17 **Abstract**

18  
19 The article investigates changes in the interaction between business organisations,  
20 local governments and public technology intermediaries resulting from business  
21 organisations' shifts towards higher value product segment opportunities.  
22 Specifically, we analyse how local governments can (or not) align their industrial  
23 policies to the industrial transformations – both technological and organisational –  
24 underpinning firms' value creation-capture dynamics. The concept of *structural cycle*  
25 is introduced here to study the two interdependent processes of 'technology  
26 transition' and 'organisational reconfiguration' characterising those firms shifting  
27 towards higher value product segments. This private-public nexus is investigated in  
28 the Emilian Packaging Valley context. The mixed-method study focuses on the case  
29 of IMA Spa, its shifts from the food to the pharmaceutical value product segment of  
30 the packaging machine industry and its changing relationships with regional public  
31 policies and institutions. A number of industrial policy implications for sustainable  
32 value creation dynamics in local production systems are finally derived.

## 1. Introduction

Modern manufacturing systems consist of complex and dynamic interdependencies spanning across various industries and sectors. These interdependences unfold in a wide range of technological, organisational and institutional dimensions and involve different types of system actors. These include business organisations, both competing and cooperating in multi-tiered and 'glo-cal' production systems, but also various types of public and public-private technology intermediaries and multi-level public policy actors. Within these manufacturing systems, structural economic dynamics are mainly triggered by changes in the technology platforms underpinning industrial sectors and changes in the firms' resource-capabilities. In turn, the adoption of new technologies at full industrial scale often requires organisational reconfigurations involving both the Marshallian 'internal' and 'external' firm.

Industrial sectors are based on different technology platforms integrating various sets and types of technologies whose configurations and interfaces change over time in response to technology push and market pull dynamics (Dosi, 1982; Tasse, 2007). Some of these technology platforms underpin production processes of closely-related industrial sectors as well as different value product segments within the same industrial sector. Technologies are thus linked by a set of dynamic interlocking relationships spanning across different sectors and different value product segments. The emergence of these dynamic interdependencies as well as the technology transition from one type of technology platform to another tends to follow cyclical patterns. Often these technology transitions open new value product segments opportunities for business organisations. The existence of technology cycles is particularly evident in relation to technology transitions underpinning firms' shifts from mature declining product segments to new, rising value product segments within the same industrial sector.

The paper investigates how the interaction between business organisations, local governments and various types of local technology intermediaries changes in particular conjunctures, that is, when business organisations shift towards higher value product segments within the same industry. Specifically, the paper provides a theoretical and empirical analysis of the ways in which local governments may (or not) align their industrial policies and public technology intermediaries to the industrial transformations – both technological and organisational – affecting business organisations and the local production system in which they are embedded.

The concept of *structural cycle* is introduced here to describe two interdependent processes of 'technology transition' and 'organisational reconfiguration'. These two processes characterise those business organisations moving from mature or declining value product segments to new, higher value product segments within the same industrial sector. Within local production systems, the challenges associated

1  
2  
3 with technology transitions and organisational reconfigurations are major concerns  
4 for local governments. The reason is that sustainable value creation dynamics in  
5 local production systems depend critically on the capacity of its business  
6 organisations – especially system integrator firms – to capture value *along* and *across*  
7 technology cycles. In other words sustainability depends on the ability of these  
8 firms and other organisations to shift from mature or declining product segments to  
9 new higher value product segment opportunities.  
10  
11

12  
13 The effectiveness of local governments' support largely depends on their industrial  
14 policies (and, their public technology intermediaries - PTIs) being aligned to these  
15 structural cycles. The existing industrial policy literature has failed to take into  
16 account issues of the technology cycle and organisation reconfigurations that are  
17 taking place in the moment policy-makers are setting out key plans. This is  
18 particularly important given that industrial policy is orientated to the future so  
19 policy-makers should be aware not only of these transformations taking place at the  
20 moment of policy creation but also the cycle of transformations taking place across  
21 all moments of long-term policy implementation.  
22  
23  
24

25  
26 The analytical approach of the paper builds on a theoretical synthesis combining  
27 structural dynamics theories of the Cambridge school, resource-capability theories of  
28 the firm and evolutionary approaches to technological change, including life cycles  
29 theories. Structural dynamics approaches focus on the sectoral re-composition and  
30 business cycles of the economic system. They also identify those macroeconomics  
31 conditions that must be satisfied to reach certain policy objectives (e.g. full  
32 employment). Given their meso-macro perspective, however, micro-learning  
33 dynamics, technological change and firm-level organisational reconfigurations  
34 remain largely unexplored. In contrast, the resource-capability theories of the firm in  
35 combination with evolutionary analyses of technological change focus exactly on  
36 those micro technological and organisational processes and dynamics constituting  
37 what we have called here 'structural cycles'. These structural cycles, in turn, result in  
38 changes to the technology coefficients of the overall production matrix of the  
39 economic system, as highlighted in structural economic dynamics theories.  
40  
41  
42  
43  
44

45 While a complete theoretical synthesis is beyond the scope of this paper, section 2  
46 sketches a number of theoretical interfaces and complementarities between these  
47 heterodox theories. Building on this synthesis, section 3 introduces the concept of  
48 structural cycle as a new heuristic for conducting micro-structural analyses of the  
49 private-public nexus (and its changes) in local production systems. It is argued that  
50 local government's industrial policies and technology intermediaries can support  
51 (and, sometimes, steer) shifts towards higher value product segments by aligning  
52 public policies to structural cycles. These policy interventions must be selective,  
53 operate at different levels of the industrial system and provide differentiated  
54 support to the actors in the local production system.  
55

58  
59  
60

1  
2  
3 The second part of the paper (section 4) deploys the new structural-cycles policy-  
4 alignment framework in the context of the Emilian Packaging Valley (EPV), the  
5 highest concentration of packaging machine producers in the world. The empirical  
6 analysis builds on a multi-methods and multi-disciplinary approach combining  
7 patent data analysis, engineering-informed analysis of packaging machinery  
8 technologies, in-depth firm-level qualitative data collection and regional-level  
9 industrial policy mapping.  
10  
11

12  
13 The firm-level analysis starts from the system-integrator IMA Spa (IMA hereafter),  
14 one of the world leaders in the packaging machine industry, and the Regional  
15 Government of Emilia-Romagna in Italy, including its various PTIs. The case study  
16 analysis builds on the structural-cycle policy-alignment theoretical framework and  
17 develops an innovative way to analyse changes in the private-public nexus. Building  
18 on both the theoretical and empirical contributions of the paper, the last section  
19 concludes by sketching a number of implications for industrial policy. It also  
20 emphasises the policy relevance of developing a structural-resource-capability  
21 theoretical synthesis. This heterodox synthesis would enhance local industrial policy  
22 effectiveness and their responsiveness to industrial transformations.

## 29 **2. Industrial transformations: Towards a structural-resource-capability** 30 **synthesis** 31

32  
33 Industrial transformation is a complex process as it involves both the continuous  
34 sectoral re-composition of the economic system and changes in the quality and  
35 composition of demand (Kuznets, 1971; Kaldor, 1972; Landesmann and Scazzieri,  
36 1990; Pasinetti, 2007). In particular, structural change entails both a process of inter-  
37 sectoral transition (i.e. moving across sectors, from low to medium and high  
38 productivity sectors) and of intra-sectoral deepening (i.e. moving within sectors,  
39 from low to high value added activities and product segments). Alongside these  
40 sectoral re-compositions, the increasing division of labour among business  
41 organisations depends on the increasing 'extent of the market'. In turn, the extent of  
42 the market depends on the deepening of the production matrix (Young, 1928).  
43  
44  
45

46  
47 Building on the seminal contributions of economists such as Joan Robinson (1956  
48 and 1977) and Nicholas Kaldor (1967 and 1972), Luigi Pasinetti and Richard  
49 Goodwin developed multi-sectoral models for the analysis of structural dynamics.  
50 Despite the different criteria adopted in the identification of productive sectors  
51 (according to their dynamic features in the case of Goodwin and to their final  
52 outputs in the case of Pasinetti), structural economic dynamics theories share the  
53 same theoretical apparatus. First, they frame economic growth as a sector-specific  
54 process (not sector-neutral or activity-neutral as in the more traditional neoclassical  
55 model such as Solow's). This means that both productivity (learning in production)  
56  
57  
58  
59  
60

