students, and the development of adaptive technologies for personalised feedback in automatic formative assessment (Børte et al., 2023; Panero & Aldon, 2016; Weigand et al., 2024).

The use of award-winning lessons as study samples introduces certain limitations of this study. Firstly, these lessons, designed to showcase best practices, may not represent typical classroom settings, which limits the generalisability of our findings to everyday teaching. Secondly, teachers and students might perform differently under competition conditions, potentially affecting the authenticity of interactions and technology use. Finally, this study found that the *Adapt* stage of formative assessment occurred less often, highlighting the need to explore its underpinning causes to better support the complete formative assessment process. Several practical factors may contribute to this pattern. Teachers often face tight schedules and feel pressure to stay aligned with predefined lesson plans, especially in high-stakes or demonstration contexts, making it difficult to make real-time instructional adjustments. Additionally, although formative assessment is generally recognised as important in mathematics education, *Adapt* is sometimes viewed more as a post-lesson reflection than as a process occurring during instruction. Furthermore, many teachers may lack access to professional development that supports teachers in using digital tools to inform instructional decisions, rather than solely for presenting content or collecting responses. Future research could first examine how the *Adapt* phase of formative assessment is enacted in regular, naturalistic, and more diverse classroom settings. This would help determine whether the patterns identified in this study extend beyond the current context and inform further inquiry into the factors that shape adaptation practices within formative assessment.

Have you thought about short-cuts? – A recommendation for the design of assessment tasks

Lukas Donner[1] and Evita Lerchenberger[2]

[1]University of Duisburg-Essen, Germany; lukas.donner@uni-due.de

[2]University of Graz, Austria

The multiple-choice test format is used for formative and summative assessment as well as for mathematical competitions. A main focus of task design concerns the formulation of the wrong answer options, i.e. distractors. Findings from dual-process theory and about misleading problem-solving processes might influence the construction of distractors, as otherwise superficial strategies may hinder problem-solving approaches intended by the task designer(s). Within this paper, we bring together research results of our analysis of tasks of the international competition Mathematical Kangaroo *and the analysis of students' approaches on a particular task of the* Austrian Standardised Competence-Oriented Written School-Leaving Examination*. Based on that, a recommendation for the design of assessment tasks seems reasonable.*

Keywords: task design, multiple-choice, dual-process theory, competition, exit exams.

Introduction

The multiple-choice test format is used as part of the diagnosis of conceptions of students in several age levels on various mathematical subjects (e.g. Carlson et al., 2010; Akveld, 2023; Klingbeil et al., 2023) or even to analyze the mathematical content knowledge of ongoing teachers (e.g. Ball et al., 2008). Several tasks of national tests like the Dutch educational test (van Stiphout & Groenheiden, 2020) and school leaving examinations in countries like Norway (Smestad & Fossum, 2020) or Austria are formulated in multiple-choice format. This short list of examples is certainly not exhaustive. However, it already highlights the fact that the multiple-choice format is used for the purpose of formative as well as summative assessment for learners of several different stages of mathematical education and expertise.

Apart from mathematical assessment, several mathematical competitions consist of multiple-choice tasks. A main representative for this type of competition for students of all grades is the annual internationally conducted *Mathematical Kangaroo* in which more than 6 million students are taking part (AKSF, n.d.). The competition is held in six age levels with two grades being combined into one age level. The competition consists of several tasks for each age level, giving approximately 2,5-3 minutes on average per task. For choosing the right answer option, 3, 4 or 5 points are given for easy, medium or hard problems respectively. In contrast to most multiple-choice test in summative assessment, incorrect answers lead to a deduction of ¼ of achievable points of the specific task, so that the mathematical expectation is 0 for pure guessing (and in particular it is not positive). Therefore, it might be a good strategy not to choose an answer for some of the tasks within one competition. A competition's task for students of grades 9-10 is depicted in Table 1.

Tasks in multiple-choice format always consist of a so-called item stem, and answer options in which, in addition to the correct answer option, incorrect answer alternatives, so-called distractors, are also

given. The item stem generally consists of text and a question and sometimes (quite often) additionally an accompanying graphic.

Table 1: Task of the Mathematical Kangaroo (grades 9-10, hard task)

Some integers are written on a board, amongst them the number 2018. The sum of all these integers is 2018. The product of these integers is also 2018. Which of the following could be the number of integers written on the board?
(A) 2016 (B) 2017 (C) 2018 (D) 2019 (E) 2020

Designing high-quality multiple-choice tasks is challenging (Gierl et al., 2017). Within this paper, based on the dual-process theory, we focus on a particular property of some multiple-choice tasks, regarding both item stem and answer options, which might favour superficial solving-strategies. This property is extracted by task analysis of the Mathematical Kangaroo which is conducted by both authors. In order to justify our assumption that these findings of the analysis of competition tasks can be transferred to tasks designed for the purpose of assessment, our research aim is to investigate a possible link between this task characteristic and students' approaches on summative assessment tasks. To pursue our aim, we select a particular task from the Austrian school leaving examination which has this property and analyzed students' written descriptions on how they approached this task. Through this analysis, we highlight a little-discussed aspect of the creation of tasks and, in particular, of answer options for multiple-choice tasks.

Theoretical background

Dual-process theory

Within the dual-process theory, which is a discipline of cognitive psychology, two types of thought processes are differed: intuitive and analytical/reflective. A process is classified as Type 1 (intuitive) if it does not require any working memory resources, otherwise it is classified as a Type 2 process (reflective) (Evans and Stanovich, 2013). In other words, Type 2 processes require a certain amount of effort, whereas an intuitive solution may come to mind before a task has been fully analyzed. The latter is usually accompanied with great conviction of its correctness and with a feeling that it does not need to be varified (Van Dooren and Inglis, 2015). The phenomenon, that Type 1 processes might fail can be demonstrated by a task from the Cognitive Reflection Test (Frederick, 2005): 'A bat and a ball cost $1.10. The bat costs $1.00 more than the ball. How much does the ball cost?'. The intuitive answer is that the ball would cost 10 cents. However, this intuition is wrong. The salient feature of the task ('one dollar more') leads to a certain reaction ('the bat costs 1 dollar'), but precisely this reaction must be inhibited (in the sense of controlled) (De Neys et al., 2013). More generally spoken, a main "theoretical approach is one in which rapid autonomous processes (Type 1) are assumed to yield default responses unless intervened on by distinctive higher order reasoning processes (Type 2)" (Evans and Stanovich, 2013, p.223). However, it must be pointed out that the view of a fundamental superiority of Type 2 processes over error-prone Type 1 processes is wrong (ibid).

Within mathematical education research, among others, Vinner contributed to the explanation of misleading problem-solving processes by characterizing *pseudo-analytical thought processes*

(Vinner, 1997): Students identify aspects of a task that appear superficially relevant and then spontaneously execute typical solution approaches for these features. Vinner argues that one reason for applying these strategies is the fact that they sometimes lead to correct results. One example is the incorrect application of the so-called 'keyword strategy', which is an essential element of the construct 'superficiality' developed by Schlager (2020). "It seems that children are strongly inclined to start conducting a calculation that is explicitly shown in the problem (i.e. the subtraction) even when inhibiting that tendency and first considering which strategy to apply would be desirable" (Torbeyns et al., 2009, p.714). The existence of this strategy also serves as an explanation, why solving the bat and ball problem requires an analytical thought process.

Design of multiple-choice tasks

The basic principles according to which good multiple-choice tasks are created are a clear formulation of the item stem, as well as formulating meaningful distractors. What is meant by meaningful distractors differs depending on the purpose of the respective instrument. In order to having high diagnostic value, the distractors may represent typical errors or possible misconceptions of students within the specific topic at hand. Traditionally, experts create distractors by imitating possible approaches of students towards the tasks (Gierl et al., 2017). This strategy of developing distractors is based on the (in many cases justified) assumption that the selection of a distractor can additionally provide information about students' approaches, which is essential for accurate diagnosis of students' conceptions and errors (e.g. Klingbeil et al., 2023).

It is notable that by focusing exclusively on creating meaningful distractors, it is implicitly assumed that students approach the tasks analytically, with sufficient motivation and with clear focus on the task as a whole. However, alternative approaches, which could be explained by psychological phenomena (apart from pure guessing) which may lead to students' conducting undesired strategies are given remarkably little attention in current didactic discourse. For instance, neither content-related reflections nor evaluation of the plausibility of distractors can reason the following finding: By analyzing tasks of common intelligence matrix tests, Mittring and Rost (2008) demonstrate both empirically and by theoretical analysis, that the correct answer option of a considerable number of tasks within these instruments can be determined by simply comparing it with the given distractors and *without taking the item stem into account*.

Results

Analysis of particular tasks of the Mathematical Kangaroo

In Donner and Lerchenberger (2024), we analyzed the answer frequencies of 690 tasks of several years of the Austrian version of the Mathematical Kangaroo for all age levels from grade 3 onwards. In a first step, we extracted tasks in which a large proportion of participants chose one particularly frequently chosen distractor (at least 40% of all answers given), while at the same time this distractor was chosen at last twice as often as the right answer option. Surprisingly, 64 of all 690 tasks fulfill these requirements of containing one particularly frequently chosen distractor in combination with a quite unpopular right answer option. In a second step, we evaluated these tasks using qualitative content analysis (Kuckartz, 2018). It was conducted based on theoretical background of dual-process

theory and mathematical intuition, and by imitating possible approaches which may lead in a most directly manner to the specific particularly chosen distractor. We were able to determine 5 different categories for these distractors (for more details, see Donner and Lerchenberger, 2024). Two of the categories could be described as Type 1 processes, one of which is the category "AD" (*answer direct*). Within this paper, we will focus solely on this category. AD contains tasks, in which the particularly frequently distractor can be taken directly from the item stem. It appears 13 times in the analyzed subset of tasks and it occurs in almost all age levels of the competition. The task depicted in Table 1 is a representative of this category, as distractor (C) was chosen by 56,4% of all participants who gave an answer, whereas the right answer (B) just accounted for 12,7% of all answers given. (The remaining distractors (A), (D) and (E) were chosen by 11,2%, 12,3% and 7,4% of all answers given, respectively). A possible (and obvious) reason why distractor (C) 2018 was that attractive is that the number 2018 appears several times in the item stem.

A further, related finding emerged when analyzing tasks with particularly high solution frequencies. Lerchenberger and Donner (2024) found that several tasks that were solved exceptionally well by the Austrian participants share characteristics with tasks of the category *answer direct,* in a sense that the right answer option can already be found within the item stem. We assume that the reasoning of choosing/guessing the answer option is based on a superficial, intuitive Type 1 process in these cases, too. This assumption can be underlined by the fact that significantly more students decided to choose an answer option to tasks where an answer option is part of the item stem than tasks which were estimated to be of comparable difficulty but at which none of the distractors has this property.

Empirical insights in problem-solving processes of a task of the *Austrian Standardised Competence-Oriented Written School-Leaving Examination*

In order to justify our assumption that the findings from the tasks of the Kangaroo competition can be transferred to tasks designed for assessment, we were interested in investigating problem-solving processes of tasks from the standardized school leaving examination (grade 12) in Austria. For that reason, a task was extracted with the potential option for students to apply the strategy *answer direct*. Table 2 serves as an example of a task with this property: The correct solution is $k = 6$. Exactly the same number is depicted (in a completely different role) in the last line of the task's item stem.

Table 2: Task "Data set" from the Austrian Standardised Competence-Oriented Written School-Leaving Examination (Bundesministerium für Bildung, Wissenschaft und Forschung, 2019)

Below, you will see an ordered data set. One of the values is k where $k \in \mathbb{R}$.

1	2	3	5	k	8	8	8	9	10

Determine the value of k such that the mean of the whole data set has the value 6.

k = _____

It can be assumed that at least two variants of solving this task are intended. An algebraic approach corresponds to solving the following equation for k: $\frac{1+2+3+5+k+8+8+8+9+10}{10} = 6$. As an alternative,

one can argue that as the mean of the 9 values given in the data set is 6, the unknown value k must coincide with this mean in order not to change the mean of the whole data set.

As part of an unpublished pilot study of Lerchenberger (2023), the second author of this article collected data of 20 eleventh-grade students' written solutions as well as the written descriptions of their approaches to the task depicted in Table 2. In joint analysis of these documents, the two authors of this article found that among the eleven correct answers, both variants described above occurred. However, it also turned out that some students very quickly came up with the correct result completely differently, by just inserting the number $k = 6$ *because it was already there*. A typical student's answer to describing the approach to the task in a superficial manner is shown in Figure 1.

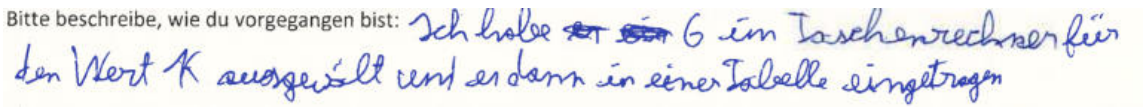

Figure 1: Student's approach to task depicted in Table 2. [*Please describe how you solved the problem: I selected 6 in the calculator for the value k and then entered it in a table*]

The student's argument depicted in Figure 1 describes the verification of the chosen number via calculator, but it does not give any hint why this number was chosen in the first place. It is important to emphasize that there is no plausible reason why exactly this number should be a good guess, as there are uncountably many real numbers in the interval [5,8]. A narrow reason, which corresponds to our findings described above, is that the number 6 was used because it was given in the item stem (*answer direct* in a sense that the solution can already be found within the task). This interpretation indicates the presence of this superficial strategy working on this task. The task designer(s) would have had a possibility to avoid enabling students to argue via this surely not intended pseudo-analytical thought process of obtaining the value for k by specifying a different arithmetic mean in the item stem. Further research is needed to answer the question, whether the solution frequency of the particular task is influenced by changing the mean and simultaneously reducing the amount of successful strategies. But in the form as it was used (see Table 2), it is highly doubtful whether students have to demonstrate the intended mathematical competence the task supposed to check.

Discussion

There are numerous recommendations for the process of creating sound multiple-choice tasks as well as suggestions for design criteria when creating multiple-choice tasks in general (e.g. Gierl et al., 2017) as well as for the purpose of formative or summative assessment in mathematics education. Thereby, findings of research on intuition and cognitive psychology hardly seem to be in focus of (didactical) reflection. The dual-process theory recommends that under certain conditions, intuitive solutions may come to mind before a task has been fully analyzed (Evans and Stanovich, 2013). Furthermore, the student may stay in a Type 1 process unless intervened on by distinctive higher order reasoning processes (Type 2). Pseudo-analytical thought processes are prime examples in which superficial task characteristics significantly influence intuitive approaches.

Following on from this theoretical basis and expanding the spectrum of possible misleading strategies in multiple-choice tasks, a task analysis of particularly frequently selected distractors in the Kangaroo of Mathematics leads to the assumption that strategies based on superficial task characteristics could possibly appear attractive for many students in numerous multiple-choice tasks (Donner and Lerchenberger, 2024; Lerchenberger and Donner, 2024). Besides others, a main superficial strategy may be to choose a distractor as answer, which is already part of the item stem (*answer direct*). This strategy is strongly related to the 'keyword strategy'. Our analysis of students' approaches on the task of the Austrian school exit examination points out that the phenomenon is not restricted to multiple-choice tasks. The latter result is consistent with empirical findings on students' use of superficial strategies when solving word problems (e.g., Schlager, 2020).

The findings of our study have to be seen in light of some limitations. The Mathematical Kangaroo is not created with the focus on mathematical assessment. Moreover, the specificity of the competition, that many tasks should be answered – but not exactly justified – in a very short time with the aim of achieving a high score, is different from a typical situation of assessment. However, we think that there are two reasons why the findings are of wider relevance for the purpose of mathematical assessment. First and foremost, the strategy *answer direct* can be applied independently of the content and intention of the (mathematical) multiple-choice task, it just depends on the structure of item stem and distractors. Second, the empirical results of problem-solving approaches of students dealing with the task of the Austrian school-leaving examination indicate, that the same kind of thoughts are relevant for task-designers of examination tasks, which only require students to give short answers (e.g. a number): Some students' strategies consist of pseudo-analytical thought processes like direct guessing based on information given in the item stem. As a next step, we want to qualitatively analyze students' problem-solving processes of competition tasks as well as assessment tasks by methods of thinking aloud as well as by eye-tracking method, to get an even more direct insight to the problem-solving processes than by written description of their approaches.

Summing up, it could be worthwhile to pay more attention on such phenomena of superficial strategies in task-design, as task characteristics which foster Type 1 processes, may hinder analytical approaches and therefore influence the diagnostic value of certain tasks. We recommend that if a distractor is an element (e.g. number) that is already mentioned as part of the item stem, it should be based on a conscious decision of the designer(s) and not happen out of carelessness. Moreover, we recommend that if superficial strategies like *answer direct* lead to the right solution of a (multiple-choice) task, the beneficial use of these kind of strategies should be omitted whenever students shall demonstrate higher-level competence than pseudo-analytical thought processes by solving the particular task. An additional question in order to designing sound distractors, that may expand the list which most likely already contains questions like 'What are common errors for solving this problem?' or 'What are the common misconceptions about this mathematical object?' is the following: 'Have I thought about short-cuts?'.

How are different competences represented in standard solutions? An empirical study on statewide exit exams in mathematics in Germany at the end of upper secondary education

Christina Drüke-Noe[1] and Sebastian Bauer[2]

[1]Pädagogische Hochschule Weingarten, University of Education, Weingarten, Germany, druekenoe@ph-weingarten.de

[2]Karlsruher Institut für Technologie, Karlsruhe, Germany

Statewide exit exams in Germany are based on the national educational standards and can convey normative expectations with respect to teaching and to testing. This paper examines one part of these exams set at the end of upper secondary education in one German state (Hesse) in the years 2019 until 2023. Tasks set in this part are to be worked upon without any aids and can thus be considered to test basic competences. Analyses of the tasks, their standard solutions and the allocated points reveal that these tasks require all six competences as set in the educational standards and indicate that the numbers of points allocated reflect the approach to test basic competences.

Keywords: Statewide exit exams, mathematics, solutions, basic competences, backwash effect.

Introduction

"Assessment can play a significant role in improving the quality and relevance of the skills that are acquired at school" (Eurydice, 2012, p. 10). In various European countries and in addition to other forms of written assessment like class tests, students take central written exams at the end of a particular educational stage. In secondary education such exams are frequently taken at the end of upper secondary education (ISCED level 3) and in some countries additionally at the end of lower secondary education (ISCED level 2), which marks the end of compulsory schooling (see Drüke-Noe & Kühn, 2017, Kühn & Drüke-Noe, 2013). Usually at least Mathematics and the language of instruction are among the subjects tested. These exit exams are mostly compulsory for all students (Eurydice, 2009), which hints at the relevance of these exams. They are to test 'key competences' "which represent a combination of knowledge, skills and attitudes that are considered necessary" (Eurydice 2012, p. 7). 'Mathematical competence and basic competences in science and technology' is one of the eight key competences defined. These competences are either promoted by a national strategy or by applying large-scales initiatives (Eurydice, 2012) and are thus relevant in different forms of assessment. Across Europe, standardized tests are also supposed to focus on basic skills (Eurydice, 2012, p. 10).

In Germany, several conceptualizations describe basic skills at the end of compulsory schooling from a normative and/ or an empirical perspective (cf. overview in Drüke-Noe & Siller, 2019), but there is no general conceptualization that applies to the end of upper secondary education. For example Weber and colleagues (2023) define basic competences needed to begin university studies which require mathematics, but this conceptualization sets no framework for the design of exit exams.

Despite this lack of a theoretical framework for basic skills at the end of upper secondary education, this study examines for one German state (Hesse) a specific part of an exit exam at ISCED level 3

that can be assumed to explicitly address these skills (competences). This is done for two main reasons: one is the European-wide requirement to tackle low achievement in basic skills (mother tongue, mathematics and science) (Eurydice, 2012). A second one is that already in year 9 there is regular empirical evidence from standardized assessment that on average one quarter of all German students miss minimal educational standards (Kölm & Mahler, 2019; Pant et al., 2013) and thus lack basic skills; very similar findings come up in regular international studies like PISA. Though there is no comparable empirical evidence for upper secondary education, it is at least of interest to see which normative standards exit exams can set that are supposed to test basic competences. The German state of Hesse therefore serves as an example in this study.

Statewide exit exams in Germany at the end of upper secondary education (ISCED level 3)

In all 16 German states, written and oral examinations are obligatory parts of the general university entrance qualification (Allgemeine Hochschulreife, Abitur), which students acquire at the end of upper secondary education. As the educational system is federally organized by the 16 German states, specific exam regulations vary in all of them. As a consequence, since 2007 different national initiatives have been gradually implemented under the guidance of the Institute for Quality Development in Education (IQB) that aim at centralizing (parts of) the Abitur exam and its structure. Respective initiatives are only sketched here, though. One is the introduction of national educational standards in 2012 (see below). Another one is the development of a national pool of Abitur tasks (including their solutions and further documents) which has been going on since 2013/14.

The tasks in this pool are developed on the basis of the educational standards and thus cover five content areas (i.e. all three domains analysis, analytic geometry/ linear algebra and stochastics), six competences (K1: argumentation (arg), K2: problem solving (pro), K3: modelling (mod), K4: use of representations (use), K5: working technically (wor), K6: communication (com)) and three different levels of cognitive demand (low, medium, high). For each of the three domains the pool provides two different kinds of tasks: One is for an exam part without aids (part A). These are unrelated tasks, each of a so-called small size. The second kind for the exam part with aids (part B). These tasks are more extensive and divided into related sub-tasks. Since 2014 and to a yearly growing extent, an increasing number of states has been adopting tasks from this national pool and presented them identically or slightly modified in their final exams. The proportions of these tasks in a state's exam vary, however.

Statewide exit exams in one German state (Hesse)

The state of Hesse serves as an example in this study as in this state like in almost all other ones the exams are centrally set and thus based on the state curricula (or the core curricula) as well as on the educational standards (KMK, 2012) and specific regulations for the state Abitur. In Hesse, students take exit exams in five subjects, i.e. in their two advanced courses and additionally in three regular ones. The combination of subjects must meet certain requirements but Mathematics and German are always tested. The exams in both advanced courses and in one regular course are written ones. Only the other two subjects are not tested centrally. Both the written and the oral exams relate to the content of the four semesters in years 12 and 13. The exams must cover all three levels of cognitive demand and the focus is to be on the medium one. The total duration of an exam depends on the type of course (regular course: 255 min, advanced course: 300 min). The grade achieved is included in the overall

grade for the general university entrance qualification using a fixed calculation key. In Hesse, the written exit exam in mathematics consists of two parts, which are both compulsory and must be completed by all students: in regular courses, part 1 (45 min) tests all three domains and is to be solved without a calculator or a collection of formulas; this is why it is called aid-free (hilfsmittelfreier Teil). Since these tasks must be solved without any aids, they can provide information about the students' expected basic competences. Part 2 lasts further 210 min and only in this part students are allowed to choose from one of two calculus tasks and additionally either a task on linear algebra/ analytical geometry or one on stochastics (for details see Hessian Ministry of Culture, 2019). Parts 1 and 2 of the Hessian exam correspond with parts A and B of the national pool. Parts of the tasks in this exam are adopted from the pool, the rest is developed by exam designers in Hesse. Information on the origin of a single task is not publicly accessible. Officially, the Hessian Ministry of Culture finally holds responsible for the assembly of tasks in an exam, their standard solutions and the classifications according to the educational standards.

Marking exit exams – standard solutions

In this contribution we use the term standard solution to name the document which teachers use to mark the students' work and to assign points. The names for this document vary, though. Terms like example solution or model solution or range of expectations are known, too. The different names hint at the level of detail and rigidness of the specific document. A standard solution is to implement an assessment that is as objective as possible, and it also explicates the exam designers' normative expectations as regards a correct solution ideally expected by the students. All teachers are provided with the standard solution and are obliged to use it when marking the students' exams.

According to one of the accompanying documents set up by the IQB, a standard solution shows a possible solution for each subtask, only contains aspects that align with the educational standards, and highlights that correct solutions not explicitly named are equally to be accepted (IQB, 2020, p. 3). In Hesse, for each subtask this document contains the expected correct solution and the number of points to be awarded. Additionally, it contains two tables: one informs about the classification of each subtask as regards the competences needed to solve it. The other table shows per task (not per subtask) how the number of points is distributed per level of cognitive demand. Although teachers have to use this document, they still have some flexibility as in accordance with the regulations in IQB (2020) the standard solution in Hesse contains the following remark (Hesse, Abiturprüfung, regular course, 2019, standard solution, p. 1; translation by authors):

> The given solution specifically contains all essential aspects that have to be taken into account when working on the individual tasks. Based on experience, it shows those solutions that the examinees will usually apply. Solutions that deviate from the given ones but can be viewed as equivalent are also to be accepted.

Two teachers mark the students' work independently. The second teacher can either agree with the first teacher's assessment or submit an own one. If both results differ, a new and consistent assessment must be created together.

Due to the backwash effect of exit exams and also due to the fact that the application of a standard solution is mandatory, this document can set normative expectations as regards the marking of class

tests or as regards the distribution of points among tasks and their competences. Though there is some research on characteristics of tasks set in exit exams (see below), at least to our knowledge there is no research on standard solutions in such exams.

Research on statewide exit exams

International research on statewide exit exams addresses various perspectives like governance and accountability or national differences between these exams (Drüke-Noe & Kühn, 2017; Klein & van Ackeren, 2011) or the impact of such exams on either the selection of tasks for teaching (e.g. Cheng & Curtis, 2012; Neil, 2003) or the design of class tests (Drüke-Noe, 2023). In these contexts a direct or indirect backwash effect of exams on teaching and learning is frequently discussed (e.g. Biggs & Tang, 2011; Boud & Falchikov, 2006; Prodromou, 1995). Especially summative forms of assessment like exit exams can have this effect and thus exert a considerable influence on both teachers and students. These exams set standards as to what is to be achieved or considered important as for example research on design principles of class tests clearly indicates (Drüke-Noe, 2024).

As regards task characteristics in exit exams in mathematics at the end of lower secondary education, Kühn and Drüke-Noe (2013) identify a low level of cognitive demand of the tasks set at this level in most German states. Applying routines and using facts (working technically) is a dominant competence, whereas more complex ones, such as problem solving or argumentation, are far less needed to solve these tasks. For eight European countries, both authors come to very similar findings (Drüke-Noe & Kühn, 2017), i.e. only a limited spectrum of competences is tested and the tasks are mainly of a low cognitive demand. Frenken and colleagues (2024) analyse Abitur tasks (ISCED level 3) set in 2020 and 2021. They consider the cognitive potential with respect to mathematical competences and analyse the basic ideas involved as well as the digital tools used. The authors identify a generally low level of cognitive potential as regards argumentation, problem solving, modelling and communication. They also see hardly any differences between the tasks with or without different digital tools (computer algebra (CAS) and scientific calculator) and conclude that the potentials of CAS are apparently hardly used.

Methods

The following research question is addressed in this study: How do the points relate to competences (and are some competences somehow more relevant) and does the prevalence of individual competences change in the course of time?

Data material and data analysis

The sample includes all tasks set in part 1 of the Hessian exit exams (ISCED level 3) in regular courses (years 2019 until 2023) and the standard solutions, which indicate 20 points each year.

All analyses are based on subtasks. This is done for three reasons: one is that in most cases the solution informs on points per subtask and only rarely details this any further. A second one is that information on required competences is only globally given per subtask. A third one is that in line with regulations for this part these tasks are all of a small size only, which is why no further differentiation is made within a subtask.

Based on the standard solution only, the global information on required competences and the number of points assigned are combined to model their relation. Only in very few subtasks, the solution details further how to distribute the points within a subtask, which is then considered, too. To model the relation of competences to points, both researchers decide from a normative didactic perspective how to distribute the points among the competences of that subtask. This is done consensually by both authors taking into account which part of a subtask's processing and thus which competence(s) are in the focus of the cognitive activities. The example in Figure 1 is to illustrate this approach. The standard solution names three competences (argumentation, problem solving, working technically) and allocates 5 points. Since the main cognitive activities are problem solving and working technically, 2 points are assigned to each and only 1 point to argumentation.

Two points A(-6|8|1) and B(3|8|-5) and the equation of a line g with $g: \vec{x} = (-1 \quad 2 \quad 1) + r(2 \quad -3 \quad 1), r \in \mathbb{R}$ *are given. Confirm that* $\overline{AB}$ *and g intersect.*

Figure 1: Task 4, year 2019; translation by authors (layout of column vectors modified)

The numbers of competences and of points can differ either way. The number of points per competence agreed upon ranges from 0.5 (minimum) to 3 (maximum); units are no smaller than 0.5 points. This approach allows for a statistical evaluation and descriptive analysis of how points are distributed among the individual competences in the classifications underlying the (sub-)tasks.

Results

Each year four tasks are set that cover all domains. These tasks comprise 7 to 11 subtasks per year (2019: 7, 2020: 7, 2021: 8, 2022: 11, 2023: 8). Overall, the solutions indicate a range of one to three competences per subtask and a range of 1 to 5 points is allocated; the smallest unit is 1 point.

Table 1: Minimum and maximum number of points per competence

Competence	K1 (arg)	K2 (pro)	K3 (mod)	K4 (use)	K5 (wor)	K6 (com)
Minimum number of points; frequency	0.5; 6	0.5; 10	0.5; 3	0.5; 9	0.5; 8	0.5; 4
Maximum number of points; frequency	1.5; 2	2.0; 3	1.5; 3	3.0; 1	3.0; 1	1.0; 2

Based on our model, the data in Table 1 informs on the relation of points to competences. It shows the minimum and the maximum of points assigned per competence and additionally the frequency of these combinations. The minimum is 0.5 points for each of the six competences. This relation occurs least frequently for modelling and for communication, and it occurs most frequently for problem solving, use of representations and working technically. In all five years, 0.5 points per competence are allotted 40 times which amounts to 20 points out of a total of 100 points (total sum in five years). The highest numbers of points per competence differ: they range from 1 point (communication), which occurs twice, to 3 points (use of representations, working technically), which both occur once.

Figure 2 (left side) shows for each year the cumulative occurrence of the six competences. To do so, the points assigned to individual competences per subtask are added up per year. In the course of these years, problem solving and working technically are most strongly represented with 26.5 points each (out of the 5-year-total of 100 points). Together, both therefore account for over half of the points. The points vary from a minimum of 4.5 points (2020) to a maximum of 7 points (2019) for

problem solving and from a minimum of 3 points (2023) to 8 points (2019) for working technically. The two competences argumentation and communication are the least important ones with a cumulative score of 10 points and 4 points respectively. The prevalence of these two competences is relatively uniform, with argumentation ranging from 1 point to 2.5 points per year and communication from 0.5 points to 1 point. Modelling also accounts for a smaller share only with a cumulative 11 points, but the span ranges more widely from 0 points in 2019 to 4.5 points (i.e. just below a quarter of the total annual points) in 2022. The use of representations accounts for a total of 22 out of 100 points. Its span is the greatest and ranges from 2 points to 8 points in 2023.

In the course of time, the prevalence of argumentation, problem solving and communication is fairly constant, whereas that of working technically seems to be slightly decreasing. No clear time trends can be identified for the use of representations and modelling. The sum of points for both the use of representations and working technically is quite homogeneous over the years. It only varies between 8.5 and 11 points and either the one or the other competence contributes more to this sum.

Figure 2 (right side) illustrates the importance of competences per year measured by the number of points assigned to each of the six. Grouping the data accordingly (low: 0.5 or 1 points per competence, medium: 1.5 or 2 points, high: 2.5 or 3 points) and adding up the respective numbers of points per competence per year serves to qualify the relation of three levels of importance with reference to a yearly total of 20 points. Over the years, the proportion of competences of low importance ranges from 8.5 points (2023) to 16.5 points (2022) and reveals a fairly wide span. In 2022, for example, to a relatively great extent the subtasks are muchly characterized by a low importance of single competences, while in 2023 a total of 11.5 points is assigned to competences of medium and high importance (not be confused with levels of cognitive demand which are not considered in this study).

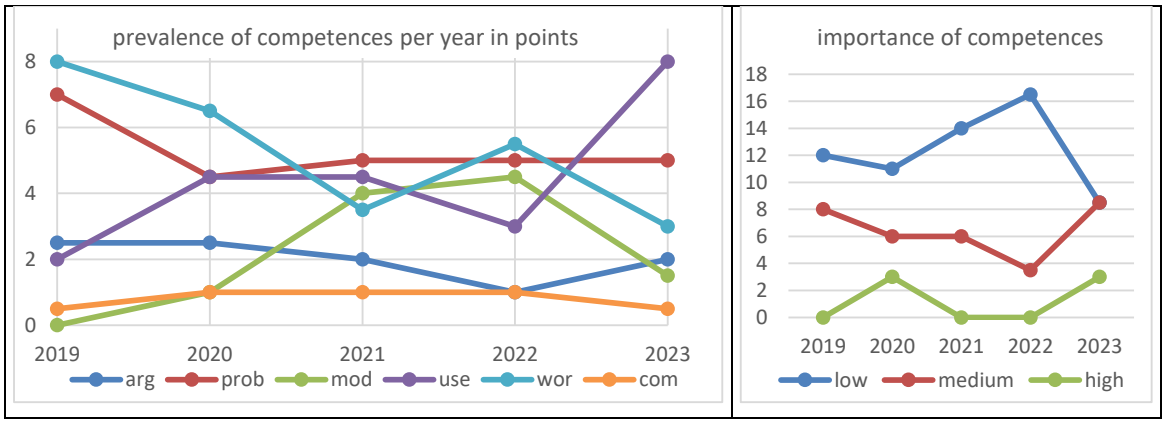

Figure 2: Prevalence (left) and importance (right) of competences per year

Conclusion, limitations and implications

The results show that part 1 of this exit exam tests a broad spectrum of all six competences and thus indicate a broad spectrum of tasks. In accordance with national regulations these tasks are short (small) as in a considerable proportion of subtasks a low number of points is assigned to each competence. This result supports the assumption that this exam part indeed addresses basic competences. The relative importance of the six competences varies: problem solving and working technically are rather important as the highest numbers of points are assigned to these two, while

argumentation and communication are of fairly low importance in all years. The importance of modelling varies but is generally low, which is in accordance with expectations as regards basic competences. The importance of the use of representations and working technically apparently interrelates and this surprising result requires further investigation.

