38 **Abstract:** Dimsyl anion promoted the polarity reversal of benzils in a Stetter-like reaction with  
39  
40 chalcones to give 2-benzoyl-1,4-diones (double arylation products), which in turn were converted  
41  
42 into the corresponding tetrasubstituted olefins via aerobic oxidative dehydrogenation catalyzed by  
43  
44 Cu(OAc)<sub>2</sub>.  
45  
46

49 Atom-economical reactions represent a powerful tool in synthetic organic chemistry and a means to  
50  
51 mitigate its negative effects on the environment.<sup>1</sup> In this context, the formation of multiple bonds in  
52  
53 a single organocatalytic transformation is of great significance to readily access diverse structural  
54  
55 motifs displaying all portions of the starting materials.<sup>2</sup> Bi-functional molecules constitute valuable  
56  
57 substrates for the design of organocatalytic domino sequences; nevertheless, the use of highly  
58  
59  
60

1  
2  
3 reactive  $\alpha$ -diketones has been rarely investigated in this type of approach,<sup>3</sup> in which the double  
4  
5 carbonyl functionality of 1,2-diones exhibits electrophilic behavior at the carbonyl carbon and  
6  
7 nucleophilic character at the alpha position. A complementary mode of carbonyl reactivity is,  
8  
9 however, possible for this class of substrates; as demonstrated by our group,  $\alpha$ -diketones can be  
10  
11 rendered nucleophilic at carbonyl carbon (umpolung reactivity) through the catalysis of thiamine  
12  
13 diphosphate (ThDP)-dependent enzymes<sup>4</sup> and *N*-heterocyclic carbenes (NHCs)<sup>5</sup> in nucleophilic  
14  
15 acylations. Recently, we also discovered the capability of methylsulfinyl (dimsyl) carbanion **A** to  
16  
17 induce the polarity reversal of diaryl  $\alpha$ -diketones (benzils) in chemoselective cross-benzoin  
18  
19 condensations with aldehydes.<sup>6</sup> Dimsyl anion, generated by deprotonation of the DMSO solvent,  
20  
21 served as surrogate of hazardous cyanide ion promoting the formation of benzoylated benzoin in a  
22  
23 atom-economic fashion through sequential nucleophilic *C*- and electrophilic *O*-arylations (Scheme  
24  
25 1). As a logical extension of the study on the benzoin reaction, we reasoned that utility of dimsyl  
26  
27 anion catalysis could be further enhanced by conducting a double *C*-arylation process on activated  
28  
29 alkenes, thus providing a novel variant of the parent Stetter reaction (hydroacylation process).<sup>7</sup> We  
30  
31 also envisaged that the resulting activated 1,4-dicarbonyls could be further elaborated going back to  
32  
33 the alkene stage via a catalytic oxidative dehydrogenation step to produce all carbon tetrasubstituted  
34  
35 olefins from chalcones through a simple and effective one-pot process (Scheme 1). On the other  
36  
37 hand, tetrasubstituted alkenes with conjugated systems are challenging synthetic targets<sup>8</sup> with  
38  
39 unique structural and electronic features in material science<sup>9</sup> as well as useful building blocks for  
40  
41 synthetic chemistry.<sup>10</sup>