1  
2  
3 and demand (learning in consumption) grow at different rates from sector to sector.  
4 Second, as stressed by Pasinetti (2012:553), “[t]he vision behind structural dynamics  
5 originates from the consideration of a permanently evolving economic system”.  
6 Relative economic magnitudes evolve constantly through time and the ongoing  
7 disproportional dynamics shape a certain specific structure of the economic system  
8 at each point in time. Third, structural economic dynamics unfold at different levels  
9 of aggregation according to a specific ‘hierarchy of change’ determined by both the  
10 elements of the systems and their interdependences (Simon, 1962; Landesmann and  
11 Scazzieri, 1990; Andreoni and Scazzieri 2013).  
12  
13  
14

15  
16 In multi-sectoral models, technological change is recognised as one of the main  
17 triggers of structural economic dynamics and the unfolding interdependencies  
18 across sectors. The seminal contribution by Albert Aftalion (1927) theorised a link  
19 between the specific time-requirements for the production of new industrial  
20 equipment and the cyclical fluctuations characterising economic systems. In  
21 Nicholas Kaldor’s assessment of economic growth, production technologies are the  
22 main triggers of productivity increases within manufacturing industries, but also  
23 agriculture (Kaldor, 1966 and 1985). Goodwin stressed the existence of technology  
24 interdependencies emphasising how “an important innovation in energy, or  
25 transport, or *automated control*, will gradually lead to alteration of least-cost processes  
26 in many other sectors and thus will initiate technological change over a long period.  
27 This will persist over time, not only because any such improvement undergoes  
28 prolonged small improvements, but also because it usually needs extensive  
29 adaptation to a *variety of uses*” (Goodwin, 1987, p. 147; italics added).  
30  
31  
32  
33

34  
35 Although these theories provide powerful lenses to frame multi-sectoral  
36 interdependencies (within different time horizons) and assign a central role to  
37 technological change, the latter is mainly treated as a theoretical exogenous construct  
38 to explain the sources of structural dynamism. This implies a number of limitations.  
39 First the ‘real’ technological dynamics, their development and cyclical deployment  
40 in different sectors cannot be easily explained. Similarly, the ways in which  
41 technological change requires (and, in some cases produces) organisational  
42 reconfiguration in firms (and the production systems in which they are embedded)  
43 is neglected. Finally, while shifts from low-tech sectors to more advanced sectors  
44 have been widely researched, industrial transformation consisting of transitions  
45 from mature product segments to new higher value product segments *within* the  
46 same industrial sector remain largely ignored.  
47  
48  
49  
50

51 These limitations call for an investigation of potential theoretical interfaces linking  
52 structural economic theories and micro-structural theories of the firm, industrial  
53 organisation and technological change. Two of these theoretical interfaces are  
54 particularly important for understanding the ways in which the relationships  
55 between business organisations and public policies change over time. One relates to  
56 value creation dynamics and technological change within business organisations,  
57  
58  
59  
60

1  
2  
3 triggering structural dynamics and changes in technology coefficients of the overall  
4 production matrix. The other connects sectoral re-compositions (including changes  
5 in the value of product segments and related technological changes) and  
6 organisational reconfigurations within business organisations (and the production  
7 systems in which they are embedded).  
8  
9

10 Starting with the first theoretical interface, in the resource-capability theory of the  
11 firm, value creation dynamics (underpinning industrial transformations) are mainly  
12 explained as learning processes whereby business organisations accumulate (but  
13 also continuously develop) their internal pool of resources in response to new  
14 production opportunities (Penrose, 1959; Teece, 2007). In contrast to Coase's  
15 transaction cost theory of the firm (Coase, 1937), in the resource-capability  
16 framework creating a firm may in fact denote the highest value option for the  
17 creation and development of internal resources-capabilities (Penrose, 1959;  
18 Richardson, 1972; Demsetz, 1988; Best, 1990; Lazonick, 2010).  
19  
20  
21  
22

23 Penrose's (1959:149) definition of the firm as "a pool of resources the utilisation of  
24 which is organized in an administrative framework" introduces two related path-  
25 breaking propositions for understanding how structural change and disproportional  
26 economic dynamics originate within business organisations. First, the firm is a  
27 collection of physical and human resources that can be deployed in a variety of ways  
28 to provide a variety of productive services. In other words, "the services yielded by  
29 resources are a function of the way in which they are used – exactly the same  
30 resource when used for different purposes or in different ways and in combination  
31 with different types or amounts of other resources provides a different service or set  
32 of services" (Penrose 1959:25). Therefore, heterogeneity within sectors and across  
33 firms, results from business organisations' almost unique pool of internal resources  
34 *and* the ways in which firms combine and deploy them in different value product  
35 segments. These combinations and re-combinations allow firms to shift to higher  
36 value product segments or even move to similar or closely complementary sectors  
37 (Andreoni, 2014). The second related proposition is that the growth of the firm  
38 occurs through the recognition and exploitation of productive opportunities,  
39 specifically of "all of the productive possibilities that its entrepreneurs see and can  
40 take advantage of" (Penrose, 1959:31).  
41  
42  
43  
44  
45  
46

47 As for the second theoretical interface, learning dynamics do not simply concern the  
48 'internal' organisation of the firm, they also relate to its 'external' organisation and,  
49 ultimately, to the overall industry organisation and its sector-specific structure.  
50 George B. Richardson's work (1960 and 1972) is among the first to focus on how  
51 industry organisation develops as a result of both competition dynamics and inter-  
52 firm cooperation. The drivers of these 'co-opetitive' dynamics, in particular the  
53 reasons why certain business organisations choose their 'dancing partners', are  
54 explained in relation to firms' internal capabilities.  
55  
56  
57  
58  
59  
60

1  
2  
3 Richardson (1972:888) describes industries and their firms as entities in which a large  
4 number of activities are carried out through the adoption of an appropriate cluster of  
5 capabilities “or, in other words, with appropriate knowledge, experience, and skills.”  
6 Capabilities are built and accumulated via a continuous process of internal resource  
7 development *but also* as a result of capabilities-driven organisational  
8 reconfigurations involving the ‘internal’ as well as ‘external’ firm (Wilkinson, 1983;  
9 Best, 1999; Pitelis, 2002; Pitelis and Teece, 2009; Lazonick, 2010; Pitelis, 2012;  
10 Andreoni, 2014). Richardson (1972) emphasised how business organisations tend to  
11 specialise in the execution of a certain set of interrelated production tasks (i.e. similar  
12 activities) that only require a limited set of capabilities. At the same time, in  
13 expanding or upgrading the value of their product segments, firms need to acquire  
14 closely complementary but dissimilar capabilities. Business organisations have two  
15 options: either gaining control of the capabilities of other business organisations (e.g.  
16 through acquisitions and inter-firm cooperation) or obtaining access to them (e.g.  
17 through the institution of the market).  
18  
19

20  
21  
22  
23 Therefore, as Marshall (1920) noted, evolution through the division of labour tends  
24 to favour both greater specialisation (increasing capabilities) and closer integration  
25 (an increasing number of organisational configurations to coordinate capabilities and  
26 activities). Thus, capabilities dynamics are at work at the very basis of the  
27 organisation of industry, especially of local production systems organisational  
28 structure and change. They also affect sectoral trajectories and their unfolding  
29 interdependencies over time. In fact, similarities and complementarities in  
30 production tasks do not simply shape the organisation of industry, they also  
31 generate technological interdependencies across sectors and different product-value  
32 segments within the same sector (Rosenberg, 1976 and 1994; Loasby, 1999; Andreoni,  
33 2014).  
34  
35  
36  
37

38  
39 Evolutionary economics have focused on these different trajectories of technological  
40 change triggered by co-evolving demand-pull and technology-push dynamics  
41 within a ‘technology paradigm’ model (Schumpeter, 1911; Nelson and Winter, 1982;  
42 Dosi, 1982). Specifically, by investigating changes in ‘organisational routines’ by  
43 heterogeneous and rationally-bounded individuals and organisations, evolutionary  
44 approaches have provided a behavioural-foundation of firm-level processes of  
45 techno-organisational change (Simon, 1983 and 1991; Nelson and Winter, 2002; Dosi  
46 et al. 2000). These approaches are consistent with resource-capability theories of the  
47 firm and their emphasis on firms’ micro-learning and organisational dynamics.  
48  
49  
50  
51  
52

### 53 3. Structural cycles: technology transition, organisational reconfiguration and 54 policy alignment 55 56 57 58 59 60

1  
2  
3 The structural-resource-capability synthesis introduced in section 2 allows the  
4 formulation of a number of hypotheses about how the relationship between business  
5 organisations and public policy changes both over time and in particular  
6 conjunctures (i.e. when firms capture the opportunity of shifting toward higher  
7 value product segments). This synthesis provides the analytical categories for  
8 reconstructing the specific technological and organisational dynamics within  
9 business organisations and their bi-directional causal link with meso-level  
10 structural dynamics. Moreover, a structural-resource-capability synthesis also offers  
11 a framework for stylising the different potential models that governments and PTIs  
12 can follow to respond to (or steer) these industrial transformations. Specifically, this  
13 paper focuses on the public policies that local governments can implement in the  
14 critical conjuncture when business organisations shift towards higher value product  
15 segments.