These empirical results are subject to several limitations, though: firstly, all analyses rely on the exam designers' classification of competences given in the standard solutions. Secondly, information on the exam designers' qualifications is not accessible and we do not know how and why they assign points (Do they consider competences at all?, Why do they only assign full points?, Which other considerations influence the assignment of points (e.g. verbs like "Confirm"?)). Thirdly, we assume that classifications are valid over the five years. Since we assume a backwash effect from standard solutions and teachers must follow them, too, we refrained from newly classifying all tasks ourselves.

In further studies, it would be interesting to include information on the exam designers' intentions, to extend our approach to part 2 of the exam and to include the levels of cognitive demand to allow more detailed analyses. With respect to regular teachers and to understand the influence of standard solutions and their backwash effect better it would be interesting to examine how teachers really use them and if they consider the six competences at all when assessing students' work.

Introduction of a practical element in oral examination of mathematics: Teachers learn first

Frode Olav Haara[1]

[1]Western Norway University of Applied Sciences, Faculty of Education, Arts and Sports, Sogndal, Norway; frode.olav.haara@hvl.no

Revision of a national curriculum for compulsory school may bring along requests for revising structures affected by the revision, like for instance summative assessment practice for pupils at the end of compulsory school. This paper reports on use of a participation based model for teachers' professional development as foundation for a cooperative development project about moving from an oral exam to an oral-practical exam for pupils in mathematics at the end of 10th grade in the Norwegian school system. About 40 lower secondary school mathematics teachers from a Norwegian municipality were key representatives in the project. A self-study approach was applied, because of the opportunities it offers to describe and experience teacher development from the inside. The results describe how priorities made in compliance with the participation based model produced consequences for both teachers and pupils preparing for the up-coming oral-practical exam.

Keywords: Teacher learning, assessment, mathematics.

Introduction

As part of a revision of the Norwegian curriculum for compulsory school (1st grade – 13th grade) in 2020 it was decided by the *Norwegian Ministry of Education and Research* (KD) that the oral exam in mathematics (OM) that pupils might be drawn to conduct at the end of 10th grade (15-16 years old pupils), was to be extended with a practical element (UDIR, 2020a). Thereby the oral exam in mathematics was replaced by an oral-practical exam in mathematics (OPM). This replacing required an extension of the OM from consisting of a presentation of mathematics by the pupil related to a context presented 48 hours before the exam, and subject specific questions from the examinators, to also include *a practical element*. This change brought along distinctive and significant attention among both Norwegian educational researchers and mathematics teachers, made public both through publications (e.g. Haara & Taraldsen, 2020) and social medias. Documents regarding this change were published by the *Norwegian Directorate for Education and Training* (UDIR) (UDIR, 2020b; 2022), but this only to some extent made preconditions and consequences of a change from OM to OPM clear for school leaders in the municipalities and for the teachers supposed to organize and conduct this new, summative evaluation for tensed and exited pupils.

In October 2022 a municipality of about 25000 residents, with seven grade 10-schools and about 40 lower secondary school teachers of mathematics, made contact with the teacher education institution where the author of this paper works. The rationale for the municipality's request was the experienced need for a joint development of understanding of UDIR's guidelines for OPM within the municipality, and facilitation of the mathematics teachers' adjusting of priorities in directing and conducting an OPM instead of an OM. The municipality's project group, consisting of two teachers, two headmasters and the assistant head of education in the municipality, myself, and a colleague of mine from the teacher education institution, set two goals for what we identified as a cooperative

development project: To develop guidelines for the implementation of OPM, and to gain both a common understanding and confidence related to OPM, when it comes to preparation, implementation and assessment. Based on these goals, we developed and implemented a plan that we believed would meet such a request, making this municipality and of course the participating teachers in this municipality ready and set for conduction of the first, national round of OPM in June 2023.

We do know quite a lot about what makes teachers' professional learning both develop and persist (Guskey, 2002; Pedder & Darleen Opfer, 2013; Timperley et al., 2007; Wenger, 1998). This knowledge became core when making priorities for development and implementation of the cooperative development project, priorities that placed the teachers in a participative position through expectations of involvement in defining content and developing arenas for experience and learning in the cooperation. Inspiration for this was found in the participation-based intervention model developed by Haara et al. (2020), making the participating teachers' professional development their goal, and not someone else's objective. We do, however, know less about consequences of priorities made for a cooperative teacher learning approach when one aims to reach consensus about a vaguely defined concept (here: OPM). I therefore ask: *What were the priorities for the cooperative teacher learning approach regarding the introduction of OPM in a Norwegian municipality, and what consequences for both teachers and pupils preparing for OPM did the priorities bring along?*

Theoretical foundation

The participation-based intervention model for teachers' professional development developed by Haara et al. (2020) is founded on three conditions well-grounded in research on teachers' professional development (Pedder & Darleen Opfer, 2013; Timperley et al., 2007; Wenger, 1998; Wylie & Lyon, 2015). The model emphasizes involvement of the teachers in designing of the content, external representatives' direct involvement prior to and at joint gatherings, and providing of sufficient time in between joint gatherings to foster participation-based activity and progress at each school. Timperley et al. (2007) established about 20 years ago that teachers' learning outcomes tend to be better when they may influence the way competence development is organized than if frames and content are decided completely by externals. Important factors, according to Timperley et al. (2007), are that teachers must have the opportunity to participate in a community of learning peers, and to experience that they have actual impact on the progress of the developmental process. This aligns with the important features of learning communities, described by Wenger (1998), where one learns from and together with peers. In a study on implementation of formative assessment practice in mathematics Wylie and Lyon (2015) made experiences that operationalize the conclusions made by Timperley et al. (2007). The cooperative approach needs to balance between joint gatherings conducted by external representatives of significance with all the participating teachers attending, and workshops facilitated at each involved school. At these workshops in Wylie and Lyon's (2015) project the teachers had the opportunity to share experiences stemming from their try-outs regarding formative assessment practice, reflect on these experiences, and receive input and advices from their colleagues. A perspective on cooperative learning development that wants to be recognized as participatory-based, therefore needs to start where the participating teachers are, and leave no one behind. In such projects, according to Pedder and Darleen Opfer (2013), it becomes a collective rather than an individual responsibility to develop the practice.

Context and implementation

Each of the seven participating schools appointed a "resource teacher" who attended a Zoom-meeting where the project group presented the cooperative development project. This was followed by watching two short videos at each school that my colleague and I recorded as preparation for the teachers' project participation, where we kind of opened up Pandora's box on what the official guidelines from UDIR (2020a; 2020b; 2022) actually say, and what *practical* in OPM might be. In the videos we pointed out that it would be necessary to revise both organisation, preparation time (for the pupil), and actual conducting of the exam when including a practical element, and then entertained each other with various, plausible interpretations of what a practical element could be recognized as.

At the first joint gathering (December 2022) emphasis was put on content, form and organising of OPM, where my colleague and I orchestrated for the participating teachers' actual experiences both regarding understanding of what a practical element in OPM might be, organising of such an exam, and how a group exam organising might be possible if the pupils are familiar with collective working methods like for instance Liljedahl's (2020) *Building Thinking Classrooms* approach. This was followed by engaged discussions among the teachers and prolonged into cooperative work at each of the seven schools during the winter of 2023 where the mathematics teachers developed suggestions of organising and tasks for OPM. The teachers were encouraged to experiment with content and form, with an open mind towards making both good and bad experiences. All pupils that were eligible for OPM in June 2023 in the municipality took part in this experimental try-out at the school where they belonged. I observed some of these sessions at one school. After the try-outs at a school the teachers and the pupils evaluated and shared their experiences, and the teachers collected impressions related to the keywords *Done*, *Learned*, *Smart*. Based on this each school prepared a stand for sharing with teachers from the other six schools at the next joint gathering, towards the end of February 2023. The sharing of tasks and experiences at the joint gathering provided both bilateral discussions at each stand and multilateral discussions in a plenary session after the stand-based exchange of experiences was finished. Part three of this gathering was devoted to my colleague's and my orchestrating of discussion and reflection about what to emphasize when assessing a pupil who conducts an OPM. An important premiss for the assessing is UDIR's (2020b, pp. 4) explicit aim "for the pupil to have the opportunity to demonstrate competence in as large a part of the subject as possible based on what is possible within the exam format" (translated by me from Norwegian). The keyword in this is competence, and in what way competence might be shown by the pupil. In short the teachers concluded, for the locally developed OPM, first that the tasks mainly had to reflect the competence targets stated in the national curriculum for 10^{th} grade. Second, in order for the pupil to be able demonstrate mathematical competence as extensively as possible, the teachers needed the opportunity to focus on mathematics emphasized in earlier grade levels than 10^{th} grade as well. And third, it had to be based on a broad understanding of the term *practical*.

This joint gathering was followed by another round of try-outs at each school in early April 2023, where the teachers and pupils piloted an actual OPM for all the pupils in 10^{th} grade. Then in June 2023 the municipality was informed by the County Governor's education branch that three of the schools were chosen for conducting of OPM. At the three schools 6, 12 and 18 pupils were drawn for this exam, respectively.

In September 2023 we had the third and final joint gathering. It focused on the experiences with the actual conducting of OPM, both pilots and actual exams, and reflections by the teachers on preparing for such an endeavor as moving from OM to OPM through a cooperative development project.

Method

The fact that the author of this paper was one of the participants involved in the reported study, places the paper within an action research perspective, narrowed down to have a self-study approach (Zeichner, 2007), since I was the sole producer of data. According to Loughran (2004: pp. 154) this is an approach to understand "from the inside out rather than the outside in". In the study reported in this paper, teachers who reflected on their own practice as teachers responsible for OM and future OPM with an aim of improving their own and others' practice, my colleague and I, were involved. Together, we tried to understand the roles both as a pupil and as a teacher from the inside and out, rather than from the outside and in. I prepared for a systematic investigation of practice, developing a personal narrative based on observations and onsite impressions made at the formal learning arenas of the project. This choice of approach served two main purposes. First, the investment in professional development with the participants, and enhanced understanding of how OPM may facilitate for pupils' display of mathematical competence in practice, requires analysis related to possible normative effects provided by the project. Second, the self-study approach was chosen because of the proximity I could accomplish as both a project participant, lecturer and as a researcher. Hence, in order to be able to address the research question in a trustworthy manner and offer mathematics teacher arguments for changing or not changing teacher practice, I made it a priority to be as close as possible to the actual activity, and thereby sacrificed some observational distance on the altar of involvement. This provided an intended and appreciated interaction between practice and research focus, with awareness to influence such a perspective may have on both the actual practice and the theoretical understanding of the practice.

The choice of methodical approach challenged my role as researcher because of the proximity to the production of data, and although my knowledge about the field of research is an important prerequisite for viable interpretations, I have strived to follow Feldman's (2003) criteria for securing validity and reliability in a self-study-based project. I do so far, and will in the forthcoming parts of the paper do this by: providing detailed descriptions of how data were produced and make explicit what counts as data, showing why the self-study approach was chosen with arguments for consequences of this choice together with what would have been consequences of a more distant researcher position, and finally being utterly aware that the self-study approach is a moral issue. Therefore I have been careful in my registration of observations, and relied on both the acknowledgement of the model applied for the cooperative development project and my knowledge about teachers' professional development and assessment in mathematics in my interpretative work.

The results are based on my narrative developed through participation in the project. Hence, this is not a regular, qualitative study primed to provide arguments for the reliability of empirical data. However, the study provides close contact with actual teacher learning experiences, as well as research perspectives on these experiences through the theoretical grounding of conditions for such learning. The teaching experiences related to the study and the reliance on data is difficult to replicate.

Tasks from conducted OPM will be easy enough to collect again and again, but it is impossible to reproduce qualitative observations and on-site impressions from these teachers' first meeting with development from directing and conducting OPM because nothing was filmed or taped. This may seem to be a rather unpredictable way to work in qualitative research, but this is not a paper about teachers' learning seen from the outside. It is a paper about teacher development opportunities experienced from the inside.

The three conditions given by Haara et al.'s (2020) model have produced the framework for providing observations and on-site impressions on which my narrative was developed. I do, however, find my narrative development through interpretation of observations and impressions to be inspired by the constant comparative analysis method (Glaser, 1965). My analysis has therefore consisted of four phases; placing and comparing of observations and impressions in categories, comparing of categories and their qualities, delimiting the interpretation and understanding based on a summary of the categories and their qualities, and description of the interpretation and understanding as a basis for discussing the paper's research question. Operationalized this means that new observations and impressions contributed to ensure that my interpretations were refined through an interaction between deduction and induction. New observations and impressions were seen in conjunction with prevailing interpretations and a growing body of studied literature, and influenced by my constantly revised preconception, provided revisions of the interpretations on which my narrative was first developed and then revised several times. My interpretations are based on four rounds of personal notes on observations and impressions: a first round immediately after the first gathering, with emphasis on organizational-, progress-, and result-based impressions, a second round after the second gathering, with emphasis on sharing of experiences from practical element try-outs at each school, a third round after observing OPM pilots with pupils at a school participating in the project, and a fourth round after the third gathering, when some of the teachers had gained actual experiences with directing and conducting OPM in June 2023.

Results

The first gathering revealed that in fact the vast majority of the teachers were unsure about the content of the term *practical*. The rest of the teachers, and these were mainly the youngest in the group, were silent. Some of the most experienced and profiled teachers tried to argue for the sustainability of the prevailing understanding of practice at OM, in order to seek similarity with OPM, like for instance that it would be better if there was a more drastic change that was made clear, because it was not so easy to look for adjustments in what one already was familiar with, or stating that it was common to bring something concrete like for instance dices, a tape measure and such, to the OM. On the other hand, some teachers identified that *something is rotten in the state of Denmark*, so to speak, and called in utter frustration for what might be reckoned as a possible shift of paradigm (Kuhn, 1996), through acknowledging the development project opportunity as a possibility to try something completely new, when hearing the attempts to adapt a new element to the prevailing understanding of what OM represents. The first gathering did not end in any consensus, but revealed agreement about the fact that change in the curriculum had brought along a necessary adjustment of the assessment system. The practical element was broadly acknowledged, but the discussions prolonged into the hallway after the gathering about what the element could be represented by, and arguments for what one

already was doing at OM. This kind of professional disagreement and bringing of social school culture to the surface, contributed to the legitimation of the cooperative development process, and highlighted that the teachers need to have content and form priorities at OPM that reflect the teaching that has been offered to the pupils. If consensus was reached at the first gathering, it was about these two issues.

The second gathering brought along experiences with reports about experimental change from previous practice in intermediate work that had been tried out since the first gathering: arrangements where the pupil had chosen a mathematical theme and then faced problems related to this theme in an examination room where lots of physical equipment were available for use, and group based arrangements with use of vertical boards, where pupils in pairs worked on exploring a mathematical relationship. Several arrangements, on the other hand, only represented shades of change from OM, by still assigning the pupil with a context-related topic for a preparation period, like for instance a trip to a remote cabin, a holiday to somewhere far, a prospect for a playground, etc., where the pupil had to create tasks by using mathematics from the curriculum and present them and their solutions at the exam. In this process, several schools left it for the pupils themselves to define *practical*. The discussions based on sharing of the newly acquired experiences saw the argumentation of difficultness in making significant changes for the up-coming spring once again being put forward, because one had worked with the pupils all the way from 8th grade and onwards with a standard OM in mind. However, something else seemed to find viable conditions for growth, as well. The cooperative development project opened for thinking differently and together about one's own teaching, and through the project's structure for possibilities regarding revision of teaching. The possibility of such revisions may, according to the participating teachers, over time affect how the practical element of OPM can be implemented.

The third and final gathering showed that the actual conduction of OPM in June 2023 at the three schools that were chosen for this exam, maintained a structure and priorities that where quite similar to what OM had contained the previous years. This could not be seen as a surprise, and the argumentation for this was to find in the teachers' arguments for forwarding of the established OM-policy found at the first gathering and to some extent at the second gathering. Hence, the third gathering showed that the first round of OPM appeared to be rather knowledge and product oriented, but the cooperative development group of teachers seemed to be ready to move in the direction of competence and process orientation for the future OPM, based on changed priorities in the teaching.

Discussion and conclusions

The necessity of making changes of one's practice may be a kind of painful experience. It is both common and understandable to strive for adjustment of new input to a prevailing policy (Glaser, 1965; Kuhn, 1996). Change may develop in a continuous manner, but sometimes a collective leap of some kind forces its way, as described by Kuhn (1996). A cooperative development project as the one elaborated on in this paper, based on a participation-based intervention model for teachers' professional development that prioritizes to start where the participating teachers are (Timperley et al., 2007), is a fundamentally democracy based project within a significant community of practice (Wenger, 1998) showing wide open that it is a collective responsibility to make the joint project effort

relevant and to influence both the actual practice and the theoretical understanding of the practice (Pedder & Darleen Opfer, 2013).

The first gathering saw resistance towards change rise to the surface through the voices of prominent and self-confident teachers. Righteously they advocated the signalized adjustment needs with the introduction of OPM distributed from UDIR (2020a; 2020b; 2022) to be adjusted to the prevailing content and form policy used in OM. On the other hand, well-founded and practice grounded input from external representatives of significance provided the participating teachers with sound examples of possibilities of change regarding both content and form priorities that proved the possibility of well-grounded change of practice. This seemed to enable confidence to grow and pave the way for arguments for change to meet the understandable arguments for standstill. This growth was nurtured, as in the study by Wylie and Lyon (2015), by the organized expectation that the teachers would try out specific attention to a practical element regarding both content and form in small scales at their own school. Such try-out experiences supplied teachers who advocated change with support in self-made practice based experiences. This support made it easier for them to challenge arguments from teachers who rather advocated adjustment of understanding of a practical element to the prevailing OM-policy. These discussions moved towards a negotiated consensus, where the joint group of teachers recognized it as an argument for moderate change that the 10th grade pupils had not been taught with OPM in mind, but with OM in mind. This seems like a pragmatic echo of an argument for conserving the prevailing policy, but is nevertheless an argument that brings the pupil into the equation of change. The teachers' desire for consensus seemed to solve this by settling for change of teaching practice when starting with a new group of 8th grade pupils, with OPM in mind. However, an actual joint implementation of such a change, starting from each teacher's starting point of course, is impossible to confirm because the teachers have already moved on from the initial starting point.

Hence, two consequences of the cooperative teacher learning approach are identified, providing implications for policymakers and future research. First, there was a registered movement towards a joint understanding of the practical element in mathematics. Second, a collective agreement of need for change of priorities in teaching of mathematics in order to reach a deliberate development from OM to OPM for the pupil was identified. This implies that the registered initial change in acknowledging the practical element and attitude towards teaching priorities will not be allowed to slide back to adjustment seeking defense of prevailing OM-policy contentment. Time will show how a policy regarding content and form in OPM will develop among teachers, and research ought to investigate what changed or not from OM to OPM, why this happened, and what measures that were taken to initiate changes requested by policy makers. A cooperative development approach that bases the teachers' learning on their participation in defining, developing and reaching milestones, deserves to be among the measures investigated.

Students' reactions to speech input requests in a digital formative assessment of conceptual understanding

Students' conceptual understanding can be assessed by eliciting their explanations and argumentations, e.g. in oral communication between student and teachers. In written formative assessments, however, many students avoid writing so that their responses offer only limited insights. This study explores to what extent digital formative assessments requesting speech input rather than typed responses could encourage students to provide more detailed and informative explanations and argumentations. In a qualitative study with 53 fifth and sixth graders, we observed that students produced longer responses, incorporating multiple arguments. These responses provided a more robust basis for assessing students' conceptual understanding. Additionally, we observed that these improvements were especially strong when students employed an everyday language register.

Keywords: Digital formative assessment, oral speech formats, conceptual understanding.

Challenges in assessing conceptual understanding

Although procedural skills and conceptual understanding are equally important learning goals in mathematics, many digital summative and formative assessments hold a strong procedural focus (Hoogland & Trout, 2018). Therefore, we investigate ways to enhance formative assessment (Black & Wiliam, 2009) of deep conceptual understanding. A prerequisite for this assessment is to make conceptual understanding visible.

Deep conceptual understanding includes the abilities to translate a concept between different (e.g., verbal, graphical, symbolical, or contextual) representations, to explain the meaning of particular concept elements and the connection between these representations, and to connect different concept elements in a wider network of elements e.g. for argumentations (Hiebert & Carpenter, 1992). These abilities tend to be more difficult to assess than procedural skills and shallow factual knowledge (Çekiç & Bakla, 2021), and can ideally be assessed in oral conversations between teacher and students (Clarke et al., 2002). Nevertheless, some digital formative assessment tools show that written assessment of these abilities is possible (Olsher et al., 2023), with carefully designed multiple-choice items and open items with longer answer formats, requesting students to write explanations of meanings or argumentations on connecting different representations. However, research documented the repeated challenge that students often provide only brief answers, lacking elaboration and detailed thinking processes, especially mathematically weaker students (Brennan et al., 2010). This heavily weakens the informativity of the assessment, as the students' thought processes remain hidden. Reasons for these limited brief answers can vary: Students might lack motivation for the time-consuming process of writing or typing extensive explanations. Alternatively, students might have

internalized implicit norms of what kind of response (and language register of that response) is expected. Research on the development of writing skills for students with disabilities show that speech input technology can have benefits for text quantity and quality (Almgren Bäck et al. 2024). This challenge occurs less in oral conversations in which students can express their ideas orally to a clearly determined recipient. With the new technological affordances of digital tools, this raises the following question: *To what extent can digital formative assessments requesting speech input rather than typed responses encourage students to provide more detailed and informative explanations and argumentations?* We report on an exploratory study in which fifth and sixth graders could give their answer via speech input (as a voice message or via dictating their answer) in formative assessment tools.

Speech input as assessment approach to support students' language production

When students' lack of motivation to give extensive answers might be due to the tediousness of writing or typing, it might be helpful to reduce this burden by allowing students to give their answer via speech input. Similar to mode effects that have been reported for the change from paper-and-pencil to computer-based assessment, we pursue the assumption that also the change from written to oral modes might make a difference in students' answers. This assumption is nurtured by findings from non-mathematical areas: Pereira et al. (2019) employed a ChatBot in a massive open online course where higher education students submitted voice messages. The authors found that 49 % of all answers showed a high degree of reasoning and were developed in depth, all while being produced spontaneously. Gavras et al. (2022) found that adults' oral answers (about political attitudes), also submitted via voice recording, were up to 40 % longer than written answers, were lexically richer and overall related to a broader range of topics. The authors remark that "Interestingly, in the oral answers, respondents articulate their question answering process, expressing how they came up with their answers, indicating a kind of think-aloud" (Gavras et al., 2022, p. 884). For some adults, speech input increased affective blocks due to anxiety to speak (Satar & Özdener, 2008). All findings refer to adults, no study was found about younger students.

Some indications can be found from learning (not assessment) situations with younger students (Schreiber & Klose, 2017): Fourth graders who were engaged in preparing mathematical audio-podcasts used substantially different language compared to writing, with longer answers. Their spontaneous audio-recordings were found to be longer, more in the everyday language (characterized by everyday phrases and less complex sentence structures) and to have more traits of a personal talk (e.g., with a clear addressee) than the final versions. By re-working on the script, the language use developed towards more academic language in more condensed sentences and more elaborate phrases. We anticipate that also in assessments, spontaneous oral answers might elicit longer and more everyday language use than written or well-planned oral answers.

Combining all observations mentioned above, the use of audio recordings bear promises related to the language register, the extend of answers and the enacted discourse practices. In our study of fifth and sixth graders' reaction to speech input requests in digital formative assessments, we focus on the mathematical topic of meanings multiplication (as counting in units) for which earlier studies revealed that students engage in explaining how different representations are connected and in

describing the underlying multiplicative unit structures is the main window to students' understanding (Lesh, 1979; Prediger et al., 2025). We explore how the language use changes with the offered oral or written modes.

Methods

Methods of data collection. For the explorative interview study, we used our formative assessment tool Mastering Math – Online-Check (Hankeln et al., 2025) and integrated speech input in two versions, by requesting to send a voice message (with students' possibility to listen it and submit a second corrected or extended message) or to dictate a response that was automatically transcribed, so that afterwards the text could be read and edited by the students, and compared it to 414 written responses collected in earlier studies. Oral data was collected in interview settings with 53 fifth and sixth graders. In a rotated design, each student worked on seven tasks on multiplication and division, some in voice message version, some in dictation version. This lead in total to 371 student responses. Figure 1 shows an example item on multiplication that assesses if student recognize the bundled units of three dice with two dots each, representing the multiplication 3 x 2. Before the assessment, an introductory item invited students to read aloud a fictive student's answer to a task on addition or subtraction, formulated in the everyday language to exemplify that spontaneous answers are welcome. After their work on the items, students were asked about their experiences with speech input, if they prefer typing or speech input and which of the two versions (voice message or dictation tool).

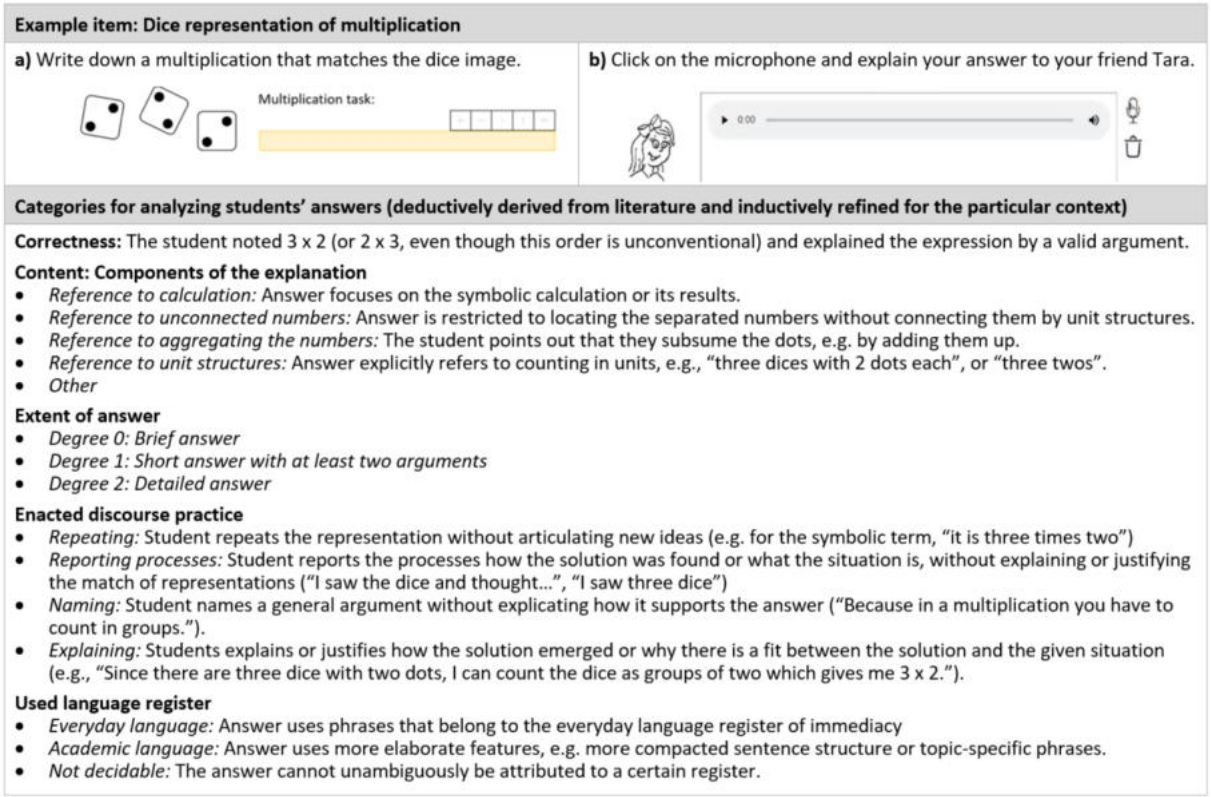

Figure 1: Example item on representing multiplication and analytic categories

Methods of qualitative data analysis. In this paper, we qualitatively analyse the students' oral answers. By comparing students' oral answers to written responses we had already collected in earlier studies, we generated hypotheses on typical characteristics that can later be quantitatively tested, also to compare the two versions of voice message and dictating (Hankeln et al., submitted). The qualitative analysis started with categories deductively derived from literature which were then inductively refined for the particular context by coding for each answer. The categories were (a) correctness, (b) components of the explanation, which are the different arguments that could be used in the answer, (c) extensiveness of the answer, (d) enacted discourse practices and (e) language register. Figure 1 details the categories for an exemplary item we use in this paper. While correctness is dichotomously coded with zero or one point, most categories have several codes with relevant distinctions.

Empirical findings

The qualitative analysis of students' responses led to five hypotheses on potential characteristics of students' speech input use that will be illustrated with one example each (and put the generated hypotheses to tests in a future quantitative analysis):

(1) Students' responses given via speech input seem to elicit more everyday language use than in written answers.

A phenomenon that emerged with the integration of speech input is the frequent occurrence of responses that were coded as everyday language, as Anna's explanation of her non-correct expression 2x2x2=8:

> Anna: So it's 2 times 2 times 2, because there are 3 dice with...2. And if you lump all the dice together, it would be 6, but because it's "times", it's 8. Because if you want to slap out 8 without multiplying, you would have to have 4 times 2
> [authors' remark: with 4 times 2, she refers to four dice with two dots each]

We could not see everyday phrases such as those underlined above in typed responses collected in earlier studies with the same items. With "lump together" and with "slap out without multiplying", Anna seems to refer to an additive process. She does not see the bundled structure of three units with two dots each but relates the representations to each other on a superficial level. Even though she recognizes the 3 as the number of dice, she uses every visible 2 in her expression and even proposes a different representation for another operation to get her result 8. Thus, this example (and various further cases in our data set) does not only plausibilize the hypothesis drawn from the literature (Schreiber & Klose, 2017), it illustrates that by inviting the students in oral models seem to go along with the invitation to express her understanding of the situation in her own language of comfort, and by this, more extended insights into the students' (in this case still flawed) understanding are gained.

(2) Students seem to address more components when they give their answers via speech input.

For explaining why their symbolic expression matches the given dice image in the example item, students mainly addressed four components for their explanations (listed in Figure 1): They either referred to the calculation only, the unconnected numbers, aggregating numbers additively, or the targeted unit structures. Tony, for example, noted the symbolic representation "2x2+2=6" in the dice item and justified his response with a detailed answer (with codes for components in brackets):

Tony: Because you see 3 dice, each with 2 dots on it *[unit structures*]. And then you could calculate, um, if you... then there are 2 dots. Then you could, um, count 1, with 1, 2, 3, 4, 5, 6 [*aggregating the numbers*]. And then you would also know that there are 6. Then you can count 2 times 2 plus 2. That would also be 6 [*calculation*].

When describing the situation, Tony makes use of conceptually rich phrases for articulating multiplicative units ("3 dice each with 2 dots on it"), without explicitly relating this observation to a multiplication. Instead, he focuses on the result as the most important indicator for the match between the representations. The disrupted language Tony uses and the omissions he makes are indicators for typical everyday language, with a think-aloud documentation of his solution process.

While the written answers addressed one or two of these components each, it is remarkable that like Tony, many oral explanations addressed more different components. From this observation we derive the hypothesis that inviting speech input might not only increase the extent of answers (with more detailed answers), but seem to increase their comprehensiveness by addressing more components.

(3) Extent of answers seems to be influenced by students' attitudes towards the input format.

In the end of the interviews, students expressed their approval or hesitation about speech input. Arguments against the speech input included disliking listening to own voices, but also that student felt it easier to sort their thoughts while writing or that the written response is less personal. Students who favoured the speech input, however, found speech input being less tedious, without requiring additional work to reformulate answers, and appreciated that their answer are more complete as they would tend to forget arguments while writing. Student seem to hold different views of the norms for this answer format. Marc for example explains his hesitation when using speech input as follows:

Interviewer: You're now telling me what you were thinking. Why do you think you can't say the same thing in the voice message?
Marc: Because that's not a solution. That's just saying what I think. [..] Simply thinking is not a solution, it should be a solution.
Interviewer: What would such a solution look like? So, what is a solution for you?
Marc: Something correct, not just what you think.

These remarks show the importance of the implicit norms with which a student measures quality of his or her answers. Even though it is the aim of the speech input format to grasp students' informal ways of thinking, Marc aims at giving a final, correct and perhaps compacted answer sentence instead of making his reasoning explicit. This aim is hard to achieve in a spontaneous oral communication.

A first qualitative analysis led us to hypothesize a connection between their attitudes and the extent of answers: Students who do not see the need to give sophisticated responses but engage in oral communication to a friend in everyday language, seem to feel free to express their reasoning more explicitly without being restricted to a purely academic register. Those who believe to be expected to give sophisticated answers seem to provide brief answers more often.

(4) Students' responses seem to engage in discursively richer discourse practices.