**SCHEME 1.** Double arylation of aldehydes and activated alkenes with benzils promoted by the dimsyl anion **A**.

The reaction of benzil **1a** with chalcone **2a** was initially investigated to verify the feasibility of the project (Table 1). Reaction selectivity was a major issue to be addressed since formation of the desired double *C*-arylation product **3aa** could be accompanied by generation of by-products **4aa** and **5aa** via competitive double *C,O*-arylation and hydroacylation pathways, respectively (*vide infra*). Gratifyingly, under the conditions previously described for the generation of dimsyl anion **A** (anhydrous DMSO, 30 mol% *t*-BuOK, r.t.), the reaction of equimolar **1a** and **2a** gave the expected compound **3aa** (34%, entry 1) with only trace amounts of the Stetter product **5aa** and no evidence of **4aa**. While a mild heating (50 °C) of the reaction mixture had a negative effect on the reaction output (entry 2), an increase of *t*-BuOK amount (100 mol%) improved the yield of **3aa** (46%, entry 3), thus highlighting the importance of the excess of base to produce the necessary quantity of dimsyl anion ( $\text{p}K_{\text{a}} [\text{DMSO}] = 35.0$ ;  $\text{p}K_{\text{a}} [t\text{-BuOK}] = 32.2$ ).<sup>11</sup> In line with our previous findings, the reaction output was strictly correlated to the strength of the base in DMSO, that is *t*-BuOK > Cs<sub>2</sub>CO<sub>3</sub> ≈ CsOH > DBU >> Et<sub>3</sub>N (entries 4-7). Optimal reaction conditions delivering **3aa** in 75% yield (entry 8) were finally established using an excess of benzil **1a** (2 equiv.). For the sake of

comparison, the catalytic activity of cyanide anion was also tested detecting the same reaction selectivity and a comparable but appreciably higher yield of **3aa** (83-82%, entries 10-11).

**TABLE 1.** Optimization of the model double C-arylation of chalcone **2a** with benzil **1a**.<sup>a</sup>

<sup>a</sup>Reaction conditions: benzil **1a** (0.50 mmol), chalcone **2a** (0.25 mmol), and anhydrous solvent (1.0 mL). <sup>b</sup>**2a**: 0.50 mmol. <sup>c</sup>Temperature: 50 °C.

<sup>d</sup>Reaction performed in the presence of 4 Å MS. <sup>e</sup>**2a**: 1.00 mmol.

1  
2  
3 In addition, commercially available NHC salts **B-G** were screened under suitable conditions  
4 evaluating the effects of altering the solvent, temperature, and base. After some experimentation, it  
5 was found that the sole triazolium salt **B-DBU** couple catalyzed the reaction in CH<sub>2</sub>Cl<sub>2</sub> affording  
6  
7 **3aa** in modest yield (15%, entry 12). Indeed, the more hindered triazolium salts **C-D** (entries 13-14)  
8 and thiazolium,<sup>12</sup> imidazolium, and imidazolium pre-catalysts **E-G** (entries 15-17) proved to be  
9 totally inactive, being the observed formation of **3aa** in DMSO the result of a background activity  
10 of the dimsyl anion.  
11  
12

13  
14  
15  
16  
17  
18 The substrate scope of the disclosed double *C*-arylation reaction was initially examined with  
19 benzils **1a-h** and chalcones **2a-g** displaying various substitution patterns under two sets of  
20 conditions (Table 2). In general, the process promoted by the dimsyl anion (100 mol% *t*-BuOK,  
21 DMSO; conditions 1) provided a safe and environmentally benign access to 2-benzoyl-1,4-diones **3**  
22 and **3'**, albeit with slightly diminished yields (2-18%) compared to the same process catalyzed by  
23 the toxic KCN (25 mol%, DMSO; conditions 2). Relative efficiencies of reactions between benzil  
24 **1a** and chalcones **2a-g** bearing electron-withdrawing, -neutral, and -donating groups indicated a  
25 more pronounced effect of substituents on the benzoyl ring of chalcone, obtaining higher yields of **3**  
26 with electron poor aromatic rings (entries 1-7). Investigation on the electronic requirements for the  
27  $\alpha$ -diketone **1** showed the 2,2'-pyridyl **1b** with an electron-withdrawing moiety as a highly reactive  
28 substrate (entries 8-9); unexpectedly, the use of electron-deficient 4,4'-dinitrofluoromethylbenzil **1c**  
29 and 4,4'-difluorobenzil **1d** led to a significant reduction of reaction efficiency (entries 10-11)  
30 mainly because of the diketone self-condensation side-reaction.<sup>13</sup> Combination of the electron-rich  
31 4,4'-dimethylbenzil **1e** and activated chalcone **2b** rendered the corresponding product **3eb** with  
32 good conversion (entry 12).