16  
17  
18  
19  
20  
21 At the micro level, the development of new technologies or their deployment in new  
22 higher value product segments can open new opportunities for value capture with  
23 new products. These will be ultimately shaped by technology-push and market-pull  
24 dynamics and will require organisational reconfigurations at the level of the firm  
25 and within the local production system. These micro-level technological transitions  
26 and organisational reconfigurations tend to follow *time specific* patterns of change,  
27 also of a cyclical nature, and arise from *location specific* production systems. The  
28 reason is that changes and reconfigurations unfold within specific technological and  
29 sectoral structures, often imposing hierarchical constraints and a specific 'rhythm' to  
30 change (Simon, 1962). In turn, these micro technological and organisational  
31 dynamics may affect sectoral re-compositions and their speed of change. They can  
32 also establish new technological relationships between industrial sectors and their  
33 underpinning technology platforms (Tassey, 2007; Andreoni, 2014).

34  
35  
36  
37  
38 Building on these stylisations, one of the main analytical challenges is to disentangle  
39 the way in which technological and organisations dynamics unfold according to  
40 *specific time patterns* and *in specific organisational settings*. On this basis, it becomes  
41 possible to assess the changing relationships between business organisation and  
42 public policies. From the meso-macro perspective, the complementary challenge  
43 consists of understanding how sectoral dynamics, their speed and magnitude, result  
44 from *time specific* patterns of technological and organisational change in *specific*  
45 *production systems*.

46  
47  
48  
49  
50 In the existing literature, some (limited) advances have been made towards meeting  
51 these challenges already. For example, alongside developments in evolutionary  
52 economics, and partially building on them, the 'product life-cycle' and 'industry life-  
53 cycle' theories have investigated *time specific* patterns of technological change for  
54 specific products or specific industrial sectors respectively (Segerstrom et al., 1990;  
55 Klepper, 1997). Product life-cycle theories extrapolate time specific patterns of  
56 change by focusing on the relationships between product innovation, demand  
57  
58  
59  
60

1  
2  
3 growth and firms' entry patterns. Additionally, industry life-cycle models *à la*  
4 Klepper tend to include the possibility of increasing returns and continuous  
5 opportunities for product and process innovation in the industry. Here,  
6 technological change is seen as co-evolving with the industry market structure and  
7 changes in the vertical structures of firms over time.  
8  
9

10 These theoretical perspectives are, however, limited in three main respects. First,  
11 despite their partial emphasis on specific firms' behaviour and market dynamics at  
12 later stages of the cycle, mature industrial systems are mainly investigated from the  
13 point of view of industry concentration and firm selection, increasing oligopolistic  
14 price-competition and technological lock-in. Less emphasis is given to the ways in  
15 which firms undergo processes of *technology transition* triggered by changes in the  
16 technology platforms underpinning the industry and the discovery of new value  
17 product segments (within the same industry). In other words, the resource-capability  
18 *dynamics* underpinning technology transitions are not captured.  
19  
20  
21  
22

23 Second, despite the emphasis on changes in market structures, the way in which  
24 technology transitions trigger (and are made possible by) organisational  
25 reconfiguration *in specific settings* – i.e. local production systems – is again  
26 underexplored. The reason is that life-cycle theories mainly understand product and  
27 industry cycles from the point of view of large firms without enough consideration  
28 of changes in local production systems along the cycle. This limitation has been  
29 recently highlighted by those contributions focusing on cluster life-cycles (Menzel  
30 and Fornahl, 2009), the life-cycle of industries from the point of view of  
31 agglomeration externalities (Neffke et al., 2011) and, finally, the value co-creation  
32 dynamics in clusters and entrepreneurial ecosystems (Pitelis, 2012).  
33  
34  
35  
36

37 Third, despite the emphasis on industry life-cycles, the ways in which technology  
38 transition and organisational reconfigurations in local production systems trigger  
39 processes of structural change within and across sectors is not even considered. In  
40 other words, no link is established between time specific patterns of change within  
41 industries and the overall structural dynamics reshaping the economic system.  
42  
43

44 The concept of *structural cycle* is introduced here as a first theoretical attempt to  
45 address these limitations and better capture the two fundamental processes of  
46 technology transition and organisational reconfiguration characterising business  
47 organisations shifting towards higher value product segments. Structural cycles are  
48 defined as *transformational phases of technology transition and organisational*  
49 *reconfiguration that business organisations experience when they shift towards higher value*  
50 *product segments opportunities*.  
51  
52  
53

54 *Technology transitions* in mature industrial systems entail both disruptive changes in  
55 the main technology platform underpinning a certain industry and the emergence of  
56 new higher value product segments within the same industry. These technology  
57 transitions are sector specific and follow specific time patterns, sometimes of a  
58  
59  
60

1  
2  
3 cyclical nature. Technology transitions can induce product segment value  
4 diversification and drive improvements in mature product segments. This is because  
5 new platform technologies may open up new possibilities in the industry and  
6 expand the functionalities of the more traditional product-systems (Hobday, 2000).  
7  
8

9 Technology transitions and *organisational reconfiguration* are strongly intertwined. A  
10 new technology platform makes investment in resource-capability building  
11 necessary. As capability theories of the firm highlight, business organisations  
12 respond to this challenge by either adopting vertical integration strategies or  
13 establishing strategic horizontal partnerships. These partnerships often involve  
14 various (more or less direct) collaborations with companies within the same local  
15 production system. Within these production systems, however, technology  
16 transitions tend to have disproportional effects on different business organisations.  
17 Only a few companies will be able to operate competitively within the new industry  
18 technology platform and capture the opportunities for new higher value product  
19 segments in the industry. The structural cycle is a product of these cumulative  
20 dynamics resulting from technology transition and organisational reconfigurations  
21 (Fig 1).  
22  
23  
24  
25  
26  
27  
28

29 [Figure 1 about here]  
30  
31  
32

33 The structural cycles we have described so far entail the transition of business  
34 organisations from one product segment to a new higher value one within the same  
35 industry. However, this transition within the same industrial sector may induce  
36 potential cross-sectoral dynamics as well. This means that the technology transitions  
37 and organisational reconfigurations experienced by some firms in mature industrial  
38 systems may also prepare the same firms to diversify into closely related industries.  
39 The ideas of knowledge and industry relatedness (Breschi et al., 2003; Neffke, et al.  
40 2011) and intersectoral learning (Andreoni, 2014) offer insights about how the  
41 structural cycles described here are linked to business diversification and structural  
42 economic dynamics across sectors.  
43  
44  
45  
46

47 The concept of structural cycle is not simply a heuristic for disentangling and better  
48 interpreting the industrial transformation processes. It also facilitates the analysis of  
49 how to best intervene in these transformation processes, helping to ensure public  
50 policies aimed at supporting industrial transformation are aligned with the *time*  
51 *specific* patterns of technological and organisational change in *specific production*  
52 *systems*. Without such *structural cycle – industrial policy alignment* the effectiveness of  
53 policy interventions is limited. Industrial policy effectiveness depends on  
54 governments' capacity to address structural constraints and opportunities at  
55 different levels of the industrial system and in a selective and timely way (Chang,  
56  
57  
58  
59  
60

1  
2  
3 1994; Mahoney et al., 2009; O'Sullivan, et al. 2013; Mazzucato, 2013; Andreoni, 2016;  
4 Chang and Andreoni, 2016).