With the formal extent of answers and the number of addressed components, also the discursive quality seems to change with the speech input: While the short typed answers like "Because 3 x 2 equals 6" often were less informative, the more extensive responses via speech input also allow a

more reliable diagnosis which discourse practices a student applies. For example, Cara explains in her voice message in the dice item:

> Cara: I observed that there were 3 dice, and in each of these 3 there were 2 dots, and I always counted those 2 dots as 2 dots, and that resulted in 6, and then the task is to get 2 times 3, or also 3 times 2.

Cara shows a profound conceptual understanding of a multiplication and is able to express the bundled structure with her words. She successfully *reports* her processes of translating the image into a symbolic expression, yet does not *explain* the match between the symbolic and graphic representation. While we hypothesize that students seem to engage in discursively richer discourse practices in orally compared to written answered items, we also concede that the increase in extent allows for capturing the sophisticated differences of reporting a translation process and explaining the connection of representations. These kind of insights have substantial value for adaptive language-responsive teaching.

(5) The correctness of responses is not influenced by the input format.

As reported under (3), students reacted differently to the speech input. While some students kept the approach to formulate their answer carefully before starting the recording, some students started talking spontaneously. One could assume that this spontaneous talking without a second thought could have led to less correct solutions. However, we observed several times the phenomena that students started answering and while they were still recording their answer, they remarked a contradiction and changed their argumentation. Therefore, we assume that the correctness of the final answer does not change, however spontaneous misconceptions and fragile understandings become more visible as they are rarely documented in the written answers.

Discussion

The first results of this exploratory study seem to confirm the transferability of observations by Pereira et al. (2019) from adults to fifth and sixth graders that using speech input can lead to answers that are developed in more depth with a higher degree of reasoning. We add that the language used by students in this study often contained elements of everyday language. As students are rarely able to express especially intermediate states of conceptual understanding with rather formal academic language (complex sentence structures and sophisticated condensed phrases), this change opens new opportunities to gain access to students' individual understandings also in classroom assessments.

Like in Gavras et al. (2022), speech-input responses seem to address more components and often express how students came up with their answers, even when the question actually requested a different discourse practice. Important to note is that even if students gave more extensive answers in the speech input, the correctness of answers seems to be unchanged. From the diagnostic point of view, this would indicate that reducing the burden of typing an answer does not make an item easier, but students seem to make use of the time to integrate additional arguments, giving thus more insight into their net of representations and thereby allowing a more comprehensive diagnostic of students' understanding.

However, findings from a decade ago that speech input might generate hesitations due to anxiety to speak freely (Satar & Özdener, 2008) could still be valid for some students, even though this type of messages is nowadays much more present in our everyday communication via smartphone and messengers. Students like Marc clearly expressed their dislike of this format but justified it mostly with their insecurity of what norms apply to such kind of response to a test item. Therefore, a careful introduction and transparency of the expected input is needed for this item format.

As this study was of exploratory nature, the hypotheses generated still wait to be tested in a quantitative analysis for all the 372 responses. Additionally, several methodological questions are still open. Concerning this study, a qualitative interview-study was chosen to ensure a smooth proceeding even in the case of technical issues. The one on one setting however might have had an impact on the answers students have given. Therefore, a replication is needed to ensure ecological validity of the findings. In this study, eight students were taking part in the interviews at once in the same room. It still has to be evaluated how well the speech recognition functions with more students speaking simultaneously.

Another important aspect that has been left out so far lays in the evaluation of the voice inputs. Even though some teachers have expressed their interest to listen to students' audio files, transcribing and pre-coding the audio-files with the help of Large Language Models is desirable, especially since students' responses tend to get longer in speech inputs.

Conclusion

Innovations in the field of digital technologies open new opportunities to overcome problems in digital assessments (Olsher et al., 2023), in our study we focused on students' hesitation to write or type extensive answers about their individual understanding. The first observations reported and hypotheses generated in this paper give insights that using a speech input might bear potentials to bring orality into computer-based assessment to collect more extensive responses. As students show to take into account the recipient of their answers and use everyday language (Schreiber & Klose, 2017), their responses are somewhat closer to their thinking process than their written answers. The number of words in students' responses increases when using speech input, which is not only due to the repetition of words typical for oral modes, but also due to the fact that students take into account more components of an explanation. As their responses do not get more correct with higher extents, the responses seem to make visible flaws for example in the connection of different concept elements that were not accessible before. However, as the innovative format might break with internalised norms for example what counts as a mathematical response, speech input might also unsettle some students so that the introduction of this item format has also to be carefully designed.

Acknowledgment. The design and research around the Mastering Math Online-Check is conducted within the project SchuMaS (funded by the German Ministry of education, grant no. SMS2101L-01PR2101C and the Ministry of Education in Hessia).

Preservice teachers' formative assessment strategies they intend to implement in a real classroom

Gözde Kaplan-Can[1] and Çiğdem Haser[2]

[1]Middle East Technical University, Faculty of Education, Ankara, Türkiye; gkaplan@metu.edu.tr

This study investigated formative assessment (FA) strategies that preservice mathematics teachers (PMTs) plan to implement in real classrooms. Twelve fourth-year PMTs who were enrolled in a four-year teacher education program for middle grades (grades 5-8) participated in the study. Lesson plans prepared by PMTs to implement in their practice teaching school and one-to-one interviews on these lesson plans constituted the data of the study. Findings showed that almost all participants included three or more FA strategies in their plans. The 12 PMTs addressed a total of 18 sub-strategies in their lesson plans. Teachers asking questions, making observations, and providing feedback in the form of clues or hints were the most mentioned FA sub-strategies. Other common strategies planned to be used in real classrooms were teacher and student review of the lesson.

Keywords: Formative assessment, preservice teachers, teacher education.

Introduction

Formative assessment, or assessment for learning, is a method of collecting information on students' progress in everyday classroom activities. While there are various definitions of FA, the definition provided by Black and Wiliam (2009) was referred to in this study since it encapsulates the essence of many other definitions. Black and Wiliam (2009) suggested that classroom practices can be formative when teachers, students, or their peers collect, analyze, and use evidence of student progress to make decisions about future instructional steps. These decisions are expected to be more effective or better grounded than those without such evidence.

This definition highlights the importance of involving all participants in the classroom—the teacher, the learner, and their peers—in the assessment process. Although teachers typically use evidence of student learning to guide their instructional decisions and enhance student performance, students also play a role by regulating their own thinking and learning to assess their current status and determine how to progress (Black & Wiliam, 2009). Additionally, the definition emphasizes that evidence of student learning should influence future instructional steps, which is the big idea of the FA strategies suggested by Wiliam and Thompson (2008).

Wiliam and Thompson (2008) introduced a model for FA, which identifies three key participants (the teacher, the learner, and peers) and three essential instructional processes: understanding where learners are in their learning, where they need to go, and how to get them there. The framework outlines five key strategies: (A) Clarifying and sharing learning intentions and criteria for success; (B) Engineering effective classroom discussions and other learning tasks that elicit evidence of student understanding; (C) Providing feedback that moves learners forward; (D) Activating students as instructional resources for one another; (E) Activating students as the owners of their own learning.

It also emphasizes a big idea: using evidence of student understanding to adapt instruction and to meet their needs (Wiliam, 2007).

Strategy A can be used at the start of the lesson, during coursework, and at the end of the lesson. For instance, teachers can set targets (Wiliam et al., 2004) and share student-friendly learning goals to clarify the lesson's aim (Wylie & Lyon, 2015). During coursework, providing expectations or success criteria prior to completing the assignment (Wylie & Lyon, 2015) and giving clear instructions to the students about the assignment and process (Moss & Brookhart, 2009) can also help students grasp what they need to do to achieve the assignment. To implement this strategy, teachers might focus on the learning objectives rather than the task itself. They can provide opportunities for students to evaluate their work using clearly defined criteria and encourage discussions about the quality of their work (Leahy et al., 2005; Wylie & Lyon, 2015). Teachers might also ask students to review the lesson content to check their understanding at the end of the lesson. Strategy B involves questioning and observing to create meaningful classroom discussions that reveal students' comprehension. Teachers can ask questions to stimulate students' thinking, identify misconceptions, and adjust instruction to address learning needs (Leahy et al., 2005). They can also ask hinge-point questions to check if students ready to move on during the coursework and/or range-finding questions to learn about students' previous knowledge (Wylie & Lyon, 2015). Questions to ask at the end to see if students have grasped the main idea can also provide evidence regarding students' learning (Wylie & Lyon, 2015). Evidence collected about students' work through class observations can also assist in creating effective classroom discussions. Providing feedback that advances students' learning (Strategy C), fostering student collaboration and participation in activities (Strategy D), and encouraging students to take charge of their own learning (Strategy E) are also crucial for FA (Moss & Brookhart, 2009). Teachers can give feedback by providing written or oral comments on students' work. Classroom activities that promote reflection on learning, such as writing or discussing their current understanding or evaluating each other's work, can support Strategy D and E (Wylie & Lyon, 2015).

Research showed that classroom practices involving FA can improve students' mathematics success (Palm et al., 2017). For this reason, teachers must know how to plan and implement FA, as they are expected to tailor their instruction to meet students' needs (Wiliam, 2007). However, research revealed that teachers fail to share assessment criteria with their students and do not use peer and self-assessment frequently (e.g., Guo & Xu, 2021). It is known that some social, educational, and cultural factors affect how to implement FA (e.g., Hume & Coll, 2009; Qin & Yi, 2021) and how to plan it. Lack of professional development in assessment is also one of the barriers to plan and integrate FA into teaching practice (DeLuca et al., 2012). Thus, teacher education programs need to train PMTs to increase their understanding of FA and to break their barriers to plan and implement assessment. On the other hand, teacher education models face challenges in effectively fostering the development of preservice teachers' understanding and assessment practices (DeLuca & Johnson, 2017). Therefore, it is worth investigating how preservice teachers plan FA that is crucial for students' learning.

Effective FA practice depends on well-designed strategies. This means teachers must carefully plan how to assess student learning and interpret the results in advance. Although there is documentation on teachers' approaches to FA, there is limited understanding of how these assessments are developed

and applied in practice (Ayala et al., 2008). Based on this, this study investigated which FA strategies PMTs plan to implement in real classrooms. Specifically, the study aimed to answer the research question: What are the FA strategies PMTs plan to implement in real classrooms? It is our intention that the findings will provide teacher education programs in mathematics with a documentation of preservice teachers' assessment plans and practices, which may further be utilized for improving these plans and practices in their future careers.

Methods

In order to answer the research question, the FA strategies PMTs integrated into their lesson plans to implement in middle school mathematics classrooms were investigated, and one-to-one interviews on these lesson plans were conducted with the participants.

The study involved 12 fourth-year preservice mathematics teachers (PMTs) enrolled in a four-year teacher education program for middle grades (grades 5-8). Participants were selected purposefully among 35 PMTs who had already taken a course on assessment in mathematics classrooms before the study, considering their diverse answers to a task involving an incomplete and improper lesson plan on equivalent fractions and a case where preservice teachers were asked to assume the role of an inservice mathematics teacher implementing this lesson plan. The lesson plan was improper for several reasons (see Kaplan, 2015). It was incomplete since any wording implying a FA strategy was excluded from the lesson plan. The task also involved four questions, asking PMTs about the strengths and weaknesses of the lesson plan and how to improve the lesson plan regarding to the deficiencies they found. Considering PMTs' responses to these questions, PMTs who did not mention any of the FA strategies (n=3), who referred to one of the strategies (n=5), and who mentioned at least two FA strategies (n=4) were asked to participate in the study to reach a diverse sample of participants. All participants volunteered for the study.

The study was conducted within the scope of the Practice Teaching course. As part of this course, PMTs were required to prepare and implement two lesson plans in their practice school, including an assessment. In this study, 12 lesson plans, one lesson plan by each PMT, were analyzed considering the FA strategies that Wiliam and Thompson (2008) proposed. After examining each lesson plan, semi-structured one-to-one interviews were conducted with the participants and audio recorded. The interview protocol consisted of 17 questions asking how PMTs prepared the lesson plan, PMTs' reasoning for including the strategies, and their intention to use them.

The lesson plans and interview transcripts constituted this study data. Data were analyzed through content analysis. Participants' statements in lesson plans and interview transcripts that implied FA were categorized under the five FA strategies (Wiliam & Thompson, 2008). Subsequently, these categories were further divided into sub-categories based on descriptions existing in the literature. The first author engaged in an iterative analysis process that required switching between data and codes while placing expressions into the sub-categories. The intercoder agreement was also utilized to ensure the categorization. Another researcher who conducts research on teacher assessment and an expert in qualitative research coded the lesson plans separately. Any disagreements between these researchers were discussed until a complete agreement. In this process, some descriptions were

combined under one code, or the same codes were placed under different FA strategies since they serve for several strategies. Some examples were provided in the findings section.

Findings

Nearly all participants incorporated three or more FA strategies into their plans, except one participant (P4), who included only two strategies (A and B). The FA strategies that PMTs intended to implement in their lessons can be categorized under the sub-strategies outlined in Table 1. Altogether, 12 preservice teachers included a total of 18 sub-strategies in their lesson plans.

Table 1: PMTs' planned FA strategies (In lesson plan + In interview only)

Strategy	Planned Sub-Strategy	Number of participants
A	Start of the lesson: making aim clear	(3+1)
	Coursework: summary of the topic	2
	Coursework: giving clear instructions	4
	End of the lesson: teacher review	9
	End of the lesson: student review	(7+1)
	End of the lesson: informing students about the next topic	3
B	Teacher asking questions ● Range-finding Qs ● Hinge-point Qs ● Qs that prompt students to think ● Qs at the end to see if students grasped the main idea (Qs, HW, journal or exit cards)	 11 2 (7+1) 11
	Observing students' work	(8+2)
	Sharing student-generated solutions	2
	Establishing discussion environment	4
	Deepening discussion to engage more students	4
C	Giving clues/help/hints	(7+2)
	Reflecting on the answer to the board	1
D	Peer assessment: assessing each other's work	(1+2)
	Peer Assessment: explaining solutions to the peers	6
	Working in collaboration	(2+1)
E	Reflection: student review of the lesson	(7+1)
	Reflection: writing journal	2

Preservice teachers who mentioned Strategy A included several sub-strategies for clarifying and sharing learning intentions. PMTs gave place to teacher review (n=9) and student review (n=7, with one noted in the interview) of the content in their lesson plans. Three participants indicated they would inform students about the next topic at the lesson's end, while two planned to conduct a lesson review during the coursework. Four participants emphasized the importance of providing clear instructions to keep students engaged in the activity. However, only three participants in their lesson plans and one in the interview intended to begin their lesson by clearly stating its aim. As shown in Table 1, none of the participants mentioned giving students a scoring rubric or marking criteria at any stage of the lesson.

Almost all participants referred to Strategy B related to creating discussion environment through various sub-strategies such as asking questions, observing students' work, sharing student-generated

solutions, and deepening discussions to involve more students. A common approach was using range-finding questions to assess students' prior knowledge, such as asking, "If I am p years old, what will my age be after 5 years?" or "If she has f flowers, how many flowers will she has if she multiplies the number by 5 and adds 6?" (P9), while introducing algebraic expressions. Additionally, questions at the end of the lesson were used to check students' understanding of key concepts, such as asking, "What is the definition of perimeter?" or "How do we calculate the perimeter of regular shapes?" (P12), after a lesson on the length of polygons. Eleven participants mentioned these types of questions. Some participants also included questions designed to prompt deeper thinking (n=7) and hinge-point questions (n=2) in their lesson plans. One participant, who did not include such questions in his lesson plan, discussed how he would encourage students to think critically during the interview. Eight preservice teachers indicated they would walk around the classroom and observe students during activities, while two participants who did not mention observations in their lesson plans highlighted their intent to do so during the interview. They emphasized that they planned to observe students working individually or in groups. Four participants noted that they would work to involve more students in discussions, while two participants stated that they would illustrate different solution approaches during class discussions (P5). Four others mentioned creating a discussion environment without detailing a specific strategy. However, during the interview, one participant (P1) mentioned she intended to foster discussions when students could express agreement or disagreement with their peers. Similarly, P5 explained that she wanted to share different student solutions to create a discussion environment by asking students for their opinions on their peers' solutions. Participants' comments suggested that these discussion environments could also serve as an opportunity for peer assessment, aligning with Strategy D (activating students as instructional resources for one another).

More than half of the participants (n=7) mentioned Strategy C (providing feedback that moves learners forward) in their lesson plans, with an additional two participants discussing it during the interview. They indicated they planned to provide hints or clues to students who needed assistance during the coursework. For example, P3 emphasized in her lesson plan that "the teacher walks around the classroom, and if a student is struggling to draw a rhombus, the teacher may offer clues and help." P3 was also the only participant who noted in her lesson plan that if students were unable to draw a rhombus, the teacher would ask them to look at the board and draw the shape while reminding them of its properties.

Eight participants mentioned Strategy D, with six referring to peer assessment and two indicating the creation of a collaborative learning environment in their lesson plans. Those who focused on peer assessment primarily included statements about asking students to explain their solutions to their classmates (n=6). Only one participant detailed a plan for students to assess their peers' solutions displayed on the board and to share whether they had different perspectives (P11). Two participants mentioning collaborative learning stated that students would work in pairs (P8) and in groups of three or four (P12). During the interview, another participant (P1) emphasized that if students struggled with solving questions, she would group them into pairs or small groups. Conversely, one participant preferred not to create groups, referring to the class size as "I cannot conduct a group activity in that

class. There are 35 students, so group work can lead to much noise. Besides, the classroom is not suitable for group work" (P2).

Participants who referred to Strategy E (activating students as the owners of their own learning) primarily focused on encouraging students to reflect on their current understanding of the topic. We categorized students' review of the lesson under both Strategy E and Strategy A, as having students review the lesson in their own words can help them reflect on what they know and identify gaps in their understanding. Additionally, two participants planned to ask students to write a journal about what they learned in class, which provides another way for students to reflect on their learning. Writing a journal could also offer valuable feedback for the teacher, helping to improve future lessons based on students' needs, which is the big idea of FA.

Conclusion

Findings showed that almost all participants included three or more FA strategies in their lesson plans. Considering the significant effect of FA on students' learning (Lee, et al., 2020), this is a promising finding. When the use of each strategy was examined individually, it was seen that PMTs planned to use mostly Strategy B and C in a real classroom. Teachers asking questions, making observations, and providing feedback by giving clues or hints were the most mentioned FA sub-strategies categorized as Strategy B and C. Preservice teachers mostly included range finding questions to learn about students' previous knowledge and questions at the end of the lesson to see if students grasped the main idea of the lesson in their lesson plans. Similar findings from previous research showed that teachers used questions to check students' understanding (Antoniou & James, 2014). Related to Strategy C, PMTs stated that they would provide feedback in the form of giving clues or hints to students when they need them, but they did not give examples of these situations. This raises a question about how prepared teacher candidates are for potential questions from students.

Although research suggested sharing lesson goals or objectives with students in a way that students can make sense of them at the start of the lesson (Wylie & Lyon, 2015), PMTs mostly preferred to use Strategy A at the end of the lesson through teacher and student reviews. On the other hand, previous studies demonstrated that preservice teachers were not be able to implement especially the end and assessment parts of their lesson plans due to various barriers such as lack of time or classroom management issues (Kaplan-Can & Haser, 2023). Therefore, although PMTs planned to use this strategy at the end of their lessons, they may not be able to implement it as they planned. The same situation applies to Strategy E. As seen in Table 1, PMTs included Strategy E in their lesson plans as student reflections at the end of the lesson. They did not include any sentence in their plans about students assessing their own work, which is one of the ways to activate students as the owners of their own learning (Wylie & Lyon, 2015). Hence, it can be anticipated that due to some barriers faced by PMTs as a result of their practical experience (Kaplan-Can & Haser, 2023), PMTs may not be able to implement Strategy E either in a real classroom. This situation needs to be investigated further. To clarify this, research could be conducted on how PMTs implement the lesson plans they developed.

Working in collaboration is one of the opportunities for students to share and criticize their ideas or solutions with their peers, so it can be considered as a FA sub-strategy (see Andersson et al., 2017).

However, only a few participants planned to form pairs or groups during the coursework. One of these PMTs justified why she preferred not to create groups by referring to the large class size. Hence, it can be concluded that the effect of barriers is also evident in using Strategy E. This study's findings also revealed that the strategies are not mutually exclusive. For instance, engineering effective classroom discussions that elicit evidence of student understanding (Strategy B) may also serve as an opportunity for peer assessment (Strategy D). Hence, future studies could explore the relationship between these five key strategies.

Findings suggest that PMTs have plans for FA in mathematics classrooms, but these plans should be diversified to meet the needs of diverse groups of students effectively. They may consider classroom size as an important factor in determining FA strategies. PMTs can be encouraged and guided to devise effective FA strategies that would include students in rather crowded classrooms. Interviews indicated that they may have additional intentions in the classroom that do not appear in their lesson plans. However, indicating these intentions in the lesson plans, such as providing hints or clues, can provide them with a thorough thinking of these intentions within the classroom and prepare them better for their practice. Teacher education programs in mathematics should emphasize the importance of FA for effective mathematics teaching and learning for the preservice teachers.

Written tests through the lens of mathematical competence: how a teacher perceives feedback from test and data collected.

Alice Lemmo[1], Grazia Cotroni[2] and Laura Polidoro[1]

[1] University of L'Aquila, Italy; alice.lemmo@univaq.it

[2] Convitto Nazionale "Cotugno", L'Aquila, Italy.

Literature is critical with respect to the use of mathematics tests as a formative assessment method. The main criticism concerns the non-specific feedback provided and the failure to focus on how to move the teaching-learning process forward. In this contribution, we present a case study of a primary teacher who uses some suggestions to design and assess a mathematical written test by means of mathematical competence. We discuss the feedback the teacher perceives during the test design phase and the analysis of the data collected. The test design and the subsequent data provide the teacher with feed up, feed back and feed forward. Focussing on mathematical competence in the test design helps the teacher understand where and how she is going with her students and offers suggestion for future activities. Additionally, analysing the levels at which each competency appears in students' responses gives the teacher insights about activities to be undertaken.

Keywords: Mathematical written test, Feedback, Classroom assessment.

Introduction

In a previous contribution (Lemmo, 2023), we present some considerations concerning mathematical written tests as assessment methods that pursue curricular guidelines, educational goals and support the teaching and learning process. In detail, we present some suggestions for designing and evaluating mathematical tests aimed at formative assessment purposes. Consistent with the definition of *classroom assessment* (cf. De Lange, 1999), written tests could be a means for teachers to assess students' skills and understanding, using the outcomes to refine instruction and support the progression of student learning. Providing feedback that moves learners forward is one of the five strategies suggested by Black and Wiliam (2009) for activating effective formative practices. Feedback plays a central role by reducing the discrepancy between current and desired understandings with respect to an educational goal (Hattie & Timperley, 2007). Hattie and Timperley (2007) state that "Feedback has no effect in a vacuum" (p.82): with this sentence, they mean that teachers and their students should create learning contexts to which feedback is addressed, and dealing with tasks and tests should be one of these. In this contribution, we aim to investigate which kind of feedback our suggestions for designing and evaluating tests provide to a teacher. In particular, we present a case study of a primary school teacher who designs and evaluates a mathematics written test for her 4th grade students. Through an interview with the teacher during the design and evaluation phases, we show how and when the use of these suggestions results in effective feedback for her.

Theoretical background

Hattie and Timperley (2007) state that " "Tests" are one method used by teachers and students to address this question [How am I going?] and, […] often fail to convey feedback information that helps teachers and their students to know how they are going." (p.89). This concern lies in the

structure of written tests and the subsequent use of the data collected: tests are often composed of tasks in which students are asked to use procedural understanding, and the data consists in how well each task is performed and how many correct or incorrect answers there are.

In this section we explore some theoretical lenses with the aim of framing our suggestions for the design and evaluation of mathematical written tests. We start by describing the pedagogical lenses of powerful feedback, then we propose a shared definition of mathematical competence. Finally, we weave together pedagogical and mathematical theoretical lenses, explaining our suggestions for designing and evaluating mathematical tests through the lens of mathematical competencies.

The model of powerful feedback

Hattie and Timperley (2007) define feedback as "information provided by an agent (e.g., teacher, peer, book, parent, self, experience) regarding aspects of one's performance or understanding. […] Feedback thus is a "consequence of performance." (p. 1). The authors propose a *model of feedback*, outlining three questions to ask: (1) Where am I going? (What are the goals?), (2) How am I going? (What progress is being made toward the goal?), and (3) Where to next? (What activities need to be undertaken to make better progress?).

These questions correspond to *feed up* (1), *feed back* (2), and *feed forward* (3). Both teachers and students should seek answers to each of these three questions. The first question deals with educational goals: clarifying and sharing learning intentions and criteria for success to promote goal-directed action. In this perspective, feedback and educational goals are strictly related to each other in order to reduce the discrepancy between students' current understandings and goals. The second question concerns information connected to performance goals, for example in terms of success or failure on a specific task or part of it. Hattie and Timperley (2007) stress that feedback is effective when "it consists of information about progress, and/or about how to proceed" (p. 89) and is more effective when its focus is on correct rather than incorrect responses. From the teachers' point of view, it provides information that helps them understand how they (and their students) are going in terms of the criteria for success. Finally, the last question aims to provide information that leads to broader possibilities for learning (and teaching). For teachers, it means enhancing strategies and processes to work on the tasks, contents, situations, students' understanding and so on.

Mathematical competence

Dealing with tasks involves several and different mathematical competencies; for example, in determining the domain of a function or calculating the result of an expression: students have to know specific properties or theorems, use mathematical symbols and formalism, but they also have to deal with representations and undertake mathematical reasoning. Therefore, a test composed of a certain number of tasks allows for the collection of rich data in terms of competencies.

Niss and Højgaard (2019) define mathematical competence as being composed of two main components: *Posing and answering questions in and by means of mathematics* and *Handling the language, constructs and tools of mathematics,* further divided into four competencies each.

Handling the language, constructs and tools of mathematics is characterised by the ability to read, interpret, translate and use a wide range of representations (e.g. verbal, symbolic, tabular, graphic, or

visual) of mathematical objects, relationships and processes (*Mathematical representation competency*); the ability to relate to and deal with mathematical symbols, symbolic expressions and the formalisms that govern them (*Mathematical symbols and formalism competency*); engaging in written, oral, or gestural mathematical communication in different genres, styles and registers (*Mathematical communication competency*) and the ability to handle aids and tools for mathematical activity, which may be physical or non-physical (*Mathematical aids and tools competency*).

On the other hand, *Posing and answering questions in and by means of mathematics* involves posing and understanding generic mathematical questions, distinguishing between types of mathematical statements, and engaging in abstraction and generalization of concepts across varying contexts and domains (*Mathematical thinking competency*). Additionally, it requires the ability to pose and solve mathematical problems in a wide variety of mathematical domains and to critically analyse and evaluate one's own and others' solutions to problems (*Mathematical problem handling competency*) as well as the construction of models in extra-mathematical domains (*Mathematical modelling competency*). Finally, this component includes the analysis or production of arguments to justify mathematical statements, rigorous demonstration based on logical deduction from certain axioms, and similar processes (*Mathematical reasoning competency*).

Mathematical competence is expressed in various contexts and situations and requires a great variety of mathematical resources. Hence, each competency can never be fully or exhaustively possessed by individuals. Niss and Højgaard (2019) describe the mastery level of each competency through three dimensions: the *degree of coverage,* which is the extent to which all aspects framing the competency are part of the individual's baggage; the *radius of action,* which refers to the range of different circumstances and situations in which an individual can effectively apply the competency; and finally, the *technical level,* which indicates the degree of sophistication in the mathematical concepts, results, theories, and methods that the individual can utilize when demonstrating the competency.

Suggestions for designing and evaluating tests through the lens of mathematical competence

Lemmo (2023) describes some suggestions for outlining mathematical competence as a multidimensional and complex construct in a written test. In this perspective, both students and teachers could grasp the multi-faceted nature of teaching and learning mathematics.

As said before, a student needs to use different competencies with different mastery levels to solve a task; therefore, the teachers should highlight such aspects in both the *design* and *evaluation* phases (Drüke-Noe, 2023). In the design phase, teachers choose the tasks that compose the test; in the latter, they focus on the analysis and interpretation of the collected data. In both processes, teachers should focus on all the eight competencies with respect to different mastery levels. For example, they should propose more than one task (with different levels of complexity) for each competency to gather rich information and go beyond the results of the test and the number of right/wrong answers.

If teachers design tests composed of procedural tasks and they only provide a positive message when faced in correct results, this could be perceived by the students as a focus on procedural and not conceptual or relational aspects. This phenomenon is confirmed by Black and Wiliam (2009):

typically encourages superficial and rote learning, concentrating on recall of isolated details, usually items of knowledge which pupils soon forget . . . teachers do not generally review the assessment questions that they use and do not discuss them critically with peers, so there is little reflection on what is being assessed. (p. 17)

Conversely, the assessment message could change to favor mathematical processes and ideas, when teachers emphasize the competencies students employ. In this perspective, tests could provide feedback that enhances the processes used and the metacognitive attributes of each task.

Niss and Højgaard (2019) describe each competency in dept, paying attention to different tasks and assignment that relate to them. However, the three dimensions (degree of coverage; radius of action and technical level) are not explored in detail in their study. To better describe these dimensions, Lemmo (2023) translates them into 5 levels. Students at level 1 exhibit a limited space of work, as they depend on resources provided by the teacher, operate within a restricted range of familiar situations, and demonstrate a low technical level. In contrast, students with high competency (level 5) display a wide range of action across all situations, including unfamiliar ones. They possess an extensive space of work that reflects the use of personal resources, and they manage a refined technical level with autonomy and consistency.

Figure 1 illustrates what the teacher should compile and provide to the student during the test evaluation. The message given to the students focuses on the level of competencies they master in areas such as technical level, resources, and situations. The example in Figure 1 describes a student who exhibits an advanced level in asking and answering questions in, with, and about mathematics but remains at a basic level in using mathematical language and tools. The data presented in Figure 1 allow observation and interpretation of the student's actual situation in the test and could guide the student and the teacher in addressing situations that focus on representation competency in the future.

	Competencies	Level
To deal with mathematical language and tools	Representation	2
	Symbols and formalism	2
	Communication	3
	Aids and tools	4
To ask and answer in, with, about mathematics	Reasoning	4
	Modelling	3
	Problem Handling	3
	Mathematical thinking	4

Figure 1: Example of a student and teacher' s return form our suggestions (Lemmo, 2023, p. 4008)

This form of feedback encourages the selection of comprehensive tasks, emphasizing not the solution the student arrives at, but the approach taken to each task. Consequently, the emphasis on the number or severity of errors diminishes, shifting focus to how the student engages in solving tasks and the test as a whole. The suggestions seem to fit the model of powerful feedback. They seem coherent with feed up (1), feed back (2), and feed forward (3): each competency with its level shows both

students and teacher where and how they are going; further, reflecting on the different levels provides information about where to next.

In this contribution, we aim at investigating whether and how using mathematical competence in designing and evaluating written mathematical tests contributes to powerful feedback in terms of *feed up*, *feed back*, and *feed forward* from the teacher's perspective.

Methodology

We present the suggestions for designing and evaluating written mathematical tests in a teacher training program that involved five teachers in a primary school of a small city in central Italy (Lanciano, Chieti). Only one teacher was available to be observed and interviewed during the design and evaluation phases. We asked her to use the suggestions for designing and evaluating a mathematical test, we observed and interviewed her during both phases. In line with the aim of this contribution, we focus on the observation and interview related to the feedback she received from one written test and the data collected in one of her classes. We particularly observed the teacher at work on the evaluation phase of the test; during this observation, we asked her for more details about her choices and the feedback she received from the collected and evaluated data of the test.

The teacher has been teaching mathematics for 10 years, and she has a degree in Primary Education Sciences, which means that she attended courses and successfully passed exams in Docimology and Experimental Pedagogy. The class consists of 20 fourth-grade children, including 9 girls and 11 boys. According to the teacher, the class has a relaxed and collaborative mood, where the children have established a solid relationship with each other and with their mathematics teacher.

Results and discussion

Before the design and evaluation phases, we discussed about mathematical competence. The description of the 8 competencies was not immediately clear and easy for the teacher to use. She suggested decreasing the number of competencies to consider in order to make the design of the test simpler and the presentation of the results to the students clearer. In particular, she suggested grouping some competencies. In particular, she gathered: Symbols and formalism & Aids and tools, Reasoning & Mathematical thinking, and finally, Modelling & Problem solving. We asked her "what do you usually want to assess through a test and how you evaluate it?" The teacher answered that she usually focuses on mental calculation, confidence in moving through the different algorithms, and simple problem solving, and she evaluates test by assigning a score for each task.

In design process, the teacher did not reveal difficulties in proposing tasks. However, tasks involving Communication and Problem handling/Modelling were the only challenges for her. This provides an interesting feed up for her: she is not familiar with situations and tasks related to Communication and does not usually present her students problems requiring a high level of competency (in terms of unfamiliar situation). At the conclusion of the design process, during the interview, the teacher recognised that she had never structured a test in that way. She usually proposes tasks connected to familiar situation and so she has never proposed tasks requiring activation of high levels of competence. This awareness allowed the teacher to rethink her methodological choices in the past (feed up) in order to modify them in the future (feed forward). Regarding competencies, she decided

to promote more activities focused on communication and problem solving in the future. Furthermore, she also suggested to presenting unfamiliar situations to her students.