51  
52 The employment of unsymmetrical benzils **1f-h** produced the two regioisomers **3** and **3'** in variable  
53 isomeric ratios. The mono-substituted 2-chloro benzil **1f** exhibited the highest capability in  
54 controlling the chemoselectivity (**3:3'** cr) of the double *C*-arylation process as it reacted with  
55 chalcone **2b** yielding almost exclusively the isomer **3fb'** (5:95 cr; entry 13). This result implied that

dimethyl/cyanide anion favorably added to the less hindered carbonyl carbon of **1f**. Similarly, a comparison of the reactivity of mono-substituted 4-Cl and 4-OMe benzils **1g** and **1h** toward chalcone **2a** indicated the preferential attack of the catalyst to the diketone carbonyl carbon with lower electron density (entries 14-15). A limitation of the dimethyl anion-based methodology appeared evident from the representative couplings of enone **2h** (R = H) with benzil **1a** and activated 2,2'-pyridyl **1b** (entries 16-17). The expected products **3ah** and **3bh** were, in fact, detected in only trace amounts by MS analysis of the crude reaction mixtures;<sup>14</sup> by contrast, the cyanide-catalyzed couplings proceeded smoothly affording **3ah** and **3bh** in moderate and good yield, respectively.

1  
 2  
 3 All these findings are in agreement with the following mechanistic proposal. Similarly to what  
 4  
 5 reported for the cyanide catalysis,<sup>15</sup> addition of dimsyl anion **A** to the more electrophilic carbon  
 6  
 7 (blue colored) of  $\alpha$ -diketone **1** forms the intermediate **I**, which in turn evolves to the carbanion **III**  
 8  
 9 via the epoxide **II**. Then, conjugate addition of **III** to chalcone **2** (R = Ar) affords the anion **IV**,  
 10  
 11 which finally liberates the double C-arylation product **3/3'** and the promoter **A** through an  
 12  
 13 intramolecular Claisen-type reaction. Carbonyl group formation is supposed to be the driving force  
 14  
 15 for the elimination of dimsyl anion in the final step of the proposed mechanism;<sup>16</sup> on the other hand,  
 16  
 17 regeneration of the promoter **A** requires the presence of stoichiometric *t*-BuOK because of the  
 18  
 19 higher acidity of the product **3/3'** compared to that of DMSO.<sup>17</sup> It can also be speculated that  
 20  
 21 formation of the hydroacylation product of type **5aa** (Table 1), occasionally detected in trace  
 22  
 23 amounts in some substrate combinations, originates from partial hydrolysis of the species **IV** with  
 24  
 25 benzoyl group elimination. It is important to emphasize that involvement in the catalytic cycle of  
 26  
 27 benzoyl group elimination. It is important to emphasize that involvement in the catalytic cycle of  
 28  
 29 the acyl anion equivalent **III** and dimsyl anion **A** has been previously supported by ESI-MS/MS  
 30  
 31 experiments and trapping of **A** with benzophenone.<sup>6</sup>  
 32  
 33  
 34  
 35  
 36

54 **SCHEME 2.** Proposed mechanism of the double C-arylation reaction promoted by the dimsyl  
 55  
 56 anion **A**.  
 57  
 58  
 59  
 60

Next, to demonstrate the utility of the double *C*-arylation process we showed that the 2-benzoyl-1,4-diones **3/3'** could be converted into the corresponding all carbon substituted olefins **6/6'** in a straightforward manner. Accordingly, the copper-catalyzed oxidative dehydrogenation of isolated **3/3'** was briefly investigated in DMSO; full conversions in **6/6'** were achieved using 10 mol% of Cu(OAc)<sub>2</sub>·H<sub>2</sub>O, *t*-BuOK (1 equiv.), and air as the terminal oxidant (80 °C, 2 h).<sup>18</sup> This result paved the way for the development of a convenient one-pot two-step process for the direct elaboration of chalcones **2** into the doubly aroylated olefins **6/6'**. Hence, to the solution of benzil **1** and chalcone **2** in DMSO was initially added *t*-BuOK (100 mol%) or KCN (25 mol%); then, after having established the completion of the reaction by TLC analysis, the reaction mixture containing the 2-benzoyl-1,4-dione **3/3'** was treated at 80 °C with Cu(OAc)<sub>2</sub>·H<sub>2</sub>O (10 mol%) giving the desired tetrasubstituted olefins **6/6'** in satisfactory overall yields (Table 3).