5  
6 The alignment of industrial policies to structural cycles requires governments taking  
7 an entrepreneurial role in critical phases of technology transition and organisational  
8 reconfiguration. Engaging business organisations with an entrepreneurial approach  
9 requires the design of selective packages of policy interventions and the  
10 development of various types of PTIs such as applied technology and training  
11 centres, university-based technology development centres and specialised public-  
12 private industrial labs (Andreoni, 2016).

13  
14  
15  
16 More specifically, entrepreneurial governments can operate along three main axes.

17  
18 First, local governments can support business organisations in the development of  
19 system interfaces and infrastructure, as well as support them in the discovery of new  
20 product segments and market opportunities. These activities may involve various  
21 types of public-private partnerships mediated by co-founded PTIs, incentive  
22 schemes for strategic public-private partnerships and local industry associations.  
23 Given their technology platform focus, these PTIs and public policies will tend to  
24 have an indirect cascade effect on the entire local multi-tiered production system in  
25 which these system-integrator business organisations operate.

26  
27  
28  
29 Second, governments can provide direct support to dynamic first- and second- tier  
30 suppliers in the adoption of (and adaptation to) new technology platforms. These  
31 include new production technologies, software-hardware integration technologies,  
32 advanced instrumentation and standardisation and the development of specific  
33 technology platform components.

34  
35  
36  
37 The third and final axis of public policy intervention targets those companies which  
38 are not directly leading the structural cycles in mature industrial systems but are  
39 indirectly involved through sub-contracting and supplier relationships in local  
40 production systems (mainly SMEs and second-tier suppliers). While these  
41 companies may benefit from the existence of various PTIs, their readiness to change  
42 also depends on the availability of well-trained technicians and access to advanced  
43 instrumentations and other enabling infra-technologies (Tasseey, 2007; Andreoni,  
44 2016).

45  
46  
47  
48 To recap, the first industrial policy axis involves a *direct interaction* with leading  
49 companies, that is, system integrators in local production systems who have direct  
50 access to the final market. These are also the companies that generally lead the initial  
51 stages of technology transition and orchestrate local networks of producers. The  
52 second and third axes of intervention target the overall *readiness to change* of the local  
53 production system via diffused technical capabilities building and provision of  
54 enabling infra-technologies. The following section will provide an empirical analysis  
55  
56  
57  
58  
59  
60

of structural cycles in the context of the packaging industry and an in-depth investigation of the private-public nexus in the EPV.

#### 4. The public-private nexus in the Emilian Packaging Valley (EPV): the case of IMA

The world packaging-machine industry accounts for a total turnover of over 33 billion US\$ and is composed of four main product segments: food, beverage, personal care, and pharmaceutical packaging. Over the past 15 years, the industry has grown at a cumulative rate of 15%, with the pharmaceutical packaging value product segment (Pharma hereafter) growing at over 20%. Together with Baden-Württemberg and Hessen in Germany, Emilia-Romagna (ER) in Italy is the regional industrial system with the highest concentration of firms producing automatic packaging machines (Fortis and Carminati, 2014)<sup>1</sup>. Although a large number of SMEs operating as subcontractors have historically composed the local production system in the EPV (Brusco, 1982), four global leaders are also located in this area: IMA, GD, SACMI and Marchesini. Among them, IMA has been the most successful in shifting towards the highest value product segment of the packaging industry – i.e. Pharma. Moreover, the regional public institutions in ER, including the government, universities and the PTIs have been traditionally very active supporters of the regional industrial system (Amin, 1999; Bianchi and Labory, 2011). Building on the structural cycles – policy alignment framework, we decided to study the ways in which the interactions between IMA and ER's public institutions and policies have been changing as a result of IMA's shift towards the Pharma segment of the packaging industry.

#### 4.1 Methods

This study adopts a mixed-method, multi-staged and multi-disciplinary approach. Technology-cycles and changes in the industry's technology platforms are difficult to capture. Despite a number of limitations, patent data are often used as proxy for technological activities and change (Keller, 2004). Clearly, inventions are not all patented, but the most relevant and valuable inventions are often patented (Griliches, 1990). In order to track the technology-cycles and major transformations in the technology platform underpinning the sector, we first conducted patent analysis at the industry, product segment and company levels as well as at the packaging machine system and sub-system levels.

First, this analysis begins by building on the OECD, REGPAT database (February 2015) which reports patent applications to the European Patent Office (EPO). Focusing on the period from 1980 to 2010 we looked at technologies that are

1  
2  
3 classified in section B65 (conveying; packing; storing; handling thin or filamentary  
4 materials) of the International Patent Classification (IPC). Two subsets of  
5 technologies were identified as specific for packaging of the food and tobacco  
6 segment (F&T) and the pharmaceutical products segment (Pharma). In particular,  
7 we looked at the additional IPC subclasses mentioned by patent documents grouped  
8 at the sectoral level (Schmoch et al., 2003)<sup>2</sup>. Thus, we obtained a comprehensive  
9 group, and two segment subgroups, of packaging technologies. The data extracted  
10 are only a subset of all patented inventions in the global packaging industry.  
11 However, they present two fundamental advantages for cross-segmental  
12 comparisons: (i) they are homogeneous with respect to filing procedures and  
13 granting practices and (ii) they represent a sort of positively selected subset of  
14 inventions (OECD, 2009).  
15  
16  
17  
18

19  
20 Second, the patent analysis was triangulated with an engineering-informed scoping  
21 study focusing on changes in automation control systems, packaging technologies  
22 including insulation, sensors, data tracking, big data and advanced materials. We  
23 then focused on the adoption and integration in packaging machines of automatic  
24 control systems based on electronics, information and communication (EIC)  
25 technologies<sup>3</sup> to investigate why and how these technologies were necessary to shift  
26 towards higher value product segments, specifically Pharma. The technology  
27 scenario was then validated with a structured technical questionnaire compiled by  
28 technologists in two local leading companies (IMA and Marchesini).  
29  
30  
31

32  
33 Third, we conducted an in-depth case study focusing on the technology transition  
34 and organisational reconfiguration of IMA. IMA is today's world leader in the  
35 production of packaging machines and integrated packaging lines for the Pharma  
36 segment with a world market share of 16%. Since 1960s IMA has grown dramatically,  
37 from being a medium-sized enterprise employing 50 people with revenues around  
38 €500 thousands to becoming a global group with 4.600 employees and €854.6 million  
39 revenues in 2014. The case study included a total of 30 interviews conducted  
40 between June 2014 and May 2015. Interviews targeted IMA and a selected number of  
41 its key first-tier and second-tier suppliers. Among them, Logimatic Srl and I.E.M.A.  
42 Srl are first-tier subcontractors operating in mechanical assembly and electrical  
43 components development respectively. Both of them were deeply involved in the  
44 most recent phase of IMA's organisational reconfiguration. Data were also  
45 triangulated with targeted interviews with one of IMA's main local competitors  
46 (Marchesini).  
47  
48  
49  
50

51  
52 Fourth and finally, regional policy documents were scanned to map changes in the  
53 public policy approach and types of support to the packaging industry. The data  
54 were validated through interviews with key players, including the Regional  
55 government, ASTER and LIAM. The ER regional government has adopted a wide  
56 and articulated range of industrial policies since the 1970s. According to Istat data,  
57 the ER manufacturing system contributes one quarter of regional GDP and  
58  
59  
60

1  
2  
3 employment. It includes around 39,000 companies spanning across the machine  
4 tools, packaging, medical devices, plastics, agro-tech, food and automotive sectors.  
5 While many studies highlighted the entrepreneurial approach of the regional  
6 government to industrial policy in specific historical moments (Brusco, 1982; Bianchi  
7 and Bellini, 1991; Amin, 1999; Bianchi and Labory, 2011), our analysis attempted to  
8 assess the extent to which these industrial policies that are relevant for the packaging  
9 industry have been aligned (or dis-aligned) to its main industrial transformations  
10 over time.  
11  
12  
13  
14  
15