In evaluation process, the teacher showed concern. First, she was afraid of how time-consuming it would be. Looking at the whole test instead of evaluating each individual task seemed for her more difficult. In her experience, she used to evaluate tests using scores; the sum of tasks' scores determines the final mark. For example, she assigns scores corresponding to each correct task, then she evaluates the students' products counting the errors or missing answers she identifies; finally, she subtracts part of the points from the task's score. This procedure contrasts with our suggestion to evaluate tasks by analysing the competencies students demonstrate through the 5 levels. In the interview after the evaluation process, the teacher revealed an interest in processes rather than products, even though in the past she focused her attention on single tasks without offering her students an overview that extended beyond the specific test procedures and knowledge. The teacher stated that she usually does not provide written or articulated messages for students, but she communicates the final scores of each task and their sum. However, when she described the scores, she focused on the processes activated by the students and not simply on the outcome. In a different way, suggestions offer a description of the processes activated in the whole test by giving a more general perspective.

Without any suggestion from us, the teacher decided to average the levels of each competency her students demonstrated in the test (Figure 2). She stated that this information was useful for having a snapshot of her students; in this way, she gained a clear awareness of the situation in terms of competencies and their corresponding levels. With respect to Reasoning & Mathematical thinking, the class reached an intermediate level, demonstrating the ability to recall properties of mathematical concepts and to reason in mostly familiar situations. Considering Representation, Symbols and formalism & Aids and tools and Communication, the class ranked slightly above the basic level. An area for improvement is Problem Handling & Modelling, where students achieved the lowest level.

	Competencies	Level
To deal with mathematical language and tools	Representation	2
	Symbols and formalism & Aids and tools	2
	Communication	3
To ask and answer in, with, about mathematics	Reasoning & Mathematical thinking	5
	Problem Handling & Modelling	3

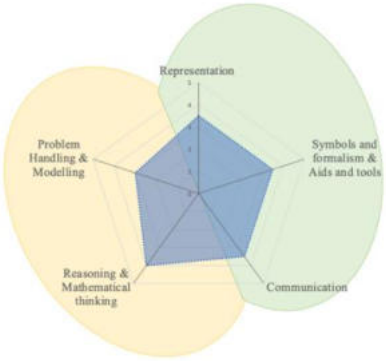

Figure 2: Average levels of class's competency

In the interview, the teacher stated that the graph representing of each student and the average was not enough: she could not understand how and where her students were distributed among the different competencies and their corresponding levels. For this reason, she independently constructed a new graph (Figure 3).

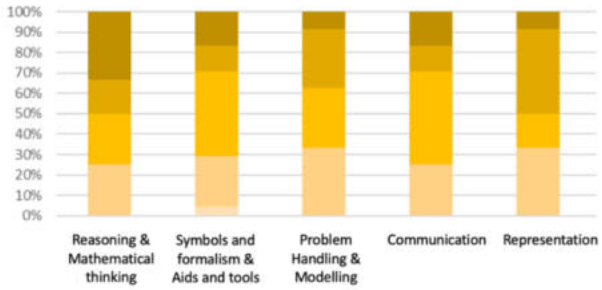

Figure 3: Levels of class for each competency

This graph enriches the feed back provided by the results. For example, although in Representation, Symbols and Formalism & Aids and Tools the class shows a similar level, in Representation there are several students with low level. Similarly, the average of Communication and Handling problems & Modelling is equal, but there are few students who reveal high levels in Handling problems & Modelling. On the other hand, concerning Reasoning & Mathematical Thinking, there is very high number of high-level students. Symbols and Formalism & Aids and Tools is the competency that most surprised the teacher because it is the only one that includes level 1 students. These data are interesting for increasing teacher awareness of students' situation and how to move class activities forward. She was surprised because the competencies on which to develop future activities were not the same as the design phase had led her to assume. Teacher stated that in the future she will work more on problem-solving and communication, also involving representations and mathematical symbols and tools. Furthermore, she will try to present students with more unfamiliar situations that require them to use personal resources to promote higher levels of competency.

Conclusions

In previous contribution (Lemmo, 2023), we offered suggestions for designing and evaluating a written mathematics test. These suggestions have been presented as a theoretical perspective; in this contribution, we aim to show how a primary school teacher used them and whether and how these suggestions contributed in terms of the feedback she received. From a general perspective, working with and interviewing the teacher showed that the suggestions provided feed up, feed back and feed forward. The design process provided feed up in terms of the activities she proposed to her students: she realised that she used to present familiar situations that required students to use resources provided by the teacher in communication and problem solving. The average of levels (Figure 2) and the graph of the levels for each competency (Figure 3) confirmed this consideration and provided feed back in terms of some specific competencies: Representation, Symbols and Formalism & Aids and Tools.

The suggestions used by the teacher and her personal adaptation seem to give her an overview of the class. In this regard, we did not imagine that our suggestions would prompt the teacher to customise the analysis tools, driven by her desire to know even more about her class in terms of competency levels (Figure 2 and 3). In addition, the teacher's suggestion to decrease the number of competencies to consider is interesting: she chose to merge the 8 competencies into 5. In further study, it will be interesting to understand in depth why this choice was made and whether it is more or less functional

in terms of feedback. This might suggest using different theoretical frameworks on mathematical competence, composed of a smaller number of components (e.g., Kilpatrick, 2001).

There are also some critical points: for example, exploring the suggestions with only one teacher does not allow for general and solid conclusions. To get a clear picture of the feedback, it is also essential to take into account the reaction of the class and to observe the teacher's choices over time. In addition, it would be interesting to discuss and describe the design and evaluation processes in detail. In this case, the test concerned numbers (multiplication between natural numbers); exploring other areas may provide further details to foster this research. The aim of this study was to analyse how a teacher used our suggestions and explore the information that their use gives back her in terms of feedback. We did not impose any particular mathematical content on the teacher in order to leave her freedom of choice and greater fluency in using the suggestions in both design and evaluation phases. This choice does not allow general conclusions on how to move the teaching-learning process forward. We do not delve into details about the difficulties/obstacles encountered by students and how the teacher will intervene in the future. At a later stage, we will focus on more specific aspects in order to provide pathways and training for moving students' learning forward.

Evaluating a multi-indicator assessment scoring approach to support mathematical literacy teaching and learning

Marta Mikite[1], Ģirts Burgmanis[1], Ilze France[1] and Dace Namsone[1]

[1]University of Latvia, Interdisciplinary Centre for Educational Innovation, Riga, Latvia;

marta.mikite@lu.lv

This study examines the effectiveness of a scoring approach for mathematical literacy assessment by evaluating each response of the students using multiple indicators. This approach could be helpful in order to assess higher-order thinking skills and problem-solving in complex tasks. This method allows for detailed feedback and enables partly effective differentiation of student abilities. 122 students took a test with six items of varying complexity. Using this scoring approach, these six tasks form 17 individual items. A Rasch analysis confirms the reliability and validity, although improvements in the person separation index are necessary. The results highlight the method's potential for providing precise feedback, supporting tailored instruction and targeted interventions based on individual student performance, and it is essential when designing a national assessment. Further research is needed to explore the possibilities of applying this approach in other contexts.

Keywords: Mathematical literacy, Rasch analysis, assessment scoring approach, marking scheme.

Introduction

Latvia's national assessment system does not support the achievement of national objectives (Cross-Sectorial Coordination Center, 2020), as shown by the results of the Programme for International Student Assessment (PISA). The PISA 2022 results reveal that Latvian students perform above average in mathematics at the lower proficiency level but below average at the higher level (OECD, 2023b). Although individual student data could potentially enhance learning quality, it remains not used due to concerns regarding the ability of assessments to accurately differentiate between students' capabilities (Pestovs & Namsone, 2019). Previous research on exams has shown that they lack tasks with high cognitive demand, tasks with authentic contexts and tasks that require explanation (Mikite & France, 2023; Pestovs & Namsone, 2019). This type of exam gives the misleading illusion that completing several tasks with similar low cognitive demand indicates high performance. This is why the National Assessment in Primary School Education is being developed as a part of a support system for learning mathematical literacy. The new assessment aims to provide feedback at different levels of the education system – municipality, school, classroom and, most importantly, at student level. To measure higher-order thinking and problem-solving skills, students are often required to solve complex extended tasks. The challenge lies in designing assessments that evaluate these skills effectively, especially when the time for students to complete tasks is limited (Mertler, 2003). Time limits lead to using a small number of tasks, which results in low reliability and limits the ability to differentiate between students based on their performance (Bond & Fox, 2015). This pilot study aims to develop an assessment scoring approach for this kind of assessment where students solve complex problems. The new scoring approach evaluates a single student response using multiple indicators, treating each indicator as a separate item. The research question is whether this scoring scheme ensures both reliability and validity while allowing for the effective differentiation of students based

on their performance levels. This involves examining if the scoring method can consistently measure student responses and accurately reflect their varying abilities in mathematical literacy.

The concept of mathematical literacy is operationalised in various ways by different authors. The PISA study models three components of mathematical literacy, i.e. content, process, and context (OECD, 2023a). Another study identifies the following elements of mathematical literacy: (1) Mathematical knowledge, (2) Contexts, (3) Dispositions, (4) Tools, and (5) Critical orientations (Bolstad, 2020), building on research by Goos and colleagues on numeracy (Goos et al., 2014). It can be concluded that mathematical literacy is the ability to formulate problems, which requires you to understand a situation in multiple ways, for example, in texts, diagrams, and pictures. After that mathematical procedures need to be applied and solutions need to be interpreted based on the content and context of problems. Mathematical literacy determines the ability to succeed in private, social and professional areas. After graduation, citizens are expected to be creative and engaged, making non-routine judgments (OECD, 2023a). When developing an assessment, it is crucial to ensure that the essential components of mathematical literacy are retained so that the measurement accurately reflects what it intends to capture.

For assessing mathematical literacy, the two most common approaches are structured questions and selected-response questions (May et al., 2023). Selected-response (e.g., multiple choice, true/false, matching) questions are often chosen because they are easier and quicker to assess due to the use of dichotomous scoring. However, more comprehensive information on students' performance can be obtained by analysing students' responses to structured tasks (Mertler, 2003). These approaches naturally lead to two main scoring approaches – dichotomous scoring, which determines whether an answer is correct or incorrect, and partial credit, which allows for multiple levels of correctness. A national diagnostic evaluation should combine these two approaches to ensure the data obtained are reliable and valid, provide the most accurate feedback possible to support future learning, and are relatively easy and fast to score.

Method

This pilot study involved 122 students from three schools, differing in urbanisation level and average performance in national mathematics exams. This test was taken in the early semester of a 7th grade. The students completed the test in 60 minutes. The authors then scored the test using the assessment approach, that is, scoring one answer with multiple indicators. In this way, the six tasks form 17 items, of which 13 are dichotomous, and four are scored partial credit at three performance levels. The national assessment is in its initial stages of development, and this is the first pilot study.

In developing the national assessment, the authors have formulated 12 major indicators of mathematical literacy. They are grouped into three categories corresponding to the problem-solving steps: formulating, employing and thirdly interpreting and communicating. The test studied in this research measures four of the major indicators: (1) recognising a mathematical situation in given texts in different contexts, (2) creating or drawing objects, figures in space and on a plane, their arrangement on a plane, observing quantities and relationships, (3) calculating length, area and volume in real situations using properties of objects, figures in plane and space, (4) evaluating a mathematical solution and interpreting it.

The tasks were selected with varying complexity based on the framework developed before (Mikite et al., 2024). The framework consists of three dimensions: (1) the context of the situation in which the problem is given, (2) the complexity of the mathematical model, and (3) the strategic complexity connecting the context and the mathematical model. Each dimension has three possible levels of complexity. Six tasks with different levels of complexity were selected to form the student test.

The test specification is given in Table 1. The idea of the Q-matrix (Tatsuoka, 1983) is adopted in developing the specification. The columns represent the major indicators described above, and each row represents a task in the test. Instead of ones, as in a traditional Q-matrix, this table shows the corresponding minor indicators assessed in each task. For convenience, the levels of complexity in three dimensions are added on the left side of the table according to the framework in Table 1. D1, D2 and D3 stand for the three dimensions of complexity described above.

Table 1: Test specification

Level of complexity			Task	Indicator 1 (formulating)	Indicator 2 (employing)	Indicator 3 (employing)	Indicator 4 (interpreting and comunicating)
D1	D2	D3					
1	1	1	**1.**	1_1 Recognises a geometric solid in a picture	1_2 Understand what plane shapes form a solid in a picture		1_3 Provide an answer using text and drawing of figures
2	1	1	**2.**	2 Find the necessary information from a variety of sources			
1	2	2	**3.****	3_1 Understands a situation given in simple text and picture	3_2 Locates a geometric figure on a plan and subdivides the figure to calculate area	3_4 Calculate the area of a combined figure using the rectangular formula	
3	2	3	**4.**	4_1 Understands a situation given in a complex text that sets limitations *	4_2 Demonstrate an understanding of the circle and the relationship between its elements *		
2	3	3	**5.**	5_1 Understands the situation given in the text	5_2 Demonstrates a deep understanding of the positioning of spatial figures	5_3 Determine the largest number of small rectangular prisms contained in the largest *	5_4 Explains the solution
3	3	3	**6.**	6_1 Understand a new/unfamiliar situation in simple text and picture		6_2 Estimates the volume *	6_4 Justify the solution

** The partial credit scoring is used to assess these indicators.*

*** There is another indicator, 3_3 measured in this task. It is beyond these major indicators as it relates to measurement, which is a separate primary indicator in the construct.*

The assessment scoring approach analysed in this study is based on the concept that each minor indicator is evaluated separately. The item numbers associated with these indicators are displayed in

the table and are used for further analysis in the study. Task 5 in Figure 1 serves here as an example to illustrate the scoring.

The dimensions of a small calendar are 1 cm x 11 cm x 15 cm. What is the largest number of these calendars that can be sent in a box with dimensions 16 cm x 24 cm x 9 cm?

Figure 1: Task 5

A student's answer is analysed using four different indicators. The first is whether the student understands the situation and question – that smaller objects must be combined into a larger one. The second is if the student can draw or mentally rotate the given shapes and start to solve the given problem. The third indicator is rated partial credit. One point is assigned if the student finds the solution *9*, which is a valid solution but not the best. Two points are received in item 5_3 if the student finds the best solution, which is *18*. In 5_4, the student receives a point if he explains his solution.

To answer the research question of whether this scoring scheme ensures both reliability and validity while allowing for the effective differentiation of students based on their performance levels, we run Rasch analyses using Winsteps 4.6.2. We analysed reliability, person and item separation indices and general targeting using a Wright map. Local independence and unidimensionality were analysed using Winsteps Table 23 to validate this scoring approach. Rasch model fit statistics were analysed to evaluate the individual items, which in this case are assessments of individual indicators (Bond & Fox, 2015). To examine if the scoring approach can consistently measure student responses and accurately reflect their varying abilities in mathematical literacy, we analyse how students can be grouped based on their performance levels and the type of individualised feedback that can be provided to each student. This approach ensures the method can differentiate between students' abilities and offers precise feedback tailored to their specific needs.

Results

The overall reliability of the test demonstrates strong internal consistency, with a person reliability of 0.75 and an item reliability of 0.97, indicating that the test items are consistent and stable (Bond & Fox, 2015). The item separation index of 6.19 further confirms that the test items cover a wide range of difficulty levels, allowing for precise differentiation between them (Linacre, 2011). However, the person separation index of 1.73 suggests that the test is less effective in distinguishing between students of different ability levels. One of the reasons for the low separation index could be poor targeting.

The overall targeting between item difficulty and student ability is partially successful (Figure 2). There is a significant gap between the mean value of students and items. 67% of students are below 0 logits, which is the item mean. This indicates that the test was too difficult for this group of students, or in other words, lower-performing students needed more tasks to demonstrate their performance. There are 41 students (34% of all students) in the -1 to -3 logit range, but only two items (12% of all items). This described mismatch helps to explain the low person separation index observed in the results, but it does not directly address the scoring aspect, which is the primary focus of this study.

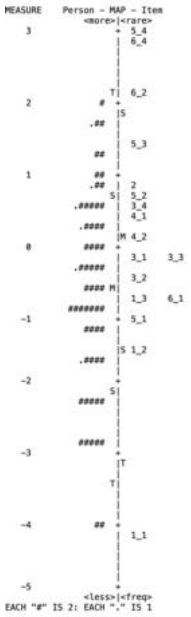

Figure 2: Wright map

A serious concern when assessing a single response with multiple indicators is whether local independence between these items is compromised. Table 2 shows the largest standardised residual correlations. All positive values are between 0.2 and 0.5, indicating that there are no significant problems that could seriously degrade the quality of the measurement (Linacre, 2011).

Table 2: Largest standardised residual correlations

Correlation	Item	Item
0.49	5_2	5_3
0.46	3_1	3_3
0.45	6_2	6_4
0.45	3_3	3_4
0.45	3_1	3_4
0.40	5_3	5_4
0.38	1_2	1_3
0.38	6_1	6_2
0.35	5_2	5_4
0.35	3_1	3_2

Correlation	Item	Item
0.31	5_1	5_2
0.30	4_2	4_1
0.26	5_1	5_1
-0.41	1_1	5_4
-0.35	3_4	4_2
-0.31	3_3	4_2
-0.29	3_2	5_2
-0.28	3_3	5_3
-0.26	3_4	6_1
-0.25	3_1	5_1

As the following criterion for evaluating measurement quality, dimensionality was assessed to verify that the test measures a single underlying construct. The Rasch model explains 43.5% of the total variance, while 56.5% remains unexplained. Notably, the eigenvalue for the first contrast is 2.75, which exceeds the critical threshold of 2, suggesting potential multidimensionality in the data. Furthermore, the second contrast's eigenvalue is 2.48, which also approaches the threshold, indicating that these contrasts may reflect a secondary dimension. Despite these findings, the percentage of variance explained by the first contrast (9.1%) and the second contrast (8.2%) is relatively low, suggesting that any multidimensionality is weak and may not significantly impact the unidimensionality assumption required by the Rasch model (Linacre, 2011).

Table 3 summarises the key item statistics, including item measures, Infit, Outfit, and Point-Measure correlations (PTMEASURE-AL). The Infit and Outfit mean square (MNSQ) values generally fall within acceptable ranges (0.5 to 1.5), indicating a good model fit for most items (Linacre, 2011). Additionally, the PTMEASURE-AL correlations, representing the correlation between each item's score and the overall ability measure, are positive and mostly strong. This suggests that the items are well-aligned with the measured construct and contribute effectively to differentiating between individuals based on their ability level.

Table 3: Item Measure, Infit, Outfit, and Point-Measure Correlation

ITEM	MEASURE	INFIT		OUTFIT		PTMEASUR-AL CORR
		MNSQ	ZSTD	MNSQ	ZSTD	
1_1	-4.27	1.13	0.52	2.12	1.43	0.18
1_2	-1.62	1.21	1.86	1.22	1.17	0.39
1_3	-0.92	0.99	-0.10	0.99	0.01	0.52
2	0.65	1.04	0.40	1.34	1.16	0.38
3_1	-0.42	0.82	-2.08	0.99	-0.03	0.60
3_2	-0.69	0.84	-1.78	0.73	-1.84	0.62
3_3	-0.42	0.96	-0.46	0.90	-0.58	0.53
3_4	0.44	0.83	-1.67	0.65	-1.49	0.57

In summary, the Rasch analysis indicates that the measurement is reliable and valid in terms of item performance, with high item reliability and item separation. This suggests that the scoring method itself is effective. However, the low person separation index highlights challenges in differentiating between students' abilities, pointing to the need for improved test alignment to better capture the range of student abilities.

Based on the wide range of item difficulty, it is possible to group items and set boundaries on the Wright map to define performance levels. The descriptions of each level are formed based on the content of the tasks within each group. However, if the person separation index is low, it may be more effective to provide feedback based on raw scores. This scoring approach enables the formulation of highly accurate and detailed feedback reflecting both correct aspects of student performance and areas for improvement (Bond & Fox, 2015).

Discussion

This method builds upon studies where such an approach, measuring one response using multiple indicators, was analysed using qualitative methods, such as Muliawanti & Kusuma (2021). Quantitative data analysis in this study is crucial in the context of national assessments, where the data must demonstrate both reliability and validity to ensure data-driven decisions about student performance and instructional support.

This approach not only provides precise feedback about what the student did correctly and where improvements are needed, but it is also easier to implement in practice. Most indicators can be assessed dichotomously, simplifying the evaluation process while maintaining accuracy. This makes the method particularly efficient for large-scale assessments, where rapid and reliable scoring is essential (Bond & Fox, 2015).

Future research should focus on increasing the test's ability to distinguish between students with different ability levels, as indicated by the person separation index. One way to achieve this is through better targeting, ensuring that the test aligns more closely with student ability levels. Additionally, two other factors limit the current study. First, the Rasch analysis was conducted on a relatively small sample, which may affect the stability of the estimates. Second, low student motivation or engagement during testing can lead to underperformance. If students are disengaged or do not take the test seriously, their responses may not reflect their true ability, resulting in poor person separation even with well-targeted items (Mislevy, 1996). Third, although mathematical literacy is part of the curriculum, it is unclear how explicitly teachers emphasize it in practice. Since mathematical literacy involves broader problem-solving skills than traditional mathematics, this gap may also contribute to mismatches between student ability and test performance (Bond & Fox, 2015).

To strengthen the current findings, additional studies in varied educational settings are essential, as the current results are limited to the specific context of this pilot. Conducting similar studies in diverse contexts would help to verify whether this scoring approach is consistently reliable and valid for broader applications, such as national assessments.

Conclusion

The scoring approach used in this study, where a single student response is assessed using multiple indicators, effectively measures mathematical literacy with high reliability and validity. This method enables detailed, individualised feedback that identifies student strengths and areas for improvement, which is crucial for supporting learning in national assessments. However, improving the person separation index would enhance the ability to differentiate students more precisely, allowing for a better understanding of their abilities. This allows educators to understand what students can and cannot do, providing evidence-based insights to adapt the curriculum and plan appropriate interventions.

The contribution of mathematics didactics to interpreting the results of a standardized national assessment

Julia Pilet[1] and Brigitte Grugeon-Allys[1]

[1]Univ Paris Est Creteil, Université Paris Cité, CY Cergy Paris Université, Univ. Lille, Univ Rouen, LDAR, F-94010 Creteil, France; julia.pilet@u-pec.fr

Standardized national and international assessments are widely used to evaluate student learning, but how can they be turned into tools for education professionals to help teachers better meet students' learning needs? This paper provides tools from mathematics didactics for interpreting, in a way that complements statistical methods for item responses, the performance scale of students' mathematical skills in a French national assessment. Our contribution consists in the didactic characterization of the assessment items and in relating the scale groups to an a priori defined level of mathematical activity. In this way, we characterize the knowledge mobilized by each group and rank them from one group to another in relation to the expectations of the school curricula. The analyses focus on school algebra at the end of middle school.

Keywords: Assessment, students' learning, school algebra.

Introduction

Standardized national and international assessments are widely used to evaluate students' mathematical knowledge and skills. However, they are rarely used by education professionals (inspectors, teacher trainers, teachers), especially in France, to help them manage heterogeneous learning more effectively in the classroom. It seems to us that they can provide interesting clues for managing heterogeneous learning in the classroom. To this end, we show that mathematical didactics can provide tools for interpreting the results of standardized assessments that are complementary to those of statistical methods used in such assessments.

In France, the Cycle des Évaluations Disciplinaires Réalisées sur Échantillon[1] (CEDRE) assessment of students' mathematical skills at the end of middle school in 2019 was designed to provide an overall view of students' knowledge and skills at the end of middle school in relation to the objectives set by the French curricula (Ninnin & Salles, 2020). Every six years, it is conducted by the Direction de l'Evaluation, de la Prospective et de la Performance (DEPP) using a statistically representative sample of the school population in metropolitan France.

In CEDRE, the statistical study of student responses leads to a six-group performance scale, determined by a psychometric approach using item response methods. The number of groups is set by the DEPP. The average score corresponds to the average performance of the students in the initial assessment sample (in 2008). The DEPP sets it by construction at 250 and the standard deviation at 50. This means that around two-thirds of students have a score between 200 and 300. The lowest

[1] https://www.education.gouv.fr/cycle-des-evaluations-disciplinaires-realisees-sur-echantillon-cedre-en-fin-d-ecole-et-fin-de-2870

groups on the scale include the scores of the 15% of students with the lowest scores. Those at the top are made up of the highest scores and include 10% of the students. In between, the scale is divided into three groups with equal score amplitudes. The performance scale is therefore developed *a posteriori*, i.e., on the basis of student responses. Because the item response model places student scores and item difficulty on the same scale, it determines the skills mastered by each group of students through their success on items that are characteristic of the group, i.e. items that students in the group pass with at least a 50% probability. This characterization of groups indicates the performance of students in terms of knowledge and skills, but in a very general way. It does not prioritize the learning outcomes of different groups with respect to the types of tasks in the same mathematical domain, and the knowledge and reasoning mobilized by students. In our view, this is essential if we want CEDRE results to be usable in the classroom to better manage the heterogeneity of students' learning. In addition, depending on the way an item is constructed, it can be passed through different procedures involving different types of knowledge that are more or less old in the curriculum. A detailed didactic analysis of the items is therefore necessary to identify the knowledge, properties and reasoning that can be mobilized to solve them and that can be taught at previous schooling levels. This paper addresses the following question: what kind of didactic analysis of the items and the students' results, in particular their difficulties, would help to link the performance scale groups to a hierarchy of knowledge as taught in the curricula? We illustrate this in the field of algebra.

Theoretical background

Didactic characterization of an item with the ATD

Each CEDRE item corresponds to a task. In the Anthropological Theory of Didactics (ATD), the mathematical activity involved in solving a task is modeled by two blocks: that of know-how, described by the type of task and the technique(s) enabling it to be carried out, and that of knowledge, described by the properties and the reasoning justifying these techniques (Chevallard and Bosch, 2020). Each assessment task is thus described *a priori* in terms of the type of task to which it belongs, the techniques targeted and possible, and their justification.

A task can be accomplished by one or more techniques, but these techniques do not all have the same scope (Chevallard and Bosch, 2020), i.e., their domain of validity. Depending on the characteristics of the task, they may or may not be effective. Some techniques can accomplish a part of tasks of the same type, while failing on another part. For example, the trial-and-error technique, used in primary school, is no longer effective in middle school for problems involving equations of the type $ax + b = cx + d$ with a, b, c, d integers and a and c non-zero integers and with a non-decimal rational solution. These problems, beyond the scope of the trial-and-error technique, require an algebraic technique aimed at solving a much wider range of problems.

Furthermore, a task is characterized by its complexity, that is, the notions it brings into play, their level of operationalization (Robert, 2003; Roditi & Salles, 2015), and the reasoning to be mobilized. In particular, this concerns the new or old nature of the mathematical notions involved, the fact that resolution steps or adaptations are left to the student, and the values of the didactic variables that characterize the task. For example, "develop the expression $3(x + 5)$" is less complex than "develop $2x(-5x + 3)$".

Didactic validity of an assessment

In addition to the psychometric validity of an assessment, we also investigate the didactic validity of an assessment (Grapin & Grugeon-Allys, 2018). It is based on an epistemological reference to the mathematical domain to be assessed, developed from research on didactics in the domain and on school curricula (for instance, for algebra, see Grugeon-Allys et al. (2022) and Grugeon-Allys & Pilet (2024)). The study of the didactic validity of an assessment focuses, on the one hand, at the local level, on the relevance and representativeness of each task (technique used and justification) in relation to what is being assessed. On the other hand, at the global level, it ensures that all the tasks cover the mathematical field in relation to the epistemological reference, i.e. that the types of tasks are sufficiently varied and that tasks of the same type are of different complexity. The validity is therefore based on an a priori analysis of the tasks, aimed at specifying the knowledge involved, inferring possible techniques and situating them in relation to the curriculum.

Some findings on school algebra

A large body of research links students' difficulties to the discontinuities (Kieran, 2007) that exist between arithmetic and algebraic thinking and to the specificity of algebraic semiotic practices. The Kieran's (2007) model of algebraic activity is based on three types of activity. Generative activity concerns the formation of algebraic objects (formulas, algebraic expressions, and equations) in order to solve problems (modelling, generalizing, proving) that requires translation between different registers of representation (algebraic scripts, numerical scripts, graphical representations, geometric figures, natural language). Transformational activity involves transforming expressions and equations in a way that preserves their equivalence. This may involve substitution, development, factoring, simplifying algebraic expressions and solving equations. Transformational activity is based on the structure of objects (sum, product). Global/meta-level activity involves solving modeling, generalization, proof, and equation problems. It leads to algebraic justifications and proofs as opposed to arithmetic reasoning.

These three activities call on the different status of letters (variables, unknowns, as opposed to label letters), equality as a relation of equivalence as opposed to equality "to perform," the complementary procedural and structural characteristics of the objects of algebra.

Three levels of mathematical activity

For each mathematical domain assessed, on the basis of the previous overview of school algebra research results, we (the project researchers) define *a priori* and hierarchize three levels of mathematical activity (Grugeon-Allys et al., 2022; Grugeon-Allys & Pilet, 2024). They inform the conceptualization level of the notions constructed by students. These levels are defined by the hierarchical use of notions, properties, and reasoning expected at the end of middle school in relation to epistemological breaks. They take into account the age of the notions according to the programs, the range of techniques and the complexity of the tasks. To make it easier to present these levels, we will start by presenting level A, which is the level expected by the educational institution, followed by level C, which is the lowest level, and finally the intermediate level B.

Level A corresponds to a mathematical activity that mobilizes expected knowledge and an appropriate level of conceptualization of concepts. For example, in algebra, Level A students mobilize algebra on their own to solve modeling, generalization, proof, and equation problems. They do so in cases that require reformulations between the statement and the register of algebraic language, cases we call semantic non-congruence. They transform (develop, factorize, reduce) algebraic expressions of expected complexity. They know how to mobilize properties (simple and double distributivity, conservation of an equality) and understand expressions in their procedural and structural aspects.

Level C corresponds to a mathematical activity that mobilizes old knowledge from primary school. It indicates a low level of conceptualization of notions, with a fragile entry into the construction of expected knowledge. In the case of algebra, for example, these students have not made the epistemological break between arithmetic and algebra. They often mobilize arithmetic techniques to solve algebraic problems, using examples to prove their point. They use techniques for transforming algebraic expressions and equations whose scope is limited to very simple cases, leading students to use them beyond their reach and to use incorrect rules ($3 + 2x \rightarrow 5x$). They understand algebraic expressions only in their procedural aspect.

Level B is intermediate and indicates a mathematical activity that mobilizes early middle school knowledge in simple, isolated tasks (Robert, 2003). Entry into the mathematical activity aimed at the end of middle school is in progress. For example, Level B students have negotiated the epistemological break between arithmetic and algebra, but in simple cases. They are able to mobilize algebra in some of the expected problems (modeling, proving, equating), often when the use of a letter is suggested to them and in cases that do not require a reformulation between the statement and the algebraic expression.

Method

In CEDRE 2019, the psychometric approach is to divide students into six groups on a performance scale. Each group of students is then *a posteriori* associated with characteristic items, i.e. items that the students in the group pass with a probability of at least 50%. We would like to extend the interpretation of the groups for algebra by associating each group on the achievement scale with a level of mathematical activity and by specifying what distinguishes one group from another in terms of knowledge and reasoning.

Our methods start with the *a priori* analysis of each of the 26 algebraic items according to the didactic tools introduced earlier (type of task, technique, complexity, scope of a technique). As this analysis indicates the complexity and possible resolution techniques, we can link *a priori* each task with the level of mathematical activity it requires. We then carry out *a posteriori* analyses based on the students' responses and the results of the psychometric analyses. Knowing the characteristic items of each group, we relate each group on the performance scale to a level of mathematical activity in algebra by considering the level to which most of the characteristic items belong. In addition, we also compare items within the same type of tasks, but performed by different groups, in order to identify breaks in learning between groups. For certain multiple-choice items, we compare the percentage of responses per distractor between groups. For error-related distractors, this analysis provides

information about the dominant error categories in each group in terms of students' constructed knowledge and conceptual development. These analyses allow us to classify the successful tasks and the knowledge required to solve them by group.

Results

Relating performance scale groups to levels of mathematical activity in algebra

Table 1 shows the results of the *a priori* analyses of the items (but without detailing them in this paper) and their relationship to the groups. In this table, each group has mastered the types of tasks and knowledge built up in the lower numbered groups.

Table 1: Performance scale groups and levels of mathematical activity

Group	Analysis of characteristic items in algebra of the group	Level
5	2 items of level A Tasks involving algebra as a tool for generalization and proof. Solving first-degree equations with rational solutions.	A
4	3 items of level A Modeling tasks in statements that are not semantically congruent with algebraic expressions. Calculation tasks with double distributivity and rewriting involving the denotation of algebraic expressions. Substitution tasks with relative numbers.	
3	16 items: 2 of level C and 14 of level B Modeling tasks in semantically congruent statements with algebraic expressions Tasks to prove that an assertion is true or false. Calculation tasks with simple distributivity, without rewriting and with structural aspect of algebraic expressions. Tasks to reduce simple first-degree expressions with rewriting.	B
2	5 items of level C Tasks involving the representation of a relationship by an algebraic expression or equation in very simple cases with semantically congruent registers. Calculation tasks with procedural aspect of algebraic expressions, allowing arithmetic practice (primary knowledge). Substitution tasks with whole numbers in simple algebraic expressions.	C

1	No item in algebra	
<1	No item in algebra	

Learning algebra remains as difficult as ever in middle school. Students in groups <1 and 1 did not pass any algebra items. This result is consistent with the knowledge and skills of students in these groups in the domain of "numbers and problem solving", also assessed in CEDRE. They were successful in items that mainly involved early primary numerical knowledge, such as the positional aspect of numbers (numeration). They have not sufficiently developed the different aspects of number (decimal aspect, different ways of writing the same number or numerical calculation, properties of numbers and operations, equality as an equivalence relation) to engage in algebra. Group 2 students have a better understanding of the equivalence of equality and the decimal aspect of a number. The three groups <1, 1 and 2 belong to activity level C and therefore have a mathematical activity that is expected in primary school.