**TABLE 3.** One-pot two-step synthesis of tetrasubstituted olefins **6/6'**.

<sup>a</sup>Yields (dimethyl catalysis/cyanide catalysis). <sup>b</sup>Diastereomeric ratio determined by <sup>1</sup>H and <sup>13</sup>C NMR analyses of crude reaction mixtures.

<sup>c</sup>First step performed using Cs<sub>2</sub>CO<sub>3</sub> (100 mol%) as the base.

To provide an insight into the mechanism of aerobic oxidative dehydrogenation,<sup>19</sup> **3aa** oxidation was initially performed in the presence of the radical scavenger TEMPO; **6aa** was obtained as the major product, thus suggesting that radicals were not involved in this reaction. Also, it was verified that **3aa** dehydrogenation could proceed in the absence of *t*-BuOK (or KCN) with lower kinetics but still high conversion efficiency. A parallel ESI-MS investigation on **3aa** oxidation without the base was then carried out to identify key intermediates of the catalytic cycle. When an acetonitrile solution of **3aa** was treated with Cu(OAc)<sub>2</sub>·H<sub>2</sub>O, formation of the ionic cluster **V** corresponding to [**3aa**+Cu<sup>II</sup>(AcO)]<sup>+</sup> was observed at *m/z* 540 (<sup>63</sup>Cu).<sup>20</sup> Relevant is the fact that **V** released AcOH during the MS/MS fragmentation with formation of the species **VI** (*m/z* 480), in which copper(II) replaces the lost proton.<sup>20</sup> Elimination of AcOH in the presence of deuterated acetonitrile unequivocally confirmed the proton abstraction from the substrate. It can be hypothesized that a similar mechanism of copper-mediated C-H activation may also occur in solution,<sup>19a</sup> β-hydride elimination should then complete the formation of the double bond in **6aa** with generation of a copper species,<sup>21</sup> which is converted to the active catalyst by molecular oxygen.

**SCHEME 3.** Proposed mechanism for the copper-catalyzed aerobic dehydrogenation of **3/3'** based on an ESI-MS/MS study.

1  
2  
3 In conclusion, we have developed a novel umpolung reaction consisting in the double arylation of  
4  
5 chalcones with benzils promoted by dimsyl or cyanide anion. The utility of the resulting 2-benzoyl-  
6  
7 1,4-diones has been also demonstrated by their facile conversion into the corresponding  
8  
9 tetrasubstituted olefins.  
10

## 11 12 13 14 **Experimental Section**

15  
16 Potassium *tert*-butoxide was purified by sublimation (200-220 °C at 1 mmHg) before utilization.  
17  
18 Reactions were monitored by TLC on silica gel 60 F<sub>254</sub> with detection by charring with  
19  
20 phosphomolybdic acid. Flash column chromatography was performed on silica gel 60 (230-400  
21  
22 mesh). <sup>1</sup>H (300 MHz), <sup>13</sup>C (75 MHz), and <sup>19</sup>F (282 MHz) NMR spectra were recorded in CDCl<sub>3</sub>  
23  
24 solutions at room temperature. Peaks assignments were aided by <sup>1</sup>H-<sup>1</sup>H COSY and gradient-HMQC  
25  
26 experiments. ESI-MS routine analyses were performed in positive ion mode with samples dissolved  
27  
28 in 10 mM solution of ammonium formate in 1:1 MeCN/H<sub>2</sub>O. For accurate mass measurements, the  
29  
30 compounds were detected in positive ion mode by HPLC-Chip Q/TOF-MS (nanospray) analysis  
31  
32 using a quadrupole, a hexapole, and a time-of-flight unit to produce spectra. Residual water of  
33  
34 commercially available anhydrous DMSO (0.016% w/w) was determined by Karl Fisher analysis.  
35  
36 Diketones **1a,b**, **1d**, **1e**, **1h** and chalcones **2a-d** are commercially available compounds. Diketones  
37  
38 **1c**,<sup>22</sup> **1f**,<sup>6</sup> **1g**,<sup>6</sup> chalcones **2e-g**,<sup>23</sup> and enone **2h**<sup>24</sup> were synthesized as described. The 2-benzoyl-1,4-  
39  
40 dione **3ah** is a known compound.<sup>7a</sup>