#### 16 **4.2 Technology cycles and transitions in the packaging industry**

17  
18 Looking at the technology scenario for the overall packaging industry (Fig. 2), there  
19 is clear evidence of strong technology dynamism reaching two peaks in 1992 and  
20 2004. This was followed by a stabilisation phase and one of decline respectively,  
21 partially caused by the financial crisis. Nonetheless, at the product segment level, we  
22 observe two very different patterns for the F&T and Pharma segments of the  
23 industry. Technology applications in the F&T segment remain fundamentally stable  
24 over the entire period, with 60 patents applications per year on average. This  
25 suggests that the F&T segment reached a stage of technology maturity starting from  
26 the late 1980s.  
27  
28  
29  
30

31 In contrast the Pharma segment underwent a long and sustained technology  
32 expansionary cycle over the entire period, with a strong acceleration starting from  
33 1998, reaching its peak in 2004. On average, the number of patents applications in  
34 the Pharma segment went from 116 a year from 1980 to 1997, to 350 a year from 1998  
35 to 2004. Thus, the expansionary technology-cycle in the packaging machine industry  
36 was fundamentally driven by the Pharma segment.  
37  
38  
39  
40  
41

42 *[Figure 2 about here]*  
43  
44  
45

46 The Pharma-led expansionary technology-cycle had also spill over effects on the  
47 other product-segments within the packaging machine industry. In particular, a  
48 number of technologies responding to specific needs of the Pharma segments started  
49 affecting other segments of the packaging industry, especially the F&T segment.  
50 From 1998 until 2004, the technological dynamism in the F&T segment was highly  
51 correlated with the strong technological acceleration in the Pharma segment,  
52 although patents in the F&T segment never went above 100 even in this phase given  
53 the segment maturity.  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 This point can be further emphasised by comparing the cyclical components of  
4 patent counts at sectoral and value product segment levels. If we extract the  
5 standardised cyclical components of the patent applications patterns as plotted in  
6 Fig. 2 and we remove the segment specific trends<sup>4</sup>, we can then identify both the  
7 technology cycles for each product segments – F&T and Pharma – and the  
8 technology-cycle of patents applications common to both segments. As shown in Fig.  
9 3, the dramatic technology dynamism in the Pharma segment between 1998 and 2004  
10 was the main driver of the increase in common patents for the two segments and the  
11 second technology expansionary cycle in the F&T segment.  
12  
13  
14  
15  
16  
17

18 *[Figure 3 about here]*  
19  
20  
21

22 During the last 30 years, the most dramatic technological change in the packaging  
23 industry has been the transition from mechanics to mechatronics, that is, the  
24 adoption and integration in packaging machines of automatic control systems based  
25 on electronics, information and communication (EIC) technologies. Patent data  
26 reveal how references to EIC technologies underpinning automatic control systems  
27 for the packaging industry followed a cyclical trend<sup>5</sup>. Until the mid-1980s control  
28 system patents were generic, that is, it is not possible to find significant variations  
29 across product segments. However, from 1985 onwards specific patent applications  
30 for control system technologies were fundamentally driven by the Pharma segment  
31 (Fig. 4). In other words, the Pharma segment was the main driver behind the  
32 technology transition in the packaging industry's platform technology and the  
33 transition from mechanics to mechatronics.  
34  
35  
36  
37  
38  
39  
40  
41

42 *[Figure 4 about here]*  
43  
44  
45

46 This technology transition changed the fundamental technology platform  
47 underpinning the packaging machine industry, that is, automated control systems.  
48 Specifically, this transition opened higher value product segment opportunities  
49 resulting from the increasing operational speed and configuration flexibility of  
50 packaging machines, the full traceability of packaged products and the possibility of  
51 integrating and standardising entire packaging production lines. These technology  
52 properties are particularly important and sometimes vital in the field of  
53 pharmaceuticals and medical disposals because of their extremely high standards of  
54 quality, dosage precision, sterilisation and traceability.  
55  
56  
57  
58  
59  
60

1  
2  
3 With the exception of speed and fast-flexible machine reconfiguration, these  
4 properties are relatively less important in the F&T segment. The fact they are less  
5 important does not exclude the emergence of new production opportunities for this  
6 segment. In fact, as shown in Fig. 3 and 4, after 1998 the F&T segment has been  
7 partially re-aligning its technology cycle with respect to the automation technologies  
8 for control systems. In sum, the evidence from patent analysis supports the idea that  
9 shifts towards higher value product segments are triggered by the availability of  
10 new technologies and that, in the case of the packaging industries, these  
11 technological changes were associated with a new technology platform based on EIC  
12 technologies.  
13  
14  
15  
16  
17

### 18 19 **4.3 Technology transition and organizational reconfiguration in the Emilian** 20 **Packaging Valley: the case of IMA** 21

22  
23 The growth of IMA was driven by interlinked technological developments along the  
24 packaging industry's technology-cycles. The transition towards higher value  
25 product segments also required continuous organisational reconfigurations,  
26 especially in relation to its regional production system. While the first phase of  
27 IMA's growth mainly relied on the Food segment, the Pharma segment became its  
28 main technological, industrial and financial driver from 1995 onwards. In 2008, at  
29 the peak of IMA's expansion in this segment, Pharma accounted for almost 85% of  
30 its revenues (Fig. 5).  
31  
32  
33

34 IMA's technology journey started in 1961 with a packaging machine for water  
35 sparkling powder, followed by the production of two packaging machines (the C20  
36 and C25 models) for tea bags and drugs in powder form respectively. The first  
37 important technology jump occurred in 1975 with the first blistering machines (the  
38 C60 model) for relatively less elementary applications in the Pharma segment. The  
39 following twenty years were driven by the global success in the Food segment and  
40 the production of increasingly high performance packaging machines for the  
41 industry segment. However, during the second part of this period (1975 – 1995) IMA  
42 actively engaged the technology transition from mechanics to mechatronics and in  
43 the increasing integration of EIC technologies in the packaging industry's platform  
44 technology. From a technological perspective, this slow process of resource-  
45 capability development prepared IMA's shift towards higher value product  
46 segments.  
47  
48  
49  
50  
51

52 The technology cycles followed by IMA can be traced by looking at its application  
53 patents to the EPO from mid 1990s (Fig. 5). The dramatic increase in technology  
54 patents in the Pharma segment between 1995 and 2005 shows IMA's shift from the  
55 F&T to the Pharma segment was driven by a technology transition. In this transition  
56 electronics, information and communication technologies (in combination with other  
57  
58  
59  
60

1  
2  
3 advancements in insulation technologies and advanced materials) transformed the  
4 packaging machine's technology platform. IMA's technology transition thus mirrors  
5 the one followed by the entire packaging industry spurred by the Pharma segment,  
6 although IMA anticipated the industry technology cycle by three years (see section  
7 4.2).  
8  
9

10  
11  
12 *[Fig. 5 about here]*  
13  
14  
15

16  
17 As already noted for the packaging industry as a whole, within IMA this Pharma-led  
18 technological transition had a positive spill-over effect on the more mature product  
19 segment Food which registered an upsurge in F&T patent applications from 2002  
20 onwards. This suggests how, over the past decade, IMA's technology transition  
21 towards Pharma has been increasingly transforming IMA resource-capability across  
22 segments and potentially preparing a new technology-cycle with new advancements  
23 in the F&T segment such as smart packaging for high-value F&T products.  
24  
25

26  
27 IMA's technology transition is strongly intertwined with its organisational  
28 reconfiguration and internationalisation which started in the 1980s. However,  
29 despite many mergers and acquisitions in the global industry, IMA's major  
30 organisational reconfigurations relate to both its internal structure and its strategic  
31 relationships with the ER regional production system.  
32  
33

34 IMA went through two main internationalisation phases. Between 1982 and 1988,  
35 IMA started its commercial expansion into the US and Europe (UK, France,  
36 Germany and Austria as a doorway to the Eastern European bloc countries). During  
37 the following two decades, the commercial expansion continued in Portugal, Spain  
38 and Thailand coupled with industrial collaborations in Japan and China and  
39 acquisitions in Germany. Today the IMA group is present in 80 countries, although  
40 almost 50% of its employees are still in Emilia-Romagna.  
41  
42  
43