More detailed analyses of three items characteristic of groups 2, 3 and 4

CEDRE 2019 includes three items (Table 2) relating to the same type of tasks *Representing a calculation program or its result by an algebraic expression.* Each is characteristic of one of groups 2, 3 or 4.

Table 2: Items succeeded in by group for *Representing a calculation program or its result by an algebraic expression*

Group 2	Group 3	Group 4
Program A: Select a number, square this number, add 2 Which of the following expressions always gives the same result as program A, whatever the value of the starting number x? ○ $(x+2)^2$ ○ x^2+2 ○ 2^2+x ○ $x+2$	Program: Select a number, square this number, multiply the result by 2, add 3 to the result We call a the number chosen at the start. Which formula is associated with this calculation program? ○ $a^2\times 2+3$ ○ $(a\times 2)^2+3$ ○ $a^2+2\times 3$ ○ $(a+2)^2\times 3$	The square of the product of 2.5 and x corresponds to the expression: ○ $2{,}5x^2$ ○ $(2{,}5+x)^2$ ○ $(2{,}5\times x)^2$ ○ $2\times 2{,}5x$

An *a priori* analysis of the items indicates that items in groups 2 and 3 differ in the complexity of the calculation program, which is related to the number of steps (two steps for group 2 and three steps for group 3), but the representations are semantically congruent in both cases. Items in groups 3 and 4 are distinguished by the involvement of procedural and/or structural aspects, semantic non-congruence between representational registers, and the nature of the numbers. In group 4, success

requires the mobilization of additional properties such as the structural aspect of an expression and operative priorities.

Table 3: Percentage of responses per distractor for group 4 item

Distractor	Group <1	Group 1	Group 2	Group 3	Group 4	Group 5
$2{,}5x^2$	30,00%	33,47%	36,07%	38,84%	19,42%	18,22%
$(2{,}5+x)^2$	23,72%	24,24%	17,04%	8,17%	5,62%	0%
$\mathbf{(2,5\times x)^2}$	**23,60%**	**28,97%**	**36,23%**	**49,38%**	**73,54%**	**80,70%**
$2\times 2{,}5x$	7,57%	7,19%	7,47%	2,98%	1,60%	1,36%
No answer	14,97%	6,31%	3,33%	0,43%	0%	0%

In addition, Table 3 also shows the percentages of distractors on the group 4 item. The non-response rate, below 15% for group <1, decreases to zero for groups 4 and 5. Although this item characterizes group 4, almost a quarter of students pass it from group <1 onwards, but errors are present in the majority of all groups below 4. Confusion between double and square (error $2\times 2{,}5x$) concerns around 7% of students in each group up to group 2. Confusion between addition and multiplication (error $(2{,}5+x)^2$) persists strongly up to group 2 and disappears by group 5. Students in group 3 are more likely to recognize multiplication, but without always taking into account the operative priority (error $2{,}5x^2$), which is recognized only by the majority from group 4.

Conclusion

The aim of this research is to interpret the six-group performance scale obtained from the psychometric analysis in a complementary way, in order to better identify the knowledge acquired at the end of middle school and the errors in each group, and to hierarchize them from one group to another as taught in the curricula. To this end, we have proposed methods based on epistemological and didactic contributions and applied it to the domain of algebra. The *a priori* analysis gives access to the conditions for item success and allows an *a posteriori* interpretation of the groups to which characteristic items. We then associate a level of mathematical activity for algebra with each group on the performance scale. One limitation of the study is that it focuses only on the domain of algebra and only on the CEDRE 2019 assessment. However, the approach seems transferable to other mathematical domains and other assessments, in particular the national diagnostic assessments at the beginning of the year offered at all school levels in France.

We hypothesize that this new characterization of groups will be a lever to make the CEDRE results more usable by trainers and inspectors in the service of teachers' practice and students' learning. With an appropriate transposition, carefully highlighting what distinguishes one group from another, this new characterization can be used in training courses to indicate what is a priority in regulating teaching and supporting students in their learning.

Changing the assessment paradigm – What predicts students' choice of assessment method in an undergraduate mathematics course?

Johanna Rämö[1], Liisa Myyry[2], Jokke Häsä[3] and Yan Zi[4]

[1]University of Eastern Finland, Finland; johanna.ramo@uef.fi

[4]The Education University of Hong Kong, Hong Kong

In this paper, we investigated undergraduate students' perceptions on mathematics assessment by letting them choose the summative assessment method in a mathematics course and studying what predicts their choice. The participants (n=333) were given two choices for the summative assessment method of the course: they could choose whether their grade was determined by self-assessment or examination. Using deductive content analysis, we analysed the justifications students gave for their choices. Most common reasons for the students' choices were Perceived usefulness, Psychological safety and Affective attitude. A further inductive content analysis revealed that in these categories students valued learning gains, accuracy of assessment, absence of stress, and new experiences. The results give indications on what aspects should be considered when designing university mathematic assessment, especially when introducing new assessment methods to students.

Keywords: Self-assessment predictors, student perceptions, undergraduate mathematics.

Introduction

Assessment is changing in universities to reflect the needs and affordances presented by the modern society. For some time already, researchers have emphasised the need to increase student agency in assessment (Adie et al., 2018). Recently, the COVID-19 pandemic shook the academia as teachers were forced to find innovative methods to compensate for the lack of traditional classroom exams. One such method is self-assessment. Self-assessment has the benefit that it is independent of time, space and equipment constraints. It can also not be outsourced to another person. Moreover – and more importantly – practising self-assessment increases self-regulation and reflection skills (Panadero et al., 2017) and it is an important aspect of *authentic assessment*, as it is necessary for successful workplace performance and personal development (Ashford-Rowe et al., 2014).

Despite the benefits associated with alternative assessment methods, the academic community seems resistant to changing the prevailing testing and grading focused assessment practices, making self-assessment applications relatively rare at the course-level (Boud et al., 2016). Some studies have found that in mathematics, not only teachers but also students prefer traditional closed-book exams, as they find them the most accurate and trustworthy assessment method (Iannone & Simpson, 2017). Therefore, to change the assessment culture, one of the things we need to understand are the factors that influence students' attitudes towards assessment. As students' preferences may depend on the field they study and its traditional assessment regime (Iannone & Simpson, 2017), it is important to study student perceptions in different disciplines.

Self-assessment predictors and perceptions

Self-assessment has garnered increasing interest due to its promising impact on self-regulated learning (Panadero et al., 2017) and academic achievement (Yan et al., 2022). As self-assessment is a learning process that demands volitional effort and commitment, it is crucial to pinpoint the factors that could influence or predict self-assessment. This is particularly relevant in the context of digital learning environments where students are expected to be autonomous learners, responsible for conducting learning activities such as self-assessment independently and under their own control. A lack of comprehension regarding the potential facilitators and obstacles of self-assessment may impede the realisation and optimisation of its benefits.

A review by Yan et al. (2023) found that both individual and instructional factors play a role in shaping students' engagement with self-assessment. Individual factors refer to students' cognitive and psychological needs and include *Perceived usefulness*, *Affective attitude*, *Self-efficacy*, *Important others' opinions*, and *Psychological safety.* Instructional factors encompass how the teaching is organised. They comprise *Practice and training, External feedback, Use of instruments, Environmental support, and Self-assessment purpose*.

In this paper, we study self-assessment predictors of mathematics undergraduate students. In mathematics, assessment practices differ from many other fields. In Finland, the most common assessment method in school mathematics is a closed-book exam (Atjonen et al., 2019). Alternative assessment methods such as self-assessment and peer assessment are more common in other subjects than mathematics. This means that it is very likely that students entering university mathematics courses do not have any experience of alternative assessment methods in the context of mathematics. In what comes to university mathematics, Iannone and Simpson (2022) have found that assessment is still very traditional in the UK: exams dominate university mathematics assessment heavily.

Also, student perceptions on assessment are different in mathematics than in many other fields. In their review, Struyven et al. (2005) reported that, in general, higher education students think that alternative assessment methods enabled a better quality of learning and were fairer than traditional methods. However, their review did not investigate disciplinary differences in student perceptions. Iannone and Simpson (2015), on the other hand, have studied mathematics students in British universities and found that they prefer closed-book exams and other traditional assessment methods. When comparing mathematics students and education students in the UK, Iannone and Simpson (2017) found differences. Both student groups preferred assessment methods that differentiated students with respect to academic ability. However, education students thought that projects and dissertations achieved this purpose, whereas mathematics students thought closed book exams were better in this regard.

Based on the evidence above, disciplinary factors need to be taken into account when studying students' perceptions of assessment. In this study, the novelty is analysing self-assessment predictors in the context of mathematics and describing mathematics students' reasons for choosing between self-assessment and a more traditional option, the exam. Another new viewpoint in our study is the element of real choice: students must choose whether their grade is determined by self-assessment or

examination. We use the framework by Yan et al. (2023) to analyse what explains the students' choice. Our research questions are the following:

1. Which factors explain students' choice of assessment method (self-assessment or examination) in an undergraduate mathematics course?
2. How are these factors manifested in students' justifications for their choice of assessment method?

Context and participants

The participants of the study were undergraduate students in a Finnish research-intensive university. They took part in a first-year linear algebra course, which lasted 7 weeks and was worth 5 credits (ECTS). Typical major subjects among the students were mathematics (including mathematics education), computer science, statistics, economics, and physics. For most students, the course was their first university mathematics course. The teacher of the course was the first author of this paper.

During the course, all students were engaged in a structured self-assessment process in which they assessed their competencies, using a rubric designed by the teacher (see the DISA model; Häsä et al., 2021). They completed three self-assessment exercises, in which they assessed what skills they mastered. The rubric used in the self-assessment contained mathematical skills, such as "I know what a subspace spanned by one or two vectors looks like," and generic skills, such as "In my answers, I write complete and comprehensible sentences that others can understand." It should be noted that the students did not assess a product they had produced, but rather the competencies they had gained so far. Students were offered automated feedback on the accuracy of their self-assessments via the digital DISA tool (Häsä et al., 2021), which compared students' assessments against the weekly mathematical tasks they had completed during the course.

At the end of the course, the students' grades were determined by either self-assessment or exam. The students had to choose *at the beginning of the course*, which kind of summative assessment they wanted to take. If a student chose self-assessment for the summative assessment method, they completed one more self-assessment at the end of the course and gave their own grade. Students' assessments were checked against the mathematical tasks they had completed, using the same DISA tool that generated the feedback in the self-assessment exercises. If a student's self-assessment was significantly different from the work they had done, the teacher had a possibility to intervene. For students who chose the examination as the summative assessment method, the grade was determined by an exam along with bonus points earned from weekly tasks.

At the beginning of the course, the students were explained the different summative assessment options of the course. Because self-assessment in the context of mathematics was new to many students and all students would do self-assessment exercises, the teacher explained to the students what the benefits of self-assessment are. After this, the students chose the summative assessment method they wanted to take (exam of self-assessment) and gave a justification for the choice. However, the students could change their choice before the end of the course if they wanted to.

The participants of the study were the 333 students (86% of the course population) who gave their informed consent for using their responses in research purposes. The data consists of the justifications the students gave for their choice of assessment method ("On what basis did you make your choice?"). These justifications were non-anonymous and were collected in the second week of the course. The Moodle platform that was used in the teaching of the course was also used for data collection. Of the participants, 83% (n=275) chose self-assessment and 17% (n=58) examination.

Method

The students' answers were coded with the Atlas-ti programme for qualitative data analysis. The justifications ranged from a few words to several sentences, and each justification could include several reasons for the choice. Each reason formed one analysis unit. Altogether, 1147 analysis units were identified, which makes an average of 3.44 analysis units per student.

First, a deductive content analysis (Elo & Kyngäs, 2008) was performed based on the framework by Yan et al. (2023). The first and second author conducted the analysis by first familiarising themselves with the data, then discussing the interpretation of the categories given by the theoretical framework, and finally analysing one half of the data each. Since the students had made their choice of the assessment method at the beginning of the course, their justifications concerned individual factors rather than instructional factors. Therefore, the categories of the content analysis were chosen to be the individual factors of the theoretical framework: *Perceived usefulness*, *Affective attitude*, *Self-efficacy*, *Important others' opinions*, and *Psychological safety*. As the context of the study was quite specific, a new category, *Need of flexibility,* had to be created. Six analysis units were difficult to interpret and could not be coded. After the deductive analysis, an inductive content analysis (Elo & Kyngäs, 2008) was performed within each of the three largest categories, dividing them into subcategories. The inductive analysis was performed by the first author.

Results

The distribution of students' justifications into different categories is given in Table 1. Numbers reported in the table are students, and the percentages represent column-relative frequencies. The largest categories found in students' answers were Perceived usefulness, Affective attitude and Psychological safety. Of the students who chose self-assessment, 46% made a justification concerning Perceived usefulness, 27% concerning Psychological safety and 27% concerning Affective attitude. Among the students who chose the examination, Perceived usefulness was found in 17%, Psychological safety in 36% and Affective attitude in 24% of the answers. Since these three categories were large, a further inductive content analysis was applied to them.

Many of the students who reported Perceived usefulness anticipated that the chosen assessment method would improve their *learning*:

> I believe that self-assessment supports deeper learning more effectively, because often when studying for an exam, learning may remain superficial.
>
> Preparing for an exam requires reviewing topics and browsing through the subject area, which strengthens my skills and learning.

Table 1: Distribution of students' justifications for the choice of summative assessment method

Predictor		Student choice	
		Self-assessment (*n*=275)	Examination (*n*=58)
Perceived usefulness		127 (46%)	10 (17%)
	learning	52 (19%)	6 (10%)
	behaviour	30 (11%)	4 (6.9%)
	self-assessment skills	45 (16%)	0
	usefulness in general	13 (4.7%)	0
Psychological safety		75 (27%)	21 (36%)
	accurate measurement	45 (16%)	11 (19%)
	stress-free	39 (14%)	11 (19%)
Affective attitude		73 (27%)	14 (24%)
	interesting	60 (22%)	0
	pleasant	15 (5.5%)	14 (24%)
Self-assessment self-efficacy		20 (7.2%)	11 (29%)
Important others' opinions		4 (1.5%)	0
Need of flexibility		49 (18%)	0

Students also felt that the choice of assessment method would affect their *behaviour* during the course:

> I believe that by choosing self-assessment, I will invest more effort in the weekly assignments. This way, the learning process will be more consistent, and I will likely remember things better even after the course.
>
> I feel that taking an exam at the end of the course motivates me to work hard during the course more than self-assessment.

The students who chose self-assessment mentioned also that it improves their *self-assessment skills*, which would be useful in their studies or in working life. These justifications did not appear in the answers of those students who chose the examination. Finally, there were students whose justification was just a *general mention of usefulness*.

The second largest main category was Psychological safety. In this category, many students wanted the assessment method to *measure their skills accurately*:

> Self-assessment might better reflect the overall skills and work done throughout the course, an exam can sometimes go surprisingly poorly.
>
> I believe that taking an exam is a more reliable way to obtain information about the understanding of course topics than self-assessment.

Another common justification in this category was to choose an assessment method that felt *stress-free*. Many students found exams stressful: "Exam situations make me nervous, and I can't do my best work under a strict time limit." On the other hand, some students were more comfortable with exams than self-assessment: "Familiar and safe". Students also evaluated the risk level of the assessment method. For example, they wanted to make sure they would pass the course or receive a good grade.

The third largest main category was Affective attitude. In this category, students reported *interest* towards self-assessment: "I also think this kind of final assessment method sounds interesting, and I haven't tried it before." However, none of the students who chose the examination mentioned interest or curiosity towards it. In addition, students justified that either self-assessment or exam was a *pleasant* choice. They liked the assessment method, or it felt natural for them.

The remaining main categories were considerably smaller than the three biggest main categories, so they were not split into subcategories. Self-assessment self-efficacy included students' answers in which they stated that they either can or cannot assess their own skills. In the category Important others' opinions, students had been impacted by their teachers' motivational speech or more experienced students' opinions.

The category Need of flexibility was added to the framework and was specific to the context of this study. The self-assessment could be done online, during several days, but for the examination, students had to come to the campus at a specific time. Many students who chose self-assessment reported that they appreciated the flexibility of the assessment method.

Discussion

In this study, we let mathematics undergraduate students choose the summative assessment method of a course from two options: self-assessment and examination. The chosen method determined the student's grade. We analysed students' justifications for their choice using content analysis based on the framework by Yan and colleagues (2023).

Our results show that the usefulness of the assessment method was important to the students, in particular in what comes to learning gains, organising one's studying and learning skills that are relevant for life-long learning. This aligns with findings in other disciplines such as engineering education (Partanen et al., 2023). The students also valued self-assessment skills and felt they would be important to them in the future.

A second prominent category in students' answers concerned psychological safety. Students wanted to choose the assessment method that measured their skills better. This is in line with Iannone and Simpson (2017). It is notable that many students thought that self-assessment is more accurate than the examination. Regarding psychological safety, students also reported feeling stress and anxiety about exams and therefore chose self-assessment. On the other hand, there were students who were uncomfortable with self-assessment and chose examination instead.

Also, the affective factors played a major role in students' justifications. Many students were interested in trying a new assessment method. This is different from the studies of Iannone and Simpson (2015; 2017) who found that mathematics students prefer traditional assessment methods. Even though the studies cannot be compared directly – their students were in a mathematics programme whereas our students were merely students in a mathematics course – there are indications that something in our context encouraged students to have a positive attitude towards alternative assessment methods. It may be due to the way self-assessment was presented to them, or the Finnish education system in which grades do not play a major role. It was beyond the scope of this study to analyse the relationship of students' study programme and the justification they give for the choice of assessment method, but in the future, this would be worth investigating.

It is likely that not all students' justifications reflect their perceptions exactly. The students' answers were not anonymous, and they might have felt that certain kinds of answers were not appropriate. For example, it is likely that some students thought that they needed to give a rational justification and not mention their emotions. However, emotions have a central role in shaping students' perceptions on assessment (Crossman, 2007), and they should not be overlooked. In the future, interviews could provide a more nuanced and multidimensional insight into students' perceptions.

Our study sheds light on the aspects of assessment that are important to the students. This information can be used in organising assessment and communicating about it to the students – in particular, when encouraging students to try out a new form of assessment such as self-assessment. Our results indicate that teachers should emphasise the learning gains and relevance for working life, make sure that students feel that the assessment method is accurate and fair, reduce the stress experienced and offer flexibility in the assessment arrangements. However, one should be careful when generalising our results to different socio-cultural contexts.

Using subscores from the high-stakes assessment to explain first-year performance in Mathematics courses

Tatiana Sango[1]

[1]University of Cape Town, Centre for Educational Assessments, Cape Town, South Africa; tatiana.sango@uct.ac.za

The use of data analytics in predicting student success in first-year courses has been gaining momentum in South Africa. With that, various assessment data points are used to map out incoming students' academic profiles and help design curriculum support mechanisms. Scores on the high-stakes assessment subdomains could be used to explain the variance in course performance and suggest that subdomains with the greatest relative importance have the strongest association with the variance in performance in a course. Calculating subdomain scores (subscores) and establishing the meaningful weighting of each subdomain in a test is important. This study compares how different subscore calculation methods, such as IRT and number-correct, affect reporting and the ranking of subdomains in a relative importance analysis of a first-year mathematics cohort.

Keywords: Test scores, IRT, relative importance analysis, high-stakes tests, subscores.

Introduction

The use of data analytics in student success initiatives has been gaining momentum in South Africa. Various assessment data points, such as matric results in the National Senior Certificate (NSC) subjects and the National Benchmark Tests (NBT) scores, are used to understand incoming students' academic profiles and help design curriculum support mechanisms. The NBT is a high-stakes assessment which offers higher education institutions supplementary information to support the selection and placement of prospective students into suitable academic pathways. It assesses students' readiness for higher education studies in Academic Literacy (AL), Quantitative Literacy (QL) and Mathematics (MAT) domains. Students who take the MAT test typically aim to enrol in mathematically demanding disciplines, such as Engineering, Health Sciences, or Commerce, and most sit for the test during their final year of Grade 12. The MAT assessment probes their depth of understanding and knowledge of mathematical concepts essential for success in these fields. The test is 3 hours long and is developed by subject matter experts from participating universities (NBT, 2023).

In recent years, the decision was made to report on the proficiency of incoming first-year student cohorts at the test subdomain level. Understanding the AL, QL and MAT subdomain scores is considered valuable for identifying areas where prior learning may influence first-year performance. Subdomain scores are used to explore their relationship with historical course outcomes, and relative importance analysis (RIA) explains variance in course performance, highlighting the subdomains most strongly associated with that variance (DASS, 2024). One suggested intervention described by Naidoo (2023) integrates this information into the first few weeks of first-year courses to support concept development and address possible gaps identified by the NBT diagnostics.

This paper presents an initial investigation into the impact of calculating the subscores using the item-response theory (IRT) and the traditional number-correct method on the order of subdomains in the relative importance analysis for a first-year Engineering mathematics course.

Theoretical framework and research questions

NBT employ item response theory to estimate the test-taker's proficiency in Academic and Quantitative Literacy and Mathematics. These assessment domains, AL, QL and MAT, are each defined by a framework that outlines specific content areas, skills and abilities, organised into subdomains and clusters of items (NBT, 2023). The MAT test specification comprises items that are distributed across multiple competence areas, subdivided into different clusters, and categorised according to cognitive level. The NBT Mathematics domain is further divided into five subdomains, with each having an established weighting in a test blueprint (see Table 1).

Table 1: NBT Mathematics domain and subdomains

M1 - Algebraic processing (25% - 30%) = 15 scored items	Involves recognising and manipulating patterns, sequences, and algebraic expressions, solving exponential equations, and interpreting measurement-related problems.
M2 - Number sense (8% - 10%) = 4 scored items	Encompasses operations with various types of numbers, understanding number systems, performing calculations without the need for calculators, and making mathematical judgments.
M3 - Functions and graphs (20% - 25%) = 12 scored items	Focuses on understanding and analysing functions and their properties, interpreting and solving related graph problems, and applying principles of differential calculus.
M4 - Trigonometric functions and graphs (15% - 20%) = 9 scored items	Involves solving trigonometric equations, understanding trigonometric identities, and applying trigonometric concepts to two- and three-dimensional problems.
M5 - Geometric reasoning (20% - 25%) = 12 scored items	Includes understanding properties of shapes, calculating perimeter, area, and volume, and linking geometric properties with algebraic concepts.

The cognitive skills needed across the MAT subdomains are categorised into four cognitive levels: Knowing (recall, simple routine procedures; about 44% of the test), Performing routine procedures (all information is directly available; about 23% of the test), Performing complex procedures (a strategy is required to identify information; about 25% of the test), and Solving problems, reasoning and reflecting (complex contexts and procedures; about 8% of the test).

Multiple test forms are assembled and administered in each testing cycle, with a total of 52 scored items across five subdomains. The assumption is that, in addition to the overall mathematics ability measured by the MAT test, there are potentially some unique traits being measured by these subdomains. It was established that the data can be efficiently modelled with the three-parameter logistic (3PL) IRT model, whereby parameters of discrimination (a), difficulty (b) and pseudo-guessing (c) are estimated, which is appropriate for achievement-type tests where guessing can play an important role in examinee responses. The test forms are further linked by common items referred to as anchor items. The linking and equating process is performed based on a linear transformation using the Stocking & Lord method (1983), which implies rescaling the item parameters from the X form (current) to the Y form (base) (ASC, 2012).

Research questions:

- Given the current test framework, what can be observed about the reporting of subscores?
- How does the method of calculating subscores impact the ranking of subdomains in the relative importance analysis?

IRT-based subscores

There are numerous studies of different methods of subscore calculation and reporting in educational assessments, highlighting common issues related to test design and reliability. One notable concern is the total test length and the distribution of items across subdomains or sections of the test, which may impact the reliability of the obtained scores. A common method of calculating subdomain scores is by dividing the number of items answered correctly by the total number of items in each subdomain, which is used to report the percentage of correct responses. These indicators are then aggregated for a larger group of candidates to observe proficiency in the subdomain of interest. The problem associated with this method is often reported in the literature, with the main concern raised about the number of items in a test subdomain (Fan, 2016; Hambleton,1980; Kern, 2007; Provasnik et al., 2020). A lower number of items often leads to low reliability and could also make room for inaccurate interpretations, where the subdomain scores are used for making curriculum adjustment decisions. Looking at this from another angle, the raw (number-correct) scores are not necessarily accurate reflections of a test taker's ability, and more than a handful of items would be required to gain a more accurate understanding of a person's proficiency in a subdomain. These concerns could be partially elevated using a different method of calculating the subdomain scores, such as the Item Response Theory (IRT). One of the benefits of IRT is that it estimates the probability of a correct response on an item for a student of a particular ability estimate, which could address the concern of a low number of items in a test subdomain.

Many high-stakes assessments are not designed to be multidimensional, limiting their ability to provide an accurate representation of students' abilities in content areas defined by specific subdomains. The assessment instrument in this study exclusively consists of multiple-choice questions; thus, the data under consideration is binary, based on dichotomous item responses (correct or incorrect). Bejar (1980) notes that factor analysis of binary data can often be problematic and proposes the use of IRT for investigating test dimensionality. In this method, the assumption is made that item parameters should remain consistent between total-test-based estimates and content-area-based estimates. If the parameters differ, then the probability of passing the item will differ for a given level of achievement. This suggests that performance on a given item depends on performance in other items in the same test form.

When choosing a method of calculating the subscores, some studies have shown that IRT-based scores are better (or similar) predictors of performance than number-correct scores (Bock et al., 1997; Camilli & Dossey, 2019; Kreitchmann et al., 2024), and other studies argue against this claim (Ferrando & Chico, 2007; Kern, 2007). This divergence in findings underscores the importance of considering multiple perspectives when interpreting test results and making further inferences about student performance. There is agreement in the literature that a nuanced approach to subscores

calculation and reporting is necessary, and often, it is a combination and augmentation of different methods that leads to improved accuracy and reliability.

Methods

Two data sets of test scores were used in this study. The item responses of 3 354 examinees from a single administration of a MAT test form were used to estimate IRT parameters. These parameters were estimated in two different ways, and the item difficulty parameters were compared between the total-test-based estimates and content-area-based estimates. The subscores were then calculated from the total-test-based parameter estimates for a smaller data set (n = 144), and IRT-based subscores were compared to number-correct subscores. These subscores were used in a relative importance analysis to assess the contribution of MAT subdomains as predictor variables for final results in the first-semester mathematics course.

Step 1: Choice of parameter estimation method and reliability of subscores

The program Xcalibre Version 4.2 (Guyer & Thompson, 2011) was used to estimate item parameters for the normal approximation (D = 1.7) of the three-parameter logistic model. Xcalibre implements marginal maximum likelihood estimation of IRT item parameters. As the subscores on the MAT test are of interest to this study, some elements of Bejar's method were considered useful in evaluating item parameter estimation methods. The estimated *b*-parameters were compared across the test items between the total-test-based estimates and content-area-based estimates.

Step 2: Comparison of IRT-based and number-correct subscores

The number-correct subscores method involves calculating the percentage of items answered correctly within a specific subdomain. For example, if a student answers 6 out of 12 questions correctly in a geometric reasoning subdomain, their number-correct score (as a percentage) would be 50%. This method is straightforward but does not account for the difficulty of items or the underlying ability of the test-taker. Additionally, the possible number-correct scores in a subdomain with 4 items will always be 0%, 25%, 50%, 75%, or 100%. In contrast, IRT-based subscores utilise a probabilistic model to estimate a student's ability based on their responses to test items. IRT models consider item characteristics, such as difficulty and discrimination, allowing for a more nuanced understanding of a student's abilities. For instance, a student might perform well on difficult items, indicating a higher ability level than suggested by a simple number-correct score.

Step 3: Comparison of the impact on RIA and what could this mean in practice

When dealing with multiple predictors, a key question is which one is most important for predicting the outcome variable. Although correlation indicates the relationship between two variables, it is not effective with multiple predictors. A recommended approach is to calculate the "relative importance" of predictors. Relative importance package `realimpo` with the recommended metric `lmg` provides a decomposition of the model-explained variance into non-negative contributions (Groemping, 2006). The relative importance analysis based on the method by Lindeman, Merenda, and Gold (1980) is a variance decomposition of correlated predictor variables (each predictor's contribution to R-squared) that tells you how much of the variance in the model is explained by each predictor.

Results

In 3PL models, the distribution of *b*-parameters gives insight into the spread and range of item difficulties. Comparing *b*-parameters across test items between total-test-based and content-area-based estimates revealed differences, with the difficulty level in subdomains with fewer items estimated significantly higher in the content-area-based method (see Table 2). When scored using both parameter sets, the M2 subdomain, having the fewest items, showed a weaker correlation with the total MAT score: 0.5039 with content-area-based estimates compared to 0.6169 with total-test-based estimates. Thus, the total-test-based estimation method was preferred.

Table 2: Parameter estimates and MAT score correlations

	M1	M2	M3	M4	M5
Mean *b*-parameter estimates: Total-test-based	0.68353333	1.58425	0.64825	0.94233333	0.86733333
Mean *b*-parameter estimates: Content-area-based	0.746	2.759	0.73133333	1.10811111	1.00391667
MAT score correlation: Total-test-based	0.8992	0.6169	0.8797	0.8223	0.8542
MAT score correlation: Content-area-based	0.9002	0.5039	0.8844	0.8150	0.8426

A cohort of Engineering students in a first-year Mathematics course wrote this test at the start of the semester. The subscores were calculated (after equating to the base form) for a sample of 144 Engineering students in a first-year Mathematics course who remained enrolled in the course and received final results for the first semester. Table 3 provides an overview of the full test, including its subdomains (M1 to M5). The reliability of the full test (51 calibrated items, 1 item was removed due to a low discrimination parameter) is high, with a Cronbach's alpha of 0.876, indicating strong internal consistency, but the subdomains' reliability differs. Subdomain M1 has acceptable reliability (0.705), and subdomains M3 and M5 show moderate reliability, with alpha values of 0.621 and 0.657. However, subdomains M2 and M4 have very low alpha values (0.363 and 0.501, respectively), which could be due to the number of items associated with each subdomain (4 items and 8 items, respectively). Notably, M2 (0.609) and M4 (0.700) also show relatively lower correlations with the total test score compared to the other subdomains.

Table 3: Cronbach's Alpha for the Full Test and Test subdomains

Test	Full Test	M1	M2	M3	M4	M5
Items	51	15	4	12	8	12
Alpha	0.876	0.705	0.363	0.621	0.501	0.657
Full Test Scores Correlations	1	0.848	0.609	0.810	0.700	0.832

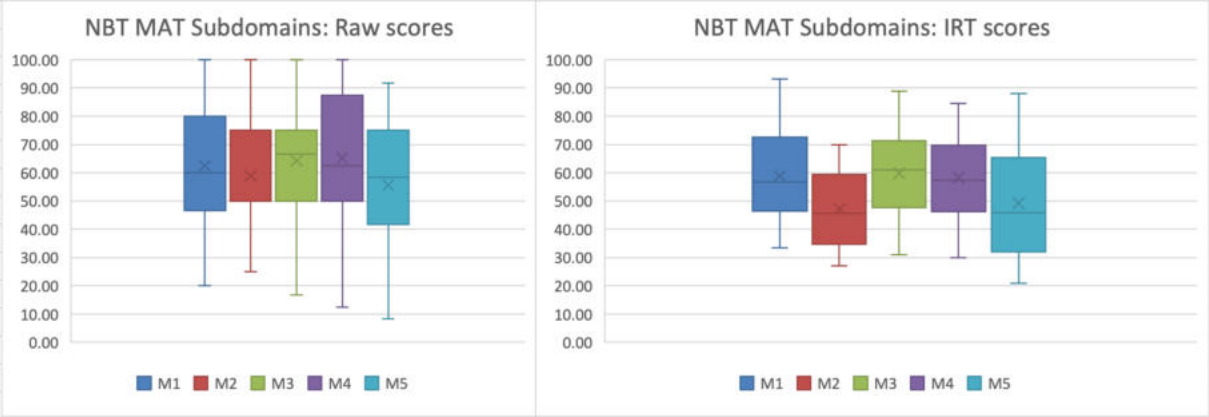

Figure 1: Distribution of scores within subdomains, n = 144

The distribution of scores within subdomains and the relative importance analysis were done on a smaller sample (n = 144) of first-year students in a mathematics course who had their final first-semester course scores. This is a first-year Engineering calculus course and includes concepts such as Functions, Limits, Continuity and Differentiability.