### 47 **Optimization of the model double C-arylation of chalcone 2a with benzil 1a.**

48  
49 *Entries 1-9.* To a vigorously stirred mixture of benzil **1a** (105 mg, 0.50 mmol), the stated amount of  
50  
51 chalcone **2a**, and anhydrous DMSO (1 mL), the stated amount of base (mol% based on **1a**) was  
52  
53 added in one portion. Then, the mixture was degassed under vacuum and saturated with argon (by  
54  
55 an argon-filled balloon) three times. The mixture was stirred at the stated temperature for 16 h, then  
56  
57 diluted with H<sub>2</sub>O (5 mL), extracted with CH<sub>2</sub>Cl<sub>2</sub> (2 × 25 mL). The combined organic phases were  
58  
59  
60

1  
2  
3 washed with brine (5 mL), dried ( $\text{Na}_2\text{SO}_4$ ), concentrated, and eluted from a column of silica gel  
4  
5 with 10:1 cyclohexane-AcOEt to give **3aa**.

6  
7 *Entries 10-11.* To a vigorously stirred mixture of benzil **1a** (105 mg, 0.50 mmol), **2a** (54 mg, 0.25  
8  
9 mmol), and anhydrous DMSO (1 mL), potassium cyanide (8.1 mg, 0.13 mmol) or  
10  
11 tetrabutylammonium cyanide (34 mg, 0.13 mmol) was added in one portion. Then, the mixture was  
12  
13 degassed under vacuum and saturated with argon (by an argon-filled balloon) three times. The  
14  
15 mixture was stirred at the stated temperature for 16 h, then diluted with  $\text{H}_2\text{O}$  (5 mL), extracted with  
16  
17  $\text{CH}_2\text{Cl}_2$  ( $2 \times 25$  mL). The combined organic phases were washed with brine (5 mL), dried  
18  
19 ( $\text{Na}_2\text{SO}_4$ ), concentrated, and eluted from a column of silica gel with 10:1 cyclohexane-AcOEt to  
20  
21 give **3aa**.

22  
23  
24  
25 *Entries 12-17.* To a vigorously stirred mixture of benzil **1a** (105 mg, 0.50 mmol), **2a** (54 mg, 0.25  
26  
27 mmol), stated amount of azolium salt (20 mol% based on **1a**) and anhydrous DMSO (1 mL), the  
28  
29 stated base (0.25 mmol) was added in one portion. Then, the mixture was degassed under vacuum  
30  
31 and saturated with argon (by an argon-filled balloon) three times. Then, the mixture was degassed  
32  
33 under vacuum and saturated with argon (by an argon-filled balloon) three times. The mixture was  
34  
35 stirred at the stated temperature for 16 h, then diluted with  $\text{H}_2\text{O}$  (5 mL), extracted with  $\text{CH}_2\text{Cl}_2$  ( $2 \times$   
36  
37 25 mL). The combined organic phases were washed with brine (5 mL), dried ( $\text{Na}_2\text{SO}_4$ ),  
38  
39 concentrated, and eluted from a column of silica gel with 10:1 cyclohexane-AcOEt to give **3aa** (no  
40  
41 product formation in entries 13-15).  
42  
43  
44  
45  
46  
47