44 IMA's internationalisation reflects the strong concentration dynamics in the  
45 packaging machine producer industry as well as in customer markets. For instance,  
46 if we look at the producers of packaging machines for the Pharma segment we find  
47 that the four world leaders (IMA and Marchesini in Emilia-Romagna and Bosch and  
48 Uhlmann in Baden-Württemberg) account for 50% of world market share. IMA  
49 commands 16% of world market share in the Pharma segment and around 80% in  
50 certain subsets of the Food segment (e.g. tea bags). Today's leading companies in the  
51 F&T and Pharma customer markets require packaging machines producers to be  
52 able to operate at a certain production scale, but also to provide customised product  
53 solutions and critical post-sale services (e.g. MRO, software upgrading, training etc.).  
54  
55  
56  
57 Therefore, reaching a critical mass was extremely important for IMA.  
58  
59  
60

1  
2  
3 Increasing operational scale, however, requires continuous organisational  
4 reconfiguration as the growth of the firm generally leads to rigidities and difficulties  
5 in addressing specific technology needs. IMA's technology transition towards the  
6 Pharma segment triggered (and was made possible by) three main organisational  
7 reconfiguration stages.  
8  
9

10 First, during the 1980s IMA started preparing and supporting its technology  
11 transition towards Pharma by increasing its production capacity in packing,  
12 blistering and dosing technologies. IMA acquired a number of companies mainly  
13 located within the regional industrial system (CMS, Zanasi, Farmatic, Farmomac,  
14 PM System and Cestind Centro Studi Industriali) and in 1990 merged these  
15 companies within one unique organisational division. The relationships with its  
16 subcontractors mainly located in the ER local production system were not purely  
17 horizontal, as traditionally described in the industrial district literature (Becattini,  
18 1979; Brusco, 1982). Although local producers were independent, IMA developed a  
19 dense network of subcontracting and commercial relationships and organised their  
20 activities as a product system integrator.  
21  
22  
23  
24

25 Second, between 1995 and 2005, IMA went through a new phase of M&A, followed  
26 by an organisational reconfiguration along customer operating lines and  
27 internationalisation. IMA's acquisitions mainly involved companies specialised in  
28 specific manufacturing tasks and processes, such as blistering and cartooning  
29 (Precision Gears, IN), end-line (BFB), washing and sterilisation (Libra) and capsules  
30 (Kilian, DE and GS Coating). During this period, IMA acquired and integrated a  
31 number of complementary resources and capabilities essential for expanding its  
32 operations in the Pharma segment and entering specific niches, such as granulators  
33 (ICO Oleodinamici) and tube-filling (CO.MA.DI.S.). At the same time  
34 internationalisation continued through the acquisitions of complementary  
35 capabilities (Swiftpack, U.S.) and industrial collaborations (IMA-Telstar, China).  
36  
37  
38  
39  
40

41 Thirdly, following on from its dramatic expansion, since mid-2000, IMA has entered  
42 another organisational reconfiguration phase. This started with a systematic process  
43 of organisational integration as well as changing relationships with the local  
44 production system. The first major step in 2007 consisted in the creation of a new  
45 company, *IMA Libra* incorporating the activities of Libra Pharmaceutical  
46 Technologies and of IMA Aseptic Processing & Filling Division. In 2008 the IMA  
47 group also assumed a new organisational structure featuring four leading business  
48 areas: IMA Flavour Srl (Tea & Coffee Packaging Solutions), IMA Active Division  
49 (Solid Dose Solutions), IMA Life Srl (Aseptic Processing & Filling Solutions) and  
50 IMA Safe Srl (Packaging Solutions). At the end of this organisational reconfiguration,  
51 after a number of other acquisitions such as VIMA Impianti (2006), Zanchetta (2007),  
52 BOC Edwards Pharmaceutical Systems (2008) and PharmaSiena Service (2009), in  
53 2011, IMA created two holding-divisions: *IMA Industries* (machines for the  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 packaging of tea, coffee, food and cosmetic products) and *IMA Pharma* (machines for  
4 the processing and packaging of pharmaceutical products)<sup>6</sup>.  
5

6  
7 Despite major acquisitions and internationalisation, during this last phase the most  
8 significant organisational reconfiguration is the one related to IMA's changing  
9 relationship with the local suppliers' network. The technology transition in the  
10 packaging industry (see section 4.2) had disproportional effects on the different  
11 subcontractors and suppliers in the ER regional production system. In response,  
12 from the mid-1990s, IMA has implemented a number of strategies targeting critical  
13 partners in the regional production system. Overall, IMA supported various  
14 processes of technological upgrading by its sub-contractors and suppliers as well as  
15 engaging in the de-risking of their production activities with medium-long term  
16 guaranteed scheme contracts. This gave a number of companies in the local  
17 production system both time and technological support to catch up with the  
18 packaging industry's overall structural cycle.  
19  
20  
21  
22

23 Strategic organisational reconfigurations of the different local production system  
24 actors were also supported. First, second-tier suppliers started aggregating in new  
25 groups and, sometimes, first-tier suppliers acquired minority shares into said new  
26 groups. IMA supported first-tier suppliers in their growth and restructuring  
27 processes by conferring capital investments and acquiring minority shares (generally  
28 below 35%). In turn, a number of financial operations and cross-participations in  
29 IMA's minority shares (about 3%) cemented this new organisational configuration at  
30 the system integrator – first-tier suppliers interface. The reorganisation of the  
31 ownership structure also led to the introduction of a more integrated corporate  
32 governance structure as well as a number of agreements to share operational risks  
33 and reduce operational costs via buying consortia.  
34  
35  
36  
37

38 This organisational reconfiguration had a major impact on the local production  
39 system. Traditionally the packaging local production system was an open system.  
40 SMEs endowed with advanced instrumentation and production capabilities  
41 (including rapid prototyping, hybrid 3D machine tools, injection moulding, etc.)  
42 used to work with all the major leading companies (Bigarelli and Russo, 2012). As a  
43 result of IMA's third round of organisational reconfiguration and consolidation,  
44 some of these SMEs have started establishing more formal and exclusive  
45 relationships with IMA. In the long run, of course, this may potentially affect the  
46 Marshallian 'atmosphere' in the cluster and make public policy interventions even  
47 more important.  
48  
49  
50  
51  
52

#### 53 54 **4.4 Industrial policy alignment and the role of public technology intermediaries in** 55 **Emilia-Romagna.** 56 57 58 59 60

1  
2  
3 In those industries affected by profound technological and organisational  
4 transformations, the effectiveness of industrial policies strongly depends on their  
5 alignment with the industry's structural cycles. This is because the specific needs of  
6 productive organisations change along these structural cycles. Therefore, matching  
7 these needs (as well as steering certain transitions) requires properly aligned public  
8 policies, including time-specific technology support, production services and  
9 training.  
10  
11

12  
13 Since 1970s ER's industrial policies went through three major phases and developed  
14 along two main axes, that is, sectoral and technology policies *and* industrial training  
15 policies. While the former witnessed significant adjustments in each of these three  
16 major industrial policy phases, industrial training policies remained substantially the  
17 same during the first two phases (1974 – 1985 and 1985 – 2003) and underwent an  
18 important reform only during the third and final phase (2003 – ). The packaging  
19 sector and technologies have been among the main industrial policy targets of the  
20 ER regional government and received various forms of direct and indirect support  
21 (Fig. 6).  
22  
23  
24  
25  
26  
27

28 *[Fig. 6 about here]*  
29  
30  
31

32 The sectoral and technology policies started in 1974 with the establishment of *ERVET*  
33 (ER Governmental Agency for the Economic Valorisation of the Territory). This  
34 coordination agency launched and organised a regional network of sector-focused  
35 research centres targeting SMEs (Regional Law no. 44/1973). *ERVET*'s service centres  
36 provided various types of manufacturing extension services, including technology  
37 diffusion, technical assistance and consultancy, market analysis and scouting, fair  
38 and exhibition services, specialised and continuous training. These activities were  
39 aimed at supporting SMEs in capabilities development, technology absorption,  
40 scaling up production capacity alongside increasing quality, product certification  
41 and standards. These services were all extremely important for companies like IMA  
42 whose production relied extensively on local SMEs. Without reaching a certain  
43 threshold of production quality in the provision of components, SMEs in the  
44 packaging industry would have remained de-linked from the technology-cycles in  
45 the food packaging segment.  
46  
47  
48  
49  
50  
51  
52