Score distributions within each subdomain are shown in Figure 1. IRT appears to offer a more normalised scoring method across subdomains, reducing the variability across different subdomains, while raw scores (number-correct) capture the direct, unadjusted performance. The IRT scores distribution within subdomains shows that it takes into account a person's ability in all items on the test and provides an estimate of their ability within a specific subdomain. In simpler terms, even if a student answers no questions correctly in a subdomain with fewer items (e.g., Number sense with a

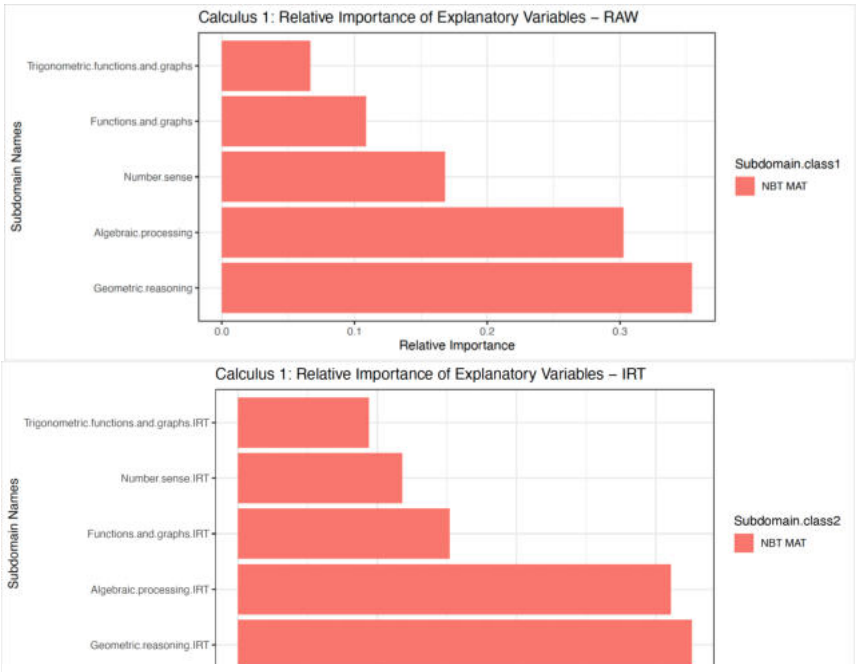

Figure 2: Relative Importance based on raw subscores and IRT, n = 144

total of 4 items in the test), it doesn't necessarily mean that the student has zero proficiency in that subdomain. We can assume that the level of proficiency is low, but not non-existent.

The relative importance is shown in Figure 2, which shows that geometric reasoning comes as the strongest of the five subdomains, closely followed by algebraic processing. Geometric reasoning involves higher-order thinking, and its cognitive complexity could potentially serve as a proxy for performance in first-year calculus. It is expected that algebraic processing is one of the strongest predictor variables; however, it might be surprising that functions and trigonometry are two of the lowest subdomains. In the case of IRT-based subscores, the number sense subdomain gave way to the functions and graphs subdomain.

- RAW (number-correct): Total R-squared is 21.5% - meaning that 21.5% of the variation of grades in this course is explained by NBT MAT.
- IRT: Total R-squared is 20.7% - meaning that 20.7% of the variation of grades in this course is explained by NBT MAT.

RIA on IRT-based subscores and number-correct scores do not show very different pictures, but a slight change in the order of the two subdomains. In both models, geometric reasoning is important, but it is statistically significant in the raw score model (p-value = 0.0396) and only marginally significant (p-value = 0.0704) in the IRT model. Other subdomains (Number sense, Functions and graphs, and Trigonometric functions and graphs) were insignificant (p-values > 0.05) in both methods, with only minor changes in their coefficients.

The IRT method may offer improved measurement precision, but in this case, it has not drastically altered the overall interpretation of subdomain importance. Geometric reasoning had the highest relative importance indicator, and students' scores in this cohort showed greater variability in this subdomain (see Figure 1).

Concluding remarks and further research

With the decision to use subdomain scores for further interpretation, more efforts should be made to improve the accuracy and significance of predictions. While the relative importance output in this study of a course cohort was similar, a larger data set will be necessary to understand the impact and differences in subdomain score calculations. It will also be important to understand the effect of predictors on student performance when integrated with intervention strategies.

The use of other models, for example, the score augmentation method of supplementing subdomains with a low number of test items, can provide scope for more accurate subscore estimates. The least stable subdomains could be supplemented with additional information, such as performance in Quantitative Literacy items that are relevant to Mathematics items, particularly in MAT subdomains with fewer items (M2 and M4). Additionally, the ideal weighting of each subdomain (the number of items) in the test may need refinement to improve subscore reliability. A relative importance analysis based on cognitive levels, rather than (or in addition to) subdomains, which often show high correlations and overlap in the skills and concepts tested, could also provide a new direction for improving reporting to better inform intervention design.

The role of digital tools in enhancing classroom assessment practices

İpek Saralar-Aras[1] and Sümeyra Tütüncü[1]

[1]Ministry of National Education, Türkiye, sumeyratutuncu@gmail.com

As educational technology becomes increasingly embedded in classrooms, it is crucial to understand how these tools are utilized for both formative and summative aspects of teachers' assessments in the classroom. Through a combination of surveys and semi-structured interviews, the study probes teachers' experiences with technology-enhanced assessments. The findings highlight the benefits of digital tools, such as increased student motivation, immediate feedback, and improved visualization of mathematical concepts. However, the study also reveals the challenges teachers face, including technical difficulties, inequities in access to technology, and the added workload associated with using these tools. The study contributes to a deeper understanding of how digital tools can enhance assessment practices in middle school mathematics, offering insights into the opportunities and obstacles faced by teachers in Türkiye.

Keywords: Formative assessment, summative assessment, technology-enhanced classrooms

Introduction

Digital tools have increasingly become integral to educational environments, particularly in mathematics classrooms (Hillmayr et al., 2020, Moliner et al., 2022). These tools offer various advantages that significantly enhance classroom assessment practices (see Saralar-Aras, 2022). In middle school mathematics, tools like dynamic geometry software, graphing calculators, and online platforms provide teachers with innovative ways to assess student learning.

Formative assessments, which function as improving student learning through adjusting learning environments, are enhanced through the use of digital tools by providing immediate feedback, allowing for real-time adjustments to instruction, and facilitating a more personalized learning experience (Cosi et al., 2020). Teachers can use these tools to identify student strengths and weaknesses more efficiently, enabling a targeted approach to instruction. Digital platforms also allow for continuous monitoring of student progress, making formative assessments more dynamic and responsive to individual student needs. Summative assessments, traditionally used to evaluate student learning at the end of an instructional period (Brookhart, 2001), are also transformed by digital tools (Newhouse, 2014). These tools can automate scoring, offer diverse question types, and provide more detailed analytics, allowing teachers to better understand student outcomes. Furthermore, the visualization capabilities of digital tools help students get better understanding of tasks which facilitates more accurate assessment of their knowledge. However, while digital tools offer numerous benefits for assessment, they also come with challenges (Onasanya & Ajamu, 2024). Issues such as inequity in access to technology, technical difficulties, and the potential for misuse must be addressed to fully harness the potential of digital tools in classroom assessments.

Literature review

Introduction to educational technology in mathematics education

The integration of digital tools in mathematics education has significantly transformed teaching and assessment practices over the past few decades. As early as the 1990s, educational researchers began to explore the potential of technology to enhance learning, with a particular focus on its applications

in mathematics (Kaput, 1992). Today, educational technologies such as dynamic geometry software, graphing calculators, and online platforms have become integral components of middle school mathematics classrooms. These tools provide interactive and accessible ways to deepen students' understanding of mathematical concepts while offering new avenues for both formative and summative assessments.

Formative assessment and digital tools

Formative assessment is an ongoing process used by teachers to monitor student learning, provide feedback, and adjust instruction to improve student understanding and performance throughout a lesson or unit (Cosi et al., 2020). It is a critical component of effective teaching, providing teachers with ongoing insights into student learning and guiding instructional decisions (Black & Wiliam, 2018). Digital tools have been shown to enhance formative assessment practices by enabling immediate feedback, which is essential for adjusting teaching strategies in real-time (Shute, 2008). In addition, dynamic geometry software like GeoGebra allows students to visualize and manipulate geometric concepts, facilitating deeper engagement and understanding (Hohenwarter & Jones, 2007). Teachers can use these tools to create interactive tasks that make students' thought processes visible, aiding in assessment by providing insights into students' reasoning and understanding. By observing students' actions and choices within the software, teachers can gather valuable data that reflects student comprehension, thereby enhancing formative assessment.

Research suggests that when teachers use digital tools for formative assessments, they can more effectively identify student strengths and areas for improvement (Nicol & Macfarlane-Dick, 2006). Furthermore, online platforms and educational apps enable continuous monitoring of student progress, allowing for a more personalized approach to learning. This capability aligns with the growing emphasis on differentiated instruction in mathematics education, where teachers tailor their teaching strategies to meet the diverse needs of students (Tomlinson, 2014).

Summative assessment and digital tools

Summative assessments, aimed at evaluating student learning at the conclusion of instructional periods, have been notably transformed by digital tools. Traditionally confined to paper-based tests, which are often time-intensive to administer and score (Brookhart, 2001), summative assessments now benefit from digital tools that offer automated scoring, diverse question formats, and in-depth analytics, enabling nuanced insights into student performance (Onasanya & Ajamu, 2024). For example, tools like graphing calculators and software such as GeoGebra empower students to engage with complex mathematical problems, allowing educators to assess higher-order thinking skills that are difficult to capture through traditional assessments.

Moreover, integrating digital tools in summative assessments fosters alignment with learning objectives, enabling teachers to design tasks that more authentically mirror real-world applications of mathematics (Hillmayr et al., 2020). The visualization capabilities of these tools aid in deepening students' comprehension of abstract mathematical concepts, thus enhancing the accuracy of knowledge assessments (Clements & Sarama, 2011). Consequently, digital summative assessments not only streamline scoring and expand task diversity but also contribute to a more meaningful evaluation of student understanding.

Challenges in the use of digital tools for assessment

While digital tools offer numerous benefits for formative and summative assessments, their use also presents several challenges. One of the primary concerns is inequity in access to technology, which can exacerbate existing educational inequalities. In middle school mathematics classrooms, not all students may have access to the necessary devices or internet connectivity, creating barriers to effective assessment (Warschauer & Matuchniak, 2010). Additionally, technical difficulties, such as software glitches or connectivity issues, can disrupt the assessment process, leading to frustration for both teachers and students (Inan & Lowther, 2010).

Another challenge is the potential for digital tools to increase the workload for teachers. The implementation of technology-enhanced assessments requires significant time and effort, including learning how to use the tools, creating digital assessment tasks, and interpreting the data generated by these tools (Ertmer & Ottenbreit-Leftwich, 2010). Moreover, managing large groups of students in a technology-enhanced environment can be difficult, particularly when trying to ensure that all students are actively engaged and on task (Sawyer, 2006).

In the context of middle school mathematics in Türkiye, the role of digital tools in enhancing classroom assessment practices is multifaceted (Cumhur & Çam, 2021; Özpınar, 2020). It involves balancing the benefits of immediate feedback and personalized learning with the challenges of accessibility and teacher preparedness. As digital tools continue to evolve, their role in classroom assessments will likely expand, offering new opportunities to enhance student learning outcomes. In this context, we looked at the following research question: How do middle school mathematics teachers in Türkiye perceive the role of digital tools in enhancing classroom assessment practices?

Methods

Research design

This study was designed as a qualitative research project with some quantitative elements and conducted in two phases. In the first phase, 16 middle school mathematics teachers completed an online survey. Participants were purposively selected to ensure diversity in regional representations across Türkiye and included experienced teachers with at least five years of teaching experience. 13 teachers had over 10 years of experience while 3 had between 6 to 10 years.

The survey aimed to gain comprehensive insights into teachers' use of technology for assessment purposes focusing on five aspects: (1) the digital tools used for assessment; (2) examples of their preferred practices; (3) challenges and limitations faced; (4) professional development support received and (5) teachers' anticipations for future development of technology in assessment. It involved both close-ended and open-ended questions. To show the idea of it, a sample question from the survey was "Could you share an example of an effective and/or innovative classroom practice where you used digital technologies for assessment?". The close-ended questions gathered demographic information, identified the type of digital tools used, and assessed the frequency of their use, and inquired about professional development sessions attended that can assist their use of technology for assessment. The open-ended questions asked teachers to provide detailed responses

about their preferred practices, the challenges they encountered and their anticipations regarding the future technologies in assessment. The survey was administered electronically via Google Forms.

In the second phase, 6 teachers were selected for semi-structured interviews from the 16 who completed the survey. Selection was based on two criteria: first, these teachers demonstrated more frequent or varied responses compared to others; second, they represented diversity in gender and geographical area they teach in. The interview protocol was carefully designed to gain deeper insights into their experiences with digital tools in classroom assessment. The interviews were audio-recorded and transcribed for qualitative analysis.

Data analysis

A thematic analysis (Braun & Clarke, 2022) was employed to identify recurring patterns in terms of the opportunities and challenges in teachers' integration of digital technologies into classroom assessment practices. As the first step, teachers' reported assessment practices were categorised based on whether they related to formative or summative aspects, using the "implementation by teacher" component of the classroom assessment model proposed by Black and Wiliam (2018, p. 556). The formative aspects were categorised according to the five formative assessment strategies outlined by Wiliam and Thompson (2007, p. 63): "(1) clarifying and sharing learning intentions and criteria for success, (2) engineering effective classroom discussions and tasks that elicit evidence of learning, (3) providing feedback that moves learners forward, (4) activating students as instructional resources for one another, and (5) activating students as the owners of their own learning". The summative aspects were categorised according to teachers' aim of evaluating what students have learned typically by assigning a final grade, score, or a combination of both (Black and Wiliam, 2018). Subsequently, the recurring patterns in the benefits and challenges associated with each type of assessment were identified.

Findings

This section presents the role of digital technologies in enhancing the participant teachers' classroom assessment practices, focusing on both formative and summative aspects. Teachers' responses underscored the complexity of the issue, linking benefits and challenges to technology itself, its use in assessment more broadly, or specifically in mathematics assessment. Before going into detail, it is useful to first outline the technologies used by the participant teachers which were technological tools for classroom assessment, including online test makers/platforms (Quizz, Kahoot, Google Forms, Padlet, and Canva), mathematics software packages (GeoGebra and Cabri), digital books and a learning management system provided by the Ministry of National Education (namely, EBA).

The findings suggest that digital technologies significantly enhance formative assessment in mathematics lessons, despite some challenges. Teachers demonstrated adaptability in addressing issues such as students' limited access to technological devices and internet connectivity during formative assessments. They found it easier to switch to alternative plans and blend digital tools with traditional teaching techniques for formative purposes. However, the impact of digital technologies on summative assessment practices appears more limited due to the challenges involved. Issues such as unequal access to technological devices and reliable internet made it difficult for teachers to fully

integrate digital tools into summative assessments like digital tests and coursework projects that require the use of digital technologies. Although teachers were thoroughly probed about their use of digital tools for both formative and summative assessments, their responses were more detailed regarding formative practices. When discussing the integration of digital tools, teachers provided more comprehensive insights into the opportunities within formative assessment, while they viewed potential benefits for summative assessment as less feasible under current conditions. The following two sub-sections will present an overview of the opportunities and challenges reported by teachers.

Benefits of the use of digital technologies for effective classroom assessment

Teachers identified several opportunities that digital tools offer for enhancing classroom assessment practices. The recurring opportunities identified in teachers' responses include increased student participation, efficient use of time, easier visualization of abstract mathematical concepts, convenient access to a wide range of mathematics tasks, and provision of detailed analytics. In Table 1, the first column presents these opportunities, the second column includes teachers' responses as evidence to support these identified patterns and the third column presents the aspects of classroom assessment that were linked to these practices.

Table 1: Teacher-reported opportunities of digital technologies in classroom assessment practices

The benefits	Example supporting evidence	Link to the elements of classroom assessment
Increased student participation	Digital tools help create a stress-free learning environment. Digital games increase students' motivation. Digital tools make it easy to capture students' attention. Digital games and online competitions facilitate peer feedback.	Providing feedback that moves learners forward Activating students as instructional resources for one another Activating students as the owners of their own learning
Efficient use of time	Digital tools provide immediate feedback. Digital technologies facilitate immediate access to a variety of mathematics tasks. Digital tools enable automated marking.	Engineering effective classroom discussions and tasks that elicit evidence of learning Providing feedback that moves learners forward Summative aspects
Easier visualization of mathematical concepts	Digital tools enhance the visualization of abstract mathematics concepts such as absolute value, and geometrical concepts like 3D shapes.	Engineering effective classroom discussions and tasks that elicit evidence of learning Summative aspects
Convenient access to a wide range of assessment tasks	Digital tools provide interactive mathematics tasks. Digital tools and online resources facilitate project-based learning.	Clarifying and sharing learning intentions and criteria for success Engineering effective classroom discussions and tasks that elicit evidence of learning Summative aspects
Provision of detailed analytics	Digital tools provide detailed analysis of students' mistakes.	Formative use of summative tests Summative aspects

Challenges with the use of digital technologies for classroom assessment

While digital tools offer various opportunities to enhance classroom assessment practices, teachers also reported several challenges in using them. These recurring challenges, along with example teacher responses as supporting evidence, are outlined in Table 2.

Table 2: Teacher-reported challenges of using digital tools in classroom assessment practices

The challenges	Example supporting evidence	Link to the elements of classroom assessment
Additional workload	Teachers may need extra preparation to learn how to use specific digital technologies. Developing digital tools that align with learning intentions can be time-consuming. Additional instructions might be required for students and parents. Teachers might need contingency plans for unexpected technical issues.	Summative aspects All five formative assessment strategies
Limited access	Some useful software requires payment. Students might have limited access to technological devices and reliable internet connections.	Summative aspects All five formative assessment strategies
Limited features of existing tools and resources	Readily accessible digital or online materials may not meet the specific needs of students. Available tasks might provide limited opportunities for open-ended and long-answer questions, which are necessary to assess higher-order learning.	Summative aspect All five formative assessment strategies

These challenges can potentially limit the implementation of formative assessment strategies and the effectiveness of teachers' summative assessments. However, teachers seem to manage them more effectively in formative contexts through flexible adaptations. The limited flexibility in using digital technologies for summative assessment appears to stem from the specific demands of summative assessment, which require a higher level of accuracy and fairness in obtaining and interpreting students' scores or grades.

For instance, during interviews, two teachers expressed a preference for digital assessments due to their convenience of scoring exams. However, they noted that this is not feasible under current conditions. One teacher highlighted issues with students' access to technological devices and the potential for unstable internet connections at school. She suggested that allowing students to complete tests outside of school, where they might have better access, could lead to inequities and make it difficult to monitor for cheating. Another teacher pointed out the challenges related to the types of questions that digital technology can automatically assess. He mentioned that relying on digital tests for summative assessment would predominantly limit him to short-answer and multiple-choice questions, which could undermine a comprehensive interpretation of students' learning.

Discussion

The findings suggest that integrating digital technologies has significant potential to enhance teachers' classroom assessment practices, both in formative and summative aspects. Consistent with existing literature, the results indicate that teachers perceive digital technologies as enhancing feedback practices by facilitating immediate feedback (Shute, 2008), visualizing abstract mathematical concepts (Hohenwarter & Jones, 2007), and effectively eliciting student learning while motivating active engagement (Nicol & Macfarlane-Dick, 2006). However, despite the literature highlighting the benefits of digital technologies for summative assessment (Onasanya & Ajamu, 2024), it appears that teachers in this study may have been hesitant to adopt these technologies for summative purposes, potentially due to concerns about meeting the rigid requirements for accurate and fair grading. This difference between teachers' tendency to use digital technology seems to stem from the issues with students' equal access to digital technologies (Warschauer & Matuchniak, 2010) and technical difficulties (Inan & Lowther, 2010).

Conclusion and suggestions for future research

This study has demonstrated that digital technologies offer significant benefits for enhancing classroom assessment practices. However, the challenges associated with their integration must be acknowledged. Ensuring that all students have access to adequate technology is particularly important. Additionally, advancements in educational technology should focus on developing more valid and reliable assessment tools. Future research could explore the design of digital tools that better address teachers' needs for more effective assessment practices and conduct large-scale trials of these tools.

Acknowledgment

We are thankful to the 16 teachers who participated in our study and generously shared their time and insights.

Professional development support helping teachers overcome difficulties of implementing formative assessment

Catarina Andersson[1], Torulf Palm[1] and Mikael Winberg[1]

[1]Department of Science and Mathematics Education, Umeå University, Sweden;
catarina.andersson@umu.se

Keywords: Formative assessment, elicitation, feedback, professional development.

Background

Research has shown the potential of formative assessment (FA) to enhance student achievement in mathematics (e.g. Palm et al., 2017). However, professional development (PD) programs often struggle to effectively support teachers in implementing high-quality FA (Anders et al., 2022). To better understand difficulties in implementing FA and how to overcome such difficulties, we followed one experienced primary school teacher, who, after completing a comprehensive school-based PD, received individual support to implement FA in the common context (e.g., Hiebert et al., 2003) where the teacher provides help to students working individually on mathematics tasks. Implementing FA in this context involves: (1) eliciting evidence of student knowledge and skills, (2) interpreting and making inferences about student learning needs, and (3) providing feedback tailored to those needs.

Our goal was to understand why a highly engaged and experienced mathematics teacher, despite supportive PD, struggled to implement desired changes. Additionally, we sought to explore strategies to help teachers overcome difficulties, contributing knowledge about essential PD features for effective FA implementation.

Methods

Classroom observations revealed that the teachers in the initial PD did not consistently use the FA practices they had reported. Consequently, we offered additional individualized PD. Elsa (a pseudonym) volunteered for this study and the extended PD. The individual PD followed a cyclical process. Elsa audio-recorded her interactions with students during 2–3 lessons and then shared them. The researchers analyzed the recordings and formulated feedback to Elsa, including examples from the recordings. This feedback was discussed in a digital meeting between Elsa and a researcher. Elsa then used the feedback to refine her FA practices during the following 3–4 weeks, initiating a new cycle of co-operation. Five cycles, and thus five digital meetings, were conducted. All meetings were recorded, transcribed, and analyzed to identify barriers (i.e., difficulties and their causes) to FA implementation and strategies to address them. Using thematic analysis (Braun & Clarke, 2006), difficulties, causes, and potential strategies were categorized and their relationships illustrated. Classroom recordings were also used to track changes in FA practices over the course of the PD.

Results

The classroom recordings revealed that one key area for improvement was Elsa's feedback to students, which was often not based on the students' thinking. She did not consistently gather sufficient information about individual student learning needs to provide targeted feedback.

Two main difficulties were identified: (1) Encouraging students to share their thinking until sufficient information is received, and (2) Helping students use feedback autonomously. Each difficulty stemmed from different causes. For example, students were reluctant to share their thinking because they did not see its purpose and feared negative comments from peers.

Our study underscores the importance of having first hand and sufficient information about the individual teacher's needs when providing PD support. Such information, combined with discussions of difficulties and targeted strategies, emerged as key components of successful PD. The iterative, cyclical structure of support also proved crucial, as challenges cannot always be solved immediately.

One simplified example of this iterative process involved Elsa's struggle to encourage students to share their thinking. Elsa noted that students did not see the purpose of doing so. Together, Elsa and the researcher discussed strategies to help students understand the purpose of sharing their thinking. Over time, students would be able to see benefits of sharing their thinking by experience the advantages of receiving individualized feedback based on their expressed needs. However, to accelerate this understanding, Elsa would explain why their input was necessary and consequences of not having information about their thinking. She would also provide specific encouraging feedback when students shared valuable information (e.g., "That's a great way of thinking because..."). Eventually, Elsa would provide feedback showing students how their actions led to success (e.g., "This went well because you..."). However, this example simplifies the complexity of implementing FA in the classroom. In reality, Elsa struggled to overcome many of the difficulties.

Discussion

The additional PD provided more valid and detailed information about the teacher's FA progress than the previous school-based PD. This information made it possible to provide support better tailored to the teacher's needs, which helped the teacher to overcome some of her difficulties of implementation. Thus, in addition to identifying difficulties, and their reasons, in implementing FA, the study shows how FA characteristics of the PD are important for its success. A key question for future research is how to scale up this approach to larger groups of teachers bearing in mind that assessing teachers' needs and providing efficient feedback is not an easy endeavor.

Effects of the COVID-19 pandemic on mathematics achievement: An investigation in university math pre-courses

Andreas Büchter[1], Frank Osterbrink[1] and Natascha Scheibke[1]

[1]University of Duisburg-Essen, Faculty of Mathematics, Essen, Germany;
andreas.buechter@uni-due.de

Keywords: Mathematics Achievement, Achievement Test, Secondary School Mathematics, Pre-Course Mathematics, COVID-19 Pandemic

Introduction and background

The COVID-19 pandemic has led to some radical changes in the framework conditions for teaching and learning mathematics (Chan et al., 2021). The meta-analysis by Betthäuser et al. (2023) shows that learning outcomes in math and reading decreased worldwide in schools during the COVID-19 pandemic and how this trend varies across different countries. Results of large-scale assessments substantiate these findings for primary and lower secondary schools in Germany (grade 3: Gasteiger et al., 2023; grade 5: Schult et al., 2022; grade 9: Lewalter et al., 2023). Measures taken to contain the COVID-19 pandemic are regarded as one reason for this decrease: "The results of our study can therefore be taken as an indication that school closures and distance learning during the pandemic did indeed have an impact on students' mathematics achievement" (Gasteiger et al., 2023).

However, there is hardly any relevant data available for upper secondary level in Germany, especially for secondary-tertiary transition. Since subject-specific prior knowledge is an important part of the learning background of first-year university students, we investigated how the math performance of pre-course attendees differed before and after the COVID-19 pandemic.

Design of the study

For our study, we used an achievement test for math pre-courses with 32 tasks that we developed back in 2016. The tasks are based on the current math curriculum of the federal state of North Rhine-Westphalia, which is valid until 2025. Of the 32 tasks, 7 tasks relate to content for lower secondary level and 25 tasks to content for upper secondary level. All tasks are relevant for university math courses. Regarding the distinction between conceptual and procedural knowledge (Rittle-Johnson et al., 2001), the tasks contain different requirements, namely *mainly conceptual knowledge*, *mainly procedural knowledge*, or a *combination of both* (for examples, see Table 1).

Table 1: Examples for the different requirements

Conceptual knowledge	"Specify a function f with $\int_{-1}^{3} f(x)dx = 0$."
Procedural knowledge	"Simplify the following algebraic expression: $(6a^3b)^2 \cdot \left(\frac{1}{3}b^2z^2\right)^3$."
Combination of both	"Given is the function f with $f(x) = e^{\frac{1}{2}x}$. Specify the antiderivative of f."

The test was conducted without changes at the University of Duisburg-Essen before the COVID-19 pandemic, in the years 2017 to 2019, and after the COVID-19 pandemic, in 2023, in each case at the beginning of the math pre-courses in September.

Main results and outlook

The results show that there are practically no differences between the years 2017 to 2019, but significant differences between the years before the pandemic and 2023 (see Table 2).

Table 2: Average results for all attendees (32 tasks)

	2017	2018	2019	Ø 2017-2019	2023
correct	48 %	46 %	52 %	49 %	35 %
false	32 %	35 %	28 %	32 %	32 %
unprocessed	20 %	19 %	20 %	20 %	33 %
n	95	70	49	69	69

While an average of around 16 out of 32 tasks were solved correctly in the years 2017 to 2019, only around 11 tasks were solved correctly in 2023. At the same time, the quota of unprocessed tasks rose from an average of 20% to an average of 33%. Further analyses have not revealed any topics or types of requirements to be primarily responsible for the decline in performance.

The Faculty of Mathematics at the University of Duisburg-Essen is, therefore, intensively discussing how lectures can be adapted to the changing prior knowledge of first-year students.

How can the prison context change teachers' perspective and practices about mathematic assessment?

Veronica Manzoni[1], Silvia Regola[2] and Chiara Giberti[2]

[2]University of Modena and Reggio Emilia, Modena, Italy

Keywords: Assessment, prison context, teacher perspective, teacher practice

Rationale and theoretical framework

Black and Wiliam (2009) use the term 'assessment' to refer to all those practices, involving both teachers and students, that provide information that can be used to modify teaching and learning activities. Assessment can be differentiated by its purposes: formative assessment (FA), or assessment for learning, and summative assessment (SA) or assessment of learning (Black & Wiliam, 2009). Generally, in ordinary Italian classrooms there is a preponderance of SA (Amado & Morselli, 2023); teachers are frequently not aware of the distinction between FA and SA and assess students' learning through written and oral tests which involve a single student called to the blackboard, performing in front of the teacher and peers (Pastore et al., 2019). The role of the context in which the entire learning-teaching process takes place is crucial to better understand teachers' perspectives and practices regarding assessment (Wong et al., 2016). This is particularly true in the multi-complexity of a prison school context, which is characterised by: (i) heterogeneous classes in terms of age (from 14 to 70 years old), socio-cultural and linguistic background, literacy and personal experiences; continue turnover of students (usually up to 10 students); (ii) frequent experiences of failure encountered by students in their educational paths, in particular in mathematics, and (iii) the fact that "evaluation" in the sense of "judgment" permeates any prison setting (Decembrotto & Maffia, 2024). Furthermore, there is a lack of literature on the issue of mathematics education in the prison context and, even more, on the specific issue regarding assessment. We present the preliminary results derived from the "Learning Math in Prison" project (LeMP) with the aim to highlight if and how, the prison context can overturn some of the teachers' perspectives and practices related to assessment in mathematics compared to those of teachers' in ordinary schools.

Data and methods

Data collected during the exploration phase of the LeMP project were qualitatively analysed to shed light on teachers' perspectives on assessment in mathematics. No specific questions on assessment were proposed thus all teachers' reflections emerged spontaneously. We consider data gathered through a digital platform collecting teachers' reflections, a focus group and individual teachers' interviews. The 4 mathematics secondary school teachers involved from 3 Italian prisons had different experiences in the prison context, none of them had a specific training for teaching in prison. All data were coded independently by all three authors considering the components of the FA (Black & Williams, 2009), then questionable cases were shared and discussed.

Preliminary results and further steps

The teachers were aware of frequent students' experiences of failure in their previous school path, especially in mathematics, and they stated that this leads students to low levels of self-efficacy.

Teachers interviewed stated that assessment in prison schools differs from that in ordinary schools. Particularly, two spontaneous overturns of perspectives and practices related to assessment emerged from teachers' comments: (i) FA as almost frequently used with respect to SA; (ii) Oral tests as a practice promoting FA and personal motivation. Although teachers did not explicitly refer to FA, several aspects in their reflections can be identified as FA practices. The prison context and in particular the need to consider the frequent variation in school attendance, the classes' heterogeneity, the frequent turnover of students and their detention conditions, allows teachers to disengage from the logic of grades and led them to personalise the assessment process by considering personal starting point and needs. The data collected also revealed that, in the prison context, the practice of calling a student to the blackboard, as usually teachers do in Italian oral tests, can be a virtuous student-centred practice as far as it is *'an emersive approach [...]in which students want to emerge'* and, as one teacher stated, as one teacher stated, the student recognises himself as effective. Oral tests allow teachers to observe students' understanding and provide them with feedback, serving as implicit assessment and enhancing their self-efficacy in mathematics. These identified overturns are two examples of how spontaneously the prison school context allows mathematics teachers to create a relaxed climate without the anxiety of grades and to promote and personalise assessment based on students' educational path and motivation. These preliminary reflections will be deepened in the next phases of the project: the other aspects of FA might be present in teachers' practices but did not emerge in data collected. Further information related to mathematics assessment practices in the prison context will be collected through the analysis of teachers' learning units design and their implementation.

TWG 22: Curricular Resources and Task Design in Mathematics Education

An introduction to TWG22:
Curricular resources and task design in mathematics education

Annalisa Cusi[1], Patrick Ebers[2], Dubravka Glasnović Gracin[3], Shai Olsher[4] and Hendrik Van Steenbrugge[5]

[1]Sapienza University of Rome, Italy; annalisa.cusi@uniroma1.it;

[2]University of Duisburg-Essen, Germany; [3]University of Zagreb, Croatia;

[4]University of Haifa, Israel; [5]Stockholm University, Sweden

At CERME14, TWG22 continued to integrate macro-level research on curricular resources with micro-level research focusing on more specific units of curriculum design, namely tasks. The sessions covered several key aspects: the analysis of (digital) textbooks and curricular resources to examine their impact within broader curricular systems and to compare educational systems; the design of tasks and resources (including digital resources) across different contexts and for various purposes; and empirical studies investigating students' and teachers' interactions with curricular resources and textbooks, with particular attention to their perspectives and experiences. Throughout the sessions, participants highlighted numerous connections between TWG22 and topics explored in other thematic working groups, emphasising the potential for further collaboration.

Keywords: Curricular resources, task design, task implementation, textbook research, educational systems.

Scope and focus of the working group

TWG22 takes into consideration an interconnected dual perspective on research on curricular resources and task design in mathematics education. On one hand, at a macro level, curriculum resources – both digital and print – are the object of work for teachers, lecturers and students in various formal and informal learning contexts. These resources are chosen, adapted, (re)designed and used, by teachers and instructors, to work - individually and collaboratively - on planning lessons, organising teaching, and assessing student learning progress. Such resources, including educative curriculum materials, are often central in professional development activities. In these contexts, mathematics teachers work together with education researchers to create or transform print, digital, or hybrid resources, building their design skills and pedagogical knowledge in the process.

On the other hand, at a micro level, curriculum resources mainly consist of tasks taken from textbooks or other sources. The way tasks are presented, their sequence, and how teachers implement them in class can influence their cognitive demand, shaping students' perceptions of mathematics. This affects students' chances to make connections within mathematics and to develop concepts, skills, and mathematical habits of mind. Research literature highlights that tasks are fundamental to effective teaching. Recently, there has been a growing interest in studying task design features (including features of tasks in digital environments) that encourage specific mathematical activities, methods to analyse task affordances and principles for implementing tasks effectively. Furthermore, involving

students in designing tasks can prompt them to reflect on their own knowledge, understanding, and practices.