48 **General procedure for the double C-arylation of activated alkenes **2** with benzils **1** promoted**  
49 **by the dimsyl anion (Conditions 1, Table 2).** To a vigorously stirred mixture of benzil **1** (1.00  
50  
51 mmol), alkene **2** (0.50 mmol), and anhydrous DMSO (2 mL), potassium *tert*-butoxide (112 mg,  
52  
53 1.00 mmol) was added in one portion. Then, the mixture was degassed under vacuum and saturated  
54  
55 with argon (by an argon-filled balloon) three times. The mixture was stirred at room temperature  
56  
57 until complete disappearance or best conversion of the starting alkene (TLC analysis, ca. 2-16 h).  
58  
59  
60

1  
2  
3 The mixture was then diluted with H<sub>2</sub>O (5 mL), and extracted with CH<sub>2</sub>Cl<sub>2</sub> (2 × 35 mL). The  
4  
5 combined organic phases were washed with brine (8 mL), dried (Na<sub>2</sub>SO<sub>4</sub>), concentrated, and eluted  
6  
7 from a column of silica gel with the suitable elution system to give **3/3'**.  
8  
9

10  
11 **General procedure for the double C-arylation of activated alkenes 2 with benzils 1 catalyzed**  
12 **by potassium cyanide (Conditions 2, Table 2).** To a vigorously stirred mixture of benzil **1** (1.00  
13  
14 mmol), alkene **2** (0.50 mmol), and anhydrous DMSO (2 mL), potassium cyanide (16 mg, 0.25  
15  
16 mmol) was added in one portion. Then, the mixture was degassed under vacuum and saturated with  
17  
18 argon (by an argon-filled balloon) three times. The mixture was stirred at room temperature until  
19  
20 complete disappearance or best conversion of the starting alkene (TLC analysis, ca. 2-16 h). The  
21  
22 mixture was then diluted with H<sub>2</sub>O (5 mL), and extracted with CH<sub>2</sub>Cl<sub>2</sub> (2 × 35 mL). The combined  
23  
24 organic phases were washed with brine (8 mL), dried (Na<sub>2</sub>SO<sub>4</sub>), concentrated, and eluted from a  
25  
26 column of silica gel with the suitable elution system to give **3/3'**.

### 43 **Model aerobic oxidative dehydrogenation of 3aa.**

44  
45 To a vigorously stirred mixture of **3aa** (209 mg, 0.50 mmol), potassium *tert*-butoxide (56 mg, 0.50  
46  
47 mmol), and anhydrous DMSO (2 mL), Cu(OAc)<sub>2</sub>·H<sub>2</sub>O (10 mg, 0.05 mmol) was added in one  
48  
49 portion. The mixture was stirred at 80 °C for 2 h under atmospheric air (balloon), then cooled to  
50  
51 room temperature, diluted with H<sub>2</sub>O (5 mL), and extracted with CH<sub>2</sub>Cl<sub>2</sub> (2 x 35 mL). The combined  
52  
53 organic phases were washed with brine (8 mL), dried (Na<sub>2</sub>SO<sub>4</sub>), concentrated, and eluted from a  
54  
55 column of silica gel with 10:1 cyclohexane-AcOEt to give **6aa** (197 mg, 95%).  
56  
57