53 During the 1980s the *ERVET* network was further extended. However the regional  
54 government started realising that SMEs (and indirectly the new emerging system  
55 integrators such as IMA) increasingly faced new types of production and technology  
56 challenges. From the mid-80s key industrial sectors (including the packaging one)  
57  
58  
59  
60

1  
2  
3 started integrating mechanics and electronics within their technology platforms as  
4 well as increasing their operational scale and markets. In response to these industrial  
5 transformations, the regional government launched a new Agency for Technological  
6 Development called *ASTER* in 1985. *ASTER* represented an important shift in two  
7 main respects. First, regional industrial policies became more technology focused  
8 and the support services started targeting the most innovative and dynamic SMEs.  
9 Second, the emergence of a local 'network of innovating SMEs' providing smart  
10 technology solutions at the level of production technologies, materials and product  
11 components became one of the key competitive assets for the entire region and its  
12 emerging leading companies.  
13  
14  
15  
16

17 The creation of *ASTER* was followed by a gradual reform of the overall regional  
18 technology infrastructure culminating in the Regional Law no. 25/1993. The many  
19 research and service centres run by ERVET (including *ASTER*) were encouraged to  
20 take a more entrepreneurial approach, in part by targeting European Structural  
21 Funds Projects and engaging more proactively with business organisations. These  
22 institutions became the main 'intermediaries' between the regional government and  
23 the business organisations (Bellini, 1996).  
24  
25  
26

27 During these two initial phases the regional industrial system benefitted from the  
28 presence of strong engineering departments in the region's universities and its many  
29 technical schools, including the Aldini Valeriani Technical School in Bologna.  
30 However, during the second phase, the signs of a misalignment between the  
31 educational system and the new industrial needs started emerging. Business  
32 organisations had to complement formal education with long-term in-firm training  
33 programmes. In the case of IMA, these training programmes could last as long as 6-8  
34 months. The re-alignment of the education system to the industrial transformations  
35 of the regional industrial system had to wait until the second half of 2000.  
36  
37  
38

39 The third and final industrial policy phase started in 2003 with the PRRIITT  
40 (Regional Program for Industrial Research, Innovation and Technology Transfer).  
41 The PRRIITT was the government most systematic attempt to re-align its PTIs to the  
42 industrial transformations characterising the manufacturing landscape from the late  
43 1990s. As shown in section 4.2, this was the beginning of the major technology  
44 transition and organisational reconfiguration in the packaging industry and the  
45 major shift for IMA towards the Pharma segment.  
46  
47  
48

49 This policy re-alignment consisted of a major technology upgrading of the regional  
50 system of PTIs and the adoption of a more flexible and cooperative approach open to  
51 various public-private partnerships (PPPs). First, the PRRIITT Measure 4 instituted a  
52 regional network of applied research laboratories and technology transfer  
53 innovation centres, named the *High Technology Network* (HTN). The HTN marked a  
54 transition from a sector-specific industrial policy to a technology policy selecting six  
55 specific technology platforms (mechanics and materials, ICT, agro-industrial,  
56  
57  
58  
59  
60

1  
2  
3 construction, energy and environment and life sciences) based on an appreciation of  
4 the developing structural trajectory of the ER local production system. ASTER was  
5 restructured and a number of regional universities and research institutions (CNR  
6 and ENEA) located in Emilia-Romagna were involved (Regional Law no. 7/2002).  
7  
8

9 Over the years, the access to the HTN was facilitated by the creation of specific tools  
10 for increasing the interaction between business organisations and the PTIs as well as  
11 aligning their technology efforts. In particular, the establishment of a regional web  
12 platform called the 'Catalogue of Competencies' played an important role in  
13 mapping existing technology offerings and production services in the region. The  
14 technology offerings and services for the mechanics, materials and ICT platforms  
15 include a wide range of critical activities for the packaging industries. These include  
16 embedded systems, automation and control, robotics, high performance and cloud  
17 computing, internet of things, software engineering, interoperability, protocols and  
18 standards, mechatronics applications, vibration and harshness analysis. The  
19 technology offerings and services for the mechanics, materials and ICT platforms  
20 include a wide range of critical activities for the packaging industries. These mainly  
21 are embedded systems, automation and control, robotics, high performance and  
22 cloud computing, internet of things, software engineering, interoperability, protocols  
23 and standards, mechatronics applications, vibration and harshness analysis. All of  
24 these activities were selected specifically because they were crucial in the  
25 technological transformation process taking place at that point in the structural cycle.  
26 For the Pharma segment, the life sciences platform has also acquired increasing  
27 relevance. Since its constitution, IMA and a number of its suppliers have established  
28 collaborations with the local universities, innovation centres and laboratories  
29 involved in the HTN.  
30  
31  
32  
33  
34  
35  
36

37 The regional government also managed to re-align the interaction between private  
38 research institutions as well as between business organisations and the HTN. In the  
39 packaging industry, at the apex of the technology transition from the mechanics to  
40 the mechatronics platform, twenty six Emilian packaging companies, including IMA,  
41 created a private company called *CRIT Research*. Before the PRRIITT, CRIT was the  
42 main technology intermediary within the packaging industry and between the EPV  
43 and international research centres. Since 2003, the CRIT was integrated within the  
44 public PTI system and new initiative of this type started receiving public support.  
45  
46  
47

48 Thanks to regional funding opportunities, in 2011 five among the companies who  
49 founded CRIT Research (IMA, SITMA, SACMI, SELCOM and Tetra Pak Packaging  
50 Solutions) created a new intermediate institution called LIAM (Industrial Laboratory  
51 for Packaging Automated Machines). This research centre offers technology services  
52 such as virtual prototyping, solutions for predictive diagnostic, software architecture  
53 machine-independent and platform-independent, access to instrumentation for  
54 testing and benchmarking different technology solutions and platforms adopted by  
55 international competitors.  
56  
57  
58  
59  
60

1  
2  
3 During this third and final phase of industrial policy, in 2008 the ER government  
4 finally addressed the increasing misalignments and gaps in the education system.  
5 Specifically, the regional reform introduced an articulated vocational and industrial  
6 training programme spanning from the secondary school to the tertiary education  
7 level. At the centre of this system were the ITs (Advanced Technical Institutes)  
8 which were totally transformed. They were made into Foundations with the  
9 participation of companies, schools, training centres, universities, and other local  
10 institutions. They offer alternative training programmes aligned to the specific  
11 industrial needs of local business organisations. Leading companies in the region  
12 have played a key role in the establishments of these foundations. For example, IMA  
13 is one of the key stakeholders of a new institute called ITSMaker (Istituto Tecnico  
14 Superiore Meccanica Meccatronica Motoristica e Packaging) focused on mechanics,  
15 mechatronics, motors and packaging technologies.  
16  
17  
18  
19

20  
21 In sum, the interaction between the regional government and the business  
22 organisations have been changing since mid-1970s. During the first industrial policy  
23 phase the public policy support to the packaging industry was mainly indirect,  
24 sector focused and SMEs targeted. During the second and third phases the ER  
25 regional government undertook important efforts towards a better alignment of its  
26 policies and the adoption of a more flexible approach. This opened a new space  
27 between the public and business organisations, including initiatives by leading  
28 companies as well as SMEs. The resulting private-public nexus appears today as a  
29 complex and dense system of interlocking relationships including multiple  
30 technological and organisational dimensions.  
31  
32  
33  
34  
35  
36

## 37 5. Policy implications and concluding remarks

38  
39 The interaction between business organisations and public policy continuously  
40 changes over time as a result of industrial transformations. Therefore, the private-  
41 public nexus is constituted by multiple evolving interfaces and relationships among  
42 multiple actors. This paper argues that in order to address the multi-dimensional  
43 and multi-level process of industrial transformation triggering these dynamic  
44 interactions, three sets of heterodox theories (structural economic dynamics,  
45 resource-capability theories of the firm and evolutionary-life cycle approaches)  
46 should be integrated towards a new *structural-resource-capability synthesis*.  
47  
48  
49