The following aspects were discussed in the TWG:

- Analysis of (digital) textbooks and curricular resources to explore how they operate within and shape broader curricular systems, and how these resources and textbooks provide a lens for studying and comparing educational systems.
- Task and resource design in various contexts (e.g., schools, teacher training) and for different purposes, with particular attention to digital environments and AI.
- Empirical research on students' interactions with curricular resources and textbooks, focusing on their perspectives and experiences.
- Empirical research on teachers' use of curricular resources and other materials specifically designed to support their practice (e.g., lesson plans, teaching guides).

In the next section, the papers presented during the conference are introduced following the order and themes in which they were grouped during the sessions.

Issues addressed during the sessions

An issue discussed in TWG22 was teachers' use of curricular resources and other materials specifically designed to support their practice. In particular, two papers focused on task design for teacher education and professional development:

- Lorenzo Pollani, Laura Branchetti & Francesca Morselli: Design principles for epistemological dépaysement of pre-service teachers within interdisciplinarity between mathematics and physics
- Patrick Ebers: Noticing of teacher students on an explorative task to exemplify the potential of using technology

Pollani and colleagues propose a theoretical paper aimed at presenting a framework for fostering epistemological dépaysement (Jahnke et al., 2002) – i.e., the critical reflection that emerges from epistemological discomfort – in pre-service teacher education focused on mathematics-physics interdisciplinarity. The authors define design principles for tasks that promote such reflection and exemplify them with a textbook analysis task. The goal is to develop interdisciplinary teacher expertise by encouraging pre-service teachers' critical reflections on their assumptions and disciplinary perspectives.

The study by Ebers explores how a video case showing two students using digital tools to solve an open-ended mathematics task can support teacher education by developing pre-service teachers' noticing skills. The analysis of 44 pre-service teachers' reflections revealed that, while many identified surface-level difficulties, few recognised deeper mathematical or tool-specific challenges, such as the special case explored by the students in the video. The findings highlight the importance of well-designed resources in preparing teachers to interpret student thinking and integrate technology meaningfully into mathematics teaching.

Another issue was how textbooks (including digital ones) operate within and shape curricular systems and how they could provide a lens for studying and comparing educational systems. Three papers were focused on this issue:

- Kevin Larkin, Silke Ladel, Ulrich Kortenkamp, Mellony Graven, Lise Westaway, Pamela Vale, Kym Fry, Tammy Booysen & Dinah-Marie Wiedenhöfer: Place value concepts as presented in German and Australian student workbooks
- Magdalini Lada, Iveta Kohanova & Birgit Pepin: Examining the paths of reasoning presented in the topic of 'patterns' in Norwegian mathematics textbooks
- Dubravka Glasnović Gracin, Goran Trupčević & Katarina Širanović: Exploring the use of digital textbooks in classrooms: focusing on automated feedback

These three contributions demonstrate that various formats of textbooks are being examined in mathematics education, all of which can be analysed through document analysis methods.

Larkin and colleagues compare how place value concepts are represented in German and Australian student workbooks. For this purpose, 102 tasks are analysed and categorised according to different concepts and subconcepts. The study reveals interesting differences between the textbooks, some of which can be explained by the numeracy range prescribed in the respective curricula; however, this does not account for all variations.

The paper by Lada and colleagues investigates two traditional mathematics textbooks used in Norway. Here, the focus is on the paths of reasoning in the topic of patterns as presented in the textbooks, shaped by national guidelines. Notably, the textbooks differ in their chosen approach – numerical versus figural. One reason identified for these differences lies in the ambiguous formulations found in the curriculum documents.

Glasnović Gracin and colleagues analyse the use of digital textbooks with a particular focus on automated feedback. This involves examining both the types of tasks already implemented and how the provided automated feedback is dealt with during classroom practice. It is noteworthy that teachers are required to consistently check the correctness of this feedback and decide how to respond to it in their teaching.

In the overarching discussion, it became clear that the criteria for selecting textbooks for classroom use can vary significantly. These criteria may be set by administrative authorities or be adjusted according to new educational guidelines.

The issue of design (of digital environments, of resources, of tasks, of units within textbooks) represents the focus of different papers. The following papers discuss the issue of the design of digital environments and resources (including AI) adopting different perspectives:

- Carlotta Soldano, Sonia Palha, Sara Bagossi, Cristina Sabena, Anders Bouwer, Erwin M. van Crasbeek & Myrto Karavakou: Digital game-based mathematics curriculum resources: methodological reflections on collaborative prototyping
- Sylvia Patricia Van Borkulo, Peter Boon & Johan Jeuring: Learning goals in view: Design of an intelligent environment for arranging and monitoring secondary mathematics education

- Burcu Nur Baştürk & Menekşe Seden Tapan Broutin: CHATGPT as a resource for pre-service mathematics teachers to design their lesson plans and lesson scenarios
- Francesco Contel & Annalisa Cusi: Students' perspectives on GPT-4's supported problem solving

Soldano and colleagues' paper examines the collaborative design process by analysing two game-based prototypes and illustrating their development through feedback and revisions. The goal of the study was to develop a methodological tool that monitors how collaborative prototyping affects the evolution of prototypes. To examine this evolution, the authors qualitatively analysed the data in these prototyping design documents using a deductive approach, namely, their educational, technological, and mathematical aspects. The MDA (Mechanics-Dynamics-Aesthetics) framework (Hunicke et al., 2004) was used to track design evolution, highlighting how collaborative processes may improve the educational potential and adaptability of digital tools for learning.

The poster by Van Borkulo and colleagues introduces the design of an AI-supported environment for secondary mathematics education, focused on aligning teaching materials with curriculum goals. The system incorporates design principles (flexibility and customisation, alignment with learning goals and their graphical representations, and performance) with the aim of creating an intelligent environment for arranging and monitoring secondary mathematics education processes.

The poster by Baştürk and colleagues explores how and for what purposes pre-service mathematics teachers in Turkey use ChatGPT to design lesson plans and scenarios. Using the Documentational Approach to Didactics (Gueudet & Trouche, 2009), the authors examined ChatGPT as a resource. Ten participants, with no prior experience with ChatGPT, used the tool over an eight-week period. The study found that ChatGPT supported them in acquiring pedagogical knowledge, validating ideas, and simulating student responses. Various "usage schemes" emerged, revealing how teachers integrated AI in lesson preparation through prompts and content co-construction.

Contel and Cusi investigate how a 15-year-old student employed GPT-4 for support during problem-solving. Using the instrumental genesis approach, the study examined the student's metacognitive processes and evolving interaction patterns with the chatbot. The analysis highlights clusters of themes that reveal the complexity of the instrumental genesis processes in human-LLM interactions, suggesting that this complexity should be considered in the design of suitable tasks involving LLMs.

Another sub-theme in design was the investigation of the features of tasks and curricular resources that promote specific aspects of mathematical thinking. The following five papers and posters elaborate on this issue:

- Hyman Bass: Task designs to support Connection-oriented mathematical thinking
- Yosep Dwi Kristanto & Zsolt Lavicza: Down-to-earth mathematics: transforming curriculum and teaching on function transformations
- James Gray: Prime Times: a game to develop multiplicative reasoning
- Jana Višňovská & José Luis Cortina: Conceptualisation of Number in Curricular Resources: Does it Matter?

- Nataly Pincheira, Paula López, Marta Gual & Ángel Alsina: A proposal of tasks to integrate sustainability in the early ages from mathematics education

Bass's paper proposes a cross-topic perspective on mathematical tasks, called connection-oriented mathematical thinking. This perspective utilises tasks that promote students' skills to interact with the connections between seemingly unrelated mathematical entities. These interactions include noticing, articulating, and explaining these connections. Suggesting the practicing connections framework, the paper demonstrates core concepts and practices of the domain; representations used within the domain; and applications outside the domain. By constructing a connection network between the different entities, the students engage and promote their ability to connect and communicate mathematical ideas.

Kristanto and Lvicza propose that teaching function transformations can benefit by promoting productive meanings to transformations and integrating mathematics with other domains. By combining Duality, Necessity, and Repeated Reasoning (Harel, 2008) and emergent graphical shape thinking as a boundary object, the study introduces a digital task sequence on the topic of climate science. The findings show how students' envisioning of a graph in terms of what is made (a trace) and how it is made (covarying quantities) supports their construction of productive meanings of function transformations.

Višňovská and Cortina explore the manifestation of continuous quantities in the development of the notion of numbers in the Australian elementary school curriculum. This analysis demonstrates how certain ideas can be restricted in the way that national curriculum documents progress in the learning and development of mathematical concepts. The analysis captured different treatments of numbers in terms of continuous quantity across the different topics and discusses reasons and implications.

The poster by Gray introduced the design and implementation of a multi-stage visual multiplication game. The cyclic design process was motivated by the intention to move students from recognising prime factors not only as a string of numbers, but also transformational and relational aspects in multiplicative reasoning. The game was experimented with in-service teachers and led to meaningful discussions but also revealed additional challenges in using opportunities to identify the greatest common divisors that promote a new design iteration.

The poster by Pincheira and colleagues introduced the design tasks for integrating sustainability into mathematics education. The study proposes a series of tasks that enable teachers to play an effective role as agents of social change by integrating sustainability in early age mathematics education. By introducing mathematical topics such as data analysis, algebra, and geometry in contexts such as food production or house construction, the tasks demonstrate a possible bridging between mathematics and the environment.

The teachers' use of textbooks, curricular resources and other materials, such as lesson plans and teaching guides was discussed by the following papers:

- Per Nilsson, Simon Sjölund, Jannika Lindvall & Andreas Ryve: Empowering mathematics instruction: Variation theory, lesson plan, and instructional quality

- Marcus Gustafsson: Upper-secondary school mathematics teachers' use of a research-based teacher guide
- Marzia Garzetti: Teacher Perspectives on Textbooks and Their Role in Implementing the Mathematics Laboratory Approach in Italy

Nilsson and colleagues' paper explores how a teacher with low mathematical knowledge for teaching, in a class with average socioeconomic status, manages to establish high instructional quality with the support of a lesson plan based on variation theory (VT) (Marton, 2015). The structured yet flexible plan supported students' understanding of fractions by guiding them through critical aspects of the object of learning. The teacher adapted the lesson in real time to student responses, demonstrating how VT can scaffold effective instruction even in complex contexts. The findings suggest that well-designed educational resources grounded in VT can potentially reduce the relative impact of the teacher compared to teacher-level factors and student-level factors.

The study presented in Gustafsson's paper explores how Swedish upper-secondary mathematics teachers use a research-based teacher guide on quadratic equations as a resource in planning teaching. The teachers' resource use is described in terms of perceived affordances and constraints and of the mobilisation of this resource into designed instruction. Using surveys and interviews with six teachers, the study identifies factors that influenced their mobilisation of different guide components.

Garzetti investigates how Italian lower secondary mathematics teachers use textbooks to implement the mathematics laboratory approach promoted by national curriculum guidelines. The results of a questionnaire completed by 609 teachers highlight that, while textbooks are widely used, mainly for exercises, they are rarely employed to support laboratory-based activities and promote collaborative and argumentative practices. Many teachers supplement textbooks with online materials or self-designed activities, especially for laboratory work. Satisfaction with textbooks increases with teaching experience, but a lack of ready-to-use resources is a common barrier, especially for less experienced teachers. The findings highlight a gap between policy intentions and classroom practices, to be further explored through qualitative follow-up studies.

The following four papers and posters relate to the theme of empirical research on students' interactions with curricular resources and specific environment, considering both the students' and the designers' perspective:

- Cristina Poli: With great freedom comes great responsibility: exploring potentials and pitfalls of using open environments through a discourse analysis
- Caterina Papa & Agnese I. Telloni: Use and perception of differentiated scaffolding by primary school students involved in mathematical tasks
- Annika Volt, Kairit Tammets & Mart Laanpere: Flexible Instructional Trajectories for Learners' Self-Regulation in 9th Grade Algebra
- Sara Gagliani Caputo, Laura Branchetti & Annalisa Cusi: Synergies and dissonances between designers' and students' perspectives on key features of digital mathematical discussion

All four contributions entail intervention studies and relate to either digital or paper and pencil environments. Together, they cover secondary and elementary school in Italy and Estonia and draw on qualitative and quantitative analysis. They address features such as personalised learning, scaffolding, online discussion, and open-ended assignments. Collectively, these studies showcase the importance of studying student experiences when designing specific instruction resources.

The poster by Poli explores, drawing on a commognitive lens (Lavie et al., 2019), grade 10 Italian students' and tutors' engagement with open-ended assignments in a digital environment. The findings suggest that while open-ended assignments can add with various tasks, they also come with demands on teachers to facilitate student learning.

Papa and Telloni study how 18 grade 3 students in Italy use and perceive differentiated scaffolding in the form of hints and prompts to a sequence of four geometry tasks. From field notes during the intervention study and student answers on a survey, the authors identified four user profiles, reflecting various levels of awareness and ways of turning the hints and prompts into action (effective use of scaffolding elements, immediate use of scaffolding elements without generalisation, using scaffolding ineffectively, recognising difficulties but refusing to use feedback). The authors conclude that a major challenge is to find ways to enable students to take advantage of the scaffolding.

Volt and colleagues investigate how 129 grade 9 Estonian students perceive a digital environment, designed to learn algebra in flexible and personalised ways. They identify four factors that seem to affect students' learning experiences (perceived efficiency, shared control, cognitive load, and importance of own role) as well as three student use profiles (independent learners, habitual learners, learners in difficulty).

Gagliani Caputo, Branchetti, and Cusi study how 63 grade 9 Italian students perceive digitally facilitated mathematical discussions. Central features of the digital mathematical discussions are its written and asynchronous nature. Comparing students' perspectives with the ones from the designers has allowed the authors to see points of alignment and divergence, which is argued to be helpful in further design cycles.

Possible directions for future research

Discussions within TWG22 highlighted the extensive connections with research from other TWGs. The papers presented were not confined to a single school level, covering the use and development of resources from early education through to university. They also addressed a wide range of mathematical topics and were carried out in various educational contexts. Moreover, curricular resources discussed were not limited to traditional print formats but included digital tools, games, and real-world contexts. Many other interdisciplinary connections were evident as well. Moving forward, we aim to explore various ways to foster interactions among different TWGs, both during and between conferences, to support these shared interests. For TWG22 specifically, discussions identified the following directions for future research:

- Focus on integrating physical resources (tasks, teacher guides, lesson plans, (digital) textbooks, AI as a resource, etc.) with human resources to better achieve educational goals;

- Deepen the study of coding schemes and representations (e.g., illustrations and diagrams) to strengthen the validity of task and resource analysis methodologies;
- Investigate collaborative task design involving communities of interest, where one actor is a digital environment (e.g., ChatGPT);
- Explore the types of support users need, considering their different dispositions, characteristics, and contexts;
- Study of curriculum features that cut across educational contexts and features that are unique to specific educational systems.

Task designs to support connection-oriented mathematical thinking

Hyman Bass

University of Michigan, Ann Arbor, USA; hybass@umich.edu

Connection-oriented mathematical thinking refers to the skills and disposition to notice, articulate, and use deep, often surprising, connections between mathematical entities that may, on the surface seem unrelated. This paper presents and analyzes some instructional designs meant to provide opportunities for students to develop this mathematical disposition and practice.

Keywords: Mathematical connections, task design, problem-solving.

Introduction

> *Science is built up with facts, as a house is with stones. But a collection of facts is no more a science than a heap of stones is a house*. Henri Poincaré

Mathematical connections are widely discussed, illustrated, and promoted, both in the research literature and in curriculum materials (e.g., Carlson & Rasmussen, 2008; Cuoco, 2005). Even at the frontiers of mathematics research, some of the most dramatic breakthroughs have been the discovery and articulation of a surprising and deep connection between seemingly distant parts of mathematics (See Greer & Harel, 1998). Making connections, or sensing, articulating, and using them, is a significant expression of mathematical thinking. This is related to what Hatano and Inagaki (1986) call *adaptive expertise*, in contrast with *routine expertise*. Routine experts have a lot of knowledge which they can apply well in familiar circumstances. In contrast, adaptive experts can flexibly apply their knowledge in a wide range of contexts, both familiar and novel. 21st century skills increasingly call for adaptive expertise.

Connections between two entities that are different can be of different kinds. A connection may be measured by some combination of: the degree of separation between the domains or contexts of the entities; their conceptual distance; the substantive depth and significance of the connection; and the extent to which the connection was hidden or unexpected. By some combination of such measures, one can distinguish "far" connections from those that are "near" and easily seen, to borrow terminology from transfer theory in cognitive psychology (Barnett & Ceci, 2002). This paper focuses on *far connections between mathematical problems*. But they could be other kinds of mathematical entities, for example, mathematical domains, theorems, methods, mathematical representations, or skills. This is distinct from the important and well-developed area of mathematical modeling, in which a real-world context is represented by and is therefore connected to a mathematical model (e.g., Arseven, 2015; Dunn & Marshman, 2019).

In many discussions of connections, the primary attention is on the entities compared, and the connection is treated as an aid in understanding them. In transfer theory for example, a connection is treated as a resource to mobilize knowledge of one entity in order to understand another entity to which the connection links it. In contrast, my primary focus is on learning to perceive the connection itself, its nature and significance, even when both entities are separately well understood.

Although mathematics instruction can present interesting mathematical connections, this paper offers some instructional designs to prompt students themselves to notice and make such connections.

Specifically, the aim of the project reported here, is a contribution to the study of what I term "connection-oriented mathematical thinking," and of how it might be supported by instructional designs.

Conceptual framework

Because mathematics instruction is often organized around solving problems, I have initially framed this project in terms of mathematical connections between different mathematical problems. Given two problems, A and B, I ask, in what way are they mathematically related, possibly even "the same," and what is nonetheless importantly different about them (typically the context)? I am mainly interested in the case when the difference is striking, yet the "sameness" is substantial, deep, and perhaps subtle or surprising. It is the existence and nature of this "sameness" that constitutes the connection on which this project focuses.

To capture this kind of sameness I use the disciplinary concept of *mathematical structure* (see Bourbaki, 1950). Broadly speaking, a mathematical structure consists of a set of objects together with some relations among subsets of them, together with some types of operations that can be performed on them. Common examples are groups, vector spaces, function spaces, geometric objects, and various combinatorial structures. For structures of the same species, there is a notion of structure preserving transformation between them, including the case of isomorphism (Greer & Harel, 1998). To unify many cases, these structures often have abstract axiomatic formulations.

In the above context, problems A and B may have underlying structures of the same species, for example structures on their solution spaces. This is already a significant connection. There may further be a structure preserving transformation from one to the other; that strengthens the connection. The transformation may even be an isomorphism, in which case we can say that A and B are structurally the same (Bassok & Holyoak, 1989; Simon & Hays, 1976). Examples are given below.

This paper proposes and analyzes instructional designs aimed at supporting student learning to notice, articulate, and use such connections, what I call "connection-oriented mathematical thinking" (COMT). Fries et al. (2021) assert that connectedness is key to the coherent mental schemas that underlie deep understanding and transferable skills. The development of COMT, like other kinds of learning, is gradual and is not fully mastered at one point in time.

Although some of the problems are challenging, I have crafted them to be conceptually connected to fundamental mathematical ideas, and to call for basic conceptual insight, not speed, extensive factual knowledge, technical virtuosity, or ingenious invention. My premise is that COMT can be made meaningfully and developmentally accessible to all students.

My instructional designs draw upon the *practicing connections framework* Fries et al. (2021). This framework emphasizes attention to three types of connections: core concepts/principles and practices of the domain; key representations used for communication and thinking within the domain; and applications outside the domain. For example, in arithmetic, the core principles include the "rules of arithmetic," the basic properties of arithmetic operations, and their conservation as the number systems expand across the grades, and into algebra, ultimately becoming the field axioms. In geometry, core ideas include symmetry and its dynamic meaning in terms of transformations. Another is similarity, viewed as geometric rescaling, and how this affects linear, area, and other kinds of geometric measure. Multiple representations of a mathematical construct are important but should

be coupled with detailed understanding of what each best affords, and of the explicit correspondences showing how they each represent the same thing.

For instruction, my design differs from Fries et al. (2021) in one important regard. They apply their framework to a statistics curriculum for community college students, recognizing the challenge of even noticing deep connections, so they propose that such connections be made explicit to students, and then practiced. The designs reported here however, propose scaffolded discovery of connections, situated in various mathematical domains across the K-16 span, with examples of gradually increasing complexity across grade levels, with the goal of developing fluency incrementally.

Literature review

The idea of making connections is not new to curricula and research in mathematics education. Much of the connection-related literature focuses on generative features of individual problem types (Kondratieva, 2011; Leikin & Levav-Waynberg, 2008; Sally & Sally, 2000; Steel et al., 2000).

Scholars have also developed several types of non-routinely connected problem sequences. One is a problem-based curriculum, in which development of the main ideas and principles of the subject domain are presented through problems, to be resolved through substantial student engagement. A post-secondary example is the "Moore method" (Jones, 2012). Another was developed by Hungarian educators Tamas Varga and Lajos Posa (Katona, 2020; Matzal, 2020).

In general, problems having the same answer may be a weak signal of mathematical connection. Exceptionally, the Catalan numbers (Bass, 2023b; Stanley, 2015) provide the common answer, for substantial reasons, to a remarkable variety of problems. Still another type of connection is a collection of diverse, seemingly unrelated problems that can, after perhaps unrelated kinds of mathematical work, all be reduced to one core problem (Bass, 2023a; Usiskin, 1968). An example will be provided.

The main type of connection studied here is for problems whose underlying structure is common, or closely related. An important longitudinal instructional example is reported in Maher and Martino (2014), in which a student, over grades 1-6, developed the underlying structure of the problems of counting all bi-colored unifix towers of given height. Another is Sriraman (2004), in which a student distills the "pigeon-hole principle" from his solution, over time, of a number of its applications.

In the literature on expertise connected knowledge has been discussed in terms of schemata (Schoenfeld, 1992). From the survey of Weber et al. (2006), "Experts can categorize problems based on their underlying mathematical structure, sometimes after reading only the first few words of the problem."

Design and analysis, illustrated in one example

What distinguishes the work reported here from the literature briefly surveyed above, is the present focus on problems for which there is an identifiable structure that is demonstrably common to all of the problems, yet the commonality of that structure may be both unexpected and not easily discerned, even by experts. Moreover, a mathematical structure of one problem and that of another may be "proximal" yet, for subtle reasons, not being identical. An early expression of this focus is evoked in Greer and Harel (1998). This, and the examples above of Maher and Martino and of Sriraman, come closest to the perspective offered here.

The products of this project, still in evolving development, are: (a) a specific approach to the construction of collections of structurally connected problems, with deep connections that are often far and unexpected; (b) explication and refinement of the concept of "common structure"; and (c) designs of instructional formats to stimulate and support connection-oriented mathematical thinking (COMT). It is worth noting in (a) that, when the connections are deep, the problems themselves need not be. In order to reify these complex ideas, I now present and analyze an example.

The basic artifacts of this work are structurally connected problem sets, so here is one, called the "3-permutation problem set."

A. What are all three-digit numbers that you can make using each of the digits 1, 2, 3, and using each digit only once?

B. What are all three-letter English words that you can make using each of the letters, a, e, t and using each letter only once?

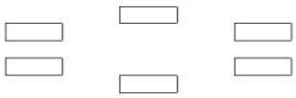
C. You are watching Arisha, Brianna, and Carmen on a merry-go-round. At each moment you see them in some order (left, middle, right). As the merry-go-round turns, what are all the different orders in which you see them?

D. If Arisha, Brianna, and Carmen have a race, and there are no ties, what are all possible outcomes: first, second, third?

E. In a 3 x 3 grid square, color three of the nine (unit) squares blue, in such a way that there is exactly one blue unit square in each row and in each column. What are all ways of doing this?

F. What are all the symmetries of an equilateral triangle?

Discernment format (intuitive): Put each problem letter in one of these boxes.



Put letters in the same box if the problems are structurally the same. If two letters are in different boxes but the problems are closely related structurally, connect the boxes with a line. Provide an explanation of each choice in your "network."

Connected structure format: Identify a mathematical structure underlying each problem. Indicate and justify when these structures are the same, and, if not, whether and how they are significantly related.

Figure 1: The 3-permutation problem set.

Two related dimensions of design are visible here. The *mathematical dimension* is the problem set itself, and its salient features. What is involved in constructing such sets? Mathematically, the problems should be diverse, yet they should involve some common mathematical structure — in this case the set of permutations of three objects — yet not all in the same way.

The *pedagogical dimension* is the framing of the task presented to the learners; two versions are offered here. My work has focused on college students, although the ideas could be adapted for broader use. Several things are worth noting. First, students are not explicitly asked to solve the problems. Indeed, parts of the task can be performed short of solving all of the problems. Second,

the work is intended to be done collaboratively in small groups and over an extended time, more than a single class period. Third, this is a novel and complex kind of mathematical work, so initiation was designed to make less rigorous, more intuitive demands on students, to open up for discussion the complexity and likely unanticipated subtleties involved. I hypothesized that the connected structure format is best used only after practice with the more accessible discernment format.

What does the underlying structure of a problem mean? And what does it mean for two problems to have the same underlying structure? The absence of definition in the example above is not an oversight. *Generic* answers to the first question seem to be unhelpful. Yet one can give a persuasive answer in particular cases, and its details emerge only in answering the second question, which takes the form of a transformation from one structure to another, or in linking both to some overarching structure. It appears to be more intuitively meaningful to identify a structure that two problems share than to discern and articulate *the* underlying structure of a single problem.

Consider the number *five*. Where is it? Can you point to it? You can hold up five fingers to exemplify five. And to show that another set also does so, you can list its members, i.e. match them with your five fingers. So, we can concretely demonstrate that two things both represent five, but *five* itself is an abstract concept naming a sameness shared by all five-element sets.

Faced with two problems, the learner might discern something similar about them, for example their solution spaces, and a transformation between them, and the structure (new, and yet un-named) emerges as the set of features, deemed to be fundamental to the problems, preserved by this transformation. This is the hoped-for discussion that could emerge from learner responses to the prompts above.

Consider, finally, an analysis of the problem set above. A defensible "connection network" is:

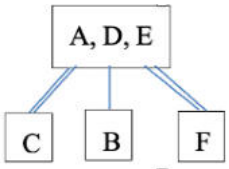


Figure 2: Defensible network for the 3-permutation problem set.

Clearly each of the solution spaces of A (digits) and D (racers) consist of all six permutations of three objects. The same, less obviously, is true of E (three blue squares). One can, for example, match the solution spaces of D and E by interpreting the columns of the (3x3)-grid square as the running lanes of the three racers, and blue squares as the runner positions at the finish line. The solution space of B (letters) consists of only five of the permutations of {a, e, t}. For problem F, a symmetry of the triangle is determined by the permutation it performs on the three vertices. Again, all six permutations occur, but this is not a priori clear, as in the case of A and E; one has to show that each permutation on performed by a geometric symmetry. Similarly, the solution space of C (merry-go-round) is a set of permutation of the three girls. It turns out that all six permutations occur, but this again requires some significant geometric reasoning.

Some people may question then why C and F are separated from A, D, E, since their solution spaces are all the same. One way to clarify this is to consider the problem set for 4, or n, in place of 3. Then the number of solutions remains n! for A, D, and E, but it is 2n for F, and n(n-1) for C, and with very

different arguments in the latter two cases. These numbers agree only when n = 3. The instructional design calls for this elaboration to n = 4 to be brought to learners' attention to prompt reflection on their previously constructed connection networks for the case n = 3.

Note that, despite the subtlety of some of these connections, these problems themselves are all reasonably accessible, say to middle school students.

Conclusions and next steps

This project was inspired by the well-recognized importance of mathematical connections, and it is directed at the least developed kinds of deep connections, those that express some of the larger scale coherence of mathematical thinking as a whole. Its conception was crafted in light of the large literature on mathematical connections; informal and cursory observations of some curricular materials; and the structures and norms of disciplinary mathematics. The designed products, reported here, are bi-partite, consisting of connected-structure problem sets, together with designs for their instructional use. While such designs may, at first sight, seem to be simply curriculum materials, they are distinctive in some ways worth noting. First, they consist of carefully curated sets of problems designed to support the teaching of COMT, itself an important and sometimes overlooked mathematical disposition and practice. Second, the problem sets are accompanied by a specific instructional design, situated in collective group work. Third, construction of the problem sets themselves was challenging and called for some novel skills. To advance this work, it will be important to develop more of them, and more diverse examples. Finally, the designs demand more than usual instructional time and multi-leveled developmental structure.

The designs discussed here were developed at first informally in a variety of my undergraduate mathematics courses, including one for secondary mathematics teachers. In those contexts, I have informally experimented with the designs, with results that informed their development.

This project is a first step in a longer-term agenda. Next steps for its advancement are:

1) More empirical evidence that connection-oriented mathematical thinking (COMT) is a broadly needed skill for students, especially those in STEM.
2) Well documented and analyzed enactments of the kinds of designs presented here, to determine to what extent they support the learning of COMT.
3) Development of measures of COMT, which is a co-requisite of 2).

Consistent with the findings of Maher and Martino (1996) and Weber et al., (2006), the learning of COMT takes time to mature. And so, one cannot expect polished student performance from fresh exposure to these complex ideas. Serious ambitions in this direction must be comfortable with modest initial outcomes, yet remain bold in aspiration. Even if enacted, COMT would not always be a deliberate goal of instruction. But, outside those dedicated episodes, the residual effect should be development of what might be called, "*connection-sensitive mathematical thinking*."

Some have argued that, under the influence of technology, notably AI, many work environments will be changing radically and rapidly (National Academies of Science, Engineering, and Medicine, 2024). And that this will call for adaptive knowledge and skills to enable continued functioning in less familiar environments. While this thinking remains speculative, it offers some potential support for the broad importance of COMT.

Acknowledgments

Deborah Ball provided invaluable feedback in the preparation of this paper, And Mark Hoover assisted in its formatting. I thank them both.

Students' perspectives on GPT-4's supported problem solving

Francesco Contel and Annalisa Cusi

Sapienza University of Rome, francesco.contel@uniroma1.it

In this paper we present an exploratory study aimed at investigating upper secondary school students' perspectives on the role that GPT-4 could play in scaffolding their problem solving processes. Data have been collected by means of semi-structured interviews developed before, during and after students' interaction with GPT-4. The data analysis, developed by the IPA methodology, is presented by focusing on a paradigmatic example of a 15-year-old student. The results of the analysis highlight clusters of themes that allow us to shed light on the complexity of the instrumental genesis processes that characterize human-Large Language Models (LLM) interaction, suggesting that this complexity should be taken into account in the design of suitable tasks involving LLM.

Keywords: GPT-4, students' perspective, instrumental genesis, problem solving

Introduction

Problem solving (PS) is a significant part of worldwide mathematics curricula. In an educational and research context that is increasingly affected by the presence of Large Language Models (LLMs), mathematical PS activities mediated by this technology represent a starting point both for empirical exploration and theoretical conceptualization of a broader class of AI assisted mathematical teaching and learning situations. Effectively approaching problems requires the necessary involvement of metacognitive processes (Schoenfeld, 1992). Given the inherently linguistic dimension of metacognitive processes, these could be effectively scaffolded by LLM-based chatbots, due to the capabilities of real-time and human-like text generation that LLMs possess. However, a number of concerns have been identified: LLMs produce either fictional or non-factual information, they lack understanding of natural and symbolic language at the semantic level, with specific implications in the field of mathematics (Frieder et al., 2024). To use LLMs for mathematics tutoring, it is crucial to improve their mathematical skills and the quality of their feedback (e.g., Schorcht et al., 2024). This suggests the need of addressing these concerns by developing research studies aimed, at the practical level, to identify criteria for the design of teaching interventions based on mathematical tasks involving the use of LLMs, and, at the theoretical level, to clarify the status of LLMs and of the interactions mediated by them in relation to existing frameworks in the context of Mathematics Education with digital resources (DRs). It is precisely at the level of the theoretical foundations that we position our contribution: following the assumption that LLMs can be impactful if used as teaching resources, we believe that to better understand which phenomena occur in human-LLM interactions is a prerequisite to inform effectively the methods for the design of tasks mediated by this technology. The research documented here is part of a broader study focusing on the role of LLMs in supporting students' metacognitive processes in problem solving (Contel & Cusi, 2024).

Theoretical Framework

The *instrumental approach to mathematics education* emphasizes the role of artifacts as essential components of learning processes and proposes to consider an instrument as a living entity throughout

the students' activity when facing mathematical problems. At the heart of this framework lies the notion of *instrumental genesis* introduced by Rabardel (2002), which is the process of developing an instrument from the interaction between a subject and an artifact, with a specific set of goals in mind. This relation is so defined in dialectical terms: the instrument develops from a given artifact, but also the artifact itself could be transformed by the instrumental genesis; drawing from Vergnaud's concept of scheme (1998), Rabardel introduces the concept of utilization scheme as "the unchanging organization of the subject's behavior for a class of situations, both in terms of action and symbolic activity" (Rabardel 2002, p. 78). An instrument therefore is defined as a material or symbolic artifact with one or more associated utilization schemes, resulting either from an autonomous construction specific to the subject, or from an appropriation of schemes formed outside of him/her. In the context of dynamic technological environments the notion of instrumental genesis has been extended, by Hegedus and Moreno-Armella (2010), to the notions of simultaneous co-actions between a user's use of a tool and a software environment's use of a tool, interpreting processes of utilization of the tool as the feedback and reactions of a user. In the authors' words:

"For instrumentation, we additionally define it as how co-actions with a tool shape the user's actions and understanding of the use of such a tool within, and with respect to, an environment. Instrumentalization is extended to how the tool is shaped by the user (user's knowledge) and the environment, i.e., when the tool is manipulated by environmental factors following a user-input." (Hegedus & Moreno-Armella, 2010, p.30).