2  
3 **General procedure for the one-pot two step synthesis of tetrasubstituted olefins 6/6'**  
4 **(Conditions 1, Table 3).** To a vigorously stirred mixture of benzil **1** (1.00 mmol), alkene **2** (0.50  
5 mmol), and anhydrous DMSO (2 mL), potassium *tert*-butoxide (112 mg, 1.00 mmol) was added in  
6 one portion. Then, the mixture was degassed under vacuum and saturated with argon (by an argon-  
7 filled balloon) three times. The mixture was stirred at room temperature until complete  
8 disappearance or best conversion of the starting alkene (TLC analysis, ca. 2-16 h), then  
9 Cu(OAc)<sub>2</sub>·H<sub>2</sub>O (20 mg, 0.10 mmol) was added in one portion. The mixture was stirred at 80 °C for  
10 2 h under atmospheric air (balloon), then cooled to room temperature, diluted with H<sub>2</sub>O (5 mL), and  
11 extracted with CH<sub>2</sub>Cl<sub>2</sub> (2 × 35 mL). The combined organic phases were washed with brine (8 mL),  
12 dried (Na<sub>2</sub>SO<sub>4</sub>), concentrated, and eluted from a column of silica gel with the suitable elution  
13 system to give **6/6'**.

$^{13}\text{C}\{^1\text{H}\}$  NMR:  $\delta$  = 194.2, 194.0, 193.1, 151.8, 142.0, 140.0, 136.5, 136.0, 134.1, 133.9, 133.6, 133.5, 131.1, 130.0, 129.9, 129.4, 129.0, 128.8, 128.7, 128.6, 128.5; IR ( $\text{CDCl}_3$ )  $\nu$ : 3063, 2920, 1653, 1651, 1588, 1585  $\text{cm}^{-1}$ . ESI MS (450.9): 473.8 ( $\text{M} + \text{Na}^+$ ). HRMS (ESI/Q-TOF) calcd for  $\text{C}_{29}\text{H}_{19}\text{ClNaO}_3$  ( $[\text{M} + \text{Na}]^+$ ) 473.0920, found: 473.0922.

#### Aerobic oxidative dehydrogenation of **3aa** in presence of TEMPO.

To a vigorously stirred mixture of **3aa** (209 mg, 0.50 mmol), potassium *tert*-butoxide (112 mg, 1.00 mmol), (2,2,6,6-tetramethyl-piperidin-1-yl)oxyl (78 mg, 0.50 mmol) and anhydrous DMSO (2 mL),  $\text{Cu}(\text{OAc})_2\cdot\text{H}_2\text{O}$  (20 mg, 0.10 mmol) was added in one portion. The mixture was stirred at 80 °C for 2 h under atmospheric air (balloon), then cooled to room temperature, diluted with  $\text{H}_2\text{O}$  (5 mL), and extracted with  $\text{CH}_2\text{Cl}_2$  (2 x 35 mL). The combined organic phases were washed with brine (8 mL), dried ( $\text{Na}_2\text{SO}_4$ ), concentrated, and eluted from a column of silica gel with 10:1 cyclohexane-AcOEt to give **6aa** (135 mg, 65%).

**Acknowledgments.** We thank the student Maurizio Mazzoni for his valuable contribution. We gratefully acknowledge University of Ferrara (Fondi FAR) for financial support. Thanks are also given to Mr. P. Formaglio for NMR spectroscopic experiments and to Dr. T. Bernardi for high-resolution mass spectrometric experiments.

**Supporting Information.** NMR spectra of **3/3'**, **6/6'** and ESI-MS spectra of **V-VI**. This material is available free of charge via the Internet at <http://pubs.acs.org>.

1  
2  
3 elimination of AcOH from **V** cannot be excluded by our MS study because this species would be  
4  
5 isobaric with **VI**; this latter isomer has been suggested to justify the subsequent  $\beta$ -hydride  
6  
7 elimination step already claimed in similar copper-catalyzed oxidative dehydrogenations (see Ref.  
8  
9 19a).

10  
11 (21) The mechanism by which  $\text{Cu}(\text{OAc})_2$  is regenerated after the supposed  $\beta$ -hydride elimination  
12  
13 step is not clear to us; recent studies have revealed that  $\text{Cu}(\text{II})$ -mediated C-H activation can proceed  
14  
15 via disproportionation of  $\text{Cu}(\text{II})$  into  $\text{Cu}(\text{I})$  and  $\text{Cu}(\text{III})$  species. Campbell, A. N.; Stahl, S. S. *Acc.*