50 These theories present strong complementarities and their integration allow for the  
51 theorisation of the intrinsic link between structural dynamics (at the macro-meso  
52 level) and changes in technology and business organisations (at the micro-meso  
53 level). Building on this synthesis, this paper proposed the concept of the *structural*  
54 *cycle* as a new heuristic to disentangle changes in the relationships between business  
55 organisations and various public actors. We defined structural cycles as  
56  
57  
58  
59  
60

1  
2  
3 transformational phases of technology transition and organisational reconfiguration  
4 that business organisations experience when they shift towards the opportunities  
5 found in higher value product segments.  
6

7  
8 This analytical heuristic does not simply point to the main dynamics characterising  
9 industrial transformations, it also suggests the importance of aligning selective  
10 policy interventions to changes in technology platforms and organisations. So, to  
11 examine these alignments we analysed, both theoretically and empirically, the  
12 specific cyclical patterns of *technology transition* and *organisational reconfiguration*  
13 underpinning the industrial transformation in the packaging industry in the context  
14 of the ER local production system. The industrial policy responsiveness of the  
15 regional government and its intermediaries was assessed by looking at the ways in  
16 which public policies and institutions were aligned to the specific structural cycle  
17 experienced by the packaging industry and, in particular, its leading company IMA.  
18  
19

20  
21 The empirical analysis elucidated a number of hypotheses and stylisations emerging  
22 from the theoretical framework.  
23

24  
25 First, the packaging industry underwent a major technology transition at the level of  
26 its technology platform. This transition (driven by the integration of electronics,  
27 information and communication technologies with more traditional mechanical  
28 technologies) allowed companies such as IMA to shift towards higher value product  
29 segments such as Pharma.  
30  
31

32  
33 Second, the combined effect of technology transition and new product-segments  
34 opportunities triggered organisational reconfigurations in the major system  
35 integrator IMA, and industrial restructuring of their local production system. IMA's  
36 organisational response to the technology transition consisted of a process of  
37 'verticalisation' of critical production tasks and the establishment of new strategic  
38 partnerships with local producers as well as public intermediate institutions. These  
39 are the two complementary dynamics we identified as a structural cycle in the  
40 packaging industry.  
41  
42

43  
44 Third, the ER regional government managed to align its industrial policy and PTIs  
45 with the structural cycle characterising the local packaging-machine production  
46 system. In the case of the EPV, this was made possible by taking into consideration  
47 the evolving needs of the different business organisations at different stages of the  
48 structural cycle and combining a mix of both direct and indirect interventions.  
49  
50

51  
52 Our case study analysis points to a number of critical policy issues for sustainable  
53 value creation dynamics in local production systems. First, governments may be  
54 more or less responsive to industries' structural cycles and public policies more or  
55 less targeted on business organisations' specific needs. Indeed, in different phases  
56 the same government can show different degrees of responsiveness and public  
57 policies can be more or less targeted. While ex-ante both governments and business  
58  
59  
60

1  
2  
3 organisations might not know how to best calibrate their evolving interactions, the  
4 creation of a private-public nexus is a critical step for discovering new opportunities  
5 and developing PPPs. The public-private nexus is the space for composing private  
6 and public interests, intermediating resources and productive opportunities and  
7 aligning the technology, organisational and industrial policy mechanisms whereby  
8 manufacturing system transform and create value.  
9  
10

11  
12 Certainly, other approaches would be helpful in extending the 'analytic  
13 generalisations' provided. A first step in this direction could be obtaining cross-case  
14 conclusions through a multiple-case study comparing local production systems and  
15 context-specific policy actions. Additionally, history-friendly modelling, which  
16 "aim[s] to capture, in stylized form, qualitative and 'appreciative' theories about the  
17 mechanisms and factors affecting industry evolution, technological advance and  
18 institutional change" (Malerba, 1999:3) could be instrumental in conceptualising the  
19 constitutive dynamics behind the concept of structural cycle and, consequently (the  
20 hypothesis of industrial policy) facilitating structural cycle alignment. Last, an  
21 extensive collection of data across cases would allow the measurement of what our  
22 in-depth analysis has highlighted and the literature has not fully disentangled nor  
23 studied yet: the intensity of industrial relatedness which make possible major shifts  
24 across product segments; how new technological trajectories at a platform level can  
25 absorb (or not) evolutionary patterns at a sectoral level; the readiness to change of a  
26 firm and whole production system; which private-public interfaces can better  
27 channel these dynamics and favour the actual alignment of public policies to  
28 structural cycles.  
29  
30  
31  
32  
33  
34  
35  
36

### 37 Notes

38  
39 <sup>1</sup> According to the *Census of Industry and Services* conducted by the Italian Institute of  
40 Statistics (Istat), in 2011 Emilia-Romagna had 512 companies operating in the  
41 manufacture of automatic machines for dispensing, dosing and packaging (NACE  
42 Rev. 2 28.29.3) with a total employment reaching 14,600 (3.22% of the total  
43 manufacturing employment in the region). Roughly one half of these companies are  
44 in the Bologna area (249 firms for 7,414 employees, equal to 7.23% of the total  
45 manufacturing employment in the region).  
46  
47

48  
49 <sup>2</sup> The sectors studied are the NACE Rev. 1 subsections 15 (Foods, beverages) and 16  
50 (Tobacco products) for F&T segment, and NACE Rev. 1 groups 24.4  
51 (Pharmaceuticals), 24.5 (Soaps, detergents, toilet preparations) and 33.1 (Medical  
52 equipment) for Pharma. Of course each selection criterion suffers limitations. In this  
53 case the definition of segment-related technologies is quite restrictive and the count  
54 of patents tracked is probably underestimated. General or transversal packaging  
55 technologies are also applied within segments and segment subsets and include  
56  
57  
58  
59  
60

1  
2  
3 distinctive technologies that are not exclusive, but rather complementary to other  
4 packaging technologies.  
5

6  
7 <sup>3</sup> EIC technologies are defined here as fractions of patents mentioning IPC subclasses  
8 related to NACE Rev. 1 30 (Office machinery and computers), 32.1 (Electronic  
9 components), 32.2 (Signal transmission, telecommunications), 33.2 (Measuring  
10 instruments) and 33.3 (Industrial process control equipment) in the NACE Rev. 1.  
11

12  
13 <sup>4</sup> The comparison of different-size variables imposes the exclusion of some data  
14 dimensions and z-scores transformation. Despite the fact that this statistical solution  
15 removes all the intensity-related issues previously discussed, it allows us to stress  
16 precisely the connections between different technological dynamics.  
17

18  
19 <sup>5</sup> Several solutions have been tested to best represent the role of control system  
20 platforms across segments. The one chosen here is the comparison between adjusted  
21 shares or weights of control systems technologies in the total. Accordingly, we count  
22 control systems fractions of patents and calculate the ratio over a total count. Shares  
23 are adjusted excluding fractions of segment-specific technologies from totals in order  
24 to avoid that the relevance of control system platform would be biased by selection  
25 criteria adopted in choosing segment subgroups.  
26  
27

28  
29 <sup>6</sup> Interestingly, since 2010 IMA's M&As have focused on the F&T segment, especially  
30 on specific packaging niches with GIMA (Bologna, 2010), the "Diary & Convenience  
31 Food" and "Chocolate & Confectionery" divisions of Sympack Corazza (Bologna,  
32 2011), CMH (joint venture with SACMI, Bologna, 2011), Ilapack (CH, 2013) and  
33 Oystar (DE, 2014). In line with the technology cycle analysis, IMA might be entering  
34 in a new technology cycle driven by higher value product segments around F&T.  
35

2  
3 The authors thank all the firms, institutions and stakeholders involved in the study for their valuable inputs,  
4 including IMA Spa (in particular Massimo Marchesini) Logimatic Srl, IEMA Srl, the Regional Government of  
5 Emilia-Romagna (in particular Patrizio Bianchi and Silvano Bertini), CRIT and LIAM of the Emilia-Romagna  
6 High Technology Network. We also acknowledge helpful comments from Mike Best, Bill Lazonick and  
7 Hassan Akram. Marco Bertinelli provided valuable technical inputs. We are finally thankful to two  
8 anonymous referees for their valuable comments to the manuscript and their constructive suggestions. The  
9 usual caveat applies.