Following a previous research (Contel & Cusi, 2024), we interpret the user (the student) and the digital environment with which he/she interacts (the GPT-4 environment) as alternately playing the roles of actors and re-actors in performing actions. According to this interpretation, the utilization schemes developed by the students in their interaction with GPT-4 influence the way in which GPT-4 re-acts and, at the same time, the development of these utilization schemes is influenced by the way in which GPT-4 scaffolds the students' problem solving processes. In this paper, we investigate students' perspectives on the instrumental genesis, by addressing the following research questions, which respectively focus on the instrumentation (RQ1) and instrumentalization processes (RQ2):

RQ1. How do students interpret the influence GPT-4 has in their problem solving processes?

RQ2. How do students interpret their use of GPT-4 as a tool to support the problem solving process?

Analytical framework and research methodology

The exploratory study that involved 19 upper secondary school volunteer students (grades 9 and 10). Students worked individually on two tasks focused on the use of algebraic language as a tool to construct proofs in arithmetic (see "Results" on page 4), with GPT-4[1] as the only means of support. GPT-4 was pre-prompted by the researchers with the following instructions, selected after careful examination of its behavior in previous simulations:

[1] GPT-4 is one version of the popular chatbot ChatGPT developed by OpenAI. For further info about the different models: https://chatgpt.com/

We want to use GPT–4 to guide 15- to 16-year-old students in conjecturing and proving in arithmetic through the use of algebraic language. GPT–4 should act as a tutor, without giving direct suggestions or confirmations, but only by asking questions that stimulate students' thinking. At the end, it should invite the student to revise the results obtained in relation to the initial objective. It would be better to ask one question at a time. Each question should be as concise as possible, using language that the user can understand, without losing rigour at the mathematical level.

A semi-structured interview was conducted before and after students' work on the two tasks. Each session lasted about 100-120 minutes. The data collected were the written notes taken by the students, the chats, the transcripts of the audio- and video-recordings of students' interaction with GPT-4 and of the semi-structured interviews.

We carried out a twofold analysis of the collected data: (1) analysis of the video-recordings of the interactions between the students and GPT-4 to highlight the characteristics of the PS processes that are developed; (2) analysis of the students' interviews to identify themes emerging from their reflections on the influence of GPT-4 and to their use of GPT-4 to support their PS processes. Level (1) of analysis was developed by referring to Schoenfeld's (1992) analytical model of PS protocol analysis. It takes into account different processes observable in different environments (e.g. with the mediation of a DR, like in this study): analysis, exploration, planning, implementation, verification. We created timeline diagrams to show the processes developed by students and the time spent on each process throughout the PS activity. Moreover, following previous findings (Contel & Cusi, 2024), the diagrams were enriched highlighting the occurrence of specific monitoring processes that are relevant in the characterization of human-LLM interaction during PS. We included 3 types of visual indicators of the moments when students asked for help activating a monitoring process; process-oriented monitoring (in Figures 1 and 2, dashed red line), conversation-oriented monitoring (dashed green line) and requests for confirmation after procedures are implemented (dashed blue line). In these diagrams it is not possible to look directly at GPT4's interventions, but, coherently as our interpretation of it as a re-actor, the change in the PS phase is started by a student's request. The co-occurrence of PS phase shifts and monitoring process activation in our interpretation shows an impactful interaction.

Interviews (2) were analyzed with the Interpretative Phenomenological Analysis (IPA) approach (Smith & Osborne, 2003). IPA aims to understand the complexity of meanings rather than to measure their frequency and it does so through a sustained examination of the text in order to identify emerging themes from the interviewed person's perspective, which are subsequently categorized into clusters; clusters are then organized in a narrative account of the interview. Starting from the findings of the previous phase we looked for instances of alignment and misalignment between the student's perspectives and the characteristics of the observed interactions according to the protocol analysis.

Results

We present the data analysis methodology by focusing on a single example, the case of Jack, a grade 9 student who was 15 years old at the time of the study. He described himself as "familiar with ChatGPT, I use it almost every day", although not specifically in the context of mathematical PS. His

previous experience with ChatGPT is the main reason why we decided to focus on his case. Previous experience drives his awareness of his own instrumentation and instrumentalisation processes; these processes are subjective, but Jack's acts and reflections focus on aspects which we consider to be relevant for the instrumental genesis process in a general way. Generality should be read here in theoretical and analytical terms rather than being interpreted as a statement about the sample derived from a statistically accurate data analysis. Jack's case is proposed as a paradigmatic one because of his "expert user" perspective and for his ability to take into account many different factors that were mentioned separately by different students.

Jack was asked to solve the following tasks through the support of GPT-4:

T1: Consider a natural number. Write down the difference between its square and the square of its antecedent. What regularities do you observe? Consider other numerical examples to help you develop your conjectures. Can you prove your conjectures?

T2: Consider a natural number. Write down the difference between its cube and the number itself. What regularities do you observe? Consider other numerical examples to help you develop your conjectures. Can you prove your conjectures?

Figures 1 and 2 show the results of the protocol analysis (level 1) relative respectively to T1 and T2. Figure 1 shows two distinct cycles of Exploration – Planning – Implementation (E-P-I); although the second E-P-I cycle starts with "Analysis", we consider the two patterns to be equivalent since Analysis and Exploration phases are not completely distinguishable. The resolution process in Figure 2 consists of two distinct macro-phases which lead quite straightforwardly to a verified solution; however, the task should not be interpreted as worked in a routinely manner: transitions between phases occur in general in correspondence of Jack's questions to GPT-4 or of answers to the previously received questions. This suggests that GPT-4's support is impactful in driving the overall process. This is testified by the fact that the two key transitions between the two cycles and before the verification phase occur after Jack's request for conversation-oriented monitoring (dashed green lines). We interpret these as moments of effective co-action between the chatbot and the student: Jack is able to steer the chatbot's help towards the desired direction, while GPT-4 re-acts positively to the student's prompt.

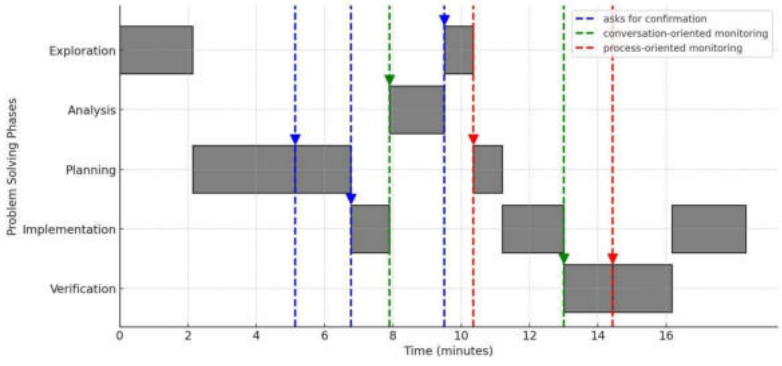

Figure 1: Timeline diagram of T1 problem solving process

Figure 2 highlights that the PS process related to resolution of T2 is more complex: this process is highly non-linear and the interaction lasts almost twice as long as T1. Pattern E-P-I, suggesting initial linearity in Jack's actions, is abandoned after the first cycle, leading to a phase characterized by jumps between Exploration and Planning.

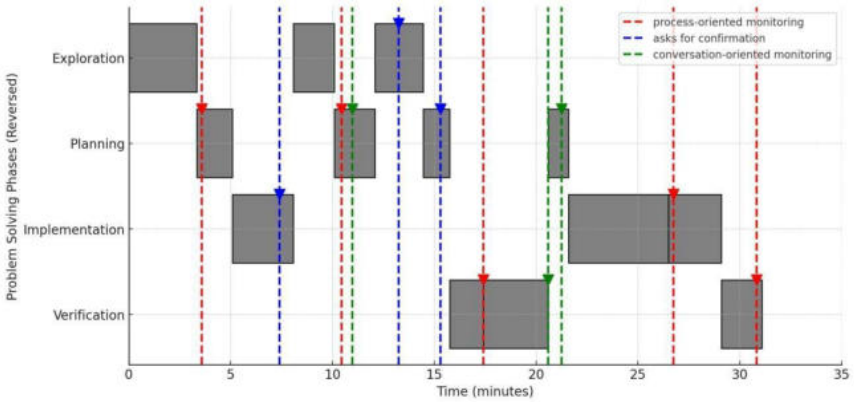

Figure 2: Timeline diagram of T2 problem solving process

The impasse is overcome at minutes 20-21, with the following conversation (in Figure 3, the two subsequent vertical dashed green lines):

1. Jack: This way seems too complex to me, are there other simpler ways?
2. GPT-4: I see, let's explore another way that might be simpler. A good strategy might be to look directly at the algebraic expansion of the difference between the cube of a number and the number itself. In other words, examine the expansion of $n^3 - n$. The question to consider is: Can you algebraically decompose the expression $n^3 - n$ in a way that will reveal a regularity or a pattern? Hint: You might want to consider the fact that $n^3 - n$ can be written as $n(n^2 - 1)$, and then examine the $n^2 - 1$ term more closely.
3. Jack: Don't tell me too much.
4. GPT-4: You're right, let's proceed step by step. Let's start with the first part of the decomposition: can you decompose the expression $n^3 - n$ into a product of simpler factors?
5. Jack: n x (n+1) x (n-1)

Jack's explicit request for a different kind of help (line 1) is a turning point, confirming the importance of metacognitive processes in the management of the DR; however, GPT-4's intervention is not aligned to Jack's will and needs, prompting the student to execute an order and partly giving him the answer, more than stimulating his autonomous cognitive and metacognitive processes.

The IPA analysis (level 2) provides insights into these phenomena: 3 clusters of themes emerged from the semi-structured interview. The first cluster of themes includes the support Jack has received by GPT-4, suggesting a possible answer to RQ1. GPT-4's help is seen as *substantial* from many different perspectives: the feedback is timely ("One thing is that this is immediate, i.e. you can ask

him[2] straight away and he gives you the answer straight away.") and being guided by many questions and prompts is helpful. He recognizes that this kind of support is somehow overly assertive ("Maybe, I don't know, in another case I would have done a different process."), having made him focus on something he would have not done. At the same time, Jack shows to be aware that what he received was not always the desired support: he evidences the difference between being helped with reasoning and being helped with the solution ("then when he had corrected me and I had asked 'what did I do wrong?' he had helped me more with the solution, that is he had told me *more than I actually wanted to know*"). The second cluster groups themes around the difficulties that Jack faced and the way GPT-4 contributed to them, suggesting further ideas to answer to RQ1, but also providing issues to bridge Jack's perspectives on the instrumentation (RQ1) and the instrumentalization processes (RQ2). A major theme is the ambiguity of language in case of misunderstandings. Jack reads many of the problematic situations he had to face through the lens of communication; he provides examples of words or constructs used by the chatbot which prevented him from focusing on some aspects of the problem, while driving him into others:

> "My block was more about the language used: 'How could you use algebra to prove your conjecture?' I thought I had to do something more complicated[...] reading the text, I would have done it, then he, by saying this, sent me into a bit of confusion just what to do, how to proceed […] he uses specific terms, exactly, and also expressions. But for someone like me who is not an expert, it is more difficult."

The other major theme is GPT-4's limitations: Jack is perplexed by its computational and symbolic capabilities, claiming that "you gotta be careful with its calculations, Chat might correct you and then state that he made a mistake himself". Jack gives much importance to the communicational issues, almost never mentioning mathematical difficulties.

The third cluster, which concerns the ways Jack tried to deal with the difficulties characterized through the second cluster, provides ideas to answer to RQ2. In relation to the issue of communication and language, he shows contrasting reflections: on the one hand, he points out that GPT-4 is adaptive since it may follow language and instructions, if properly prompted; on the other hand, Jack reveals that his behaviors were influenced by his previous experience with the chatbot:

> "so maybe it should be re-specified here 'I want to know but don't give me the solution of the final calculation'. So it should always be specified what you actually want and what you don't want, even if it has been said before."

He claims that an autonomously devised strategy is fundamental to get the support he wants:

> "One point I have made is that first it is always preferable to do the things you think for yourself, that is without the help of what he tells you that can be confusing […] Because, for example, I got

[2] Italian is a language with two categories of grammatical gender: masculine and feminine. Since there is no neutral form, in Jack's case ChatGPT is described as in masculine terms (some people use the feminine, because AI is feminine, as "intelligence"). We chose to translate coherently with this, emphasizing the student's original discourse.

> stuck before because I didn't know what to do, maybe thinking first, even if wrong, and then telling him what you have thought; first do all the reasoning, even if you want to do it algebraically, then present it in some way and see what he tells you, so whether right, wrong or whatever, instead of starting from scratch with the problem."

Jack confirms this stance in several moments; we interpret this as a personal initial utilization scheme, which helps the student to accomplish new results. Seen from the co-action perspective, we read in Jack's words a kind of synergy that brings understanding: "When we changed course, then he started from what we had said [...] *then there was the union* between what I had seen and what he wanted me to do, then there I understood." A connection is being recognized between his monitoring and the chatbot's desired behavior. Deeply linked to this last theme is that of trust and control: Jack feels in control of the situation as long as he understands the math involved;

> "In this case I trusted him, because we always remain in things I understand, that is, when there was the road I couldn't understand what he made me do and why he made me do it, there I wouldn't trust him because I just didn't understand. [...] What I have seen is that with what he gives you, and clearly with the skills you have to have, because if you do that exercise you have to have the skills, *united* you get to the result much more easily."

Discussion

With reference to RQ1, we propose evidence of the significance of GPT-4's impact in driving the overall PS process: the protocol analysis confirms the potential of this technology to interact with students. The user's perspective of this interaction as a "union" of forces suggests that this might happen in a synergic fashion, in line with the conceptualization of co-action between user and environment (Hegedus & Moreno-Armella, 2009). The correspondence between PS phase transitions and monitoring processes activated by Jack suggests that his metacognitive skills and knowledge of the artifact emerge as crucial factors, which strongly influence his interaction with the conversational agent. However, while the support is effective, the LLM does not allow for an autonomous reflection during PS: co-action, to be properly developed, requires full control of the user over the resource. Jack's reflection about control provides a bridge to RQ2: we interpret the need for control as the need to develop an effective utilization scheme, to steer the chatbot towards the desired goal. Jack shows awareness of the limitations such as the possibility of hallucinations or conversational loops leading to dead ends; it is also remarkable the connection he draws between his trust in GPT-4's support and his ability to control the underlying mathematical meanings. This awareness is reflected in the development of reflections and the performance of actions meant to manage these sources of issues. The user's reflection on its own instrumentalization processes is evident in the management of the PS process, that becomes the management of the LLM, in order to receive a support perceived as effective and aligned with the user's aim.

Our results highlight the need to reconceptualize the notion of co-action between a user and an environment (Hegedus & Moreno-Armella, 2010) in the context of human-LLM interaction, since the GPT-4 environment does not allow the environment's response to be uniquely associated with the user's action, despite the users' efforts and despite the back-and-forth dialogical structure of co-action.

Flexibility is a required feature of utilization schemes in users' interactions with an artifact, because, as Rabardel (2002) points out, utilization schemes are constantly evolving. What we see in this case, however, is something more: complex tasks such as those tested in our study can hardly be handled with a fixed approach that can be associated with a scheme that becomes stable over time. This has implications for future studies about the design of LLM-mediated mathematical tasks. More research is due to better understand the complexity of human-LLM interactions also to address the limitations of this study: the specific nature of the instrumental genesis process requires longer and more systematic observation of the students' activities; Future studies will also address the issue of prompt engineering, as this feature has a significant impact on the overall behavior of the chatbot and consequently the instrumental genesis process.

Noticing of teacher students on an explorative task to exemplify the potential of using technology

Patrick Ebers

University of Duisburg-Essen, Germany; patrick.ebers@uni-due.de

The potential of technology unfolds above all in the context of explorative tasks. This represents a major challenge for teaching, for which teacher students must be prepared. Using an exemplary task within a video case, 44 teacher students were asked to create an appropriate answer to the ideas of the students in the video case. The study shows that pupil's difficulties are noted at the levels of subject content and use of the medium, but that the pupil's thought processes are not examined. As a result, there is often a lack of in-depth diagnosis of the causes. The role of the technology for the learning process of all learners in this task is underestimated in many cases.

Keywords: Task design, open-ended approach, technology, video case, teacher noticing.

Introduction

Teachers' reactions in the classroom are based on what they notice. For this reason, (teacher) noticing has become one of the most important components of teaching expertise (Gaudin & Chaliès, 2015). The training of this skill is very often done by video cases. The presented study deals with the construction and implementation of a video case with a special focus on students' subject-specific learning using digital tools while working on an open-ended task. Since tasks play a central role in teaching mathematics (Jones & Pepin, 2016), the use of a good task is a basic prerequisite for the construction of the video case, as first own design experiments showed. For this reason, this article first presents the task used and the video case used. Learning opportunities for student teachers or professional development courses can be derived from the analysis of the video case. The use of the case is structured with four questions. In this study, the answers of 44 teacher students to these four questions are analyzed and related to the learning opportunities described. The aim is to further optimize the case and generate findings for use in teacher training and professional development.

Theoretical Background

Research on task design has been growing since the early 2000s (Kieran et al., 2015). In the study presented here, the focus is on design as implementation (Kieran et al., 2015) for teaching with technology. The presented task stands as a good exemplary for dealing with teaching with technology and is shown in a video case to be used for pre-service teacher training and professional development. The statement "We can no longer consider that teaching mathematics with technology is just an option." (Artigue, 2013, p. 2) still holds true as ICILS 2018 shows (Eickelmann et al., 2019). Tasks must therefore be used that demonstrate the power of digital tools for subject-specific learning. Research reviews have shown that the potential of technology for learning mathematics can unfold primarily in the context of open exploratory tasks (e.g. Drijvers et al., 2016). However, this is a major challenge for teachers, for which they must be prepared. But there is often a lack of time and no chance for detailed observations of individual pupil's work. Video cases therefore offer a good opportunity to look at pupil's work in detail and without pressure to act.

The aims of using cases in teacher training therefore lie in the training of teacher noticing (Santagata et al., 2021). Case based learning offers many opportunities for teachers to learn by example or to follow students' thinking as they work on tasks. Videos are ideally suited to depicting the complexity of teaching, so that noticing can be practiced without time pressure and the need to act (Staal Jenset et al., 2024). Case analysis in pairs or small groups enables a change of perspective that is not as rich without other people. The aim of video case work is therefore in particular to sharpen perception and to consider alternatives for teaching activities (Santagata et al., 2021). These are just some of the benefits that Staal Jenset et al. (2024) highlight as findings from the three major literature reviews on teacher noticing. The research related to teacher noticing is becoming increasingly diverse. In particular, studies dealing with mathematics are very present. Videos that focus on teachers' actions are frequently used. Comparative analyses between the noticing of pre-service and in-service teachers are also presented. Only a few studies focus on student thinking. In this context, Jacobs et al. (2010) focus in their study the professional noticing on children's mathematical thinking in grades K-4. A study on teacher noticing, which deals with the use of digital tools for subject-related learning, was not found in comprehensive research.

In the present study, a video case is to be created as a medium for teacher training, which offers prospective teachers the opportunity to observe the processing of a task with digital tools, to understand the pupils' thinking processes and to consider what actions the teacher can take to support the pupils. The guiding research questions of the study are: (RQ1) What do teacher students notice in pupils' interactions solving an explorative task with technology? and (RQ2) What do teacher students learn for their own professionalization when working with the video case?

Methods

The study presented here has already been preceded by several design experiments with video cases and the testing of a video case for the same task in the context of different training courses (see e.g. Thurm et al., 2022). The insights gained into the quality of the task and the type of video recording of the pupils are important foundations for the implementation of this study. To construct the video case of Lukas and Robert, a sequence was selected from existing video material in which an interesting interplay of digital tool use and subject-specific learning can be seen. The selected sequence was analyzed by the author and a master's thesis student in order to find out how the pupils work on the task with a function plotter. In a mutual exchange, difficulties were identified at a subject-specific level and at the level of media use. This led to the formulation of four questions that were used for the student teachers' task and to structure their case analysis. Mathematics student teachers for lower secondary level in Germany from the second semester were asked to analyze the video case about the work of two pupils on an open-ended task. The teacher students were already familiar with the pupils' task through their own work a week before the data were collected. 44 teacher students submitted written responses to the following four questions:

1. What are the subject-specific difficulties?
2. What difficulties are there in using the medium?
3. Where do you see a need for support?
4. What insights have you gained for your lessons?

When analyzing the data, it was investigated which subject-related difficulties and which difficulties in media use were noticed by the teacher students. With the third question, the prospective teachers were asked to put themselves in the role of the teaching teacher so that it becomes clear how they would react and where they see the reasons for difficulties. The chosen focus makes clear which aspect is particularly important to the student teachers and where they would start with their support. The last question is intended to initiate a reflection process relating to their own teaching activities. The student teachers' responses were analyzed using qualitative content analysis (Kuckartz, 2012) and then compared with the categories already developed from the analysis during case construction.

The pupils' task and the video case

The task set can first be found in Drijvers (1994). There are various German translations that do not contain literal wording, but wording that is understandable for pupils. However, the task has retained its character. It has been used for many years in the context of courses at the University of Duisburg-Essen and since 2019 as part of various research projects (e.g. Thurm et al., 2022). Figure 1 shows the translated task as it was presented to Lukas and Robert.

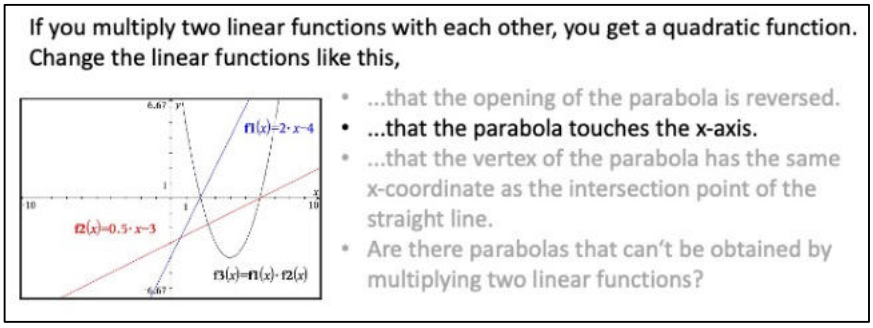

Figure 1: Pupils' task (Thurm et al., 2022, p. 4; highlighted the relevant subtask for this study)

The task is initially an unusual task and yet it can be anchored at different points in the curriculum. Lukas and Robert have already worked with quadratic functions in their lessons. For them, this is an opportunity for productive practice. The solution for this task is, that the parabola must have a double zero. To achieve this, the zeroes of the two linear functions must be identical. Based on the graphic in the task (see Figure 1), you could set $f_2 = 0.5 \cdot x - 1$ and would thus have the double zero at $x = 2$. From another sub-study, in which written solutions of pupils from a grammar school in Berlin were evaluated, it was found that many solutions were just one example or contained an example with a generalization or consisted purely of the general solution. In some cases, the pupils indicated the possibility $f_1(x) = -x$ and $f_2(x) = x$, which solves the first three subtasks at once. This shows the range of what can be expected when pupils solve the problem. The task offers the potential for the advantages of using the tool to become clear. Algebraic solutions to the task are possible, but they cannot be followed by the pupils. The tool offers the possibility of finding a different approach to the solution through the dynamic visualization. This includes the linking of graphic and symbolic representation, so that changes become visible, and the generation of examples through static representations which facilitates the work of developing and testing hypotheses. The task is therefore particularly suitable for the aim of the study. The pupils can use the tool to make rich mathematical

explorations that can be used to analyze the thought processes and the interplay of subject-specific learning with the media and the interaction of the pupils with these resources.

The video case Lukas and Robert shows two pupils from a tenth-grade comprehensive school in North Rhine-Westphalia, Germany. With the help of a function plotter, they are working on the presented task, which is an open-ended approach (Shimada, 1997). By varying the parameters (slope and y-intercept) of the linear functions, the parabola should touch the x-axis. In the video case the pupils Lukas and Robert have already completed the first subtask and are working on the second subtask. Although the task has been used frequently and the range of expected solutions is very broad, Lukas and Robert generate a surprising special case. Based on their knowledge that the parabola $h(x) = x^2$ touches the x-axis, they draw up the following plan: They want to "remove" the values in front of the x in order to generate an expression with x^2 without a prefactor when multiplying. They do not take into account in their explanations that the coefficient 1 in the product with x does not have to be written down. Both linear functions now have a slope of 1 and their graphs are parallel to each other in the coordinate system and the resulting parabola does not yet touch the x-axis (see Figure 2).

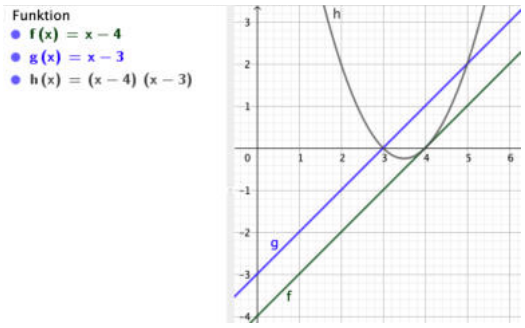

Figure 2: Reconstructed screenshot from the case of Lukas and Robert

By considering this special case, Lukas and Robert are confronted with an additional difficulty as the y-axis intercept and the zero point now have the same value in terms of magnitude (see Figure 2). They now change one of the two y-axis intercepts step by step, reflect on the resulting graph and think again about which value they want to try next. Due to the slope 1, incorrect interpretations of the parameters are made. This procedure can be assessed as systematic trial and error. The systematic variation is shown by the fact that they first consider which y-axis segment they want to change and only one. To do this, they always first say what they want to try, then comment on the result and then change the selected parameter again. In the end, they manage to find the one correct solution that was still possible for their special case with variation of the one parameter:

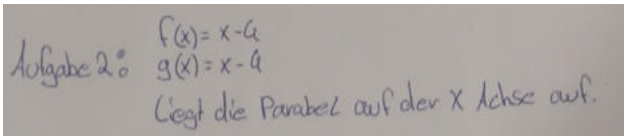

Figure 3: Written solution of Lukas and Robert

The role of the teacher in the video case is supportive. She tries to help the pupils to understand the task and explains the dependence of the parabola on the linear functions. The language chosen is not technically correct. This can also be taken into account when analyzing the case. It becomes clear

from working on the task that Lukas and Robert construct a special case that only allows the solution of equal linear functions. They find this solution and write it down. They do not reflect on their result and see no need to look for further solutions. The case analysis revealed three important levels (subject-specific skills, media use and the role of the teacher) of learning opportunities of the case, that guided the questions for the student teachers. The identified levels are shown in Table 1.

Table 1: Identified learning opportunities of the case

subject-specific skills	(a) the misconception that the coefficient for the slope is 1, even if there is no number
	(b) the confusion of the y-intercept with the zero due to the fact that the slope is 1
	(c) difficulties with linguistic correctness and the use of technical terms
media use	(a) general uncertainties during input, which are also linked to the requirements of the task
	(b) opportunities that a slider might have had advantages over manual input
	(c) a potential when switching between symbolic and graphical representation
role of the teacher	(a) correctness of used language
	(b) she could offer more help related to the specific problems

Results

To answer RQ1, the teacher students' responses to question 1 and 2 were connected. The subject-specific difficulties mentioned by the teacher students can be roughly divided into two areas: a) basic subject content and b) difficulties in processing. The statements relating to a) include comments on the meaning or confusion of the parameters. Here, students do not mention any causes such as the gradient with the value 1. In fact, no one refers to this special case. This lack of specific focus on mathematics is also described by Jacobs et al. (2010), who state that much more general pedagogical aspects are considered by pre-service teacher. It is surprising because the special case can be seen as the cause of the confusion between the value of the zero point and the parameter for the y-intercept in the case of Lukas and Robert. The confusion of the terms "y-value, f(x), x/y-axis" is mentioned and suggests that the use of correct terminology seems important to the students. Interestingly, it becomes clear at various points that the teacher students also show weaknesses in the use of terminology. Each word 'parameter' and 'factor' is only used once in each of the 44 answers, but words such as 'component' or 'element' are used instead. Four teacher students mentioned the confusion of axes. One person made it clear that this could just be a slip of the tongue and referred to a point in the video. The fact that Lukas and Robert construct a special case by generating parallel straight lines through their input is also not mentioned by the students as a difficulty or hurdle. The difficulties in working on the tasks are identified as understanding the task with the dependency of the functions and the resulting initial problems in varying the parameters. Despite the teacher's support in the video case, the teacher students very often see further difficulties, that the pupils do not know how to move the functions, as the biggest problem. Unfortunately, the teacher students also

do not recognize a systematic approach when trying things out. In 7 out of 44 answers, the procedure is described as pure trial and error.

The teacher students' answers to the question about difficulties in tool using can be divided into four categories: a) problems with input or shifting, b) undirected use in the form of trial and error, c) emphasis on skills and no difficulties and d) comments independent of the medium, based on the processing of the task or subject-specific principles. In 15 of the 44 responses, general problems in the use of tools are seen and these are attributed to a lack of routine. A total of eight of the responses mention the specific situation in which Lukas and Robert want to enter x^2 and are not familiar with the notation x^2. Three answers mention that Lukas and Robert do not know how to move the straight line. However, a drag mode is not available in this tool. One teacher student says: “It would be very helpful for the pupils if they could move the straight lines.” This is one of the few in-depth explanations of tool usage. Three of the 44 responses contain statements on b) undirected use in the form of trial and error and random insertion of numbers. One teacher student explains this by the openness of the tool, that there are too many possibilities for variations. A total of nine statements can be assigned to category c) emphasizing skills and no difficulties. Many answers remain very superficial. Twelve statements can be assigned to category d) media-independent comments. Of these, seven answers are to be understood in such a way that the teacher students indirectly reproduce the task and name this as a difficulty in using the tool. In addition, four times subject-specific basics are mentioned that lead to difficulties in completing the task.

One teacher students’ answers are highlighting an algebraic solution as optimal. It is stated that the medium tempts the pupils to solve the task geometrically. Already the answer to the first question is, that the pupils must solve the task algebraically. From the third answer it can be inferred that the pupils must be informed about the lure of the medium and that they should be led to an algebraic approach. This shows how fixated this teacher student is on their own solution path.

For answering RQ2, teacher students’ answers to question 3 and 4 were analyzed. The responses on the perceived need for support reflect the previously described levels of professional foundations and tool use. Methodological approaches were also mentioned. These include process-related and content-related support e.g. in a way that the pupils’ explorations are more structured, or the graphical representation should be analyzed in more detail. Four answers state that the task needs to be explained in more detail so that the dependencies are better understood. Content-related support should be given to pupils in the subject-specific basics of linear and quadratic functions and the meaning of parameters. Two answers are interesting which similarly describe that the pupils must first know the solution in order to then set this on the tool. This changes the role of the tool in such a way that it only serves to represent the solution and not to find it. This shows that the potential of the task for independent exploration of the relationships is not recognized or is assessed as non-existent by the teacher students. Another teacher student mentions that there are also solutions where the linear equations are not identical. In a discussion on teacher PD level, it could be mentioned that this can be used methodically so that Lukas and Robert can extend the solution they have found.

The final question on the insights that teacher students take back to their own future lessons is intended to provide information on which aspects cause them to change their way of thinking and

thus perhaps find their way into their lessons. For the case work, it is important that each specific case should contain something generalizable, which is meaningful for their future teaching (Staal Jenset et al., 2024). Unsurprisingly, the answers can again be divided into the areas of subject-specific basics, in particular the explicit repetition of individual content, and the use of the tool. The focus here is on explanations and assistance. The use of the tool is often praised, and it is emphasized that work with it should be intensified. The pupils' work with the tool is described as pure trial and error, which according to some should be better guided, and it would be better not to lose sight of the pupils so that not too much time is lost. At the same time, others positively emphasize that the time for trial and error is particularly important so that the pupils can deal with the mathematics independently. Fortunately, the latter opinion predominates in the teacher students' responses.

The following opinions regard to the task. Five out of 44 responses refer to the fact that the task needs to be explained better, and that pupils' questions need to be clarified before the task is worked on. Three times, the open exploration of the pupils and the associated character of the task was praised. One teacher student even highlights that they would like to use this kind of task themselves. It was emphasized that solving the task as a team was particularly helpful, also to stimulate discussions.

Conclusion

The teacher students perceive the nature of the task as the greatest challenge for the pupils. In addition to the recommendation to better guide the explorations with the tool or to prepare them with structure-like tasks, it is important to them that the pupils are given time to try things out. There is a difference between the perception that trying things out is aimless and praise for persistent exploration. A step-by-step instruction for exploring the relationships would be easier to grasp, particularly through dynamic visualization. Instructions on how to use a slider would be a simple means of using the tool. But it should always be clear that the tool character of the medium is retained, with which the pupils make their explorations and is not used solely for presentation their solution. In a final discussion at teacher PD level, it can be made clear why Lukas and Robert's exploration can be described as systematic experimentation. Perhaps this also changes teacher students' attitude towards the potential of the tool when working on the task. Different approaches include explicit input of parameters, sliders or, in some tools, a drag mode. Those possibilities once again show the potential of this task.

For their own future lessons, teacher students learn how difficult it is to observe the work of all pupils. It is therefore important to create the best possible conditions for independent work. To this end, they state that they would like to discuss tasks thoroughly and use tools continuously in lessons. Step-by-step introduction of various commands and tip cards should support the use of tools in order to reduce barriers to operation. Concluding discussions are intended to bundle the pupils' explorations and uncover difficulties. No one in the study rejected this type of task. The teacher students have become aware of the challenges and even noted that this way of teaching can be a long-term goal.

Acknowledgments:

Thanks to master's thesis student Maren Hulke for her cooperation in data collection and analysis.
